Reading the answers

Every question includes its answer, explanation, choice-by-choice contrasts and available evidence. Primary note proof quotes the study notes. Related reading and module passages are labelled separately; a module reference is not presented as primary note proof.

Computer Programming

Questions & Worked Answers

177 questions + 1 source variants

Question 1 | Q00017

In the conventional historical classification of programming-language generations, which generation is associated with declarative logic, constraints, AI and expert systems?

A. Fifth generation languages

B. Second generation languages

C. Fourth generation languages

D. Third generation languages

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer A: A. Fifth generation languages

The question uses the historical generation taxonomy, rather than asking which languages can implement AI. The note associates fifth-generation languages with logic, constraints and expert systems. Second generation refers to assembly, third to general high-level languages, and fourth to query languages and application generators. Those other languages can be used within AI applications, but that does not change their generation category.

Why each choice is right or wrong

A - Correct: Fifth generation is the historical logic/constraints and expert-system category.

B - Incorrect: Second generation denotes symbolic assembly.

C - Incorrect: Fourth generation denotes query languages and application generators.

D - Incorrect: Third generation includes general high-level languages such as C++ and Java.

Primary note proof

Study-note section CP03

> Machine instructions are conventionally first generation; symbolic assembly is second; general high-level languages such as C++ and Java are third. Database query and application generators such as SQL are conventionally fourth generation. Fifth generation is a loose historical category associated with declarative logic, constraints and AI/expert systems. Generations do not determine whether an implementation uses an interpreter.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 3 | lines 8-17

> Categories of programming language: - Low-level languages: - - are machine-dependent - They are designed to be run on a particular computer (not portable). Eg. Machine language and Assembly Language High-level languages - Are machine-independent - Can be run on a variety of computers. Programming language require translation source code to machine language before execution. This translation is accomplished by either a compiler or an interpreter. Compilers translate the entire source

MOE Computer Science Exit Exam · 2016 · Question 17

Question 2 | Q00027

Which one of the following is correct ordering in language processing system?

A. Source program ->Preprocessor -> Assembler -> Compiler Linker/Loader -> target machine code

B. Source program -> Preprocessor ->Linker/Loader -> Compiler /Assembler ->target machine code

C. Source program Compiler -> Assembler -> Preprocessor > Linker/Loader -> target machine code

D. Source program _> Preprocessor -> Compiler -> Assembler -> Linker/Loader -> target machine code

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer D: Preprocessor → compiler → assembler → linker/loader.

CP04 explicitly places preprocessing before compilation proper and compilation before assembly. The assembler produces object files, which are linked into an executable and then loaded. D preserves that order, although it compresses linking/loading into one label and describes the final result loosely as target machine code.

Why each choice is right or wrong

A - Incorrect: Places the assembler before the compiler, reversing their stated order in CP04.

B - Incorrect: Attempts linking/loading before compilation and assembly have produced the required object files.

C - Incorrect: Places preprocessing after compilation and assembly, contrary to the conventional toolchain order.

D - Correct: Preserves preprocessing, compilation, assembly, linking and loading in the required sequence.

Primary note proof

Study-note section CP04

> In the conventional C++ toolchain: source → preprocessing → compilation proper → assembly → object files → linking → executable → loading → execution. Preprocessing handles directives such as #include; compilation may emit assembly; the assembler emits machine instructions in an object file. The linker resolves external symbols and combines object files and libraries. The loader places an executable and required components in memory and starts it.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 4 | lines 21-30

> The compilation process of C++ program consists of the following steps. • edit source code → compile → link → execute (Editor) (Compiler) (Linker) (Loader) I. Program source code is entered into a file using a text editor. II. After the code has been entered, a compiler program is started that translates the source into an object code file. III. The object code file is linked with other object code files that come with the compiler and an executable file (or program) is created. IV. In order to execute the program, a program called the loader copies the executable file into the memory of the computer and sends an execute command to the CPU.

MOE Computer Science Exit Exam · 2016 · Question 27

Question 3 | Q00042

What does this C++ fragment print? Assume cout is available.

```
int p,q,n;
p=q=n=8;
p+=n;
p/=q;
cout<<p;
```

A. 16

B. 2

C. 24

D. 1

Hint

Trace the initial state and each executed operation in order, preserving the requested output layout.

Answer B: B. 2

All three integers initially hold 8. The compound addition changes p to 16 without changing q or n. The compound division then divides the updated p by q, giving 16/8=2. Only the final value is inserted into cout. Both compound operators are single tokens and follow ordinary integer update rules.

Why each choice is right or wrong

A - Incorrect: 16 is the intermediate value before division.

B - Correct: After addition and division, p is 2.

C - Incorrect: 24 would require another addition that the fragment does not perform.

D - Incorrect: 1 would result from dividing the original 8 by 8 and ignoring the addition.

Primary note proof

Study-note section CP08

> x+=y, x-=y, x*=y, x/=y and x%=y update x using the operation and conversion to its type. For simple variables, trace them as x=x op y. Starting p=q=n=8, p+=n gives 16 and p/=q gives 2. Starting x=10, x+=5 then x/=2 gives 7. x=x+x doubles; it does not generally add one.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 7 | lines 5-23

> Assignment Operators (=) Example: int x=5; or used with a combination of other operators‟ example, x+=2;//x=x+2, x=y=10; Arithmetic Operators (+, -, *, /, %) E.g. Assume int X=9, Y=2 X+Y, Y-X, X%Y Relational operators (==,!=, <, <=,>,>=) Relational operators evaluate to 1 (representing the true outcome) or 0 (representing the false outcome). Assume int X=9, Y=2 X==Y, X!=Y, X>Y 'A' < 'F' // gives 1 (is like 65 < 70) Logical operators (! Negation, &&, ||) Like the relational operators, logical operators evaluate to 1 or 0. Example: 5 < 6 || 6 < 5 // gives 1 In general, any nonzero value can be used to represent the logical true, whereas only zero represents the logical false !12 // gives 0 10 && 5 // gives 1 Increment/decrement Operators The auto increment (++) and auto decrement (--) operators provide a convenient way of, respectively, adding and subtracting 1 from a numeric variable. Both operators can be used in prefix and postfix form.

MOE Computer Science Exit Exam · 2016 · Question 42

Question 4 | Q00049

Look at the following fragment code :
int a = 6;
int b = 5;
while(a>b)
{
Cout<<"computer science program"<<endl;
}
Which algorithm property is not satisfied by the above C++ code algorithm?

A. Sequential

B. Feasibility

C. Finiteness

D. Definiteness

Hint

Trace the initial state and each executed operation in order, preserving the requested output layout.

Answer C: Finiteness

With a=6 and b=5, the while condition remains true because neither variable changes. Thus the intended algorithm never terminates and violates finiteness, explicitly required on PDF p.2. The steps are definite and executable; sequentiality is not the termination property. Interpret Cout as the intended cout. Module support: PDF p. 2, PDF p. 11.

Why each choice is right or wrong

A - Incorrect: "Sequential" does not match the rule or result derived here. With a=6 and b=5, the while condition remains true because neither variable changes. Thus the intended algorithm never terminates and violates finiteness, explicitly required on PDF p.2. The steps are definite and executable; sequentiality is not the termination property. Interpret Cout as the intended cout.

B - Incorrect: "Feasibility" does not match the rule or result derived here. With a=6 and b=5, the while condition remains true because neither variable changes. Thus the intended algorithm never terminates and violates finiteness, explicitly required on PDF p.2. The steps are definite and executable; sequentiality is not the termination property. Interpret Cout as the intended cout.

C - Correct: "Finiteness" matches the derived result. With a=6 and b=5, the while condition remains true because neither variable changes. Thus the intended algorithm never terminates and violates finiteness, explicitly required on PDF p.2. The steps are definite and executable; sequentiality is not the termination property. Interpret Cout as the intended cout.

D - Incorrect: "Definiteness" does not match the rule or result derived here. With a=6 and b=5, the while condition remains true because neither variable changes. Thus the intended algorithm never terminates and violates finiteness, explicitly required on PDF p.2. The steps are definite and executable; sequentiality is not the termination property. Interpret Cout as the intended cout.

Primary note proof

Study-note section CP02

An algorithm gives precise, executable steps and terminates for every legal input.

Study-note section CP16

A while(a>b) with fixed a=6,b=5 never changes its true condition.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 2 | lines 19-26

Algorithm is an ordered set of unambiguous, executable steps, defining a terminating process. Important Properties of Algorithms - Correct: always returns the desired output for all legal instances of the problem. - Unambiguous: Each step must be clearly defined, having only one interpretation. - Precise: simple but efficient - Efficient: can be measured in terms of Time and Space - Finiteness: the execution of the algorithm must terminate in a finite amount of time for each possible set of input data/must have an end.

Computer Programming module | PDF page 11 | lines 5-13

Iteration/Looping Statement: Iteration is the repetition of a statement or block of statements in a program. - Loops have as objective to repeat a statement a certain number of times or while a condition is fulfilled. - C++ has three iteration statements: the while statement, the do. While statement, and the for statement. The while loop: Its format is: while (expression) {statement;} First expression (called the loop condition) is evaluated. If the outcome is nonzero then statement (called the loop body) is executed and the whole process is repeated. Otherwise, the loop is terminated.

Question sources

MOE Computer Science Exit Exam · 2016 · Question 49

Question 5 | Q00051

In the conventional C++ build process, which program resolves external symbols and combines object files and libraries into an executable before it is loaded into memory?

A. Editor

B. Debugger

C. Linker

D. Loader

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer C: C. Linker

Combining object files and resolving their external references is the linker's role in the conventional toolchain. This occurs after object-file generation and before the executable is loaded for execution. Loading has a separate responsibility: placing the executable and required components in memory and starting it. The question asks about the build operation, so an editor, debugger or loader does not satisfy it.

Why each choice is right or wrong

A - Incorrect: An editor changes source text.

B - Incorrect: A debugger investigates program execution and defects.

C - Correct: The linker combines objects/libraries and resolves external references.

D - Incorrect: The loader places an already linked executable into memory.

Primary note proof

Study-note section CP04

> The linker resolves external symbols and combines object files and libraries. The loader places an executable and required components in memory and starts it.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 4 | lines 21-30

> The compilation process of C++ program consists of the following steps. • edit source code → compile → link → execute (Editor) (Compiler) (Linker) (Loader) I. Program source code is entered into a file using a text editor. II. After the code has been entered, a compiler program is started that translates the source into an object code file. III. The object code file is linked with other object code files that come with the compiler and an executable file (or program) is created. IV. In order to execute the program, a program called the loader copies the executable file into the memory of the computer and sends an execute command to the CPU.

MOE Computer Science Exit Exam · 2016 · Question 51

Question 6 | Q00052

Machine language is grouped under_____ generation of programming language.

A. 2nd generation language

B. 3rd generation language

C. 4th generation language

D. 1st generation language

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer D: Machine language is first generation.

CP03 calls machine instructions first generation and symbolic assembly second generation. The question asks specifically about machine language, so the first-generation option follows directly. Third and fourth generations refer to higher-level languages and query/application generators, respectively; they do not classify native machine instructions.

Why each choice is right or wrong

A - Incorrect: Second generation identifies symbolic assembly, whose instructions still require assembly into machine code.

B - Incorrect: Third generation identifies general high-level languages such as C++ and Java.

C - Incorrect: Fourth generation identifies query languages and application generators, rather than machine instructions.

D - Correct: First generation is the note's explicit conventional classification for machine instructions.

Primary note proof

Study-note section CP03

> Machine instructions are conventionally first generation; symbolic assembly is second; general high-level languages such as C++ and Java are third. Database query and application generators such as SQL are conventionally fourth generation. Fifth generation is a loose historical category associated with declarative logic, constraints and AI/expert systems. Generations do not determine whether an implementation uses an interpreter.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 3 | lines 8-17

> Categories of programming language: - Low-level languages: - - are machine-dependent - They are designed to be run on a particular computer (not portable). Eg. MOE Computer Science Exit Exam · 2016 · Question 52

Question 7 | Q00071

What words are printed, in order, when execution enters this C++ fragment at label a and ends after its final statement? Ignore padding spaces.
a: cout<<"Graduating ";
goto b;
c: cout<<" Year ";
goto a;
b: cout<<"fourth ";

A. GraduatingYear Fourth

B. Graduating fourth

C. YearFourth Graduating

D. GraduatingFourth Year

Hint

Fix the input case and cost model, then count dominant work or simultaneously live storage.

Answer B: B. Graduating fourth

Execution starts at a and prints Graduating. The unconditional goto b then transfers directly to the final output statement. That jump skips label c and its Year output, as well as the jump back to a. The statement at b prints lowercase fourth and the fragment ends. Ignoring padding spaces as specified, the two printed words are therefore Graduating followed by fourth.

Why each choice is right or wrong

A - Incorrect: Year is skipped, and Fourth changes the printed case.

B - Correct: The jump reaches b, giving Graduating followed by lowercase fourth.

C - Incorrect: Execution does not start at c, so Year cannot be the first word.

D - Incorrect: Year is never reached after b; the fragment ends there.

Primary note proof

Study-note section CP15

> A goto transfers to a label within its function; follow the label reached rather than reading lines in source order. In the sequence a: print Graduating; goto b; c: print Year; goto a; b: print fourth;, entry at a prints Graduating fourth and reaches the end. Year is not printed. Structured alternatives usually make such logic easier to reason about.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 14 | lines 15-20

> C++ goto Statement Syntax: goto label1; statements Label1: statements

Computer Programming module | PDF page 6 | lines 4-15

6. Communication through console cout (the standard output stream) o used to display information for the user Syntax: cout<<object; • Object can be variable or literals Example: int x=5; cout<<x cout<< “Hello there”; cin(the standard input stream): o used to accept information from the user. Syntax: cin>>variable name; Eg. cin>>x;

Question sources

MOE Computer Science Exit Exam · 2016 · Question 71

Question 8 | Q00074

Given the C++ declarations below, which statement correctly prints the car_model member through c1? Assume cout is available.
struct car { char car_model[25]; float price; };
car c{};
car* c1=&c;

A. Cout<<c1<<price;

B. Cin>>c1.car_model;

C. C1.price = 150000;

D. cout<<c1->car_model;

Hint

Apply the naming, type and syntax rules before deciding whether an option can be used as stated.

Answer D: D. cout<<c1->car_model;

The variable c1 is a pointer to a live car object. Accessing a member through that pointer uses ->, followed by the exact member name car_model. The corrected D therefore inserts the character array into cout; zero initialization supplies a valid empty string here. The other expressions fail to select the requested member, use dot directly on a pointer, or refer to an undeclared differently capitalized name.

Why each choice is right or wrong

A - Incorrect: This does not select price from c1 and uses the undeclared name Cout.

B - Incorrect: A pointer needs -> rather than dot; Cin also has the wrong case.

C - Incorrect: C1 differs from c1, and dot is not pointer-member access.

D - Correct: cout<<c1->car_model; selects the declared member through the live pointer.

Primary note proof

Study-note section CP27

A struct groups named members, possibly of different types. struct House{double price; int rooms;}; defines a type; House h{150000,3}; creates an object. h.rooms uses a dot. House* p=&h; p->rooms is equivalent to (*p).rooms. The pointer must refer to a live object before member access. A type definition alone does not create an ordinary instance.

Study-note section CP-S01

> For an aggregate with no default member initializers, empty braces initialize its members recursively. Numeric scalar members become zero, and the elements of a character-array member become zero characters. A zero character at the beginning of such an array makes it an empty, terminated C string. This differs from leaving an ordinary automatic scalar or array uninitialized.

Study-note section CP24

> cout<<a prints a terminated char sequence, not its numeric address.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 38 | lines 10-16

> Pointer to structure Pointers to structures may be declared as follow: struct staructuretage *pinternname; eg Employe *emp; When using a pointer to a struct, member access can be achieved with the `.' operator, but can not look graceful in expression Example: (*emp).id Equivalently, the ->'` operator can be used; for example: emp->id

Computer Programming module | PDF page 35 | lines 13-17

> Accessing members of a structure variable A structure member can be accessed using dot operator'.' notation syntax: structvariable.member; eg. st.id=4;

Question sources

MOE Computer Science Exit Exam · 2016 · Question 74

Question 9 | Q00085

Software Debugging is known as _____

A. identifying the task to be computerized

B. creating program code

C. creating the algorithm

D. finding and correcting errors in the program code

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer D: Finding and correcting errors in program code.

CP32 defines a bug as a defect and debugging as locating and correcting it. Defining the task, designing an algorithm and creating code are other development activities. They may expose defects, but none of them states the specific error-finding and correction purpose of debugging.

Why each choice is right or wrong

A - Incorrect: Identifying the task defines requirements; it does not locate and repair defects in code.

B - Incorrect: Creating code is implementation, whereas debugging investigates and corrects defects in that code.

C - Incorrect: Creating an algorithm is design; debugging concerns finding and correcting defects.

D - Correct: Finding and correcting program errors directly matches the definition of debugging in CP32.

Primary note proof

Study-note section CP32

> A bug is a defect; debugging locates and corrects it.

Study-note section CP01

> Programming includes writing, testing, debugging and maintaining instructions. A program can execute without solving its intended problem; compare its actual result with the required result.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 2 | lines 2-18

> 1. Introduction to programming Computer programming is the process of writing, testing, debugging/troubleshooting, and maintaining the source code of computer programs. Programs are the instructions that tells the computer what to do .so, writing computer programs means writing instructions, that will make the computer follow and run a program based on those instructions. We are going to write computer programs to solve problems. Problem Solving Problem: gap between the existing and the desired or proposed situation where problem solving will try to fill this gap. Problem solving: The process of transforming the description of a problem into the solution by using our knowledge of the problem-solving strategies, techniques and tools. Problem solving techniques • Analyze the problem: Carefully understand the problem • Outline the problem requirements • Does program require user interaction? • Does program manipulate data? • What is the output? • Design steps (algorithm) to solve the problem

MOE Computer Science Exit Exam · 2016 · Question 97

Question 10 | Q00099

How many times is the phrase "In the loop" printed when the following code is executed?
int i, j=8;
for(i=0; i<j; i++, j--)
3. {
if(i%2!=0) continue;
cout << "In the loop " << endl;
6. }

A. 20

B. 10

C. 3

D. 2

Hint

Trace the initial state and each executed operation in order, preserving the requested output layout.

Answer D: 2

Ignoring source line numbers, the loop body is reached at (i,j)=(0,8),(1,7),(2,6),(3,5). Even i values 0 and 2 print; odd values 1 and 3 continue to the update. The next pair (4,4) fails i<j. Therefore exactly two lines print, not 20, 10 or 3. Module support: PDF p. 12, PDF p. 13, PDF p. 7.

Why each choice is right or wrong

A - Incorrect: "20" does not match the rule or result derived here. Ignoring source line numbers, the loop body is reached at (i,j)=(0,8),(1,7),(2,6),(3,5). Even i values 0 and 2 print; odd values 1 and 3 continue to the update. The next pair (4,4) fails i<j. Therefore exactly two lines print, not 20, 10 or 3.

B - Incorrect: "10" does not match the rule or result derived here. Ignoring source line numbers, the loop body is reached at (i,j)=(0,8),(1,7),(2,6),(3,5). Even i values 0 and 2 print; odd values 1 and 3 continue to the update. The next pair (4,4) fails i<j. Therefore exactly two lines print, not 20, 10 or 3.

C - Incorrect: "3" does not match the rule or result derived here. Ignoring source line numbers, the loop body is reached at (i,j)=(0,8),(1,7),(2,6),(3,5). Even i values 0 and 2 print; odd values 1 and 3 continue to the update. The next pair (4,4) fails i<j. Therefore exactly two lines print, not 20, 10 or 3.

D - Correct: "2" matches the derived result. Ignoring source line numbers, the loop body is reached at (i,j)=(0,8),(1,7),(2,6),(3,5). Even i values 0 and 2 print; odd values 1 and 3 continue to the update. The next pair (4,4) fails i<j. Therefore exactly two lines print, not 20, 10 or 3.

Primary note proof

Study-note section CP16

Make a table with condition inputs, body output and updated values. For i=0,j=8; i<j; i++,j--, body entries are (0,8),(1,7),(2,6),(3,5). If odd i triggers continue, printing occurs twice. With outer i=1; i<5; i+=5, the outer loop runs once; an inner j=10; j>i; --j prints nine times.

Study-note section CP15

continue skips the rest of the current loop iteration: a for loop then runs its update; a while loop goes directly to its condition.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 12 | lines 19-28

The for loop. Its format is: for (initialization; condition; increase) statement; 1, initialization is executed. Generally, it is a initial value setting for a counter variable. This is executed only once 2, condition is checked, if it is true the loop continues, otherwise the loop finishes and statement is skipped. 3, statement is executed. As usual, it can be either a single instruction or a block of instructions enclosed within curly brackets { }. 4, finally, whatever is specified in the increase field is executed and the loop gets back to step 2.

Computer Programming module | PDF page 13 | lines 30-35

Using continue and break Statements - The break statement skips the rest of the statements in the loop‟s block, jumping immediately to the next statement outside of the loop. - The continue statement is similar. It also skips the rest of the statements in the loop‟s block, but instead of terminating the loop, it transfers execution to the next iteration of the loop. It continues the loop after skipping the remaining statements in its current iteration.

Computer Programming module | PDF page 7 | lines 5-23

Assignment Operators (=) Example: int x=5; or used with a combination of other operators‟ example, x+=2;//x=x+2, x=y=10; Arithmetic Operators (+, -, *, /, %) E.g. Assume int X=9, Y=2 X+Y, Y-X, X%Y Relational operators (==,!=, <, <=,>,>=) Relational operators evaluate to 1 (representing the true outcome) or 0 (representing the false outcome). Assume int X=9, Y=2 X==Y, X!=Y, X>Y 'A' < 'F' // gives 1 (is like 65 < 70) Logical operators (! Negation, &&, ||) Like the relational operators, logical operators evaluate to 1 or 0. Example: 5 < 6 || 6 < 5 // gives 1 In general, any nonzero value can be used to represent the logical true, whereas only zero represents the logical false !12 // gives 0 10 && 5 // gives 1 Increment/decrement Operators The auto increment (++) and auto decrement (--) operators provide a convenient way of, respectively, adding and subtracting 1 from a numeric variable. Both operators can be used in prefix and postfix form.

Question sources

Addis Ababa University mock exam · Question 1

Question 11 | Q00100

What does this C++ fragment print? Assume the standard streams are available; line breaks shown in the options are part of the output.

```
int main(){
int a=5,x=1,y=0,z=4;
a=(x && y) || ++z;
std::cout<<z<<std::endl<<a;
return 0;
}
```

A. 5
1

B. 5
2

C. 4
1

D. 4
2

Hint

Trace the initial state and each executed operation in order, preserving the requested output layout.

Answer A: A. 5, then 1 on the next line.

The conjunction x&&y is false because y is zero. The OR therefore evaluates ++z, which changes z from 4 to 5 and supplies a true value. Assigning that logical result stores 1 in a. The output inserts z, then a line ending, then a, so it consists of 5 followed by 1 on the next line.

Why each choice is right or wrong

A - Correct: The false left operand triggers ++z, and the logical result is 1.

B - Incorrect: A logical OR produces 0 or 1, so a cannot print as 2.

C - Incorrect: The OR evaluates ++z, so z does not remain 4.

D - Incorrect: This both omits the increment and gives the logical result as 2.

Primary note proof

Study-note section CP10

> && evaluates its right operand only if the left is true; || only if the left is false. Thus false && dangerousCall() skips the call. Bitwise & operates on bits and does not short circuit. With x=1,y=0,z=4, (x&y)||++z evaluates ++z, leaving z=5 and the Boolean result 1. The precedence ladder is grouping/postfix, unary, multiplicative, additive, shifts, relations, equality, bitwise &, ^, |, &&, ||, conditional, assignment, comma.

Study-note section CP28

std::endl inserts a newline and flushes.

Study-note section CP34

With valid C++ syntax for the stated assignments, the trace yields z=5 then a=1.

Assignment Operators (=) Example: int x=5; or used with a combination of other operators‟ example, x+=2;//x=x+2, x=y=10; Arithmetic Operators (+, -, *, /, %) E.g. Assume int X=9, Y=2 X+Y, Y-X, X%Y Relational operators (==,!=, <, <=,>,>=) Relational operators evaluate to 1 (representing the true outcome) or 0 (representing the false outcome). Assume int X=9, Y=2 X==Y, X!=Y, X>Y 'A' < 'F' // gives 1 (is like 65 < 70) Logical operators (! Negation, &&, ||) Like the relational operators, logical operators evaluate to 1 or 0. Example: 5 < 6 || 6 < 5 // gives 1 In general, any nonzero value can be used to represent the logical true, whereas only zero represents the logical false !12 // gives 0 10 && 5 // gives 1 Increment/decrement Operators The auto increment (++) and auto decrement (--) operators provide a convenient way of, respectively, adding and subtracting 1 from a numeric variable. Both operators can be used in prefix and postfix form.

Computer Programming module | PDF page 6 | lines 4-15

6. Communication through console cout (the standard output stream) o used to display information for the user Syntax: cout<<object; • Object can be variable or literals Example: int x=5; cout<<x cout<< “Hello there”; cin(the standard input stream): o used to accept information from the user. Syntax: cin>>variable name; Eg. cin>>x;

Question sources

Addis Ababa University mock exam · Question 2

Question 12 | Q00101

is a function that invokes itself?

A. Recursive function

B. Inline function

C. Built in function

D. User defined function

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer A: Recursive function

A recursive function calls itself, exactly the definition on p.18. Inline concerns implementation and built-in/user-defined concern origin; none of those categories alone entails self-invocation. Module support: PDF p. 18.

Why each choice is right or wrong

A - Correct: "Recursive function" matches the derived result. A recursive function calls itself, exactly the definition on p.18. Inline concerns implementation and built-in/user-defined concern origin; none of those categories alone entails self-invocation.

B - Incorrect: "Inline function" does not match the rule or result derived here. A recursive function calls itself, exactly the definition on p.18. Inline concerns implementation and built-in/user-defined concern origin; none of those categories alone entails self-invocation.

C - Incorrect: "Built in function" does not match the rule or result derived here. A recursive function calls itself, exactly the definition on p.18. Inline concerns implementation and built-in/user-defined concern origin; none of those categories alone entails self-invocation.

D - Incorrect: "User defined function" does not match the rule or result derived here. A recursive function calls itself, exactly the definition on p.18. Inline concerns implementation and built-in/user-defined concern origin; none of those categories alone entails self-invocation.

Primary note proof

Study-note section CP21

> A recursive function calls itself directly or indirectly.

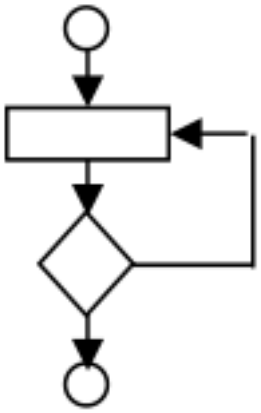
Study-note section CP19

> inline does not compel the compiler to copy a function body at a call. Small frequently used functions may be good optimization candidates, but actual expansion is the optimizer’s decision. Inline also has language linkage/definition rules, so it is not simply a speed command.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 18 | lines 23-28



> Recursive Functions - Functions that call themselves - A function that is defined in terms of itself is called recursive - There must be a base case e.g. 0! = 1 - Slowly converges towards base case - For example, Recursive functions N! = N * (N-1)!

Addis Ababa University mock exam · Question 3

Question 13 | Q00102

Which control flow statement is represented by the flowchart shown in the figure below?

A. while loop

B. do...while loop

C. if...else statement

D. for loop

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer B: do...while loop

The retained flowchart enters the rectangular body before reaching the decision diamond. Its backward arrow returns from the decision to the body. This is a post-test repetition with at least one execution, matching do-while (p.12). while and ordinary for test before the body; if-else does not loop back. Module support: PDF p. 12, PDF p. 11.

Why each choice is right or wrong

A - Incorrect: "while loop" does not match the rule or result derived here. The retained flowchart enters the rectangular body before reaching the decision diamond. Its backward arrow returns from the decision to the body. This is a post-test repetition with at least one execution, matching do-while (p.12). while and ordinary for test before the body; if-else does not loop back.

B - Correct: "do...while loop" matches the derived result. The retained flowchart enters the rectangular body before reaching the decision diamond. Its backward arrow returns from the decision to the body. This is a post-test repetition with at least one execution, matching do-while (p.12). while and ordinary for test before the body; if-else does not loop back.

C - Incorrect: "if...else statement" does not match the rule or result derived here. The retained flowchart enters the rectangular body before reaching the decision diamond. Its backward arrow returns from the decision to the body. This is a post-test repetition with at least one execution, matching do-while (p.12). while and ordinary for test before the body; if-else does not loop back.

D - Incorrect: "for loop" does not match the rule or result derived here. The retained flowchart enters the rectangular body before reaching the decision diamond. Its backward arrow returns from the decision to the body. This is a post-test repetition with at least one execution, matching do-while (p.12). while and ordinary for test before the body; if-else does not loop back.

Primary note proof

Study-note section CP14

> while(condition) checks before each body execution and may run zero times. do {body;} while(condition); runs the body once before checking; it repeats while the condition remains true. Use it when a menu or input attempt must occur at least once.

Study-note section CP34

> When entry reaches the body rectangle before the decision diamond and a decision branch returns to the body, the body executes before the condition is tested. This is a post-test do-while loop.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 12 | lines 2-7

> The do-while loop The condition in the do-while is evaluated after the execution of statement instead of before, granting at least one execution of statement even if condition is never fulfilled. do {statement; }while (condition); First statement is executed and then condition is evaluated. If the outcome of the latter is nonzero then the whole process is repeated. Otherwise, the loop is terminated.

Computer Programming module | PDF page 11 | lines 5-13

> Iteration/Looping Statement: Iteration is the repetition of a statement or block of statements in a program. - Loops have as objective to repeat a statement a certain number of times or while a condition is fulfilled. - C++ has three iteration statements: the while statement, the do. While statement, and the for statement. The while loop: Its format is: while (expression) {statement;} First expression (called the loop condition) is evaluated. If the outcome is nonzero then statement (called the loop body) is executed and the whole process is repeated. Otherwise, the loop is terminated.

Addis Ababa University mock exam · Question 4

Question 14 | Q00103

What is the output of the following code snippet?
double ph=15.3;
if(ph<@ || ph>15)
3. {
cout<< "Invalid PH value. ";
5. }
if(ph<=6.5)
cout<< "Acidic";
else if(ph>6.5 && ph<7.5)
cout<< "Neutral";
else
cout<< "Alkaline";

A. Invalid PH Value

B. Neutral

C. Alkaline

D. Invalid PH Value. Alkaline

Hint

Trace the initial state and each executed operation in order, preserving the requested output layout.

Answer D: Invalid PH Value. Alkaline

The negative-value test is ph<0. Since 15.3>15, the first independent if prints Invalid PH value. The following separate if/else-if chain still executes: ph<=6.5 is false and the middle range test is false, so it prints Alkaline. Thus both messages appear. A and C omit one message, and B takes a false middle branch. Module support: PDF p. 9, PDF p. 7.

Why each choice is right or wrong

A - Incorrect: "Invalid PH Value" does not match the rule or result derived here. The negative-value test is ph<0. Since 15.3>15, the first independent if prints Invalid PH value. The following separate if/else-if chain still executes: ph<=6.5 is false and the middle range test is false, so it prints Alkaline. Thus both messages appear. A and C omit one message, and B takes a false middle branch.

B - Incorrect: "Neutral" does not match the rule or result derived here. The negative-value test is ph<0. Since 15.3>15, the first independent if prints Invalid PH value. The following separate if/else-if chain still executes: ph<=6.5 is false and the middle range test is false, so it prints Alkaline. Thus both messages appear. A and C omit one message, and B takes a false middle branch.

C - Incorrect: "Alkaline" does not match the rule or result derived here. The negative-value test is ph<0. Since 15.3>15, the first independent if prints Invalid PH value. The following separate if/else-if chain still executes: ph<=6.5 is false and the middle range test is false, so it prints

Alkaline. Thus both messages appear. A and C omit one message, and B takes a false middle branch.

D - Correct: "Invalid PH Value. Alkaline" matches the derived result. The negative-value test is ph<0. Since 15.3>15, the first independent if prints Invalid PH value. The following separate if/else-if chain still executes: ph<=6.5 is false and the middle range test is false, so it prints Alkaline. Thus both messages appear. A and C omit one message, and B takes a false middle branch.

Primary note proof

Study-note section CP12

A standalone if may execute independently of the following if. An else binds to its nearest unmatched if; an else-if ladder executes the first true branch only. In nested if(c1){if(c2) S1; else S2;}, S2 requires c1 true and c2 false. Braces determine grouping.

Study-note section CP12

With ph=15.3, an invalid-range if can print its warning, and a separate classification ladder can also print Alkaline.

Conditional Statements A. The if Statement Syntax: if (expression) statement; First expression is evaluated. If the outcome is nonzero (true) then statement is executed. Otherwise, nothing happens. if-else statement Syntax: if (expression) statement1; else statement2; First expression is evaluated. If the outcome is nonzero (true) then statement1 is executed. Otherwise, statement2 is executed.

Computer Programming module | PDF page 7 | lines 5-23

Assignment Operators (=) Example: int x=5; or used with a combination of other operators‟ example, x+=2;//x=x+2, x=y=10; Arithmetic Operators (+, -, *, /, %) E.g. Assume int X=9, Y=2 X+Y, Y-X, X%Y Relational operators (==,!=, <, <=,>,>=) Relational operators evaluate to 1 (representing the true outcome) or 0 (representing the false outcome). Assume int X=9, Y=2 X==Y, X!=Y, X>Y 'A' < 'F' // gives 1 (is like 65 < 70) Logical operators (! Negation, &&, ||) Like the relational operators, logical operators evaluate to 1 or 0. Example: 5 < 6 || 6 < 5 // gives 1 In general, any nonzero value can be used to represent the logical true, whereas only zero represents the logical false !12 // gives 0 10 && 5 // gives 1 Increment/decrement Operators The auto increment (++) and auto decrement (--) operators provide a convenient way of, respectively, adding and subtracting 1 from a numeric variable. Both operators can be used in prefix and postfix form.

Question sources

Addis Ababa University mock exam · Question 5

Question 15 | Q00104

Which three numeric values are displayed, in order, by this C++ program? Ignore the prompt text and separator spaces; assume cout and endl are available.

```
int func(int a,int b){
a*=5;
b+=5;
return a+b;
}
int main(){
int x=9,y=3;
cout<<"Result = "<<func(x,y)<<", "<<x<<", "<<y<<endl;
return 0;
}
```

A. 12,9,3

B. 50,9,3

C. 53,9,3

D. 53,45,8

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer C: C. 53,9,3

The value parameters are separate objects initialized with 9 and 3. Inside func, a becomes 45 and b becomes 8, so the returned sum is 53. Neither update changes the caller's x or y, which remain 9 and 3. The requested numeric sequence is therefore 53,9,3. Standard int main() restores the valid enclosing program already required by CP34 without changing the parameter-passing problem.

Why each choice is right or wrong

A - Incorrect: 12 adds the original parameters instead of their updated local values.

B - Incorrect: The updated local values sum to 53, not 50.

C - Correct: The function returns 53 while the caller retains 9 and 3.

D - Incorrect: Value parameters do not change the caller's x and y to 45 and 8.

Primary note proof

Study-note section CP18

> A C++ value parameter is a separate object initialized from the argument. In func(int a,int b){a*=5;b+=5;return a+b;}, calling func(9,3) returns 53 and leaves the caller values 9 and 3 unchanged.

Study-note section CP34

Use <0 for a less-than-zero comparison and the standard int main() declaration for a C++ entry point.

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 16 | lines 13-20

Passing by Value In call by value, the actual value that is passed as argument is not changed after performing some operation on it. it creates a copy of that variable into the stack section in memory. When the value is changed, it changes the value of that copy, the actual value remains the same Example: Passing by Reference: It allows a function to modify a variable without having to create a copy of it. We have to declare reference variables. The memory location of the passed variable and parameter is the same and therefore, any change to the parameter reflects in the variable as well.

Computer Programming module | PDF page 7 | lines 5-23

Assignment Operators (=) Example: int x=5; or used with a combination of other operators‟ example, x+=2;//x=x+2, x=y=10; Arithmetic Operators (+, -, *, /, %) E.g. Assume int X=9, Y=2 X+Y, Y-X, X%Y Relational operators (==,!=, <, <=,>,>=) Relational operators evaluate to 1 (representing the true outcome) or 0 (representing the false outcome). Assume int X=9, Y=2 X==Y, X!=Y, X>Y 'A' < 'F' // gives 1 (is like 65 < 70) Logical operators (! Negation, &&, | |) Like the relational operators, logical operators evaluate to 1 or 0. Example: 5 < 6 | | 6 < 5 // gives 1 In general, any nonzero value can be used to represent the logical true, whereas only zero represents the logical false !12 // gives 0 10 && 5 // gives 1 Increment/decrement Operators The auto increment (++) and auto decrement (--) operators provide a convenient way of, respectively, adding and subtracting 1 from a numeric variable. Both operators can be used in prefix and postfix form.

Question sources

Addis Ababa University mock exam · Question 6

Question 16 | Q00105

What do arrays do?

A. Hold address of a single value

B. Hold one value

C. Hold values of the same type under a single name

D. Hold addresses of values under a single name

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer C: Hold values of the same type under a single name

An array groups a fixed number of elements of the same type (p.19), with each element selected by an index. It is not a single-value storage definition or intrinsically a collection of addresses; pointer-valued arrays are only a particular element type. Module support: PDF p. 19.

Why each choice is right or wrong

A - Incorrect: "Hold address of a single value" does not match the rule or result derived here. An array groups a fixed number of elements of the same type (p.19), with each element selected by an index. It is not a single-value storage definition or intrinsically a collection of addresses; pointer-valued arrays are only a particular element type.

B - Incorrect: "Hold one value" does not match the rule or result derived here. An array groups a fixed number of elements of the same type (p.19), with each element selected by an index. It is not a single-value storage definition or intrinsically a collection of addresses; pointer-valued arrays are only a particular element type.

C - Correct: "Hold values of the same type under a single name" matches the derived result. An array groups a fixed number of elements of the same type (p.19), with each element selected by an index. It is not a single-value storage definition or intrinsically a collection of addresses; pointer-valued arrays are only a particular element type.

D - Incorrect: "Hold addresses of values under a single name" does not match the rule or result derived here. An array groups a fixed number of elements of the same type (p.19), with each element selected by an index. It is not a single-value storage definition or intrinsically a collection of addresses; pointer-valued arrays are only a particular element type.

Primary note proof

Study-note section CP22

> A built-in C++ array has a fixed number of same-type elements in contiguous storage: int a[4]={10,20,30,40};. Valid indices are 0 through 3. a[4] is outside the array; accessing it has undefined behavior. Java checks bounds and throws ArrayIndexOutOfBoundsException. Do not predict a C++ out-of-range value from nearby memory.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 19 | lines 4-29

> Arrays - an array is a collection of fixed-size number of elements of the same type stored sequentially in memory. - An individual element of an array is identified by its own unique index (or subscript). - The number of elements must be an integer. - The size of the array is referred to as its dimension - Array in C++ is Zero indexed. Declaring of one-dimensional Array Syntax: elementstype arrayname [size]; → You can use constants such as macro definitions or const ints as the sizes of arrays. Example: int num[5]; string fruit[3]; #define numstudents 100 or const int numstudents=100; double Score[numstudents] ; double Score[numstudents] ; Initialization of an Array - Arrays can be initialized at declaration time in two different ways: Syntax: elementstype arrayname[size] = {list each value separated by comma}; E.g int num[5]={1,2,3,4,5}; elementstype arrayname[ ] = { list with any number of values }; E.g int num[]={1,2,3,4,5}; string

fruit[]={“Apple”,“orange”, “Mango”}; Accessing Array Elements - Each element could be accessed using an index into the array - When accessing an array, the index given must be a positive integer from 0 to n-1, where n is the dimension of the array.

Question sources

Addis Ababa University mock exam · Question 7

Question 17 | Q00174

In recursion, the condition for which the function will stop calling itself is .

A. Best case

B. Worst case

C. Base case

D. There is no such condition

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer C: Base case

The recursion section explicitly requires a base case and convergence toward it. That case stops further self-calls. Best and worst case describe other analyses, while denying a stopping condition conflicts with the module requirement. Module support: PDF p. 18.

Why each choice is right or wrong

A - Incorrect: "Best case" does not match the rule or result derived here. The recursion section explicitly requires a base case and convergence toward it. That case stops further self-calls. Best and worst case describe other analyses, while denying a stopping condition conflicts with the module requirement.

B - Incorrect: "Worst case" does not match the rule or result derived here. The recursion section explicitly requires a base case and convergence toward it. That case stops further self-calls. Best and worst case describe other analyses, while denying a stopping condition conflicts with the module requirement.

C - Correct: "Base case" matches the derived result. The recursion section explicitly requires a base case and convergence toward it. That case stops further self-calls. Best and worst case describe other analyses, while denying a stopping condition conflicts with the module requirement.

D - Incorrect: "There is no such condition" does not match the rule or result derived here. The recursion section explicitly requires a base case and convergence toward it. That case stops further self-calls. Best and worst case describe other analyses, while denying a stopping condition conflicts with the module requirement.

Primary note proof

Study-note section CP21

> A recursive function calls itself directly or indirectly. It needs a base case and progress toward it for all supported inputs. factorial(0)=1 and factorial(n)=n*factorial(n-1) for positive n. factorial(3) expands to 3*2*1*1=6. Negative inputs require rejection or a separate definition; they do not reach zero under n-1.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 18 | lines 23-28

> Recursive Functions - Functions that call themselves - A function that is defined in terms of itself is called recursive - There must be a base case e.g. 0! = 1 - Slowly converges towards base case - For example, Recursive functions N! = N * (N-1)!

Question sources

Addis Ababa University mock exam · Question 76

Question 18 | Q00209

One of the following statements is true

A. The typedef command is used to create a new type.

B. If the function is declared inline the compiler must copy the code in the calling function

C. All of the choices are correct

D. It is recommended to use inline functions to simple and frequently used functions

E. None of the choices are correct

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer D: Small, frequently used functions are reasonable inline optimization candidates.

CP19 recommends small, frequently used functions as possible optimization candidates, while stressing that inline never forces expansion at the call site. CP06 says typedef creates an alias rather than a distinct new type. Thus D is defensible as a recommendation; the mandatory-expansion and distinct-type claims cannot make all choices correct.

Why each choice is right or wrong

A - Incorrect: A typedef supplies an alternative name for an existing type, not a distinct new type.

B - Incorrect: Declaring inline does not require the compiler to expand the body at each call.

C - Incorrect: The distinct-type and mandatory-expansion claims are false, so all choices cannot be correct.

D - Correct: Simple, frequently called functions can be reasonable candidates, although expansion remains an optimizer decision.

E - Incorrect: The recommendation in D is supported, so it is false that none is correct.

Primary note proof

Study-note section CP19

> inline does not compel the compiler to copy a function body at a call. Small frequently used functions may be good optimization candidates, but actual expansion is the optimizer’s decision. Inline also has language linkage/definition rules, so it is not simply a speed command.

Study-note section CP06

> typedef creates an alias, not a distinct new type.

> • User-defined - Function that been created by the user. - These functions need to be declared and defined by the user. Declaration of function Function defines using the following syntax: Function_type function_name (Parameter List) { ...function body } Example: void Addition(int num1,int num2) #include<iostream> using namespace std; void Addition(int num1,int num2) { int sum=num1+num2; cout<<"The sum is:"<<sum; } int main() { int x=10,y=20; Addition(x,y);

Question sources

Mock exam 4 · Question 11

Question 19 | Q00210

Given the following lines of code, how many times will "hello" be displayed on the screen?

```
int i = 1;
while(i < 5){
int j = 10;
while (j > i){
j--;
cout << "hello" << endl;
}
i = i + 5;
}
```

A. 10

B. 9

C. 5

D. 25

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer B: 9

The outer loop starts with i=1. The inner loop decrements j from 10 through 1 and prints after each decrement: nine prints. Then i becomes 6, failing i<5, so no second outer iteration occurs. Ten counts the initial j without a successful iteration; five and 25 ignore the actual bounds. Module support: PDF p. 11, PDF p. 7.

Why each choice is right or wrong

A - Incorrect: "10" does not match the rule or result derived here. The outer loop starts with i=1. The inner loop decrements j from 10 through 1 and prints after each decrement: nine prints. Then i becomes 6, failing i<5, so no second outer iteration occurs. Ten counts the initial j without a successful iteration; five and 25 ignore the actual bounds.

B - Correct: "9" matches the derived result. The outer loop starts with i=1. The inner loop decrements j from 10 through 1 and prints after each decrement: nine prints. Then i becomes 6, failing i<5, so no second outer iteration occurs. Ten counts the initial j without a successful iteration; five and 25 ignore the actual bounds.

C - Incorrect: "5" does not match the rule or result derived here. The outer loop starts with i=1. The inner loop decrements j from 10 through 1 and prints after each decrement: nine prints. Then i becomes 6, failing i<5, so no second outer iteration occurs. Ten counts the initial j without a successful iteration; five and 25 ignore the actual bounds.

D - Incorrect: "25" does not match the rule or result derived here. The outer loop starts with i=1. The inner loop decrements j from 10 through 1 and prints after each decrement: nine prints. Then i becomes 6, failing i<5, so no second outer iteration occurs. Ten counts the initial j without a successful iteration; five and 25 ignore the actual bounds.

Primary note proof

Study-note section CP14

> while(condition) checks before each body execution and may run zero times. do {body;} while(condition); runs the body once before checking; it repeats while the condition remains true. Use it when a menu or input attempt must occur at least once.

Study-note section CP16

> With outer i=1; i<5; i+=5, the outer loop runs once; an inner j=10; j>i; --j prints nine times.

Both operators can be used in prefix and postfix form.

Question sources

Mock exam 4 · Question 12

Question 20 | Q00211

What is the output of the below given program?

```
int figure_me_out() {
static int x = 0;
if (x % 2 == 0)
x = x + 1;
else
x = x + 2;
return x;
}
int main() {
int x = 0;
for(int i = 0; i < 5; i++)
x = x + figure_me_out();
cout << x;
return 0;
}
```

A. 1

B. 19

C. 2

D. 20

E. 25

Hint

Trace the initial state and each executed operation in order, preserving the requested output layout.

Answer E: 25.

The function's static x is initialized once, then persists across calls. Its five returns are 1, 3, 5, 7 and 9: after the first update it stays odd and increases by two. Main has a separate x and accumulates all five returns, giving 25.

Why each choice is right or wrong

A - Incorrect: One is only the first function return, not the sum accumulated by main.

B - Incorrect: The five return values sum to 25; a total of 19 omits or miscomputes updates.

C - Incorrect: The function does not reset or simply count calls; its persistent values are odd.

D - Incorrect: The five odd returns total 25, not the sum of five even values.

E - Correct: Adding the five persistent-state returns gives 1+3+5+7+9, which equals 25.

Primary note proof

Study-note section CP20

> An automatic local is created anew on entry. A static local is initialized once and retains its value across calls even though its name remains local. If static x=0 changes by +1 when even and +2 otherwise, five calls return 1,3,5,7,9, whose sum is 25. Namespace/static storage integers are zero initialized; an ordinary uninitialized local int has no usable assumed zero value.

Computer Programming module | PDF page 17 | lines 14-29

> Scope of variables Scope of variables defined as the extent of the program code within which the variable can be accessed or declared or worked with mainly two types of variable scopes: local variable: - Variables defined within a function or block are said to be local to those functions - Declared inside a block{} Global Variable - variable that can be accessed from any part of the program. - They are available throughout the life time of a program. - They are declared at the top of the program outside all of the functions or blocks. NB: - Usually when two variables with same name are defined then the compiler produces a compile time error. But if the variables are defined in different scopes, then the compiler allows it. - Whenever there is a local variable defined with same name as that of a global variable then the compiler will give precedence to the local variable

Computer Programming module | PDF page 11 | lines 5-13

> Iteration/Looping Statement: Iteration is the repetition of a statement or block of statements in a program. - Loops have as objective to repeat a statement a certain number of times or while a condition is fulfilled. - C++ has three iteration statements: the while statement, the do. While statement, and the for statement. The while loop: Its format is: while (expression) {statement;} First expression (called the loop condition) is evaluated. If the outcome is nonzero then

statement (called the loop body) is executed and the whole process is repeated. Otherwise, the loop is terminated.

Mock exam 4 · Question 13

Question 21 | Q00212

What is the output of the following code fragment?

```
int f1(int n, int m){
if(n < m)
return 0;
else if(n == m)
return m + f1(n-1, m);
else
return n + f1(n-2, m-1);
}
int main(){
cout << f1(1, 4);
return 0;
}
```

A. 0

B. None of the choices are correct

C. 8

D. 4

Hint

Trace the initial state and each executed operation in order, preserving the requested output layout.

Answer A: 0

The initial call is f1(1,4). Its first condition 1<4 is true, so it returns 0 immediately. Neither recursive branch executes. Eight and four would require branches that are not entered; the none option is false because 0 is listed. Module support: PDF p. 18, PDF p. 9.

Why each choice is right or wrong

A - Correct: "0" matches the derived result. The initial call is f1(1,4). Its first condition 1<4 is true, so it returns 0 immediately. Neither recursive branch executes. Eight and four would require branches that are not entered; the none option is false because 0 is listed.

B - Incorrect: "None of the choices are correct" does not match the rule or result derived here. The initial call is f1(1,4). Its first condition 1<4 is true, so it returns 0 immediately. Neither recursive branch executes. Eight and four would require branches that are not entered; the none option is false because 0 is listed.

C - Incorrect: "8" does not match the rule or result derived here. The initial call is f1(1,4). Its first condition 1<4 is true, so it returns 0 immediately. Neither recursive branch executes. Eight and four would require branches that are not entered; the none option is false because 0 is listed.

D - Incorrect: "4" does not match the rule or result derived here. The initial call is f1(1,4). Its first condition 1<4 is true, so it returns 0 immediately. Neither recursive branch executes. Eight and four would require branches that are not entered; the none option is false because 0 is listed.

Primary note proof

Study-note section CP21

> Evaluate conditions before expanding a recursive call. For if(n<m) return 0;, f(1,4) returns immediately; unreachable recursive branches add nothing. Record each call's local parameters and pending operation, then unwind returned values. Recursion commonly uses smaller instances, but merely having a base-case branch does not prove it will be reached.

Mock exam 4 · Question 14

Question 22 | Q00270

Assume that p, x, y, and z are int variables with x = 1, y = 10, z= -3. Which of the following is true after the following statement is executed? p= (x++ * y--) + ++z;

A. p=22

B. p=17

C. p=8

D. p=16

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer C: p=8

Postfix x++ contributes old x=1 and y-- contributes old y=10; prefix ++z changes -3 to -2 before use. Thus p=1*10+(-2)=8. The new x=2 and y=9 are not the values multiplied. The other values mix old and updated operands. Module support: PDF p. 7.

Why each choice is right or wrong

A - Incorrect: "p=22" does not match the rule or result derived here. Postfix x++ contributes old x=1 and y-- contributes old y=10; prefix ++z changes -3 to -2 before use. Thus p=1*10+(-2)=8. The new x=2 and y=9 are not the values multiplied. The other values mix old and updated operands.

B - Incorrect: "p=17" does not match the rule or result derived here. Postfix x++ contributes old x=1 and y-- contributes old y=10; prefix ++z changes -3 to -2 before use. Thus p=1*10+(-2)=8. The new x=2 and y=9 are not the values multiplied. The other values mix old and updated operands.

C - Correct: "p=8" matches the derived result. Postfix x++ contributes old x=1 and y-- contributes old y=10; prefix ++z changes -3 to -2 before use. Thus p=1*10+(-2)=8. The new x=2 and y=9 are not the values multiplied. The other values mix old and updated operands.

D - Incorrect: "p=16" does not match the rule or result derived here. Postfix x++ contributes old x=1 and y-- contributes old y=10; prefix ++z changes -3 to -2 before use. Thus p=1*10+(-2)=8. The new x=2 and y=9 are not the values multiplied. The other values mix old and updated operands.

Primary note proof

Study-note section CP09

> Prefix ++x changes x and yields the new value; postfix x++ yields the previous value and also increments x. Separate the value used in the expression from the stored value after it. Starting a=8,b=5, a++ + --b uses 8+4, gives 12, and leaves a=9,b=4. Starting x=1,y=10,z=-3, (x++*y--)+ ++z gives 8 and leaves x=2,y=9,z=-2.

Computer Science model exam · Question 1

University of Gondar model exam · Question 1

Question 23 | Q00271

What will happen in the following C++ code snippet? int a = 100, b = 200; int *p = &a, *q = &b; p= q;

A. p now points to b

B. a is assigned to b

C. b is assigned to a

D. q now points to a

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer A: p now points to b

p initially stores &a and q stores &b. Assignment p=q copies the address stored in q into p, so both point to b. Neither pointee value is assigned because no dereference appears; q is not assigned at all. Module support: PDF p. 26, PDF p. 27.

Why each choice is right or wrong

A - Correct: "p now points to b" matches the derived result. p initially stores &a and q stores &b. Assignment p=q copies the address stored in q into p, so both point to b. Neither pointee value is assigned because no dereference appears; q is not assigned at all.

B - Incorrect: "a is assigned to b" does not match the rule or result derived here. p initially stores &a and q stores &b. Assignment p=q copies the address stored in q into p, so both point to b. Neither pointee value is assigned because no dereference appears; q is not assigned at all.

C - Incorrect: "b is assigned to a" does not match the rule or result derived here. p initially stores &a and q stores &b. Assignment p=q copies the address stored in q into p, so both point to b. Neither pointee value is assigned because no dereference appears; q is not assigned at all.

D - Incorrect: "q now points to a" does not match the rule or result derived here. p initially stores &a and q stores &b. Assignment p=q copies the address stored in q into p, so both point to b. Neither pointee value is assigned because no dereference appears; q is not assigned at all.

Primary note proof

Study-note section CP25

> int x=10; int* p=&x; stores x's address in p. *p reads or writes x; &p is the address of the pointer variable itself. With p=&a,q=&b, p=q redirects p to b and leaves a and b unchanged. By contrast *p=*q copies the pointed-to value. Never dereference an uninitialized, null or dangling pointer.

University of Gondar model exam · Question 2

University of Gondar model exam · Question 7

Question 24 | Q00272

Which of the following best describes the statement "C++ is a case sensitive programming language"?

A. All variables in C++ are identifiers

B. Every C++ statement should include the header file iostream.h

C. ExitExam and exitExam are distinct in C++

D. Every statement in C++ ends with semicolon

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer C: ExitExam and exitExam are distinct identifiers.

Case sensitivity means changing uppercase to lowercase can change the identifier. ExitExam and exitExam therefore name different entities in C++. Claims about headers, variable terminology or semicolon placement do not explain case sensitivity; the universal header and semicolon assertions also overstate C++ syntax requirements.

Why each choice is right or wrong

A - Incorrect: Variable names are identifiers, but this does not describe the effect of changing letter case.

B - Incorrect: Header inclusion is unrelated to case sensitivity, and headers are not included in every statement.

C - Correct: The differing initial letter case makes ExitExam and exitExam distinct C++ identifiers.

D - Incorrect: Semicolon rules concern grammar, not identifier case, and do not apply uniformly to every construct.

Primary note proof

Study-note section CP05

> In the basic ASCII identifier rules, start with a letter or underscore; continue with letters, digits or underscores. Do not use a keyword. C++ is case sensitive: exitExam and ExitExam differ; delete and float are keywords, but FLOAT is a legal identifier. variable_1234 is valid; 4thInput, T-3 and names containing spaces are not single identifiers. Avoid reserved underscore patterns in application code.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 5 | lines 2-10

> 1. Keywords (reserved words) - Unique meaning within a C++ program and must not be used for any other purposes. E.g., if, namespace for, switch, continue, float, new, default, break Etc. 2. Identifiers - Name associated with a function or data object and used to refer to that function or data object. An identifier must: o Start with a letter or underscore o Consist only of letters, the digits 0-9, or the underscore symbol _ o Not be a reserved word

Computer Science model exam · Question 3

University of Gondar model exam · Question 3

Question 25 | Q00273

Assume a and b are distinct ordinary int variables and b has an initialized value. Immediately after a=b;, which statements about the assignment and subsequent changes to b are true? Select all that apply.

A. The value of a and b are equal

B. The value of b is assigned to variable a and the later change on variable b will affect the value of variable a

C. The value of variable a is assigned to variable b and the value of variable b is assigned to variable a

D. The value of b is assigned to variable a and the later change on variable b will not affect the value of variable a

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer A, D: A. The value of a and b are equal; D. The value of b is assigned to variable a and the later change on variable b will not affect the value of variable a

Scalar assignment copies the value stored in b into the separate object a. Immediately afterward, the two values are equal. Their storage remains independent, however: changing b later does not automatically update a. Thus both the immediate-equality description and the copy-with-independence description are true. Assignment works in one direction and is neither a swap nor a reference binding between these two int variables.

Why each choice is right or wrong

A - Correct: The copied int values are equal immediately after assignment.

B - Incorrect: Separate scalar storage means later changes to b do not affect a.

C - Incorrect: Assignment copies one way; it does not swap values.

D - Correct: This correctly states both the copying direction and later independence.

Primary note proof

Study-note section CP06

> Write type name; or type name = value; for ordinary variables: int age = 20;. Declaration introduces a name and type; initialization gives its initial value; later assignment replaces a value. a=b copies a scalar value, so later changes to b do not change a. A pointer or Java object reference instead copies an address/reference.

University of Gondar model exam · Question 4

Question 26 | Q00274

Which one of the following is true statement about an algorithm?

A. Ambiguous steps are allowed in an algorithm.

B. Complex problems cannot have an algorithm.

C. An algorithm may not have a beginning and an end.

D. An algorithm should take finite amount of time to compute.

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer D: An algorithm should take finite amount of time to compute.

The module defines an algorithm as unambiguous executable steps forming a terminating process and explicitly requires finite execution for each input. A permits ambiguity, B imposes an unsupported complexity restriction, and C allows missing termination, contrary to that definition. Module support: PDF p. 2.

Why each choice is right or wrong

A - Incorrect: "Ambiguous steps are allowed in an algorithm." does not match the rule or result derived here. The module defines an algorithm as unambiguous executable steps forming a terminating process and explicitly requires finite execution for each input. A permits ambiguity, B imposes an unsupported complexity restriction, and C allows missing termination, contrary to that definition.

B - Incorrect: "Complex problems cannot have an algorithm." does not match the rule or result derived here. The module defines an algorithm as unambiguous executable steps forming a terminating process and explicitly requires finite execution for each input. A permits ambiguity, B imposes an unsupported complexity restriction, and C allows missing termination, contrary to that definition.

C - Incorrect: "An algorithm may not have a beginning and an end." does not match the rule or result derived here. The module defines an algorithm as unambiguous executable steps forming a terminating process and explicitly requires finite execution for each input. A permits ambiguity, B imposes an unsupported complexity restriction, and C allows missing termination, contrary to that definition.

D - Correct: "An algorithm should take finite amount of time to compute." matches the derived result. The module defines an algorithm as unambiguous executable steps forming a terminating process and explicitly requires finite execution for each input. A permits ambiguity, B imposes an unsupported complexity restriction, and C allows missing termination, contrary to that definition.

Primary note proof

Study-note section CP02

> An algorithm gives precise, executable steps and terminates for every legal input. Definiteness means each step has an unambiguous meaning; effectiveness means a step can actually be performed. Inputs may be absent, but a useful algorithm specifies a result. Correctness means the result meets the specification. Efficiency is desirable and measurable, but an inefficient terminating algorithm is still an algorithm. Efficiency is also a desirable property of an algorithm.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 2 | lines 19-26

> Algorithm is an ordered set of unambiguous, executable steps, defining a terminating process. Important Properties of Algorithms - Correct: always returns the desired output for all legal instances of the problem. - Unambiguous: Each step must be clearly defined, having only one interpretation. - Precise: simple but efficient - Efficient: can be measured in terms of Time and Space - Finiteness: the execution of the algorithm must terminate in a finite amount of time for each possible set of input data/must have an end.

Question 27 | Q00275

Which of the following will NOT increase an integer variable "i" by 1?

A. i+=1;

B. i=i+1; E. ++i;

C. i=i+i;

D. i++;

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer C: i=i+i;

i=i+i doubles i rather than adding a fixed one. i+=1, i=i+1, i++ and the embedded ++i all increment by one. At the special value i=1 doubling also adds one; the intended comparison is between operations for general i. Module support: PDF p. 7.

Why each choice is right or wrong

A - Incorrect: "i+=1;" does not match the rule or result derived here. i=i+i doubles i rather than adding a fixed one. i+=1, i=i+1, i++ and the embedded ++i all increment by one. At the special value i=1 doubling also adds one; the intended comparison is between operations for general i.

B - Incorrect: "i=i+1; E. ++i;" does not match the rule or result derived here. i=i+i doubles i rather than adding a fixed one. i+=1, i=i+1, i++ and the embedded ++i all increment by one. At the special value i=1 doubling also adds one; the intended comparison is between operations for general i.

C - Correct: "i=i+i;" matches the derived result. i=i+i doubles i rather than adding a fixed one. i+=1, i=i+1, i++ and the embedded ++i all increment by one. At the special value i=1 doubling also adds one; the intended comparison is between operations for general i.

D - Incorrect: "i++;" does not match the rule or result derived here. i=i+i doubles i rather than adding a fixed one. i+=1, i=i+1, i++ and the embedded ++i all increment by one. At the special value i=1 doubling also adds one; the intended comparison is between operations for general i.

Primary note proof

Study-note section CP08

> x+=y, x-=y, x*=y, x/=y and x%=y update x using the operation and conversion to its type. For simple variables, trace them as x=x op y. Starting p=q=n=8, p+=n gives 16 and p/=q gives 2. Starting x=10, x+=5 then x/=2 gives 7. x=x+x doubles; it does not generally add one.

Study-note section CP09

> Prefix ++x changes x and yields the new value; postfix x++ yields the previous value and also increments x.

Question sources

Computer Science model exam · Question 6

University of Gondar model exam · Question 6

Question 28 | Q00336

Consider native C++ translation through assembly into an object file, stopping before linking. Which statement best describes the resulting object file’s instructions?

A. Machine-independent bytecode for a virtual machine

B. A complete linked executable

C. Both a and b

D. Native machine instructions in an object file

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer D: D. Native machine instructions in an object file

The specified native pipeline stops after the assembler produces an object file and before the linker combines objects and resolves external references. Its code is therefore native machine instructions in an object file. Machine-independent bytecode belongs to a different translation target, such as javac’s output, while a complete linked executable comes later in this C++ pipeline. Neither A nor B correctly names the specified result.

Why each choice is right or wrong

A - Incorrect: Machine-independent bytecode is a different target from the specified native object instructions.

B - Incorrect: The pipeline stops before linking produces a complete executable.

C - Incorrect: Both A and B describe different targets or later stages.

D - Correct: The assembler emits native machine instructions into an object file.

Primary note proof

Study-note section CP04

> In the conventional C++ toolchain: source → preprocessing → compilation proper → assembly → object files → linking → executable → loading → execution. Preprocessing handles directives such as #include; compilation may emit assembly; the assembler emits machine instructions in an object file. The linker resolves external symbols and combines object files and libraries. The loader places an executable and required components in memory and starts it.

Study-note section CP04

> Java javac produces bytecode, which a JVM interprets or compiles at runtime.

Module passages - related reading

Computer Science model exam · Question 67

University of Gondar model exam · Question 67

Question 29 | Q00455

A _____ provides us with named storage that our programs can manipulate.

A. data type

B. constants

C. operators

D. variable

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer D: variable

A variable is a symbolic name for a memory location holding data (p.5), so it supplies named manipulable storage. A data type classifies the value, constants have fixed values, and operators specify manipulations rather than storage. Module support: PDF p. 5.

Why each choice is right or wrong

A - Incorrect: "data type" does not match the rule or result derived here. A variable is a symbolic name for a memory location holding data (p.5), so it supplies named manipulable storage. A data type classifies the value, constants have fixed values, and operators specify manipulations rather than storage.

B - Incorrect: "constants" does not match the rule or result derived here. A variable is a symbolic name for a memory location holding data (p.5), so it supplies named manipulable storage. A data type classifies the value, constants have fixed values, and operators specify manipulations rather than storage.

C - Incorrect: "operators" does not match the rule or result derived here. A variable is a symbolic name for a memory location holding data (p.5), so it supplies named manipulable storage. A data type classifies the value, constants have fixed values, and operators specify manipulations rather than storage.

D - Correct: "variable" matches the derived result. A variable is a symbolic name for a memory location holding data (p.5), so it supplies named manipulable storage. A data type classifies the value, constants have fixed values, and operators specify manipulations rather than storage.

Primary note proof

Study-note section CP06

> Write type name; or type name = value; for ordinary variables: int age = 20;. Declaration introduces a name and type; initialization gives its initial value; later assignment replaces a value. a=b copies a scalar value, so later changes to b do not change a. A pointer or Java object reference instead copies an address/reference.

Study-note section CP25

> int x=10; int* p=&x; stores x’s address in p.

D. Combine two numeric values

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer C: Combine two boolean values

The logical operators combine truth-valued operands and produce 1 or 0 (p.7). Relational operators perform comparisons; arithmetic operators combine numeric quantities arithmetically. Numeric operands may be interpreted as truth values, but the logical role asked here is combination of boolean values. Module support: PDF p. 7.

Why each choice is right or wrong

A - Incorrect: "Compare two boolean values" does not match the rule or result derived here. The logical operators combine truth-valued operands and produce 1 or 0 (p.7). Relational operators perform comparisons; arithmetic operators combine numeric quantities arithmetically. Numeric operands may be interpreted as truth values, but the logical role asked here is combination of boolean values.

B - Incorrect: "Compare two numeric values" does not match the rule or result derived here. The logical operators combine truth-valued operands and produce 1 or 0 (p.7). Relational operators perform comparisons; arithmetic operators combine numeric quantities arithmetically. Numeric operands may be interpreted as truth values, but the logical role asked here is combination of boolean values.

C - Correct: "Combine two boolean values" matches the derived result. The logical operators combine truth-valued operands and produce 1 or 0 (p.7). Relational operators perform comparisons; arithmetic operators combine numeric quantities arithmetically. Numeric operands may be interpreted as truth values, but the logical role asked here is combination of boolean values.

D - Incorrect: "Combine two numeric values" does not match the rule or result derived here. The logical operators combine truth-valued operands and produce 1 or 0 (p.7). Relational operators perform comparisons; arithmetic operators combine numeric quantities arithmetically. Numeric operands may be interpreted as truth values, but the logical role asked here is combination of boolean values.

Primary note proof

Study-note section CP10

> Relational and equality operators test values; && and || combine truth values; ! negates. In C++, zero converts to false and a nonzero number to true. Streams display bool as 0 or 1 unless boolalpha is set. With a=3,b=5, cout<<(a==b) prints 0.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 7 | lines 5-23

> Assignment Operators (=) Example: int x=5; or used with a combination of other operators‟ example, x+=2;//x=x+2, x=y=10; Arithmetic Operators (+, -, *, /, %) E.g. Assume int X=9, Y=2 X+Y, Y-X, X%Y Relational operators (==,!=, <, <=,>,>=) Relational operators evaluate to 1 (representing the true outcome) or 0 (representing the false outcome). Assume int X=9, Y=2 X==Y, X!=Y, X>Y 'A' < 'F' // gives 1 (is like 65 < 70) Logical operators (! Negation, &&, ||) Like the relational operators, logical operators evaluate to 1 or 0. Example: 5 < 6 || 6 < 5 // gives 1 In general, any nonzero value can be used to represent the logical true, whereas only zero represents the logical false !12 // gives 0 10 && 5 // gives 1 Increment/decrement Operators The auto increment (++) and auto decrement (--) operators provide a convenient way of, respectively, adding and subtracting 1 from a numeric variable. Both operators can be used in prefix and postfix form.

Question sources

Object-Oriented Programming practice questions · Question 34

Question 31 | Q00470

Which of these have highest precedence?

A. ()

B. ++

C. *

D. >>

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer A: Parentheses ().

CP10 places grouping/postfix at the top of its precedence ladder. Parentheses explicitly group an expression before surrounding operations are applied. Increment, multiplication or dereference, and right shift do not override that grouping. The precise role of * or ++ in an expression does not make it outrank explicit parentheses.

Why each choice is right or wrong

A - Correct: Parentheses explicitly group expressions and occupy the highest grouping level in the note.

B - Incorrect: Increment does not override parentheses; prefix increment is unary and postfix increment follows grouping rules.

C - Incorrect: Multiplication is below grouping; unary dereference also does not override parenthesized grouping.

D - Incorrect: Right shift ranks below both grouping and arithmetic operations in the stated ladder.

Primary note proof

Study-note section CP10

> && evaluates its right operand only if the left is true; || only if the left is false. Thus false && dangerousCall() skips the call. Bitwise & operates on bits and does not short circuit. With x=1,y=0,z=4, (x&y)||++z evaluates ++z, leaving z=5 and the Boolean result 1. The precedence ladder is grouping/postfix, unary, multiplicative, additive, shifts, relations, equality, bitwise &, ^, |, &&, ||, conditional, assignment, comma.

Question sources

Object-Oriented Programming practice questions · Question 40

Question 32 | Q00479

A _____ statement allows us to execute a statement or group of statements multiple times.

A. array

B. loop

C. function

D. exception

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer B: loop

Loop statements specify repeated computations (p.9), and iteration repeats a statement or block (p.11). Arrays group data, functions modularize code, and exceptions are not the module definition of repetition. Module support: PDF p. 9, PDF p. 11.

Why each choice is right or wrong

A - Incorrect: "array" does not match the rule or result derived here. Loop statements specify repeated computations (p.9), and iteration repeats a statement or block (p.11). Arrays group data, functions modularize code, and exceptions are not the module definition of repetition.

B - Correct: "loop" matches the derived result. Loop statements specify repeated computations (p.9), and iteration repeats a statement or block (p.11). Arrays group data, functions modularize code, and exceptions are not the module definition of repetition.

C - Incorrect: "function" does not match the rule or result derived here. Loop statements specify repeated computations (p.9), and iteration repeats a statement or block (p.11). Arrays group data, functions modularize code, and exceptions are not the module definition of repetition.

D - Incorrect: "exception" does not match the rule or result derived here. Loop statements specify repeated computations (p.9), and iteration repeats a statement or block (p.11). Arrays group data, functions modularize code, and exceptions are not the module definition of repetition.

Primary note proof

Study-note section CP14

> while(condition) checks before each body execution and may run zero times. do {body;} while(condition); runs the body once before checking; it repeats while the condition remains true. Use it when a menu or input attempt must occur at least once.

Study-note section CP32

> Exceptions transfer control to a matching handler for exceptional conditions; they do not make arbitrary undefined behavior recoverable.

Computer Programming module | PDF page 9 | lines 2-8

> Control Statements Control statements or flow control determines what is executed during a run and what is not, therefore affecting the overall outcome of the program. C++ provides different forms of statements for different purposes. Declaration statements are used for defining variables. Assignment-like statements are used for simple, algebraic computations. Branching statements are used for specifying alternate paths of execution, depending on the outcome of a

logical condition. Loop statements are used for specifying computations, which need to be repeated until a certain logical condition is satisfied

Computer Programming module | PDF page 11 | lines 5-13

Iteration/Looping Statement: Iteration is the repetition of a statement or block of statements in a program. - Loops have as objective to repeat a statement a certain number of times or while a condition is fulfilled. - C++ has three iteration statements: the while statement, the do. While statement, and the for statement. The while loop: Its format is: while (expression) {statement;} First expression (called the loop condition) is evaluated. If the outcome is nonzero then statement (called the loop body) is executed and the whole process is repeated. Otherwise, the loop is terminated.

Question sources

Object-Oriented Programming practice questions · Question 49

Question 33 | Q00482

A for loop is useful when you know how many times a task is to be repeated.

A. TRUE

B. FALSE

C. Can be true or false

D. Can not say

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer A: TRUE

A for loop has initialization, a condition and an update field (p.12). These directly express a known repetition count using a counter, so the stated usefulness is true; it does not claim that all for loops must have predetermined counts. Module support: PDF p. 12.

Why each choice is right or wrong

A - Correct: "TRUE" matches the derived result. A for loop has initialization, a condition and an update field (p.12). These directly express a known repetition count using a counter, so the stated usefulness is true; it does not claim that all for loops must have predetermined counts.

B - Incorrect: "FALSE" does not match the rule or result derived here. A for loop has initialization, a condition and an update field (p.12). These directly express a known repetition count using a counter, so the stated usefulness is true; it does not claim that all for loops must have predetermined counts.

C - Incorrect: "Can be true or false" does not match the rule or result derived here. A for loop has initialization, a condition and an update field (p.12). These directly express a known repetition

count using a counter, so the stated usefulness is true; it does not claim that all for loops must have predetermined counts.

D - Incorrect: "Can not say" does not match the rule or result derived here. A for loop has initialization, a condition and an update field (p.12). These directly express a known repetition count using a counter, so the stated usefulness is true; it does not claim that all for loops must have predetermined counts.

Primary note proof

Study-note section CP14

> for(initialization; condition; update) executes initialization once, then condition → body → update → condition. A missing condition in for(;;) acts as true. A for loop is convenient for a known count but can also be condition controlled. To print indices 0 through n-1, use i=0; i<n; ++i. Starting i=0 with i<5 and i+=2 prints 0 2 4.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 12 | lines 19-28

> The for loop. Its format is: for (initialization; condition; increase) statement; 1, initialization is executed. Generally, it is a initial value setting for a counter variable. This is executed only once 2, condition is checked, if it is true the loop continues, otherwise the loop finishes and statement is skipped. 3, statement is executed. As usual, it can be either a single instruction or a block of instructions enclosed within curly brackets { }. 4, finally, whatever is specified in the increase field is executed and the loop gets back to step 2.

Question sources

Object-Oriented Programming practice questions · Question 52

Question 34 | Q00627

Which one of the following are translate the whole source program into object code.

A. Compiler

B. Interprater

C. Linker

D. All

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer A: Compiler

The module says compilers translate the entire source before execution and produce object code (pp.3-4). Interpreters translate one line at a time. Linking combines existing object files rather than translating the source, so All cannot hold. Module support: PDF p. 4, PDF p. 3.

Why each choice is right or wrong

A - Correct: "Compiler" matches the derived result. The module says compilers translate the entire source before execution and produce object code (pp.3-4). Interpreters translate one line at a time. Linking combines existing object files rather than translating the source, so All cannot hold.

B - Incorrect: "Interprater" does not match the rule or result derived here. The module says compilers translate the entire source before execution and produce object code (pp.3-4). Interpreters translate one line at a time. Linking combines existing object files rather than translating the source, so All cannot hold.

C - Incorrect: "Linker" does not match the rule or result derived here. The module says compilers translate the entire source before execution and produce object code (pp.3-4). Interpreters translate one line at a time. Linking combines existing object files rather than translating the source, so All cannot hold.

D - Incorrect: "All" does not match the rule or result derived here. The module says compilers translate the entire source before execution and produce object code (pp.3-4). Interpreters translate one line at a time. Linking combines existing object files rather than translating the source, so All cannot hold.

Primary note proof

Study-note section CP04

> In the conventional C++ toolchain: source → preprocessing → compilation proper → assembly → object files → linking → executable → loading → execution. Preprocessing handles directives such as #include; compilation may emit assembly; the assembler emits machine instructions in an object file. The linker resolves external symbols and combines object files and libraries. The loader places an executable and required components in memory and starts it.

Study-note section CP04

> GCC documents the first four stages explicitly. A compiler need not emit a complete executable or even native machine code. Java javac produces bytecode, which a JVM interprets or compiles at runtime. Interpreters execute a program representation; “one source line at a time” is a beginner approximation. Compilation uses multiple passes, so “whole program in one step” is not literally universal.

Computer Science model exam · 2015 · Question 96

Question 35 | Q00660

In C++ programming, a variable which stores a reference to another variable is called a____

A. Pointer

B. Constructor

C. Asterisks

D. Structure

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer A: Pointer

The module defines a pointer as a variable holding the memory address of another variable (p.26). Here reference is informal wording for an address, not the distinct C++ reference type. Constructor, the asterisk symbol and structure do not name that variable category. Module support: PDF p. 26.

Why each choice is right or wrong

A - Correct: "Pointer" matches the derived result. The module defines a pointer as a variable holding the memory address of another variable (p.26). Here reference is informal wording for an address, not the distinct C++ reference type. Constructor, the asterisk symbol and structure do not name that variable category.

B - Incorrect: "Constructor" does not match the rule or result derived here. The module defines a pointer as a variable holding the memory address of another variable (p.26). Here reference is

informal wording for an address, not the distinct C++ reference type. Constructor, the asterisk symbol and structure do not name that variable category.

C - Incorrect: "Asterisks" does not match the rule or result derived here. The module defines a pointer as a variable holding the memory address of another variable (p.26). Here reference is informal wording for an address, not the distinct C++ reference type. Constructor, the asterisk symbol and structure do not name that variable category.

D - Incorrect: "Structure" does not match the rule or result derived here. The module defines a pointer as a variable holding the memory address of another variable (p.26). Here reference is informal wording for an address, not the distinct C++ reference type. Constructor, the asterisk symbol and structure do not name that variable category.

Primary note proof

Study-note section CP25

int x=10; int* p=&x; stores x's address in p. *p reads or writes x; &p is the address of the pointer variable itself. With p=&a,q=&b, p=q redirects p to b and leaves a and b unchanged. By contrast *p=*q copies the pointed-to value. Never dereference an uninitialized, null or dangling pointer.

Computer Science model exam 2 · Question 1

Question 36 | Q00661

A program that translates a high-level language like C++ to a machine language is called a

A. Disassembler

B. Coder

C. Compiler

D. Assembler

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer C: Compiler

A compiler translates the high-level source program before execution (pp.3-4). A linker combines object files and an assembler is not named here as the high-level translator; disassembler/coder do not match the stated compilation role. Module support: PDF p. 3, PDF p. 4.

Why each choice is right or wrong

A - Incorrect: "Disassembler" does not match the rule or result derived here. A compiler translates the high-level source program before execution (pp.3-4). A linker combines object files and an assembler is not named here as the high-level translator; disassembler/coder do not match the stated compilation role.

B - Incorrect: "Coder" does not match the rule or result derived here. A compiler translates the high-level source program before execution (pp.3-4). A linker combines object files and an assembler is not named here as the high-level translator; disassembler/coder do not match the stated compilation role.

C - Correct: "Compiler" matches the derived result. A compiler translates the high-level source program before execution (pp.3-4). A linker combines object files and an assembler is not named here as the high-level translator; disassembler/coder do not match the stated compilation role.

D - Incorrect: "Assembler" does not match the rule or result derived here. A compiler translates the high-level source program before execution (pp.3-4). Question sources

Computer Science model exam 2 · Question 2

Question 37 | Q00662

Given int A=0, B=10, x=1, y=2;, which C++ Boolean expression evaluates to false?

A. (B == 10) || (x < y)

B. (A > 20) || (B >5)

C. (A > 10) && (x < y)

D. (A == 0) && (B < 20)

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer C: C. (A > 10) && (x < y)

Evaluate each comparison using the declared integers and apply short-circuit logic. B==10 is true, so the first disjunction is true. Although A>20 is false, B>5 makes the second disjunction true. In C, A>10 is false, so && yields false without needing its right operand. Both comparisons in D are true. Every offered expression is well formed under the stated declarations.

Why each choice is right or wrong

A - Incorrect: B==10 is true, so this disjunction is true.

B - Incorrect: B>5 is true, so this disjunction is true.

C - Correct: A>10 is false, making the conjunction false.

D - Incorrect: A==0 and B<20 are both true.

Primary note proof

Study-note section CP10

> Relational and equality operators test values; && and || combine truth values; ! negates. In C++, zero converts to false and a nonzero number to true. Streams display bool as 0 or 1 unless boolalpha is set. With a=3,b=5, cout<<(a==b) prints 0.

Study-note section CP10

Computer Science model exam 2 · Question 3

Question 38 | Q00663

Which one of the following format is write about functions in structural Programming:

A. Type name { parameter1, parameter2, ...} (statement)

B. Name type (parameter1, parameter2, ...) { statement }

C. Type name (parameter1, parameter2, ...) {statement }

D. Name type { parameter1, parameter2, ...} (statement)

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer C: Type name (parameter1, parameter2, ...) {statement }

The module function-definition pattern is Function_type function_name(Parameter List) followed by a braced function body (p.15). C preserves that order and delimiters. A/D interchange braces and parentheses, while B puts name before type. Module support: PDF p. 15.

Why each choice is right or wrong

A - Incorrect: "Type name { parameter1, parameter2, ...} (statement)" does not match the rule or result derived here. The module function-definition pattern is Function_type function_name(Parameter List) followed by a braced function body (p.15). C preserves that order and delimiters. A/D interchange braces and parentheses, while B puts name before type.

B - Incorrect: "Name type (parameter1, parameter2, ...) { statement }" does not match the rule or result derived here. The module function-definition pattern is Function_type function_name(Parameter List) followed by a braced function body (p.15). C preserves that order and delimiters. A/D interchange braces and parentheses, while B puts name before type.

C - Correct: "Type name (parameter1, parameter2, ...) {statement }" matches the derived result. The module function-definition pattern is Function_type function_name(Parameter List) followed by a braced function body (p.15). C preserves that order and delimiters. A/D interchange braces and parentheses, while B puts name before type.

D - Incorrect: "Name type { parameter1, parameter2, ...} (statement)" does not match the rule or result derived here. The module function-definition pattern is Function_type function_name(Parameter List) followed by a braced function body (p.15). C preserves that order and delimiters. A/D interchange braces and parentheses, while B puts name before type.

Primary note proof

Study-note section CP17

A function groups a named task. C++ definition: int add(int a,int b){return a+b;}. Call it with add(x,y);, without parameter type declarations at the call site. Parameters are names in the definition; arguments are supplied expressions or values. A void function produces no return value but can have side effects and return; to exit early.

• User-defined - Function that been created by the user. - These functions need to be declared and defined by the user. Declaration of function Function defines using the following syntax: Function_type function_name (Parameter List) { ...function body } Example: void Addition(int num1,int num2) #include<iostream> using namespace std; void Addition(int num1,int num2) { int sum=num1+num2; cout<<"The sum is:"<<sum; } int main() { int x=10,y=20; Addition(x,y);

Question sources

Computer Science model exam 2 · Question 4

Question 39 | Q00664

Which of the following is a valid function call (assuming the function add exists & have two parameters)?

A. add;

B. add(a,b);

C. add a,b;

D. add(int a, int b);

Hint

Apply the naming, type and syntax rules before deciding whether an option can be used as stated.

Answer B: add(a,b);

The example Addition(x,y) on p.15 calls a function using its name and parenthesized argument expressions. add(a,b); has that form. A does not call it, C lacks parentheses, and D inserts declarations where argument expressions are required. Module support: PDF p. 15.

Why each choice is right or wrong

A - Incorrect: "add;" does not match the rule or result derived here. The example Addition(x,y) on p.15 calls a function using its name and parenthesized argument expressions. add(a,b); has that form. A does not call it, C lacks parentheses, and D inserts declarations where argument expressions are required.

B - Correct: "add(a,b);" matches the derived result. The example Addition(x,y) on p.15 calls a function using its name and parenthesized argument expressions. add(a,b); has that form. A does not call it, C lacks parentheses, and D inserts declarations where argument expressions are required.

C - Incorrect: "add a,b;" does not match the rule or result derived here. The example Addition(x,y) on p.15 calls a function using its name and parenthesized argument expressions. add(a,b); has that form. A does not call it, C lacks parentheses, and D inserts declarations where argument expressions are required.

D - Incorrect: "add(int a, int b);" does not match the rule or result derived here. The example Addition(x,y) on p.15 calls a function using its name and parenthesized argument expressions. add(a,b); has that form. A does not call it, C lacks parentheses, and D inserts declarations where argument expressions are required.

Question 40 | Q00665

A function is said to be recursive function_____?

A. If the function calls another function2 & Function3

B. If the main function calls many functions

C. If the main function calls another one function

D. If the function calls itself

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer D: If the function calls itself

A recursive function calls itself (p.18). Calling several other functions, or being called by main, does not itself constitute recursion. Module support: PDF p. 18.

Why each choice is right or wrong

A - Incorrect: "If the function calls another function2 & Function3" does not match the rule or result derived here. A recursive function calls itself (p.18). Calling several other functions, or being called by main, does not itself constitute recursion.

B - Incorrect: "If the main function calls many functions" does not match the rule or result derived here. A recursive function calls itself (p.18). Calling several other functions, or being called by main, does not itself constitute recursion.

C - Incorrect: "If the main function calls another one function" does not match the rule or result derived here. A recursive function calls itself (p.18). Calling several other functions, or being called by main, does not itself constitute recursion.

D - Correct: "If the function calls itself" matches the derived result. A recursive function calls itself (p.18). Calling several other functions, or being called by main, does not itself constitute recursion.

Primary note proof

Study-note section CP21

> A recursive function calls itself directly or indirectly. It needs a base case and progress toward it for all supported inputs. factorial(0)=1 and factorial(n)=n*factorial(n-1) for positive n. factorial(3) expands to 3*2*1*1=6. Negative inputs require rejection or a separate definition; they do not reach zero under n-1.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 18 | lines 23-28

> Recursive Functions - Functions that call themselves - A function that is defined in terms of itself is called recursive - There must be a base case e.g. 0! = 1 - Slowly converges towards base case - For example, Recursive functions N! = N * (N-1)!

Computer Science model exam 2 · Question 6

Question 41 | Q00666

What will be the return type of a function, if the function does not have a return value?

A. Int

B. Float

C. Double

D. Void

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer D: Void

The module illustrates void Addition(...) whose body prints a result without returning a value (p.15). This matches void for no returned value; int, float and double denote value-bearing return types. Capitalization in the options is treated as prose. Module support: PDF p. 15.

Why each choice is right or wrong

A - Incorrect: "Int" does not match the rule or result derived here. The module illustrates void Addition(...) whose body prints a result without returning a value (p.15). This matches void for no returned value; int, float and double denote value-bearing return types. Capitalization in the options is treated as prose.

B - Incorrect: "Float" does not match the rule or result derived here. The module illustrates void Addition(...) whose body prints a result without returning a value (p.15). This matches void for no returned value; int, float and double denote value-bearing return types. Capitalization in the options is treated as prose.

C - Incorrect: "Double" does not match the rule or result derived here. The module illustrates void Addition(...) whose body prints a result without returning a value (p.15). This matches void for no returned value; int, float and double denote value-bearing return types. Capitalization in the options is treated as prose.

D - Correct: "Void" matches the derived result. The module illustrates void Addition(...) whose body prints a result without returning a value (p.15). This matches void for no returned value; int, float and double denote value-bearing return types. Capitalization in the options is treated as prose.

Primary note proof

Study-note section CP17

A function groups a named task. C++ definition: int add(int a,int b){return a+b;}. Call it with add(x,y);, without parameter type declarations at the call site. Parameters are names in the definition; arguments are supplied expressions or values. A void function produces no return value but can have side effects and return; to exit early.

Computer Programming module | PDF page 15 | lines 29-46

• User-defined - Function that been created by the user. - These functions need to be declared and defined by the user. Declaration of function Function defines using the following syntax: Function_type function_name (Parameter List) { ...function body } Example: void Addition(int num1,int num2) #include<iostream> using namespace std; void Addition(int num1,int num2) { int sum=num1+num2; cout<<"The sum is:"<<sum; } int main() { int x=10,y=20; Addition(x,y);

Question sources

Computer Science model exam 2 · Question 7

Question 42 | Q00667

____is a header file which permits writing of data to a file.

A. ofstream

B. ifstream

C. istream

D. fstream

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer D: fstream

The module explicitly instructs including the <fstream> header to work with files (p.40). ofstream is the class for writing, ifstream the reading class, and istream is not the named file header. The question asks for the header, so fstream is the applicable choice. Module support: PDF p. 40.

Why each choice is right or wrong

A - Incorrect: "ofstream" does not match the rule or result derived here. The module explicitly instructs including the <fstream> header to work with files (p.40). ofstream is the class for writing, ifstream the reading class, and istream is not the named file header. The question asks for the header, so fstream is the applicable choice.

B - Incorrect: "ifstream" does not match the rule or result derived here. The module explicitly instructs including the <fstream> header to work with files (p.40). ofstream is the class for writing, ifstream the reading class, and istream is not the named file header. The question asks for the header, so fstream is the applicable choice.

C - Incorrect: "istream" does not match the rule or result derived here. The module explicitly instructs including the <fstream> header to work with files (p.40). ofstream is the class for writing, ifstream the reading class, and istream is not the named file header. The question asks for the header, so fstream is the applicable choice.

D - Correct: "fstream" matches the derived result. The module explicitly instructs including the <fstream> header to work with files (p.40). ofstream is the class for writing, ifstream the reading class, and istream is not the named file header. The question asks for the header, so fstream is the applicable choice.

Primary note proof

Study-note section CP29

> Include <fstream>. ofstream writes, ifstream reads, and fstream can do both. The constructor's default ofstream mode argument is ios::out; its ordinary effect is to create/truncate the file. Distinguish the default mode argument from effective out|trunc behavior. ios::app places each write at the end; ios::ate initially seeks to the end; ios::binary requests binary mode.

Study-note section CP29

> "ofstream" is a class, whereas <fstream> is the header.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 40 | lines 16-22

> File and File Management Files are used to store data in storage devices permanently. The fstream library allows us to work with files. To use the fstream library, include both the standard <iostream> AND the <fstream> header file: Input/Output with files • ofstream: Stream class to write on files • ifstream: Stream class to read from files

Question sources

Computer Science model exam 2 · Question 8

Question 43 | Q00668

Which statements about C++ structures are true? Select all that apply. In C, initialization refers to defining a structure object with initial member values.

A. A structure must contain only homogeneous members.

B. The named individual components of a structure are called members.

C. A structure object can be initialized when it is defined.

D. All are correct

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer B, C: B. The named individual components of a structure are called members.; C. A structure object can be initialized when it is defined.

A structure groups named members and can combine different member types, so it need not be homogeneous. Those named components are called members. Defining an object with an aggregate initializer supplies initial values in member declaration order, making the initialization statement true. Since A wrongly requires homogeneity, the aggregate claim that all statements are correct is false even though B and C hold.

Why each choice is right or wrong

A - Incorrect: Members can have different types; homogeneity is not required.

B - Correct: The named individual components of a structure are its members.

C - Correct: A structure object can be initialized when the object is defined.

D - Incorrect: A is false, so the aggregate all-correct claim fails.

Primary note proof

Study-note section CP27

> A struct groups named members, possibly of different types. struct House{double price; int rooms;}; defines a type; House h{150000,3}; creates an object. h.rooms uses a dot. House* p=&h; p->rooms is equivalent to (*p).rooms. The pointer must refer to a live object before member access. A type definition alone does not create an ordinary instance.

Study-note section CP27

> Aggregate initialization assigns members in declaration order.

Question sources

Computer Science model exam 2 · Question 9

Question 44 | Q00669

Which scope category describes a variable declared outside functions, usable where its declaration is visible and potentially hidden by a local variable of the same name?

A. Global Variable

B. Limited Variables

C. Local Variable

D. Partial Variable

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer A: A. Global Variable

A namespace or global variable is declared outside a function. Its declaration must be visible at the point of use, so global does not mean automatically accessible in every file or scope. A local name can shadow it, and C++ scope resolution can select a hidden global name. This makes Global Variable the appropriate category while avoiding the earlier overstatement about unrestricted program-wide accessibility.

Why each choice is right or wrong

A - Correct: Global variables have the stated outside-function scope, subject to declaration visibility.

B - Incorrect: Limited Variables is not the scope category specified by the declarations.

C - Incorrect: A local variable is declared within a function or block.

D - Incorrect: Partial Variable is not the stated C++ scope category.

Primary note proof

Study-note section CP20

> Scope is where a name can be used; lifetime is when its object exists. A local name is restricted to its block; an outer name may be shadowed. A namespace/global variable is available where its declaration is visible, not magically in every file. C++ ::name selects a global name hidden by a local one.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 17 | lines 14-29

> Scope of variables Scope of variables defined as the extent of the program code within which the variable can be accessed or declared or worked with mainly two types of variable scopes: local variable: - Variables defined within a function or block are said to be local to those functions - Declared inside a block{} Global Variable - variable that can be accessed from any part of the program. - They are available throughout the life time of a program. - They are declared at the

top of the program outside all of the functions or blocks. NB: - Usually when two variables with same name are defined then the compiler produces a compile time error. But if the variables are defined in different scopes, then the compiler allows it. - Whenever there is a local variable defined with same name as that of a global variable then the compiler will give precedence to the local variable

Question sources

Computer Science model exam 2 · Question 10

Question 45 | Q00906

What is the output of the following C++ fragment code? int a = 6, b = 8; int x = 2, y = 4; int c = (x > y ? (a--, x) : (b--, y)); cout << "a=" << a; cout << " b=" << b; cout << " c=" << c;

A. a=5 b=7 c=2

B. a=5 b=8 c=4

C. a=6 b=8 c=4

D. a=6 b=7 c=4

Hint

Trace the initial state and each executed operation in order, preserving the requested output layout.

Answer D: a=6 b=7 c=4

x>y is 2>4, false, so only the third operand (b--,y) is evaluated. It decrements b from 8 to 7 and yields y=4; a remains 6. Thus a=6 b=7 c=4. A/B incorrectly decrement a; C omits the selected decrement. Module support: PDF p. 8, PDF p. 7.

Why each choice is right or wrong

A - Incorrect: "a=5 b=7 c=2" does not match the rule or result derived here. x>y is 2>4, false, so only the third operand (b--,y) is evaluated. It decrements b from 8 to 7 and yields y=4; a remains 6. Thus a=6 b=7 c=4. A/B incorrectly decrement a; C omits the selected decrement.

B - Incorrect: "a=5 b=8 c=4" does not match the rule or result derived here. x>y is 2>4, false, so only the third operand (b--,y) is evaluated. It decrements b from 8 to 7 and yields y=4; a remains 6. Thus a=6 b=7 c=4. A/B incorrectly decrement a; C omits the selected decrement.

C - Incorrect: "a=6 b=8 c=4" does not match the rule or result derived here. x>y is 2>4, false, so only the third operand (b--,y) is evaluated. It decrements b from 8 to 7 and yields y=4; a remains 6. Thus a=6 b=7 c=4. A/B incorrectly decrement a; C omits the selected decrement.

D - Correct: "a=6 b=7 c=4" matches the derived result. x>y is 2>4, false, so only the third operand (b--,y) is evaluated. It decrements b from 8 to 7 and yields y=4; a remains 6. Thus a=6 b=7 c=4. A/B incorrectly decrement a; C omits the selected decrement.

Primary note proof

Study-note section CP11

> condition ? yes : no evaluates the condition and exactly one alternative. The comma operator evaluates its left expression, then its right, and yields the right value. Do not confuse it with commas separating function arguments.

Study-note section CP09

> Prefix ++x changes x and yields the new value; postfix x++ yields the previous value and also increments x.

Question 46 | Q00936

Which of the following is NOT property of an algorithm?

A. Finiteness

B. Definiteness

C. Correctness

D. Platform dependence

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer D: Platform dependence

The module properties include correctness, unambiguity and finiteness (p.2). Platform dependence is not a property demanded of an abstract algorithm. Definiteness corresponds to clearly defined unambiguous steps; D is the extraneous platform restriction. Module support: PDF p. 2.

Why each choice is right or wrong

A - Incorrect: "Finiteness" does not match the rule or result derived here. The module properties include correctness, unambiguity and finiteness (p.2). Platform dependence is not a property demanded of an abstract algorithm. Definiteness corresponds to clearly defined unambiguous steps; D is the extraneous platform restriction.

B - Incorrect: "Definiteness" does not match the rule or result derived here. The module properties include correctness, unambiguity and finiteness (p.2). Platform dependence is not a property demanded of an abstract algorithm. Definiteness corresponds to clearly defined unambiguous steps; D is the extraneous platform restriction.

C - Incorrect: "Correctness" does not match the rule or result derived here. The module properties include correctness, unambiguity and finiteness (p.2). Platform dependence is not a property demanded of an abstract algorithm. Definiteness corresponds to clearly defined unambiguous steps; D is the extraneous platform restriction.

D - Correct: "Platform dependence" matches the derived result. The module properties include correctness, unambiguity and finiteness (p.2). Platform dependence is not a property demanded of an abstract algorithm. Definiteness corresponds to clearly defined unambiguous steps; D is the extraneous platform restriction.

Primary note proof

Study-note section CP02

> An algorithm gives precise, executable steps and terminates for every legal input. Definiteness means each step has an unambiguous meaning; effectiveness means a step can actually be performed. Inputs may be absent, but a useful algorithm specifies a result. Correctness means the result meets the specification. Efficiency is desirable and measurable, but an inefficient

terminating algorithm is still an algorithm. Efficiency is also a desirable property of an algorithm.

Study-note section CP01

Solve one small case manually, choose an algorithm, express it as pseudocode or a flowchart, implement, test and maintain.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 2 | lines 19-26

Algorithm is an ordered set of unambiguous, executable steps, defining a terminating process. Important Properties of Algorithms - Correct: always returns the desired output for all legal instances of the problem. - Unambiguous: Each step must be clearly defined, having only one interpretation. - Precise: simple but efficient - Efficient: can be measured in terms of Time and Space - Finiteness: the execution of the algorithm must terminate in a finite amount of time for each possible set of input data/must have an end.

Question sources

Computer Science Exit Exam · 2018 · Question 49

Question 47 | Q00938

Assume that you are computer science expert and you need to develop large programs within short period of time. Finally, you have planned to provide portable program to the concerned body. Which type of programming language is preferable for the above scenario?

A. Low level

B. Machine level

C. .
High level

D. Assembly

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer C: .
High level

The decisive requirement is portability: the module says high-level languages are machine-independent and run on a variety of computers (p.3). Machine and assembly are low-level and machine-dependent. Thus C meets portability; the module does not quantify development time. Module support: PDF p. 3.

Why each choice is right or wrong

A - Incorrect: "Low level" does not match the rule or result derived here. The decisive requirement is portability: the module says high-level languages are machine-independent and run on a variety of computers (p.3). Machine and assembly are low-level and machine-dependent. Thus C meets portability; the module does not quantify development time.

B - Incorrect: "Machine level" does not match the rule or result derived here. The decisive requirement is portability: the module says high-level languages are machine-independent and run on a variety of computers (p.3). Machine and assembly are low-level and machine-dependent. Thus C meets portability; the module does not quantify development time.

C - Correct: ".
High level" matches the derived result. The decisive requirement is portability: the module says high-level languages are machine-independent and run on a variety of computers (p.3). Machine and assembly are low-level and machine-dependent. Thus C meets portability; the module does not quantify development time.

D - Incorrect: "Assembly" does not match the rule or result derived here. The decisive requirement is portability: the module says high-level languages are machine-independent and run on a variety of computers (p.3). Machine and assembly are low-level and machine-dependent. Thus C meets portability; the module does not quantify development time.

Primary note proof

Study-note section CP03

> Machine and assembly code depend on an instruction set. High-level source is easier to read and often portable after recompilation, provided it avoids platform assumptions. People can write both assembly and high-level programs. Python, Perl and PHP are commonly called scripting languages; C++ is conventionally compiled. These labels describe common use, not an absolute technical prohibition.

Question sources

Computer Science Exit Exam · 2018 · Question 51

Question 48 | Q00966

Which identifier is invalid under the basic ASCII C++ identifier rules? Treat the stray leading dot before jan2025 as an OCR artifact.

A. delete

B. for_cpp

C. jan2025

D. Hello

Hint

Apply the naming, type and syntax rules before deciding whether an option can be used as stated.

Answer A: A. delete

An ordinary identifier starts with a letter or underscore and continues with letters, digits or underscores; it must also avoid keywords. delete fails because it is a C++ keyword. for_cpp is a single identifier distinct from the keyword for, while jan2025 and Hello follow the character rules. Removing the documented stray dot makes the intended identifier comparison explicit without changing the keyword concept.

Why each choice is right or wrong

A - Correct: delete is a C++ keyword and cannot be an ordinary identifier.

B - Incorrect: for_cpp contains valid identifier characters and is not the keyword for.

C - Incorrect: jan2025 starts with a letter and continues with allowed letters and digits.

D - Incorrect: Hello contains only letters and is not a keyword.

Primary note proof

Study-note section CP05

> In the basic ASCII identifier rules, start with a letter or underscore; continue with letters, digits or underscores. Do not use a keyword. C++ is case sensitive: exitExam and ExitExam differ; delete and float are keywords, but FLOAT is a legal identifier. variable_1234 is valid; 4thInput, T-3 and names containing spaces are not single identifiers. Avoid reserved underscore patterns in application code.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 5 | lines 2-10

> 1. Keywords (reserved words) - Unique meaning within a C++ program and must not be used for any other purposes. E.g., if, namespace for, switch, continue, float, new, default, break Etc. 2. Identifiers - Name associated with a function or data object and used to refer to that function or data object. An identifier must: o Start with a letter or underscore o Consist only of letters, the digits 0-9, or the underscore symbol _ o Not be a reserved word

Computer Science Exit Exam · 2018 · Question 79

Question 49 | Q00989

Which C++ declarations denote the same signed short integer type as short n;? Select all that apply.

A. int short n;

B. unsigned short n;

C. float short n;

D. short n;

Hint

Apply the naming, type and syntax rules before deciding whether an option can be used as stated.

Answer A, D: A. int short n;; D. short n;

The ordinary short type is signed unless unsigned is explicitly requested. The note identifies short n, short int n and int short n as equivalent spellings. Consequently, A is equivalent despite its reordered specifiers, and D is equivalent because it repeats the original declaration. B changes signedness, while C combines incompatible floating and integer type specifiers rather than naming the requested type.

Why each choice is right or wrong

A - Correct: int short is an equivalent spelling of signed short.

B - Incorrect: unsigned short is a different type with different signedness.

C - Incorrect: float short is not a valid combination of these type specifiers.

D - Correct: This repeats the original signed short declaration.

Primary note proof

Study-note section CP06

> Use int for whole numbers, float/double for fractional approximations, char for a character and bool for logical values in C++. Type sizes depend on the implementation; do not import Java widths into C++. short n, short int n and int short n denote the same signed short type. const int n=5 and int const n=5 are equivalent; an ordinary const int needs initialization. typedef creates an alias, not a distinct new type.

Question 50 | Q00990

Which one of the following is NOT a high-level language?

A. C++

B. Java

C. Python

D. Assembly

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer D: D. Assembly

Machine and assembly languages are low-level because their instructions are tied to an instruction set. C++ and Java are general high-level languages in the note's conventional classification, and Python is also a high-level language even though it is commonly used for scripting. Assembly is therefore the exception requested here. Classification by language level is separate from whether an implementation compiles or interprets a program.

Why each choice is right or wrong

A - Incorrect: C++ is a general high-level language, so it is not the requested exception.

B - Incorrect: Java is a general high-level language, so it is not the requested exception.

C - Incorrect: Python is high-level; scripting usage does not make it assembly or machine code.

D - Correct: Assembly is an instruction-set-dependent low-level language.

Primary note proof

Study-note section CP03

Machine instructions are conventionally first generation; symbolic assembly is second; general high-level languages such as C++ and Java are third. Database query and application generators such as SQL are conventionally fourth generation. Fifth generation is a loose historical category associated with declarative logic, constraints and AI/expert systems. Generations do not determine whether an implementation uses an interpreter.

Study-note section CP-S02

Python is a high-level programming language with built-in high-level data types. Calling a language a scripting language describes a common way it is used; it does not make that language machine code or assembly. Language level and execution style are different classifications.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 3 | lines 8-17

Categories of programming language: - Low-level languages: - - are machine-dependent - They are designed to be run on a particular computer (not portable). Eg. Question 51 | Q00998

What does this C++ fragment print? Assume cout is available.
int x=15,y=2;
int z=x/y;
cout<<z;

A. 7.5

B. 7

C. 3

D. 12.5

Hint

Trace the initial state and each executed operation in order, preserving the requested output layout.

Answer B: B. 7

Both division operands are int, so their quotient is computed using integer division. Fifteen divided by two truncates toward zero to 7, which is stored in z and printed. The lowercase identifier matches the declared variable. A fractional quotient would require conversion before division, and none occurs here.

Why each choice is right or wrong

A - Incorrect: The fractional mathematical quotient is discarded by integer division.

B - Correct: The int quotient is 7 and is printed from z.

C - Incorrect: 3 is not the quotient of the given operands.

D - Incorrect: 12.5 follows neither integer division nor the mathematical quotient.

Primary note proof

Study-note section CP08

> Multiplication, division and remainder have higher precedence than addition and subtraction; equal-precedence arithmetic groups left to right. Integer division truncates toward zero. For integers, a == (a/b)*b + a%b when the division is valid. % requires integral operands in C++; (8.0*3)%5 is invalid. Division by zero and signed integer overflow cannot be given ordinary numeric outputs.

Study-note section CP34

> Printing Z when only z is declared refers to a different, undeclared identifier.

Module passages - related reading

> Assignment Operators (=) Example: int x=5; or used with a combination of other operators‟ example, x+=2;//x=x+2, x=y=10; Arithmetic Operators (+, -, *, /, %) E.g. Assume int X=9, Y=2 X+Y, Y-X, X%Y Relational operators (==,!=, <, <=,>,>=) Relational operators evaluate to 1 (representing the true outcome) or 0 (representing the false outcome). Assume int X=9, Y=2 X==Y, X!=Y, X>Y 'A' < 'F' // gives 1 (is like 65 < 70) Logical operators (! Negation, &&, | |) Like the relational operators, logical operators evaluate to 1 or 0. Example: 5 < 6 | | 6 < 5 // gives 1 In general, any nonzero value can be used to represent the logical true, whereas only zero represents the logical false !12 // gives 0 10 && 5 // gives 1 Increment/decrement Operators The auto increment (++) and auto decrement (--) operators provide a convenient way of, respectively, adding and subtracting 1 from a numeric variable. Both operators can be used in prefix and postfix form.

Computer Programming module | PDF page 6 | lines 4-15

> 6. Communication through console cout (the standard output stream) o used to display information for the user Syntax: cout<<object; • Object can be variable or literals Example: int x=5; cout<<x cout<< “Hello there”; cin(the standard input stream): o used to accept information from the user. Syntax: cin>>variable name; Eg. cin>>x;

Question sources

National Exit Exam practice questions · Question 12

Question 52 | Q01001

Which generation of programming languages stated for interpreted languages such as SQL?

A. 4th generation

B. 2nd generation

C. 3rd generation

D. All of the above

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer A: SQL is conventionally fourth generation.

CP03 explicitly classifies SQL with fourth-generation query languages and application generators. The question's description of interpreted languages is imprecise: interpretation is not what determines a language generation. Nevertheless, the named example SQL has a clear conventional classification, making fourth generation the supported answer.

Why each choice is right or wrong

A - Correct: Fourth generation is the note's explicit conventional classification for SQL and query languages.

B - Incorrect: Second generation refers to assembly; interpretation alone does not move SQL into this category.

C - Incorrect: Third generation describes general high-level languages, rather than SQL's stated query-language category.

D - Incorrect: SQL is not classified into all these generations merely because implementations can interpret it.

Primary note proof

Study-note section CP03

> Machine instructions are conventionally first generation; symbolic assembly is second; general high-level languages such as C++ and Java are third. Database query and application generators such as SQL are conventionally fourth generation. Fifth generation is a loose historical category associated with declarative logic, constraints and AI/expert systems. Generations do not determine whether an implementation uses an interpreter.

Question 53 | Q01130

A variable name can only contain _____?

A. alphanumeric characters

B. underscores

C. Both A and B

D. None of the above

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer C: Both A and B

The permitted identifier characters are letters, digits and underscore (p.5), so both A and B describe allowed contents and C combines them. This is not permission to begin with a digit or to use a reserved word: those separate restrictions still apply. Module support: PDF p. 5.

Why each choice is right or wrong

A - Incorrect: "alphanumeric characters" does not match the rule or result derived here. The permitted identifier characters are letters, digits and underscore (p.5), so both A and B describe allowed contents and C combines them. This is not permission to begin with a digit or to use a reserved word: those separate restrictions still apply.

B - Incorrect: "underscores" does not match the rule or result derived here. The permitted identifier characters are letters, digits and underscore (p.5), so both A and B describe allowed contents and C combines them. This is not permission to begin with a digit or to use a reserved word: those separate restrictions still apply.

C - Correct: "Both A and B" matches the derived result. The permitted identifier characters are letters, digits and underscore (p.5), so both A and B describe allowed contents and C combines them. This is not permission to begin with a digit or to use a reserved word: those separate restrictions still apply.

D - Incorrect: "None of the above" does not match the rule or result derived here. The permitted identifier characters are letters, digits and underscore (p.5), so both A and B describe allowed contents and C combines them. This is not permission to begin with a digit or to use a reserved word: those separate restrictions still apply.

Primary note proof

Study-note section CP05

> In the basic ASCII identifier rules, start with a letter or underscore; continue with letters, digits or underscores. Do not use a keyword. C++ is case sensitive: exitExam and ExitExam differ; delete and float are keywords, but FLOAT is a legal identifier. variable_1234 is valid; 4thInput, T-3 and names containing spaces are not single identifiers. Avoid reserved underscore patterns in application code.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 5 | lines 2-10

> 1. Keywords (reserved words) - Unique meaning within a C++ program and must not be used for any other purposes. E.g., if, namespace for, switch, continue, float, new, default, break Etc. 2. Identifiers - Name associated with a function or data object and used to refer to that function or data object. An identifier must: o Start with a letter or underscore o Consist only of letters, the digits 0-9, or the underscore symbol _ o Not be a reserved word

Question sources

Web Programming practice questions · Question 63

Question 54 | Q01140

What does "cout" represent?

A. Output statement

B. Input statement

C. Compiler

D. None of the above

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer A: Output statement

The module names cout the standard output stream and shows cout<<object displaying information. Output statement is the closest offered description; cout itself is a stream object. cin handles input, while a compiler translates source. Module support: PDF p. 6.

Why each choice is right or wrong

A - Correct: "Output statement" matches the derived result. The module names cout the standard output stream and shows cout<<object displaying information. Output statement is the closest offered description; cout itself is a stream object. cin handles input, while a compiler translates source.

B - Incorrect: "Input statement" does not match the rule or result derived here. The module names cout the standard output stream and shows cout<<object displaying information. Output statement is the closest offered description; cout itself is a stream object. cin handles input, while a compiler translates source.

C - Incorrect: "Compiler" does not match the rule or result derived here. The module names cout the standard output stream and shows cout<<object displaying information. Output statement is the closest offered description; cout itself is a stream object. cin handles input, while a compiler translates source.

D - Incorrect: "None of the above" does not match the rule or result derived here. The module names cout the standard output stream and shows cout<<object displaying information. Output statement is the closest offered description; cout itself is a stream object. cin handles input, while a compiler translates source.

Primary note proof

Study-note section CP28

> Include <iostream> and qualify std::cin/std::cout or introduce the names explicitly. cout is the standard output stream; << inserts values. cin is standard input; >> extracts formatted values. std::endl inserts a newline and flushes. C++ names are case sensitive: Cout, Int and std: :cout are not equivalent valid spellings of cout, int and std::cout.

Computer Science Exit Exam practice questions · Question 1

Question 55 | Q01141

Which terms can denote a defect in a program, rather than a debugging tool or the act of correcting defects? Select all that apply.

A. Bug

B. Debugger

C. Error

D. Debug

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer A, C: A. Bug; C. Error

A bug is a defect in a program, and error can also name such a defect in this question's terminology. Both nouns therefore fit the requested meaning. A debugger instead names a tool used to investigate execution, and debug names the activity of locating or correcting defects.

Why each choice is right or wrong

A - Correct: Bug denotes a program defect.

B - Incorrect: A debugger is a tool for investigating defects.

C - Correct: Error can denote the defect itself.

D - Incorrect: Debug describes the correction/investigation activity rather than the defect.

Primary note proof

Study-note section CP32

> A syntax error violates grammar; a type error can be syntactically well formed but rejected during semantic checking. A runtime error occurs during execution; a logic error gives the wrong behavior. A bug is a defect; debugging locates and corrects it. Read the first useful compiler diagnostic, inspect nearby tokens and declarations, repair and rebuild; a debugger is useful after a runnable program exists.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 2 | lines 2-18

> 1. Introduction to programming Computer programming is the process of writing, testing, debugging/troubleshooting, and maintaining the source code of computer programs. Programs are the instructions that tells the computer what to do .so, writing computer programs means writing instructions, that will make the computer follow and run a program based on those instructions. We are going to write computer programs to solve problems. Problem Solving Problem: gap between the existing and the desired or proposed situation where problem solving will try to fill this gap. Problem solving: The process of transforming the description of a problem into the solution by using our knowledge of the problem-solving strategies, techniques and tools. Problem solving techniques • Analyze the problem: Carefully understand the problem • Outline the problem requirements • Does program require user interaction? • Does program manipulate data? • What is the output? • Design steps (algorithm) to solve the problem

Question sources

Computer Science Exit Exam practice questions · Question 2

Question 56 | Q01142

is a language translators required to translate the assembly languages into machine code.

A. | a | Compiler x

B. ? | Assembler 4

C. |@| Interpreter x

D. | None of the above x

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer B: Assembler.

Compilation may emit assembly, and the assembler emits machine instructions in an object file. The translator named by the question is the assembler.

Why each choice is right or wrong

A - Incorrect: The compiler can produce assembly from higher-level source; that is the preceding stage in CP04.

B - Correct: The assembler translates assembly instructions into machine instructions contained in an object file.

C - Incorrect: An interpreter executes a program representation instead of performing the stated assembly-to-object translation.

D - Incorrect: Assembler is present and directly matches the translator role, so none of the above is false.

Primary note proof

Study-note section CP04

> In the conventional C++ toolchain: source → preprocessing → compilation proper → assembly → object files → linking → executable → loading → execution. Preprocessing handles directives such as #include; compilation may emit assembly; the assembler emits machine instructions in an object file. The linker resolves external symbols and combines object files and libraries. The loader places an executable and required components in memory and starts it.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 3 | lines 8-17

> Categories of programming language: - Low-level languages: - - are machine-dependent - They are designed to be run on a particular computer (not portable). Eg. Programming language require translation source code to machine language before

execution. This translation is accomplished by either a compiler or an interpreter. Compilers translate the entire source

Computer Programming module | PDF page 4 | lines 21-30

The compilation process of C++ program consists of the following steps. • edit source code → compile → link → execute (Editor) (Compiler) (Linker) (Loader) I. Program source code is entered into a file using a text editor. II. After the code has been entered, a compiler program is started that translates the source into an object code file. III. The object code file is linked with other object code files that come with the compiler and an executable file (or program) is created. IV. In order to execute the program, a program called the loader copies the executable file into the memory of the computer and sends an execute command to the CPU.

Computer Science Exit Exam practice questions · Question 3

Question 57 | Q01144

An error in the statement in a computer program that violates the rules of the programming.
a | Logical error x

A. ? | Syntax error ov

B. '@| Semantic error x

C. | All of the above x

D. 6 - True or false

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer A: ? | Syntax error ov

Syntax is the set of rules governing use of language symbols, while semantics concerns the meanings of syntactically correct constructs (p.3). Violating the written language rules is therefore a syntax error. Module support: PDF p. 3.

Why each choice is right or wrong

A - Correct: Syntax error matches violation of the language rules defined on p.3.

B - Incorrect: Semantic error concerns meaning rather than the syntactic rule violation described (p.3).

C - Incorrect: All would include semantic/logical alternatives, which are not equivalent to violating syntax.

D - Incorrect: This is an unrelated extracted True/false heading, not an error category.

Primary note proof

Study-note section CP32

A syntax error violates grammar; a type error can be syntactically well formed but rejected during semantic checking. A runtime error occurs during execution; a logic error gives the wrong behavior. A bug is a defect; debugging locates and corrects it. Read the first useful compiler diagnostic, inspect nearby tokens and declarations, repair and rebuild; a debugger is useful after a runnable program exists.

Computer Science Exit Exam practice questions · Question 5

Question 58 | Q01145

Keywords are words whose meanings are defined to the compiler.

A. True

B. False

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer A: True

The module calls keywords reserved words with a unique meaning in a C++ program and forbids other uses (p.5). This supports True; False contradicts their predefined role. Module support: PDF p. 5.

Why each choice is right or wrong

A - Correct: "True" matches the derived result. The module calls keywords reserved words with a unique meaning in a C++ program and forbids other uses (p.5). This supports True; False contradicts their predefined role.

B - Incorrect: "False" does not match the rule or result derived here. The module calls keywords reserved words with a unique meaning in a C++ program and forbids other uses (p.5). This supports True; False contradicts their predefined role.

Primary note proof

Study-note section CP-S03

> A keyword is a reserved word with a predefined meaning in the language grammar. It cannot be repurposed as an ordinary variable or function name. An identifier is a name used to refer to a data object or function; its spelling must obey the identifier-character rules and avoid keywords.

Module passages - related reading

Question 59 | Q01146

In which constant that can be written in a single quotes?

A. | a | String constant x

B. i? Character constant vA

C. /@| All of the above x

D. | None of the above x

Hint

Apply the naming, type and syntax rules before deciding whether an option can be used as stated.

Answer B: i? Character constant vA

The module examples use single quotes for a character such as A and double quotes for a string such as Hello There (pp.8,22). Thus Character constant is the correct category. String constant uses double quotes, so All and None fail. Module support: PDF p. 8, PDF p. 22.

Why each choice is right or wrong

A - Incorrect: "| a | String constant x" does not match the rule or result derived here. The module examples use single quotes for a character such as A and double quotes for a string such as Hello There (pp.8,22). Thus Character constant is the correct category. String constant uses double quotes, so All and None fail.

B - Correct: "i? Character constant vA" matches the derived result. The module examples use single quotes for a character such as A and double quotes for a string such as Hello There (pp.8,22). Thus Character constant is the correct category. String constant uses double quotes, so All and None fail.

C - Incorrect: "/@| All of the above x" does not match the rule or result derived here. The module examples use single quotes for a character such as A and double quotes for a string such as Hello There (pp.8,22). Thus Character constant is the correct category. String constant uses double quotes, so All and None fail.

D - Incorrect: "| None of the above x" does not match the rule or result derived here. The module examples use single quotes for a character such as A and double quotes for a string such as Hello There (pp.8,22). Thus Character constant is the correct category. String constant uses double quotes, so All and None fail.

Primary note proof

Study-note section CP07

> Single quotes denote a character literal, such as 'A'; double quotes denote a string literal, such as "A". A string includes more storage than just its visible characters when a terminator is required. sizeof reports size in bytes, with sizeof(char)==1; the byte width and other sizes are implementation dependent. sizeof(array) gives total array storage before conversion to a pointer.

Question 60 | Q01147

In which constant that can be written in a double quotes?

A. a | String constants oS

B. i? Character constants x

C. |@| All of the above x

D. | None of the above x

Hint

Apply the naming, type and syntax rules before deciding whether an option can be used as stated.

Answer A: a | String constants oS

The examples enclose strings in double quotes and characters in single quotes (pp.8,22). Therefore String constants is the intended category; Character, All and None do not fit the shown notation. Module support: PDF p. 8, PDF p. 22.

Why each choice is right or wrong

A - Correct: "a | String constants oS" matches the derived result. The examples enclose strings in double quotes and characters in single quotes (pp.8,22). Therefore String constants is the intended category; Character, All and None do not fit the shown notation.

B - Incorrect: "i? Character constants x" does not match the rule or result derived here. The examples enclose strings in double quotes and characters in single quotes (pp.8,22). Therefore String constants is the intended category; Character, All and None do not fit the shown notation.

C - Incorrect: "|@| All of the above x" does not match the rule or result derived here. The examples enclose strings in double quotes and characters in single quotes (pp.8,22). Therefore String constants is the intended category; Character, All and None do not fit the shown notation.

D - Incorrect: "| None of the above x" does not match the rule or result derived here. The examples enclose strings in double quotes and characters in single quotes (pp.8,22). Therefore String constants is the intended category; Character, All and None do not fit the shown notation.

Primary note proof

Study-note section CP07

Single quotes denote a character literal, such as 'A'; double quotes denote a string literal, such as "A". A string includes more storage than just its visible characters when a terminator is required. sizeof reports size in bytes, with sizeof(char)==1; the byte width and other sizes are implementation dependent. sizeof(array) gives total array storage before conversion to a pointer.

Computer Science Exit Exam practice questions · Question 8

Question 61 | Q01148

What is the output of the following C++ fragment?

```
#include <iostream>
using namespace std;
int main()
{
int a = 8;
int b = 5;
int c;
c = a++ + --b;
cout << c << endl;
return 0;
}
```

A. 13

B. 15

C. 11

D. 12

Hint

Fix the input case and cost model, then count dominant work or simultaneously live storage.

Answer D: 12

Postfix a++ contributes 8 to the expression and then makes a=9. Prefix --b changes 5 to 4 before use. Thus c=8+4=12. Thirteen uses old b; the other sums do not follow the two operator timings. Module support: PDF p. 7.

Why each choice is right or wrong

A - Incorrect: "13" does not match the rule or result derived here. Postfix a++ contributes 8 to the expression and then makes a=9. Prefix --b changes 5 to 4 before use. Thus c=8+4=12. Thirteen uses old b; the other sums do not follow the two operator timings.

B - Incorrect: "15" does not match the rule or result derived here. Postfix a++ contributes 8 to the expression and then makes a=9. Prefix --b changes 5 to 4 before use. Thus c=8+4=12. Thirteen uses old b; the other sums do not follow the two operator timings.

C - Incorrect: "11" does not match the rule or result derived here. Postfix a++ contributes 8 to the expression and then makes a=9. Prefix --b changes 5 to 4 before use. Thus c=8+4=12. Thirteen uses old b; the other sums do not follow the two operator timings.

D - Correct: "12" matches the derived result. Postfix a++ contributes 8 to the expression and then makes a=9. Prefix --b changes 5 to 4 before use. Thus c=8+4=12. Thirteen uses old b; the other sums do not follow the two operator timings.

Primary note proof

Study-note section CP09

Prefix ++x changes x and yields the new value; postfix x++ yields the previous value and also increments x. Separate the value used in the expression from the stored value after it. Starting a=8,b=5, a++ + --b uses 8+4, gives 12, and leaves a=9,b=4. Starting x=1,y=10,z=-3, (x++*y--)+ ++z gives 8 and leaves x=2,y=9,z=-2.

Module passages - related reading

Computer Programming module | PDF page 7 | lines 5-23

Assignment Operators (=) Example: int x=5; or used with a combination of other operators‟ example, x+=2;//x=x+2, x=y=10; Arithmetic Operators (+, -, *, /, %) E.g. Assume int X=9, Y=2 X+Y, Y-X, X%Y Relational operators (==,!=, <, <=,>,>=) Relational operators evaluate to 1 (representing the true outcome) or 0 (representing the false outcome). Assume int X=9, Y=2 X==Y, X!=Y, X>Y 'A' < 'F' // gives 1 (is like 65 < 70) Logical operators (! Negation, &&, | |) Like the relational operators, logical operators evaluate to 1 or 0. Example: 5 < 6 | | 6 < 5 // gives 1 In general, any nonzero value can be used to represent the logical true, whereas only zero represents the logical false !12 // gives 0 10 && 5 // gives 1 Increment/decrement Operators The auto increment (++) and auto decrement (--) operators provide a convenient way of, respectively, adding and subtracting 1 from a numeric variable. Both operators can be used in prefix and postfix form.

Question sources

Computer Science Exit Exam practice questions · Question 9

Question 62 | Q01149

Which data type represents logical values?

A. Integer

B. Boolean

C. Double

D. Float

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer B: Boolean.

CP06 assigns bool to logical values, whereas int represents whole numbers and float/double represent fractional approximations. Boolean is therefore the intended type category. Numeric values can participate in truth conversion, but that does not make their numeric types the dedicated representation of logical true/false values.

Why each choice is right or wrong

A - Incorrect: Integer represents whole numbers; possible conversion to truth does not make it the logical type.

B - Correct: Boolean represents logical true/false values, matching bool in the note's C++ type mapping.

C - Incorrect: Double represents fractional numeric approximations rather than the dedicated logical type.

D - Incorrect: Float represents fractional numeric approximations rather than the dedicated logical type.

Primary note proof

Study-note section CP12

> A standalone if may execute independently of the following if. An else binds to its nearest unmatched if; an else-if ladder executes the first true branch only. In nested if(c1){if(c2) S1; else S2;}, S2 requires c1 true and c2 false. Braces determine grouping.

Module passages - related reading

Question 63 | Q01150

What is the output of the following C++ fragment?

```
#include <iostream>
using namespace std;
int main()
{
int x = 25;
if (x < 20)
cout << "Low Quality" << endl;
else
cout << "High Quality" << endl;
return 0;
}
```

A. Low Quality

B. High Quality

C. No output

D. None of the above

Hint

Fix the input case and cost model, then count dominant work or simultaneously live storage.

Answer B: High Quality

The condition 25<20 is false, so the else branch prints High Quality. The then message is skipped; a defined else branch means the no-output alternative is false, and B supplies a matching option. Module support: PDF p. 9.

Why each choice is right or wrong

A - Incorrect: "Low Quality" does not match the rule or result derived here. The condition 25<20 is false, so the else branch prints High Quality. The then message is skipped; a defined else branch means the no-output alternative is false, and B supplies a matching option.

B - Correct: "High Quality" matches the derived result. The condition 25<20 is false, so the else branch prints High Quality. The then message is skipped; a defined else branch means the no-output alternative is false, and B supplies a matching option.

C - Incorrect: "No output" does not match the rule or result derived here. The condition 25<20 is false, so the else branch prints High Quality. The then message is skipped; a defined else branch means the no-output alternative is false, and B supplies a matching option.

D - Incorrect: "None of the above" does not match the rule or result derived here. The condition 25<20 is false, so the else branch prints High Quality. The then message is skipped; a defined else branch means the no-output alternative is false, and B supplies a matching option.

Primary note proof

Study-note section CP06

Use int for whole numbers, float/double for fractional approximations, char for a character and bool for logical values in C++. Type sizes depend on the implementation; do not import Java widths into C++. short n, short int n and int short n denote the same signed short type. const int n=5 and int const n=5 are equivalent; an ordinary const int needs initialization. typedef creates an alias, not a distinct new type.

Module passages - related reading

Computer Science Exit Exam practice questions · Question 11

Question 64 | Q01166

Loading executable code, which is the output of a linker, into main memory is called:

A. Linker

B. Assembler

C. Compiler

D. Loader

Hint

Trace the initial state and each executed operation in order, preserving the requested output layout.

Answer D: Loader

The module says the loader copies the linked executable into computer memory and sends execution to the CPU (p.4). Linking builds that executable; compilation translates source, so they do not name the memory-loading role. Module support: PDF p. 4.

Why each choice is right or wrong

A - Incorrect: "Linker" does not match the rule or result derived here. The module says the loader copies the linked executable into computer memory and sends execution to the CPU (p.4). Linking builds that executable; compilation translates source, so they do not name the memory-loading role.

B - Incorrect: "Assembler" does not match the rule or result derived here. The module says the loader copies the linked executable into computer memory and sends execution to the CPU (p.4).

Linking builds that executable; compilation translates source, so they do not name the memory-loading role.

C - Incorrect: "Compiler" does not match the rule or result derived here. The module says the loader copies the linked executable into computer memory and sends execution to the CPU (p.4). Linking builds that executable; compilation translates source, so they do not name the memory-loading role.

D - Correct: "Loader" matches the derived result. The module says the loader copies the linked executable into computer memory and sends execution to the CPU (p.4). Linking builds that executable; compilation translates source, so they do not name the memory-loading role.

Primary note proof

Study-note section CP04

> In the conventional C++ toolchain: source → preprocessing → compilation proper → assembly → object files → linking → executable → loading → execution. Preprocessing handles directives such as #include; compilation may emit assembly; the assembler emits machine instructions in an object file. The linker resolves external symbols and combines object files and libraries. The loader places an executable and required components in memory and starts it.

Module passages - related reading

Computer Programming module | PDF page 4 | lines 21-30

> The compilation process of C++ program consists of the following steps. • edit source code → compile → link → execute (Editor) (Compiler) (Linker) (Loader) I. Program source code is entered into a file using a text editor. II. After the code has been entered, a compiler program is started that translates the source into an object code file. III. The object code file is linked with other object code files that come with the compiler and an executable file (or program) is created. IV. In order to execute the program, a program called the loader copies the executable file into the memory of the computer and sends an execute command to the CPU.

Question sources

Computer Science Exit Exam practice questions · Question 27

Question 65 | Q01174

When control reaches a loop normally, which loop form executes its body before its first condition test, guaranteeing at least one body execution?

A. while loop

B. for loop

C. nested loop

D. do-while loop

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer D: D. do-while loop

A do-while loop performs its body first and tests the continuation condition afterward. Even when that first test is false, one body execution has already occurred. A while loop and a conventional for loop can reject entry on their first condition test. Nesting describes one loop inside another and supplies no independent guarantee that either body runs. The option names the post-test form.

Why each choice is right or wrong

A - Incorrect: while checks its condition before entering the body.

B - Incorrect: for can fail its initial condition and execute zero times.

C - Incorrect: A nested loop can have an outer condition that is false initially.

D - Correct: do-while performs its body before the first condition test.

Primary note proof

Study-note section CP14

> while(condition) checks before each body execution and may run zero times. do {body;} while(condition); runs the body once before checking; it repeats while the condition remains true. Use it when a menu or input attempt must occur at least once.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 12 | lines 2-7

> The do-while loop The condition in the do-while is evaluated after the execution of statement instead of before, granting at least one execution of statement even if condition is never fulfilled. do {statement; }while (condition); First statement is executed and then condition is evaluated. If the outcome of the latter is nonzero then the whole process is repeated. Otherwise, the loop is terminated.

Computer Programming module | PDF page 11 | lines 5-13

> Iteration/Looping Statement: Iteration is the repetition of a statement or block of statements in a program. - Loops have as objective to repeat a statement a certain number of times or while a condition is fulfilled. - C++ has three iteration statements: the while statement, the do. While statement, and the for statement. The while loop: Its format is: while (expression) {statement;} First expression (called the loop condition) is evaluated. If the outcome is nonzero then statement (called the loop body) is executed and the whole process is repeated. Otherwise, the loop is terminated.

Question sources

Computer Science Exit Exam practice questions · Question 35

Question 66 | Q01196

The _____ statement causes a loop to terminate immediately.

A. Continue

B. Goto

C. Break

D. Jump

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer C: Break

break immediately leaves the loop for the statement outside it (p.13). continue skips the remainder of the current iteration but keeps looping. Goto names a separate label transfer, and Jump is not the module statement that directly terminates a loop. Module support: PDF p. 13.

Why each choice is right or wrong

A - Incorrect: "Continue" does not match the rule or result derived here. break immediately leaves the loop for the statement outside it (p.13). continue skips the remainder of the current iteration but keeps looping. Goto names a separate label transfer, and Jump is not the module statement that directly terminates a loop.

B - Incorrect: "Goto" does not match the rule or result derived here. break immediately leaves the loop for the statement outside it (p.13). continue skips the remainder of the current iteration but keeps looping. Goto names a separate label transfer, and Jump is not the module statement that directly terminates a loop.

C - Correct: "Break" matches the derived result. break immediately leaves the loop for the statement outside it (p.13). continue skips the remainder of the current iteration but keeps looping. Goto names a separate label transfer, and Jump is not the module statement that directly terminates a loop.

D - Incorrect: "Jump" does not match the rule or result derived here. break immediately leaves the loop for the statement outside it (p.13). continue skips the remainder of the current iteration but keeps looping. Goto names a separate label transfer, and Jump is not the module statement that directly terminates a loop.

Primary note proof

Study-note section CP15

> break exits the nearest enclosing loop or switch. continue skips the rest of the current loop iteration: a for loop then runs its update; a while loop goes directly to its condition. return leaves the current function and may supply a result. In main it ends the program normally.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 13 | lines 30-35

> Using continue and break Statements - The break statement skips the rest of the statements in the loop‟s block, jumping immediately to the next statement outside of the loop. - The continue statement is similar. It also skips the rest of the statements in the loop‟s block, but instead of terminating the loop, it transfers execution to the next iteration of the loop. It continues the loop after skipping the remaining statements in its current iteration.

Question sources

Computer Science model exam 2 · Question 17

Question 67 | Q01214

A translator that translates a single-line instruction at a time is:

A. Compiler

B. Assembler

C. Interpreter

D. Linker

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer C: Interpreter

The module explicitly contrasts whole-program compilation with an interpreter translating one line at a time across pp.3-4. Therefore Interpreter fits; linking combines object files, and the other named translators are not the one-line interpreter role. Module support: PDF p. 3.

Why each choice is right or wrong

A - Incorrect: "Compiler" does not match the rule or result derived here. The module explicitly contrasts whole-program compilation with an interpreter translating one line at a time across pp.3-4. Therefore Interpreter fits; linking combines object files, and the other named translators are not the one-line interpreter role.

B - Incorrect: "Assembler" does not match the rule or result derived here. The module explicitly contrasts whole-program compilation with an interpreter translating one line at a time across pp.3-4. Therefore Interpreter fits; linking combines object files, and the other named translators are not the one-line interpreter role.

C - Correct: "Interpreter" matches the derived result. The module explicitly contrasts whole-program compilation with an interpreter translating one line at a time across pp.3-4. Therefore Interpreter fits; linking combines object files, and the other named translators are not the one-line interpreter role.

D - Incorrect: "Linker" does not match the rule or result derived here. The module explicitly contrasts whole-program compilation with an interpreter translating one line at a time across pp.3-4. Therefore Interpreter fits; linking combines object files, and the other named translators are not the one-line interpreter role.

Primary note proof

Study-note section CP04

> GCC documents the first four stages explicitly. A compiler need not emit a complete executable or even native machine code. Java javac produces bytecode, which a JVM interprets or compiles at runtime. Interpreters execute a program representation; “one source line at a time” is a beginner approximation. Compilation uses multiple passes, so “whole program in one step” is not literally universal.

Module passages - related reading

Question sources

Computer Science model exam 2 · Question 35

Question 68 | Q01231

Consider the following outline of a nested if-else structure:

```
if (condition1)
{
if (condition2)
statement1;
else
statement2;
}
```

Which of the statements below is true regarding this structure?

A. Syntactically, it is invalid to have more if clauses than else clauses.

B. Statement2 will only execute if condition1 is false and condition2 is false.

C. Statement2 will only execute if condition1 is true and condition2 is false.

D. Statement2 will only execute if condition1 is false, it does not matter what condition2 is.

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer C: Statement2 will only execute if condition1 is true and condition2 is false.

The outer body is entered only when condition1 is true. Inside that body, condition2 false selects its else and statement2. If condition1 is false neither nested branch executes. An if may omit else, so A imposes an unsupported syntactic requirement. Module support: PDF p. 9.

Why each choice is right or wrong

A - Incorrect: "Syntactically, it is invalid to have more if clauses than else clauses." does not match the rule or result derived here. The outer body is entered only when condition1 is true. Inside that body, condition2 false selects its else and statement2. If condition1 is false neither nested branch executes. An if may omit else, so A imposes an unsupported syntactic requirement.

B - Incorrect: "Statement2 will only execute if condition1 is false and condition2 is false." does not match the rule or result derived here. The outer body is entered only when condition1 is true. Inside that body, condition2 false selects its else and statement2. If condition1 is false neither nested branch executes. An if may omit else, so A imposes an unsupported syntactic requirement.

C - Correct: "Statement2 will only execute if condition1 is true and condition2 is false." matches the derived result. The outer body is entered only when condition1 is true. Inside that body, condition2 false selects its else and statement2. If condition1 is false neither nested branch executes. An if may omit else, so A imposes an unsupported syntactic requirement.

D - Incorrect: "Statement2 will only execute if condition1 is false, it does not matter what condition2 is." does not match the rule or result derived here. The outer body is entered only when condition1 is true. Inside that body, condition2 false selects its else and statement2. If condition1 is false neither nested branch executes. An if may omit else, so A imposes an unsupported syntactic requirement.

Primary note proof

Study-note section CP12

> A standalone if may execute independently of the following if. An else binds to its nearest unmatched if; an else-if ladder executes the first true branch only. In nested if(c1){if(c2) S1; else S2;}, S2 requires c1 true and c2 false. Braces determine grouping.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Otherwise, nothing happens. if-else statement Syntax: if (expression) statement1; else statement2; First expression is evaluated. If the outcome is nonzero (true) then statement1 is executed. Otherwise, statement2 is executed.

Question sources

Computer Science model exam 2 · Question 52

Question 69 | Q01256

Which of the following is a valid variable name?

A. T-3

B. GGGGG

C. float

D. 4thInput

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer B: GGGGG

GGGGG starts with a letter, uses only letters, and is not one of the given reserved keywords. T-3 contains a hyphen, float is explicitly reserved, and 4thInput starts with a digit; all violate p.5 rules. Module support: PDF p. 5.

Why each choice is right or wrong

A - Incorrect: "T-3" does not match the rule or result derived here. GGGGG starts with a letter, uses only letters, and is not one of the given reserved keywords. T-3 contains a hyphen, float is explicitly reserved, and 4thInput starts with a digit; all violate p.5 rules.

B - Correct: "GGGGG" matches the derived result. GGGGG starts with a letter, uses only letters, and is not one of the given reserved keywords. T-3 contains a hyphen, float is explicitly reserved, and 4thInput starts with a digit; all violate p.5 rules.

C - Incorrect: "float" does not match the rule or result derived here. GGGGG starts with a letter, uses only letters, and is not one of the given reserved keywords. T-3 contains a hyphen, float is explicitly reserved, and 4thInput starts with a digit; all violate p.5 rules.

D - Incorrect: "4thInput" does not match the rule or result derived here. GGGGG starts with a letter, uses only letters, and is not one of the given reserved keywords. T-3 contains a hyphen, float is explicitly reserved, and 4thInput starts with a digit; all violate p.5 rules.

Primary note proof

Study-note section CP05

In the basic ASCII identifier rules, start with a letter or underscore; continue with letters, digits or underscores. Do not use a keyword. C++ is case sensitive: exitExam and ExitExam differ; delete and float are keywords, but FLOAT is a legal identifier. variable_1234 is valid; 4thInput, T-3 and names containing spaces are not single identifiers. Avoid reserved underscore patterns in application code.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 5 | lines 2-10

> 1. Keywords (reserved words) - Unique meaning within a C++ program and must not be used for any other purposes. E.g., if, namespace for, switch, continue, float, new, default, break Etc. 2. Identifiers - Name associated with a function or data object and used to refer to that function or data object. An identifier must: o Start with a letter or underscore o Consist only of letters, the digits 0-9, or the underscore symbol _ o Not be a reserved word

Question sources

Computer Science model exam 2 · Question 77

Question 70 | Q01259

An array is declared and initialized as follows:

int A[4][4] = {{1, 2, 3, 4}, {5, 6, 7, 8}, {9, 8, 7, 6}, {5, 4, 3, 2}};

What are the values of `A[1][1]`, `A[2][3]`, and `A[3][3]`, respectively?

A. 7, 6, 3

B. 6, 6, 2

C. 6, 2, 6

D. 2, 6, 6

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer B: 6, 6, 2

Arrays are zero-indexed (p.19). Row 1 is {5,6,7,8}, hence A[1][1]=6; row 2 is {9,8,7,6}, hence A[2][3]=6; row 3 ends with 2, hence A[3][3]=2. Only B preserves all three positions. Module support: PDF p. 19, PDF p. 21.

Why each choice is right or wrong

A - Incorrect: "7, 6, 3" does not match the rule or result derived here. Arrays are zero-indexed (p.19). Row 1 is {5,6,7,8}, hence A[1][1]=6; row 2 is {9,8,7,6}, hence A[2][3]=6; row 3 ends with 2, hence A[3][3]=2. Only B preserves all three positions.

B - Correct: "6, 6, 2" matches the derived result. Arrays are zero-indexed (p.19). Row 1 is {5,6,7,8}, hence A[1][1]=6; row 2 is {9,8,7,6}, hence A[2][3]=6; row 3 ends with 2, hence A[3][3]=2. Only B preserves all three positions.

C - Incorrect: "6, 2, 6" does not match the rule or result derived here. Arrays are zero-indexed (p.19). Row 1 is {5,6,7,8}, hence A[1][1]=6; row 2 is {9,8,7,6}, hence A[2][3]=6; row 3 ends with 2, hence A[3][3]=2. Only B preserves all three positions.

D - Incorrect: "2, 6, 6" does not match the rule or result derived here. Arrays are zero-indexed (p.19). Row 1 is {5,6,7,8}, hence A[1][1]=6; row 2 is {9,8,7,6}, hence A[2][3]=6; row 3 ends with 2, hence A[3][3]=2. Only B preserves all three positions.

Primary note proof

Study-note section CP23

int a[R][C] has R rows, each with C elements. a[r][c] uses zero-based row then column. Its element offset is r*C+c in row-major storage. In the 4x4 matrix example, a[1][1]=6, a[2][3]=6 and a[3][3]=2. In Java, length belongs to each array; a traversal ending at arr.length-2 visits fewer elements than a full traversal.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 19 | lines 4-29

Arrays - an array is a collection of fixed-size number of elements of the same type stored sequentially in memory. - An individual element of an array is identified by its own unique index (or subscript). - The number of elements must be an integer. - The size of the array is referred to as its dimension - Array in C++ is Zero indexed. Declaring of one-dimensional Array Syntax: elementstype arrayname [size]; → You can use constants such as macro definitions or const ints as the sizes of arrays. Example: int num[5]; string fruit[3]; #define numstudents 100 or const int numstudents=100; double Score[numstudents] ; double Score[numstudents] ; Initialization of an Array - Arrays can be initialized at declaration time in two different ways: Syntax: elementstype arrayname[size] = {list each value separated by comma}; E.g int num[5]={1,2,3,4,5}; elementstype arrayname[ ] = { list with any number of values }; E.g int num[]={1,2,3,4,5}; string fruit[]={“Apple”,“orange”, “Mango”}; Accessing Array Elements - Each element could be accessed using an index into the array - When accessing an array, the index given must be a positive integer from 0 to n-1, where n is the dimension of the array.

Computer Programming module | PDF page 21 | lines 28-36

Multidimensional Array C++ support the creation of multidimensional array, through the addition of more than one set of brackets. Syntax: elementstype arrayname [size1] [size2] ... [sizen]; Two-Dimensional Array Declaration: elementstype arrayname [size1] [size2]; Eg. int num[2][3];//declare 2 row, 3 columns to store 6 elements Initialization of Two-Dimensional Array E.g. int num[2][3]={1,2,3,4,5,6};//2 row 3 columns Or int num[2][3]={{1,2},{3,4},{5,6}};

Question sources

Computer Science model exam 2 · Question 80

Question 71 | Q01275

Before a program is written, the programmer must ensure to:

A. Clear and understand what data are to be used

B. Clear and understand the desired result

C. Clear and understand the procedure to be used

D. All of the above

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer D: All of the above

The problem-solving checklist requires understanding the problem, its data and output, and designing algorithm steps (p.2). Thus data, desired result and procedure all belong to preparation, making All the most complete choice. A/B/C are individually necessary but incomplete as a combined checklist. Module support: PDF p. 2.

Why each choice is right or wrong

A - Incorrect: Supported component: understand the data to be manipulated (p.2); less complete than All.

B - Incorrect: Supported component: identify expected output (p.2); less complete than All.

C - Incorrect: Supported component: design the algorithm (p.2); less complete than All.

D - Correct: Combines all three preparation requirements on p.2.

Primary note proof

Study-note section CP01

> Identify inputs, outputs, legal ranges and edge cases before coding. Solve one small case manually, choose an algorithm, express it as pseudocode or a flowchart, implement, test and maintain. For the largest of three numbers, initialize best to the first input, compare the second and third, then report best. Initializing best to zero fails when all inputs are negative.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 2 | lines 2-18

> 1. Introduction to programming Computer programming is the process of writing, testing, debugging/troubleshooting, and maintaining the source code of computer programs. Programs are the instructions that tells the computer what to do .so, writing computer programs means writing instructions, that will make the computer follow and run a program based on those instructions. We are going to write computer programs to solve problems. Problem Solving Problem: gap between the existing and the desired or proposed situation where problem solving will try to fill this gap. Problem solving: The process of transforming the description of a problem

into the solution by using our knowledge of the problem-solving strategies, techniques and tools. Problem solving techniques • Analyze the problem: Carefully understand the problem • Outline the problem requirements • Does program require user interaction? • Does program manipulate data? • What is the output? • Design steps (algorithm) to solve the problem

Question sources

Computer Science model exam 2 · Question 96

Question 72 | Q01393

In the conventional language-level taxonomy, which category generally offers source that is easier to read and often portable after recompilation when platform assumptions are avoided?

A. Low-level Language

B. High-Level Language

C. Decimal-Format

D. Middle-Level Language

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer B: B. High-Level Language

High-level source is easier to read and often portable after recompilation when it avoids platform assumptions. Machine and assembly languages depend more directly on an instruction set. The question asks about this language-level property, rather than claiming that people write programs in only one category. Decimal format describes numeric notation, and middle-level is not a separate category in the specified taxonomy.

Why each choice is right or wrong

A - Incorrect: Low-level machine and assembly source depends on an instruction set.

B - Correct: High-level source has the readability and conditional portability described.

C - Incorrect: Decimal format is a numeric representation, not this language category.

D - Incorrect: The stated taxonomy assigns this property to high-level languages.

Primary note proof

Study-note section CP03

Machine and assembly code depend on an instruction set. High-level source is easier to read and often portable after recompilation, provided it avoids platform assumptions. People can write both assembly and high-level programs. Python, Perl and PHP are commonly called scripting languages; C++ is conventionally compiled. These labels describe common use, not an absolute technical prohibition.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 3 | lines 8-17

> Categories of programming language: - Low-level languages: - - are machine-dependent - They are designed to be run on a particular computer (not portable). Eg. Machine language and Assembly Language High-level languages - Are machine-independent - Can be run on a variety of computers. Programming language require translation source code to machine language before execution. This translation is accomplished by either a compiler or an interpreter. Compilers translate the entire source

Question sources

Compiler Design review questions · Question 1

Question 73 | Q01394

Which computer program accepts the high-level language and converts it into assembly language?

A. Interpreter

B. Linker

C. Assembler

D. Compiler

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer D: Compiler.

CP04 describes compilation as a stage that may emit assembly from source. The assembler then translates that assembly into object-file machine instructions, and linking combines objects and libraries. Thus the question asks for the compiler, without implying that every compiler implementation must produce assembly as its output.

Why each choice is right or wrong

A - Incorrect: An interpreter executes a representation rather than being the stated high-level-to-assembly translation stage.

B - Incorrect: The linker resolves external symbols and combines objects and libraries after their translation.

C - Incorrect: The assembler consumes assembly and emits machine instructions, rather than consuming high-level source.

D - Correct: A compiler can translate high-level source into assembly, as described in the conventional toolchain.

Primary note proof

Study-note section CP04

> In the conventional C++ toolchain: source → preprocessing → compilation proper → assembly → object files → linking → executable → loading → execution. Preprocessing handles directives such as #include; compilation may emit assembly; the assembler emits machine instructions in an object file. The linker resolves external symbols and combines object files and libraries. The loader places an executable and required components in memory and starts it.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 4 | lines 21-30

> The compilation process of C++ program consists of the following steps. • edit source code → compile → link → execute (Editor) (Compiler) (Linker) (Loader) I. Program source code is entered into a file using a text editor. II. After the code has been entered, a compiler program is started that translates the source into an object code file. III. The object code file is linked with other object code files that come with the compiler and an executable file (or program) is created. IV. In order to execute the program, a program called the loader copies the executable file into the memory of the computer and sends an execute command to the CPU.

Question sources

Compiler Design review questions · Question 2

Question 74 | Q01395

In the conventional ahead-of-time C++ toolchain, is the source translation unit compiled before its resulting program is executed, even though compilation may use several internal passes?

A. No

B. Depends on the Compiler

C. Don't Know

D. Yes

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer D: D. Yes

The conventional C++ toolchain preprocesses and compiles source, assembles object files, links an executable and then loads it for execution. Thus the specified source translation occurs before running the resulting program. This does not mean the compiler has only one internal pass or must directly emit a complete native executable. Under the explicit conventional ahead-of-time model, Yes is the definite answer.

Why each choice is right or wrong

A - Incorrect: No contradicts the stipulated ahead-of-time build sequence.

B - Incorrect: The question fixes the conventional ahead-of-time model rather than leaving the execution strategy unspecified.

C - Incorrect: The stated model supplies enough information to decide.

D - Correct: The source unit is compiled before the resulting program executes.

Primary note proof

Study-note section CP04

> GCC documents the first four stages explicitly. A compiler need not emit a complete executable or even native machine code. Java javac produces bytecode, which a JVM interprets or compiles at runtime. Interpreters execute a program representation; “one source line at a time” is a beginner approximation. Compilation uses multiple passes, so “whole program in one step” is not literally universal.

> Categories of programming language: - Low-level languages: - - are machine-dependent - They are designed to be run on a particular computer (not portable). Eg. Machine language and Assembly Language High-level languages - Are machine-independent - Can be run on a variety of computers. Programming language require translation source code to machine language before execution. This translation is accomplished by either a compiler or an interpreter. Compilers translate the entire source

Computer Programming module | PDF page 4 | lines 21-30

> The compilation process of C++ program consists of the following steps. • edit source code → compile → link → execute (Editor) (Compiler) (Linker) (Loader) I. Program source code is entered into a file using a text editor. II. After the code has been entered, a compiler program is started that translates the source into an object code file. III. The object code file is linked with other object code files that come with the compiler and an executable file (or program) is created. IV. In order to execute the program, a program called the loader copies the executable file into the memory of the computer and sends an execute command to the CPU.

Question sources

Compiler Design review questions · Question 3

Question 75 | Q01396

Which of the following file is an output of the assembler?

A. Program file

B. Object file

C. Data File

D. Task File

Hint

Trace the initial state and each executed operation in order, preserving the requested output layout.

Answer B: Object file.

In CP04's toolchain the assembler emits machine instructions in an object file. Linking subsequently combines object files and libraries into an executable. The question therefore asks for the object file, rather than an unspecified program, data or task file; those other names do not identify the assembler's defined output stage.

Why each choice is right or wrong

A - Incorrect: Program file is a vague description and does not identify the assembler's specified object-file output.

B - Correct: The assembler emits an object file containing translated machine instructions for later linking.

C - Incorrect: Data file does not identify the translated instruction object produced at the assembly stage.

D - Incorrect: Task file is not a stage output identified for the assembler in CP04.

Primary note proof

Study-note section CP04

> In the conventional C++ toolchain: source → preprocessing → compilation proper → assembly → object files → linking → executable → loading → execution. Preprocessing handles directives such as #include; compilation may emit assembly; the assembler emits machine instructions in an object file. The linker resolves external symbols and combines object files and libraries. The loader places an executable and required components in memory and starts it.

> The compilation process of C++ program consists of the following steps. • edit source code → compile → link → execute (Editor) (Compiler) (Linker) (Loader) I. Program source code is entered into a file using a text editor. II. After the code has been entered, a compiler program is started that translates the source into an object code file. III. The object code file is linked with other

object code files that come with the compiler and an executable file (or program) is created. IV. In order to execute the program, a program called the loader copies the executable file into the memory of the computer and sends an execute command to the CPU.

Question sources

Compiler Design review questions · Question 4

Question 76 | Q01398

What is the linker's role in the conventional C++ build process?

A. It translates assembly source into object files.

B. It combines object files and libraries and resolves external symbols to create an executable module.

C. It is the same as the loader

D. None of the above

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer B: B. It combines object files and libraries and resolves external symbols to create an executable module.

The assembler has already produced object files when linking begins. The linker combines those files and libraries and resolves their external symbol references to create the executable module. The loader subsequently places that executable and required components in memory. These distinct responsibilities make option B precise: A describes assembly instead, C conflates linking with loading, and D is false because B supplies the correct role.

Why each choice is right or wrong

A - Incorrect: Translating assembly into an object file is the assembler's role.

B - Correct: The linker combines objects/libraries and resolves external references to make the executable.

C - Incorrect: The loader's memory-placement role is separate from linking.

D - Incorrect: B gives the correct linker responsibility.

Primary note proof

Study-note section CP04

In the conventional C++ toolchain: source → preprocessing → compilation proper → assembly → object files → linking → executable → loading → execution. Preprocessing handles directives such as #include; compilation may emit assembly; the assembler emits machine instructions in an object file. The linker resolves external symbols and combines object files and libraries. The loader places an executable and required components in memory and starts it.

Question sources

Compiler Design review questions · Question 6

Question 77 | Q01424

Which statement is false about the conventional C++ toolchain described in the note?

A. Every compiler directly emits a complete executable without a separate linking stage.

B. A debugger is useful after a runnable program exists.

C. Source syntax errors must be repaired for successful translation.

D. Compilation may use multiple passes and may emit assembly.

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer A: A. Every compiler directly emits a complete executable without a separate linking stage.

The note separates several translation and build stages. Compilation can emit assembly, assembly produces object files, and linking resolves external symbols and combines those objects. It therefore does not follow that every compiler directly produces a complete executable. Source grammar errors must be corrected for successful translation, and a debugger is useful after a runnable program exists. These stage-based claims avoid unspecified execution-time and debugging-speed comparisons.

Why each choice is right or wrong

A - Correct: A compiler need not emit a complete executable; linking is a separate stage.

B - Incorrect: The note places debugger use after a runnable program exists.

C - Incorrect: A successfully translated C++ program has passed its source syntax checks.

D - Incorrect: Compilation can use multiple passes and can emit assembly.

Primary note proof

Study-note section CP04

In the conventional C++ toolchain: source → preprocessing → compilation proper → assembly → object files → linking → executable → loading → execution. Preprocessing handles directives such as #include; compilation may emit assembly; the assembler emits machine instructions in an object file. The linker resolves external symbols and combines object files and libraries. The loader places an executable and required components in memory and starts it.

Study-note section CP32

A syntax error violates grammar; a type error can be syntactically well formed but rejected during semantic checking. A runtime error occurs during execution; a logic error gives the wrong behavior. A bug is a defect; debugging locates and corrects it. Read the first useful compiler diagnostic, inspect nearby tokens and declarations, repair and rebuild; a debugger is useful after a runnable program exists.

Question sources

Compiler Design review questions · Question 32

Question 78 | Q01518

Which one of the following is a VALID C++ declaration statement?

A. age int;

B. int 1x, 2x;

C. int FLOAT;

D. float abebe, A-Z;

Hint

Apply the naming, type and syntax rules before deciding whether an option can be used as stated.

Answer C: int FLOAT;

The required declaration form is type followed by identifiers (p.5). int FLOAT fits: uppercase FLOAT is used as an identifier, distinct from lowercase reserved float in the intended C++ reading. A reverses type/name, B starts identifiers with digits, and D uses a hyphen in A-Z. Module support: PDF p. 5, PDF p. 5.

Why each choice is right or wrong

A - Incorrect: "age int;" does not match the rule or result derived here. The required declaration form is type followed by identifiers (p.5). int FLOAT fits: uppercase FLOAT is used as an identifier, distinct from lowercase reserved float in the intended C++ reading. A reverses type/name, B starts identifiers with digits, and D uses a hyphen in A-Z.

B - Incorrect: "int 1x, 2x;" does not match the rule or result derived here. The required declaration form is type followed by identifiers (p.5). int FLOAT fits: uppercase FLOAT is used as an identifier, distinct from lowercase reserved float in the intended C++ reading. A reverses type/name, B starts identifiers with digits, and D uses a hyphen in A-Z.

C - Correct: "int FLOAT;" matches the derived result. The required declaration form is type followed by identifiers (p.5). int FLOAT fits: uppercase FLOAT is used as an identifier, distinct from lowercase reserved float in the intended C++ reading. A reverses type/name, B starts identifiers with digits, and D uses a hyphen in A-Z.

D - Incorrect: "float abebe, A-Z;" does not match the rule or result derived here. The required declaration form is type followed by identifiers (p.5). int FLOAT fits: uppercase FLOAT is used as an identifier, distinct from lowercase reserved float in the intended C++ reading. A reverses type/name, B starts identifiers with digits, and D uses a hyphen in A-Z.

Primary note proof

Study-note section CP05

> In the basic ASCII identifier rules, start with a letter or underscore; continue with letters, digits or underscores. Do not use a keyword. C++ is case sensitive: exitExam and ExitExam differ; delete and float are keywords, but FLOAT is a legal identifier. variable_1234 is valid; 4thInput, T-3 and names containing spaces are not single identifiers. Avoid reserved underscore patterns in application code.

Study-note section CP06

Write type name; or type name = value; for ordinary variables: int age = 20;. Declaration introduces a name and type; initialization gives its initial value; later assignment replaces a value. a=b copies a scalar value, so later changes to b do not change a. A pointer or Java object reference instead copies an address/reference.

Computer Programming module | PDF page 5 | lines 24-33

5. Data Types, Variables, and Constants Variable: - Variable is a symbolic name for a memory location in which data can be stored. - Attribute of Variables: o A type, which is, established when the variable is defined (e.g., integer, float, character) o A value, which can be changed by assigning a new value to the variable Variable Declaration - Declaring a variable means defining (creating) a variable. - Syntax: data type variable name; e.g. int num; - We can create More Than One Variable at a Time e.g., int num1, num2, num3;

Computer Programming module | PDF page 5 | lines 2-10

1. Keywords (reserved words) - Unique meaning within a C++ program and must not be used for any other purposes. E.g., if, namespace for, switch, continue, float, new, default, break Etc. 2. Identifiers - Name associated with a function or data object and used to refer to that function or data object. An identifier must: o Start with a letter or underscore o Consist only of letters, the digits 0-9, or the underscore symbol _ o Not be a reserved word

Question sources

Mock exam 1 · Question 34

Question 79 | Q01519

Which of the following is not true?

A. (8.0 * 3) % 5 is evaluated to 4

B. 8 * 3 / 3 evaluated to 8

C. (5 > 3) || (5 != 5) && (2 <= 2) results in true

D. (7.0 * 3) / 5 is evaluated to 4.2

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer A: The floating-point remainder expression is invalid in C++.

The expression (8.0 * 3) has floating type, so applying % to it is invalid under CP08; it does not evaluate to 4. The integer multiplication/division in B gives 8. C is true because its left disjunct is true. D uses floating division and gives 21.0/5 = 4.2.

Why each choice is right or wrong

A - Correct: This is the false statement: floating-point operands cannot be used with the C++ remainder operator.

B - Incorrect: Equal-precedence multiplication and division group left to right: 24/3 gives the stated 8.

C - Incorrect: The first comparison is true, so the disjunction is true regardless of its right operand.

D - Incorrect: 7.0 makes the computation floating point, and 21.0 divided by 5 gives 4.2.

Primary note proof

Study-note section CP08

> Multiplication, division and remainder have higher precedence than addition and subtraction; equal-precedence arithmetic groups left to right. Integer division truncates toward zero. For integers, a == (a/b)*b + a%b when the division is valid. % requires integral operands in C++; (8.0*3)%5 is invalid. Division by zero and signed integer overflow cannot be given ordinary numeric outputs.

Study-note section CP10

> Relational and equality operators test values; && and || combine truth values; ! negates. In C++, zero converts to false and a nonzero number to true. Streams display bool as 0 or 1 unless boolalpha is set. With a=3,b=5, cout<<(a==b) prints 0.

Module passages - related reading

Mock exam 1 · Question 35

Question 80 | Q01520

Which one of the following is the result of the below given code fragment?
int a = 7, b;
b = a++;
cout<<++b;

A. 6

B. 9

C. 7

D. 8

Hint

Trace the initial state and each executed operation in order, preserving the requested output layout.

Answer D: 8

b=a++ assigns the old a value 7 to b and increments a to 8. Then ++b changes b to 8 before output. Thus 8 prints; 7 omits the prefix increment and 6/9 do not follow the trace. Module support: PDF p. 7.

Why each choice is right or wrong

A - Incorrect: "6" does not match the rule or result derived here. b=a++ assigns the old a value 7 to b and increments a to 8. Then ++b changes b to 8 before output. Thus 8 prints; 7 omits the prefix increment and 6/9 do not follow the trace.

B - Incorrect: "9" does not match the rule or result derived here. b=a++ assigns the old a value 7 to b and increments a to 8. Then ++b changes b to 8 before output. Thus 8 prints; 7 omits the prefix increment and 6/9 do not follow the trace.

C - Incorrect: "7" does not match the rule or result derived here. b=a++ assigns the old a value 7 to b and increments a to 8. Then ++b changes b to 8 before output. Thus 8 prints; 7 omits the prefix increment and 6/9 do not follow the trace.

D - Correct: "8" matches the derived result. b=a++ assigns the old a value 7 to b and increments a to 8. Then ++b changes b to 8 before output. Thus 8 prints; 7 omits the prefix increment and 6/9 do not follow the trace.

Primary note proof

Study-note section CP09

> Prefix ++x changes x and yields the new value; postfix x++ yields the previous value and also increments x. Separate the value used in the expression from the stored value after it. Starting a=8,b=5, a++ + --b uses 8+4, gives 12, and leaves a=9,b=4. Starting x=1,y=10,z=-3, (x++*y--)+ ++z gives 8 and leaves x=2,y=9,z=-2.

Mock exam 1 · Question 36

Question 81 | Q01575

Considering the below given string declaration, which one of the following statements is correct? char msg[] = "This is the final exam for C++";

A. There is an error with the initialization statement

B. strlen(msg) would return 24

C. strcpy(msg, "Hurray") would assign the content of msg to Hurray

D. cout<<msg ; would display: This is the final exam for C++

E. None of the answers are correct

Hint

Apply the naming, type and syntax rules before deciding whether an option can be used as stated.

Answer D: cout<<msg ; would display: This is the final exam for C++

The module supports char-array string initialization and output. Printing msg displays its literal This is the final exam for C++. Its length is 28 characters, not 24. strcpy(destination,source) copies Hurray into msg, not the reverse. Thus A/B/C/E fail and D matches. Module support: PDF p. 22, PDF p. 23, PDF p. 6.

Why each choice is right or wrong

A - Incorrect: "There is an error with the initialization statement" does not match the rule or result derived here. The module supports char-array string initialization and output. Printing msg displays its literal This is the final exam for C++. Its length is 28 characters, not 24. strcpy(destination,source) copies Hurray into msg, not the reverse. Thus A/B/C/E fail and D matches.

B - Incorrect: "strlen(msg) would return 24" does not match the rule or result derived here. The module supports char-array string initialization and output. Printing msg displays its literal This

is the final exam for C++. Its length is 28 characters, not 24. strcpy(destination,source) copies Hurray into msg, not the reverse. Thus A/B/C/E fail and D matches.

C - Incorrect: "strcpy(msg, "Hurray") would assign the content of msg to Hurray" does not match the rule or result derived here. The module supports char-array string initialization and output. Printing msg displays its literal This is the final exam for C++. Its length is 28 characters, not 24. strcpy(destination,source) copies Hurray into msg, not the reverse. Thus A/B/C/E fail and D matches.

D - Correct: "cout<<msg ; would display: This is the final exam for C++" matches the derived result. The module supports char-array string initialization and output. Printing msg displays its literal This is the final exam for C++. Its length is 28 characters, not 24. strcpy(destination,source) copies Hurray into msg, not the reverse. Thus A/B/C/E fail and D matches.

E - Incorrect: "None of the answers are correct" does not match the rule or result derived here. The module supports char-array string initialization and output. Printing msg displays its literal This is the final exam for C++. Its length is 28 characters, not 24. strcpy(destination,source) copies Hurray into msg, not the reverse. Thus A/B/C/E fail and D matches.

Primary note proof

Study-note section CP24

A C string is a character array ending in '\0'. "Hello" needs six char positions; strlen counts five visible characters and excludes the terminator. sizeof a fixed char array reports its allocated bytes, which can exceed strlen+1. cout<<a prints a terminated char sequence, not its numeric address.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 22 | lines 22-38

String and pointer String: - is an ordered sequence of characters - Sequence of character in which the last character is the null character „\0‟ - The null character indicates the end of the string - C++ provides following two types of string representations: o The C-style character string. o The string class type introduced with Standard C++. NB: →If a string has n characters, then it requires an n+1 element array (at least) to store it. →In order to use the string data type, the C++ string header <string> must be included at the top of the program The C-Style Character String - originated within the C language and continues to be supported within C++ - array of characters which is terminated by a null character '\0' Example: char status[5]={„G‟,‟O‟,‟O‟,‟D‟,‟\0‟};//char status[]=”Good”; cout<<status;

Computer Programming module | PDF page 23 | lines 2-8

- C++ supports a wide range of functions that manipulate null-terminated strings: strcpy(s1, s2); Copies string s2 into string s1 strcat(s1, s2); Concatenates string s2 onto the end of string s1 strlen(s1); Returns the length of string s1. strcmp(s1, s2); Returns 0 if s1 and s2 are the same; less than 0 if s1<s2; greater than 0 if s1>s2. strchr(s1, ch); Returns a pointer to the first occurrence of character ch in string s1. strstr(s1, s2); Returns a pointer to the first occurrence of string s2 in string s1.

Computer Programming module | PDF page 6 | lines 4-15

> 6. Communication through console cout (the standard output stream) o used to display information for the user Syntax: cout<<object; • Object can be variable or literals Example: int x=5; cout<<x cout<< “Hello there”; cin(the standard input stream): o used to accept information from the user. Syntax: cin>>variable name; Eg. cin>>x;

Question sources

Mock exam 3 · Question 7

Question 82 | Q01576

Given the structure below, assume ptr1 and ptr2 point to separate live house objects. Which statement copies the rooms value from the first object to the second?
struct house { double price; int rooms; };
house *ptr1, *ptr2;

A. Cout<<ptr1<< ptr2;

B. ptr2->rooms = ptr1->rooms;

C. ptr1 < ptr2;

D. ptr1 = ptr1 + ptr2;

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer B: B. ptr2->rooms = ptr1->rooms;

Each pointer must refer to a live object before its members are accessed. The -> operator selects a member through a pointer, so assigning ptr1->rooms to ptr2->rooms copies the first object’s integer member into the second. A is an output expression with a misspelled stream name, C compares pointers rather than copying a member, and D tries to add two pointers, which is not permitted pointer arithmetic.

Why each choice is right or wrong

A - Incorrect: This output expression does not copy rooms and uses undeclared Cout.

B - Correct: Both -> expressions select rooms, and assignment copies from ptr1 to ptr2.

C - Incorrect: A pointer comparison does not copy a member value.

D - Incorrect: Adding two pointers is not valid pointer arithmetic.

Primary note proof

Study-note section CP27

> A struct groups named members, possibly of different types. struct House{double price; int rooms;}; defines a type; House h{150000,3}; creates an object. h.rooms uses a dot. House* p=&h;

p->rooms is equivalent to (*p).rooms. The pointer must refer to a live object before member access. A type definition alone does not create an ordinary instance.

Study-note section CP26

Pointer addition p+q is invalid; subtracting pointers within the same array gives an element distance.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 38 | lines 10-16

Pointer to structure Pointers to structures may be declared as follow: struct staructuretage *pinternname; eg Employe *emp; When using a pointer to a struct, member access can be achieved with the `.' operator, but can not look graceful in expression Example: (*emp).id Equivalently, the ->' operator can be used; for example: emp->id

Computer Programming module | PDF page 26 | lines 2-22

Pointer - A pointer is a variable that holds a memory address of another variable. - - Its content is a memory address - A pointer is simply the address of a memory location and provides an indirect way of accessing data in memory. - It is defined to „point to“ data of a specific type. - Because a pointer variable holds the address of another piece of data, it "points to" the data Reference operator (&) and Dereference operator (*) &: read as address of - Use address operator & to get address of a variable *: read as value pointed by Declaring variables of pointer types Syntax: type *variable_name; For example: int *ptr1; //pointertoanint double*number; char*ptr2; //pointertoachar The value of a pointer variable is the address to which it points. For example, given the definitions int num; wecanwrite: ptr1=#

Mock exam 3 · Question 8

Question 83 | Q01577

Under C++17, which option best summarizes whether initialization forms A-C are valid? Treat each form as a separate declaration; 25.00 is exactly representable as float.

A. struct Time { int h = 06, m = 20; float s = 25.00; };

B. struct Time { int h, m; float s;}t = {06, 20, 25.00};

C. struct Time { int h, m; float s; }; Time t = {06, 20, 25.00};

D. All of them are correct

E. None of the choices are correct

Hint

Apply the naming, type and syntax rules before deciding whether an option can be used as stated.

Answer D: D. All of them are correct

C++17 permits default member initializers, so A's in-class values are allowed. B defines an aggregate object alongside its type, while C defines the type and then aggregate-initializes an object. The specified exactly representable floating constant is permitted here's narrowing exception. All three forms are consequently valid. The question asks for the complete summary, making D the best selection rather than any one individual example.

Why each choice is right or wrong

A - Incorrect: A is valid but alone does not summarize all three forms.

B - Incorrect: B is valid but describes only one of the three valid forms.

C - Incorrect: C is valid but is an incomplete response to the requested summary.

D - Correct: All three forms are valid under the specified C++17 assumptions.

E - Incorrect: The existence of valid forms A-C makes the none-correct summary false.

Primary note proof

Study-note section CP27

> Aggregate initialization assigns members in declaration order. Modern C++ permits default member initializers such as int rooms=3;. C++11 list initialization rejects narrowing; a constant floating value exactly representable in the target floating type can be permitted, so 25.00 to float is not necessarily narrowing. Use 25.0f for clarity and check the language version. Structures can be copied, passed and returned; a structure cannot contain a full instance of itself, but may contain a pointer to its own type.

Question sources

Mock exam 3 · Question 9

Question 84 | Q01615

If we have object from ofstream class, then default mode of opening the file is _____ .

A. ios::in

B. ios::out

C. ios::out|ios::trunk

D. ios::in|ios::trunc

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer B: B. ios::out

The ofstream constructor's default mode argument is ios::out. Its usual output-only opening behavior also creates or truncates the file, but that effect does not change the spelling of the default argument. ios::in requests input instead. The printed ios::trunk is not the valid truncation flag, and an input/truncation combination is not the output stream's default. Thus B is the unique default-mode selection.

Why each choice is right or wrong

A - Incorrect: ios::in requests input rather than the default output mode.

B - Correct: ios::out is the default ofstream mode argument.

C - Incorrect: ios::trunk is misspelled; even out|trunc describes an effect rather than the constructor's default argument.

D - Incorrect: Input combined with truncation is not the default output mode argument.

Primary note proof

Study-note section CP29

> Include <fstream>. ofstream writes, ifstream reads, and fstream can do both. The constructor's default ofstream mode argument is ios::out; its ordinary effect is to create/truncate the file. Distinguish the default mode argument from effective out|trunc behavior. ios::app places each write at the end; ios::ate initially seeks to the end; ios::binary requests binary mode.

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 41 | lines 2-9

> • fstream: Stream class to both read and write from/to files. File Modes In C++, for every file operation, exists a specific file mode. These file modes allow us to create, read, write, append or modify a file. The file modes are defined in the class ios. Let's see all these different modes in which we could open a file on disk. Create and Write to a File To create a file, use either the ofstream or fstream class, and specify the name of the file. To write to the file, use the insertion operator (<<).

Computer Programming module | PDF page 40 | lines 16-22

> File and File Management Files are used to store data in storage devices permanently. The fstream library allows us to work with files. To use the fstream library, include both the standard <iostream> AND the <fstream> header file: Input/Output with files • ofstream: Stream class to write on files • ifstream: Stream class to read from files

Question sources

Mock exam 2 · Question 4

Question 85 | Q01616

After the prompt and input of vehicleType=2, what text is printed by the switch body?

```
int vehicleType;
cout << "Enter vehicle type: ";
cin >> vehicleType;
switch (vehicleType) {
case 1:
cout << "Passenger car.";
case 2:
cout << "Bus.";
case 3:
cout << "Truck.";
break;
default:
cout << "Unknown vehicle class!";
}
```

A. Passenger Car.

B. Bus.Truck.

C. Truck

D. Bus.

Hint

Trace the initial state and each executed operation in order, preserving the requested output layout.

Answer B: B. Bus.Truck.

Input 2 begins execution at case 2, so Bus. prints first. There is no break after that output, so execution continues through case 3 and prints Truck. before reaching the break. The switch-body output is therefore Bus.Truck. The input prompt is excluded explicitly. The other options either start at the wrong case or omit one of the outputs produced by fall-through.

Why each choice is right or wrong

A - Incorrect: Case 1 is not entered when the value is 2.

B - Correct: Case 2 falls through to case 3 before the break.

C - Incorrect: The matching case prints Bus. before Truck.

D - Incorrect: The absent break after case 2 allows Truck. to print too.

Primary note proof

Study-note section CP13

A traditional C++ switch selects using an integral or enumeration value. case labels are constant expressions. Execution starts at the matching label, then continues through subsequent statements until a break, return or the end. default handles an unmatched value but need not be the last physical label.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 10 | lines 15-26

switch Statement The switch statement provides a way of choosing between a set of alternatives, based on the value of an expression. The general form of the switch statement is: switch (expression) { caseconstant1: statements; ... caseconstantn: statements; default: statements; }

Computer Programming module | PDF page 13 | lines 30-35

Using continue and break Statements - The break statement skips the rest of the statements in the loop‟s block, jumping immediately to the next statement outside of the loop. - The continue statement is similar. It also skips the rest of the statements in the loop‟s block, but instead of terminating the loop, it transfers execution to the next iteration of the loop. It continues the loop after skipping the remaining statements in its current iteration.

Question sources

Mock exam 2 · Question 5

Question 86 | Q01617

For the C++ fragment below, assume sizeof(float)==4, byte-addressed memory, a first-element address of 7000, and ordinary array-to-pointer conversion in B. Evaluate each option independently from ptr=num. Which statement is false?
float num[4]={2.0,1.0,3.0,5.5};
float* ptr=num;

A. ptr + 3 is equal to 7012.

B. num is the same as &num[0].

C. The statement cout<<num[3]; will print 5.5.

D. The statement cout<<ptr++; will print 1.0.

Hint

Trace the initial state and each executed operation in order, preserving the requested output layout.

Answer D: D. The statement cout<<ptr++; will print 1.0.

Pointer arithmetic advances by elements, not single bytes. With four-byte float elements, ptr+3 has address 7000+12=7012. The array expression ordinarily converts to &num[0], and index 3 selects the initialized value 5.5. Inserting ptr++ into cout displays its old pointer address and then advances it. It does not insert an array element’s value, so the claim that it prints 1.0 is false.

Why each choice is right or wrong

A - Incorrect: Three float elements advance the address by 12 bytes.

B - Incorrect: In the stated conversion context num becomes &num[0].

C - Incorrect: Index 3 contains the fourth initializer, 5.5.

D - Correct: ptr++ supplies the old pointer address, not the element value 1.0.

Primary note proof

Study-note section CP26

> If p points inside an array, p+k advances k elements, or k*sizeof(*p) bytes. Under the explicit assumption sizeof(float)==4 and first address 7000, p+3 has numeric address 7012. cout<<p++ displays the old address then advances p; cout<<*p++ displays the old element then advances p. ++*p changes the element. Pointer addition p+q is invalid; subtracting pointers within the same array gives an element distance.

Study-note section CP25

> An array expression commonly converts to a pointer to its first element, but the array is not itself an assignable pointer variable.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 29 | lines 2-10

> Pointer arithmetic - The C++ language allows you to perform integer addition or subtraction operations on pointers. - If ptr points to an integer, ptr + 1 is the address of the next integer in memory after ptr. - ptr - 1 is the address of the previous integer before ptr. Note that ptr + 1 does not return the memory address after ptr, but the memory address of the next object of the type that ptr points to. If ptr points to an integer (assuming 4 bytes), ptr + 3 means 3 integers (12 bytes) after ptr. If ptr points to a char, which is always 1 byte, ptr + 3 means 3 chars (3 bytes) after ptr. When calculating the result of a pointer arithmetic expression, the compiler always multiplies the integer operand by the size of the object being pointed to. This is called scaling.

Computer Programming module | PDF page 31 | lines 2-11

> - Array can bound into a pointer that points to the first element (element 0) of the array. - An array access can always be implicitly converted to a pointer access of the appropriate type. For example, consider these two declarations: int myarray[20]; int *mypointer; Mypointer=myarray;// mypointer=&myarray[0]; →Stores the address of the first element of the array in variable mypointer → After that, mypointer and myarray would be equivalent and would have very similar properties. →The main difference being that mypointer can be assigned a different address, whereas myarray can never be assigned anything, and will always represent the same block of 20 elements of type int.

Computer Programming module | PDF page 6 | lines 4-15

> 6. Communication through console cout (the standard output stream) o used to display information for the user Syntax: cout<<object; • Object can be variable or literals Example: int

x=5; cout<<x cout<< “Hello there”; cin(the standard input stream): o used to accept information from the user. Syntax: cin>>variable name; Eg. cin>>x;

Question sources

Mock exam 2 · Question 6

Question 87 | SM0009

In the conventional native-execution model, which statement about programming-language generations is false?

A. Assembly language is machine independent

B. Machine language can be executed without translation

C. Assembly language should be translated to machine language before execution

D. Fifth-generation languages are historically associated with declarative logic, constraints and AI/expert systems.

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer A: A. Assembly language is machine independent

Assembly is symbolic source tied to an instruction set; it is not machine independent. Before native execution, an assembler translates it into machine instructions. Those machine instructions are already in the target machine’s instruction format. Fifth generation is instead a historical language category associated with declarative logic, constraints and expert systems, rather than a universal hardware-performance requirement. Only A contradicts the specified language and execution model.

Why each choice is right or wrong

A - Correct: Assembly depends on the target instruction set, so this claim is false.

B - Incorrect: Machine instructions do not require assembly-to-machine translation.

C - Incorrect: Symbolic assembly is translated before native execution.

D - Incorrect: This historical association is the fifth-generation description in the note.

Primary note proof

Study-note section CP03

Machine instructions are conventionally first generation; symbolic assembly is second; general high-level languages such as C++ and Java are third. Database query and application generators such as SQL are conventionally fourth generation. Fifth generation is a loose historical category associated with declarative logic, constraints and AI/expert systems. Generations do not determine whether an implementation uses an interpreter.

Study-note section CP04

In the conventional C++ toolchain: source → preprocessing → compilation proper → assembly → object files → linking → executable → loading → execution. Preprocessing handles directives such as #include; compilation may emit assembly; the assembler emits machine instructions in an object file. The linker resolves external symbols and combines object files and libraries. The loader places an executable and required components in memory and starts it.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 3 | lines 8-17

Categories of programming language: - Low-level languages: - - are machine-dependent - They are designed to be run on a particular computer (not portable). Eg. Machine language and Assembly Language High-level languages - Are machine-independent - Can be run on a variety of computers. Programming language require translation source code to machine language before execution. This translation is accomplished by either a compiler or an interpreter. Compilers translate the entire source

Question 88 | SM0030

For standard built-in C++ arrays declared with an explicit bound, which statement is false?

A. We use [] square brackets at the time of array declaration

B. Size of an array should be constant at the time of array declaration

C. An array is a collection of similar data objects

D. Elements can be accessed only by writing a bracketed index such as a[i].

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer D: D. Elements can be accessed only by writing a bracketed index such as a[i].

A standard built-in array declaration uses square brackets and a compile-time constant bound. Its elements share one type. Element access is not restricted to bracket syntax: a[i] is equivalent to *(a+i), and a pointer to an element can also be dereferenced. Option D asserts that bracketed indexing is the only access method, which the pointer equivalence directly disproves.

Why each choice is right or wrong

A - Incorrect: An explicit built-in array bound appears inside square brackets.

B - Incorrect: Standard built-in array bounds must be compile-time constants.

C - Incorrect: Built-in arrays contain same-type elements.

D - Correct: Pointer notation can access elements, so bracketed indexing is not the only method.

Primary note proof

Study-note section CP22

> A built-in C++ array has a fixed number of same-type elements in contiguous storage: int a[4]={10,20,30,40};. Valid indices are 0 through 3. a[4] is outside the array; accessing it has undefined behavior. Java checks bounds and throws ArrayIndexOutOfBoundsException. Do not predict a C++ out-of-range value from nearby memory.

Study-note section CP22

> A standard built-in array bound must be a compile-time constant; variable-length local arrays are compiler extensions. int a[5]={1,2,3}; fills the remaining elements with zeros. An uninitialized automatic array of int is different. a[i] equals *(a+i), so elements can be accessed using pointer notation without explicitly writing brackets.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 19 | lines 4-29

> Arrays - an array is a collection of fixed-size number of elements of the same type stored sequentially in memory. - An individual element of an array is identified by its own unique index (or subscript). - The number of elements must be an integer. - The size of the array is referred to as its dimension - Array in C++ is Zero indexed. Declaring of one-dimensional Array Syntax: elementstype arrayname [size]; → You can use constants such as macro definitions or const ints as the sizes of arrays. Example: int num[5]; string fruit[3]; #define numstudents 100 or const int numstudents=100; double Score[numstudents] ; double Score[numstudents] ; Initialization of an Array - Arrays can be initialized at declaration time in two different ways: Syntax: elementstype arrayname[size] = {list each value separated by comma}; E.g int num[5]={1,2,3,4,5}; elementstype arrayname[ ] = { list with any number of values }; E.g int num[]={1,2,3,4,5}; string fruit[]={“Apple”,“orange”, “Mango”}; Accessing Array Elements - Each element could be accessed using an index into the array - When accessing an array, the index given must be a positive integer from 0 to n-1, where n is the dimension of the array.

Computer Programming module | PDF page 31 | lines 31-36

> NB: →Generally, array[n] is the same as *(array + n), where n is an integer. →Considering that int *ptr; int arr[5]; ptr = arr; ptr + 1 is equivalent to &arr[1]; ptr + 2 is equivalent to &arr[2];

Question 89 | SM0032

What values are printed by this C++ fragment? Ignore the trailing space; assume cout is available.

```
for(int n=1;n<=18;n=n+2){
if(n%7!=0) cout<<n<<" ";
else break;
}
```

A. 3 5 7

B. 1 3 5 7 9 11 13 15 17

C. 1 3 5

D. 1 2 3 4 5 6

Hint

Fix the input case and cost model, then count dominant work or simultaneously live storage.

Answer C: C. 1 3 5

The loop begins at 1 and adds two after each completed iteration. The values 1, 3 and 5 are not divisible by seven, so each is printed with a following space. At n=7 the condition is false and the else branch executes break, ending the loop before 7 is printed. Later odd values are never reached. The options show value sequences rather than exact trailing whitespace.

Why each choice is right or wrong

A - Incorrect: The loop prints 1 first and stops before printing 7.

B - Incorrect: break prevents 7 and all later odd values from printing.

C - Correct: The three printed values are 1, 3 and 5.

D - Incorrect: Adding two does not visit consecutive integers.

Primary note proof

Study-note section CP16

> For n=1; n<=18; n+=2, print n unless n%7==0 then break: output is 1 3 5. A while(a>b) with fixed a=6,b=5 never changes its true condition. In data[10]={5,10,...,50}, i=0, advancing i only if data[i]%10==0 causes no progress because data[0]=5. It prints nothing and loops indefinitely; changing <=10 to <10 alone does not repair progress.

Study-note section CP15

break exits the nearest enclosing loop or switch. continue skips the rest of the current loop iteration: a for loop then runs its update; a while loop goes directly to its condition. return leaves the current function and may supply a result. In main it ends the program normally.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 12 | lines 19-28

The for loop. Its format is: for (initialization; condition; increase) statement; 1, initialization is executed. Generally, it is a initial value setting for a counter variable. This is executed only once 2, condition is checked, if it is true the loop continues, otherwise the loop finishes and statement is skipped. 3, statement is executed. As usual, it can be either a single instruction or a block of instructions enclosed within curly brackets { }. 4, finally, whatever is specified in the increase field is executed and the loop gets back to step 2.

Computer Programming module | PDF page 13 | lines 30-35

Using continue and break Statements - The break statement skips the rest of the statements in the loop‟s block, jumping immediately to the next statement outside of the loop. - The continue statement is similar. It also skips the rest of the statements in the loop‟s block, but instead of terminating the loop, it transfers execution to the next iteration of the loop. It continues the loop after skipping the remaining statements in its current iteration.

Computer Programming module | PDF page 7 | lines 5-23

Assignment Operators (=) Example: int x=5; or used with a combination of other operators‟ example, x+=2;//x=x+2, x=y=10; Arithmetic Operators (+, -, *, /, %) E.g. Assume int X=9, Y=2 X+Y, Y-X, X%Y Relational operators (==,!=, <, <=,>,>=) Relational operators evaluate to 1 (representing the true outcome) or 0 (representing the false outcome). Assume int X=9, Y=2 X==Y, X!=Y, X>Y 'A' < 'F' // gives 1 (is like 65 < 70) Logical operators (! Negation, &&, ||) Like the relational operators, logical operators evaluate to 1 or 0. Example: 5 < 6 || 6 < 5 // gives 1 In general, any nonzero value can be used to represent the logical true, whereas only zero represents the logical false !12 // gives 0 10 && 5 // gives 1 Increment/decrement Operators The auto increment (++) and auto decrement (--) operators provide a convenient way of, respectively, adding and subtracting 1 from a numeric variable. Both operators can be used in prefix and postfix form.

Question sources

MOE Computer Science Exit Exam · Question 10-1

Question 90 | SM0055

In a C++ translation unit, int requests=0; is declared at namespace scope before the function definitions. Functions can use it wherever that declaration is visible. Which listed term describes its scope category rather than its storage duration?

A. Static

B. Automatic

C. Local

D. Global

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer D: D. Global

The declaration is at namespace scope, outside every function, so the variable has global scope in the terminology used here. Its declaration must still be visible where it is used, and a local name can shadow it. Static and automatic concern storage properties rather than identifying this outside-function scope category. The question therefore selects Global without claiming unrestricted visibility across every file.

Why each choice is right or wrong

A - Incorrect: Static storage duration does not uniquely identify scope; a static local can still have block scope.

B - Incorrect: Automatic describes storage duration and does not name the namespace-scope category.

C - Incorrect: A local name is restricted to its function or block.

D - Correct: Global is the category for this namespace-scope declaration, subject to visibility and shadowing.

Primary note proof

Study-note section CP20

> Scope is where a name can be used; lifetime is when its object exists. A local name is restricted to its block; an outer name may be shadowed. A namespace/global variable is available where its declaration is visible, not magically in every file. C++ ::name selects a global name hidden by a local one.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 17 | lines 14-29

> Scope of variables Scope of variables defined as the extent of the program code within which the variable can be accessed or declared or worked with mainly two types of variable scopes: local

variable: - Variables defined within a function or block are said to be local to those functions - Declared inside a block{} Global Variable - variable that can be accessed from any part of the program. - They are available throughout the life time of a program. - They are declared at the top of the program outside all of the functions or blocks. NB: - Usually when two variables with same name are defined then the compiler produces a compile time error. But if the variables are defined in different scopes, then the compiler allows it. - Whenever there is a local variable defined with same name as that of a global variable then the compiler will give precedence to the local variable

Question 91 | SM0088

Which one of the following is NOT an example of scripting languages?

A. Python

B. Perl

C. PHP

D. C++

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer D: C++.

CP03 identifies Python, Perl and PHP as commonly called scripting languages and C++ as conventionally compiled. This supports C++ as the intended exception. The classification describes common use rather than an absolute prohibition on interpreting C++ or compiling languages normally used for scripting.

Why each choice is right or wrong

A - Incorrect: Python is explicitly included among the note’s commonly called scripting languages.

B - Incorrect: Perl is explicitly included among the note’s commonly called scripting languages.

C - Incorrect: PHP is explicitly included among the note’s commonly called scripting languages.

D - Correct: C++ is the conventionally compiled language contrasted with the three scripting-language examples.

Primary note proof

Study-note section CP03

Machine and assembly code depend on an instruction set. High-level source is easier to read and often portable after recompilation, provided it avoids platform assumptions. People can write both assembly and high-level programs. Python, Perl and PHP are commonly called scripting languages; C++ is conventionally compiled. These labels describe common use, not an absolute technical prohibition.

programming paradigm: provides the programmer's view of code execution. The most influential paradigms are: Procedural Programming Languages Procedural programming specifies a list of operations that the program must complete to reach the desired state. Each program has a starting state, a list of operations to complete, and an ending point. This approach is also known as imperative programming. Structured Programming Languages Structured programming is a special type of procedural programming. It provides additional tools to manage the problems that larger programs were creating. Structured programming requires that programmers break program structure into small pieces of code that are easily understood. One of the well-known features of structural programming is that it does not allow the use of the GOTO statement. It is often associated with a "top-down" approach to design. Object-Oriented Programming Languages Object-oriented programming is one the newest and most powerful paradigms. In object- oriented programs, the designer specifies both the data structures and the types of operations that can be applied to those data structures.

Question 92 | SM0092

What is the output of the following C++ fragment code? int a, b; a = 13; b = 9; while((20 && 0) && (a > b)) { cout << "Plants are our life"; }

A. Displays 'Plants are our life' infinitely

B. No message will be displayed

C. Displays 'Plants are our life' 20 times

D. Displays 'Plants are Our Life' 4 times

Hint

Trace the initial state and each executed operation in order, preserving the requested output layout.

Answer B: No message will be displayed

20 is logically true but 0 is false, so 20&&0 is false. Its conjunction with a>b remains false even though 13>9. The while body is never entered, hence no message; none of the positive repetition counts or infinite-output option fits. Module support: PDF p. 11, PDF p. 7.

Why each choice is right or wrong

A - Incorrect: "Displays 'Plants are our life' infinitely" does not match the rule or result derived here. 20 is logically true but 0 is false, so 20&&0 is false. Its conjunction with a>b remains false even though 13>9. The while body is never entered, hence no message; none of the positive repetition counts or infinite-output option fits.

B - Correct: "No message will be displayed" matches the derived result. 20 is logically true but 0 is false, so 20&&0 is false. Its conjunction with a>b remains false even though 13>9. The while body is never entered, hence no message; none of the positive repetition counts or infinite-output option fits.

C - Incorrect: "Displays 'Plants are our life' 20 times" does not match the rule or result derived here. 20 is logically true but 0 is false, so 20&&0 is false. Its conjunction with a>b remains false even though 13>9. The while body is never entered, hence no message; none of the positive repetition counts or infinite-output option fits.

D - Incorrect: "Displays 'Plants are Our Life' 4 times" does not match the rule or result derived here. 20 is logically true but 0 is false, so 20&&0 is false. Its conjunction with a>b remains false even though 13>9. The while body is never entered, hence no message; none of the positive repetition counts or infinite-output option fits.

Primary note proof

Study-note section CP10

> Relational and equality operators test values; && and || combine truth values; ! negates. In C++, zero converts to false and a nonzero number to true. Streams display bool as 0 or 1 unless boolalpha is set. With a=3,b=5, cout<<(a==b) prints 0.

Study-note section CP14

while(condition) checks before each body execution and may run zero times. do {body;} while(condition); runs the body once before checking; it repeats while the condition remains true. Use it when a menu or input attempt must occur at least once.

Question 93 | SM0204

In C++, what does the cout object typically represent?

A. Standard input stream

B. Keyboard input buffer

C. Error output stream

D. Standard output stream

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer D: Standard output stream

The module explicitly calls cout the standard output stream (p.6). Standard input is cin, and keyboard buffer/error stream do not name the cout role. Module support: PDF p. 6.

Why each choice is right or wrong

A - Incorrect: "Standard input stream" does not match the rule or result derived here. The module explicitly calls cout the standard output stream (p.6). Standard input is cin, and keyboard buffer/error stream do not name the cout role.

B - Incorrect: "Keyboard input buffer" does not match the rule or result derived here. The module explicitly calls cout the standard output stream (p.6). Standard input is cin, and keyboard buffer/error stream do not name the cout role.

C - Incorrect: "Error output stream" does not match the rule or result derived here. The module explicitly calls cout the standard output stream (p.6). Standard input is cin, and keyboard buffer/error stream do not name the cout role.

D - Correct: "Standard output stream" matches the derived result. The module explicitly calls cout the standard output stream (p.6). Standard input is cin, and keyboard buffer/error stream do not name the cout role.

Primary note proof

Study-note section CP28

> Include <iostream> and qualify std::cin/std::cout or introduce the names explicitly. cout is the standard output stream; << inserts values. cin is standard input; >> extracts formatted values. std::endl inserts a newline and flushes. C++ names are case sensitive: Cout, Int and std: :cout are not equivalent valid spellings of cout, int and std::cout.

Question 94 | SM0209

What is the term for a named block of code that performs a specific task?

A. Condition

B. Variable

C. Function

D. Loop

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer C: Function

A function is defined as a block of code performing a specific task and called from a program point (p.14). A condition supplies a test, a variable stores data, and a loop provides repetition rather than the named task unit. Module support: PDF p. 14.

Why each choice is right or wrong

A - Incorrect: "Condition" does not match the rule or result derived here. A function is defined as a block of code performing a specific task and called from a program point (p.14). A condition supplies a test, a variable stores data, and a loop provides repetition rather than the named task unit.

B - Incorrect: "Variable" does not match the rule or result derived here. A function is defined as a block of code performing a specific task and called from a program point (p.14). A condition supplies a test, a variable stores data, and a loop provides repetition rather than the named task unit.

C - Correct: "Function" matches the derived result. A function is defined as a block of code performing a specific task and called from a program point (p.14). A condition supplies a test, a variable stores data, and a loop provides repetition rather than the named task unit.

D - Incorrect: "Loop" does not match the rule or result derived here. A function is defined as a block of code performing a specific task and called from a program point (p.14). A condition supplies a test, a variable stores data, and a loop provides repetition rather than the named task unit.

Primary note proof

Study-note section CP17

> A function groups a named task. C++ definition: int add(int a,int b){return a+b;}. Call it with add(x,y);, without parameter type declarations at the call site. Parameters are names in the definition; arguments are supplied expressions or values. A void function produces no return value but can have side effects and return; to exit early.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 14 | lines 21-33

> Function A function is a group of statements that structure our programs in a more modular way and executed when it is called from some point of the program. It is a block of code that performs a specific task. It is important to Dividing a complex problem into smaller chunks makes our program easy to understand and reusable. When we need function? - When you need to repeat the same process over and over in a program. - The function can be called many times but appears in the code once Function - Categories C++ functions can be divided into 2 categories: • pre-defined (standard function) / library function - Which is the definitions have been written and it is ready to be used. - User needs to include pre-defined header file (i.e., math.h, time.h,cmath) To use it: FunctionName (value) e.g., sqrt (4), floor (4.3)

Question 95 | SM0217

What does the if-else statement allow you to do in C++?

A. Declare and define functions

B. Allocate memory dynamically

C. Execute a block of code only if a condition is true, otherwise execute another block

D. Repeat a block of code multiple times

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer C: Execute a block of code only if a condition is true, otherwise execute another block

The p.9 if-else rule evaluates a condition and executes statement1 when true, otherwise statement2. This matches C. It is not a declaration, allocation mechanism or repetition construct. Module support: PDF p. 9.

Why each choice is right or wrong

A - Incorrect: "Declare and define functions" does not match the rule or result derived here. The p.9 if-else rule evaluates a condition and executes statement1 when true, otherwise statement2. This matches C. It is not a declaration, allocation mechanism or repetition construct.

B - Incorrect: "Allocate memory dynamically" does not match the rule or result derived here. The p.9 if-else rule evaluates a condition and executes statement1 when true, otherwise statement2. This matches C. It is not a declaration, allocation mechanism or repetition construct.

C - Correct: "Execute a block of code only if a condition is true, otherwise execute another block" matches the derived result. The p.9 if-else rule evaluates a condition and executes statement1

when true, otherwise statement2. This matches C. It is not a declaration, allocation mechanism or repetition construct.

D - Incorrect: "Repeat a block of code multiple times" does not match the rule or result derived here. The p.9 if-else rule evaluates a condition and executes statement1 when true, otherwise statement2. This matches C. It is not a declaration, allocation mechanism or repetition construct.

Primary note proof

Study-note section CP12

> A standalone if may execute independently of the following if. An else binds to its nearest unmatched if; an else-if ladder executes the first true branch only. In nested if(c1){if(c2) S1; else S2;}, S2 requires c1 true and c2 false. Braces determine grouping.

Question 96 | SM0231

In computer programming, what is the purpose of control structures such as loops and conditional statements?

A. To control the flow of program execution

B. To perform mathematical operations

C. To define the data types used in a program

D. To allocate memory for variables

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer A: To control the flow of program execution

The module says flow control determines what executes during a run; branches choose alternative paths and loops repeat computations (p.9). Thus these structures control execution flow, rather than merely defining types, allocating memory or computing arithmetic. Module support: PDF p. 9.

Why each choice is right or wrong

A - Correct: "To control the flow of program execution" matches the derived result. The module says flow control determines what executes during a run; branches choose alternative paths and loops repeat computations (p.9). Thus these structures control execution flow, rather than merely defining types, allocating memory or computing arithmetic.

B - Incorrect: "To perform mathematical operations" does not match the rule or result derived here. The module says flow control determines what executes during a run; branches choose alternative paths and loops repeat computations (p.9). Thus these structures control execution flow, rather than merely defining types, allocating memory or computing arithmetic.

C - Incorrect: "To define the data types used in a program" does not match the rule or result derived here. The module says flow control determines what executes during a run; branches choose alternative paths and loops repeat computations (p.9). Thus these structures control execution flow, rather than merely defining types, allocating memory or computing arithmetic.

D - Incorrect: "To allocate memory for variables" does not match the rule or result derived here. The module says flow control determines what executes during a run; branches choose alternative paths and loops repeat computations (p.9). Thus these structures control execution flow, rather than merely defining types, allocating memory or computing arithmetic.

Primary note proof

Study-note section CP12

> A standalone if may execute independently of the following if. An else binds to its nearest unmatched if; an else-if ladder executes the first true branch only. In nested if(c1){if(c2) S1; else S2;}, S2 requires c1 true and c2 false. Braces determine grouping.

Study-note section CP14

> while(condition) checks before each body execution and may run zero times. do {body;} while(condition); runs the body once before checking; it repeats while the condition remains true. Use it when a menu or input attempt must occur at least once.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 9 | lines 2-8

> Control Statements Control statements or flow control determines what is executed during a run and what is not, therefore affecting the overall outcome of the program. C++ provides different forms of statements for different purposes. Declaration statements are used for defining variables. Assignment-like statements are used for simple, algebraic computations. Branching statements are used for specifying alternate paths of execution, depending on the outcome of a

logical condition. Loop statements are used for specifying computations, which need to be repeated until a certain logical condition is satisfied

Computer Science Exit Exam practice collection · Question 91

Question 97 | SM0236

When encountering a syntax error in code, what is the first step you should take to resolve it?

A. Rewrite the entire

B. Ignore the error and continue execution

C. Usea debugger tool

D. Check the code for typos or incorrect syntax

Hint

Apply the naming, type and syntax rules before deciding whether an option can be used as stated.

Answer D: Check the nearby code for typos and incorrect syntax.

CP32 recommends reading the first useful compiler diagnostic and inspecting nearby tokens and declarations before repairing and rebuilding. Among the offered actions, checking for typos or incorrect syntax matches that early repair step. Ignoring the error cannot fix translation, and a debugger is most useful once a runnable program exists.

Why each choice is right or wrong

A - Incorrect: Rewriting everything is unnecessary; the note recommends diagnosing and repairing the relevant local code.

B - Incorrect: Ignoring a syntax error neither corrects grammar nor establishes that an executable can be built.

C - Incorrect: A debugger is useful after a runnable program exists; compiler diagnostics guide syntax repair first.

D - Correct: Inspecting tokens and declarations for syntax mistakes matches the first useful action among these options.

Primary note proof

Study-note section CP32

A syntax error violates grammar; a type error can be syntactically well formed but rejected during semantic checking. A runtime error occurs during execution; a logic error gives the wrong behavior. A bug is a defect; debugging locates and corrects it. Read the first useful compiler diagnostic, inspect nearby tokens and declarations, repair and rebuild; a debugger is useful after a runnable program exists.

Computer Science Exit Exam · Sene 2016 · Question 12-1

Question 98 | SM0276

Which C++ statement is used to terminate a loop prematurely and transfer control to the next iteration of the loop?

A. break

B. exit

C. return

D. continue

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer D: continue

The phrase transfer control to the next iteration describes continue, which skips remaining statements of the current iteration and preserves the loop (p.13). break exits the loop entirely; return leaves a function; exit is not the loop-iteration statement. Module support: PDF p. 13.

Why each choice is right or wrong

A - Incorrect: "break" does not match the rule or result derived here. The phrase transfer control to the next iteration describes continue, which skips remaining statements of the current iteration and preserves the loop (p.13). break exits the loop entirely; return leaves a function; exit is not the loop-iteration statement.

B - Incorrect: "exit" does not match the rule or result derived here. The phrase transfer control to the next iteration describes continue, which skips remaining statements of the current iteration and preserves the loop (p.13). break exits the loop entirely; return leaves a function; exit is not the loop-iteration statement.

C - Incorrect: "return" does not match the rule or result derived here. The phrase transfer control to the next iteration describes continue, which skips remaining statements of the current

iteration and preserves the loop (p.13). break exits the loop entirely; return leaves a function; exit is not the loop-iteration statement.

D - Correct: "continue" matches the derived result. The phrase transfer control to the next iteration describes continue, which skips remaining statements of the current iteration and preserves the loop (p.13). break exits the loop entirely; return leaves a function; exit is not the loop-iteration statement.

Primary note proof

Study-note section CP15

> break exits the nearest enclosing loop or switch. continue skips the rest of the current loop iteration: a for loop then runs its update; a while loop goes directly to its condition. return leaves the current function and may supply a result. In main it ends the program normally.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 13 | lines 30-35

> Using continue and break Statements - The break statement skips the rest of the statements in the loop‟s block, jumping immediately to the next statement outside of the loop. - The continue statement is similar. It also skips the rest of the statements in the loop‟s block, but instead of terminating the loop, it transfers execution to the next iteration of the loop. It continues the loop after skipping the remaining statements in its current iteration.

Computer Science Exit Exam practice collection · Question 94

Question 99 | SM0288

Which is a desirable performance quality rather than a necessary defining requirement for a useful algorithm with a specified result on every legal input?

A. Definiteness

B. Output

C. Finiteness

D. Efficiency

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer D: D. Efficiency

The note distinguishes the existence of an algorithm from how efficiently it runs. Its instructions must be unambiguous, it must specify a result, and it must terminate for legal inputs. An inefficient procedure can still satisfy all these defining requirements and correctly solve its problem. Efficiency is therefore desirable and measurable but is the exception when the question asks specifically about necessary defining requirements.

Why each choice is right or wrong

A - Incorrect: Definiteness requires unambiguous instructions.

B - Incorrect: A useful algorithm specifies a result.

C - Incorrect: Finiteness requires termination for legal inputs.

D - Correct: Efficiency is desirable but an inefficient terminating algorithm still qualifies.

Primary note proof

Study-note section CP02

> An algorithm gives precise, executable steps and terminates for every legal input. Definiteness means each step has an unambiguous meaning; effectiveness means a step can actually be performed. Inputs may be absent, but a useful algorithm specifies a result. Correctness means the result meets the specification. Efficiency is desirable and measurable, but an inefficient terminating algorithm is still an algorithm. Efficiency is also a desirable property of an algorithm.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 2 | lines 19-26

> Algorithm is an ordered set of unambiguous, executable steps, defining a terminating process. Important Properties of Algorithms - Correct: always returns the desired output for all legal instances of the problem. - Unambiguous: Each step must be clearly defined, having only one interpretation. - Precise: simple but efficient - Efficient: can be measured in terms of Time and Space - Finiteness: the execution of the algorithm must terminate in a finite amount of time for each possible set of input data/must have an end.

Question 100 | SS049

What is the output of the following C++ fragment code? for(int n = 1; n <= 18; n = n + 2) { if(n % 7 != 0) cout << n << " "; else break; }

A. 3 5 7

B. 1 3 5 7 9 11 13 15 17

C. 1 3 5

D. 1 2 3 4 5 6

Hint

Trace the initial state and each executed operation in order, preserving the requested output layout.

Answer C: 1 3 5

The loop prints n=1,3,5 because each has nonzero remainder modulo 7. At n=7 the remainder is zero, so break exits before printing 7. A includes a forbidden 7 and omits 1; B ignores break; D ignores the +2 update. Module support: PDF p. 12, PDF p. 13, PDF p. 7.

Why each choice is right or wrong

A - Incorrect: "3 5 7" does not match the rule or result derived here. The loop prints n=1,3,5 because each has nonzero remainder modulo 7. At n=7 the remainder is zero, so break exits before printing 7. A includes a forbidden 7 and omits 1; B ignores break; D ignores the +2 update.

B - Incorrect: "1 3 5 7 9 11 13 15 17" does not match the rule or result derived here. The loop prints n=1,3,5 because each has nonzero remainder modulo 7. At n=7 the remainder is zero, so break exits before printing 7. A includes a forbidden 7 and omits 1; B ignores break; D ignores the +2 update.

C - Correct: "1 3 5" matches the derived result. The loop prints n=1,3,5 because each has nonzero remainder modulo 7. At n=7 the remainder is zero, so break exits before printing 7. A includes a forbidden 7 and omits 1; B ignores break; D ignores the +2 update.

D - Incorrect: "1 2 3 4 5 6" does not match the rule or result derived here. The loop prints n=1,3,5 because each has nonzero remainder modulo 7. At n=7 the remainder is zero, so break exits before printing 7. A includes a forbidden 7 and omits 1; B ignores break; D ignores the +2 update.

Primary note proof

Study-note section CP16

> For n=1; n<=18; n+=2, print n unless n%7==0 then break: output is 1 3 5. A while(a>b) with fixed a=6,b=5 never changes its true condition. In data[10]={5,10,...,50}, i=0, advancing i only if data[i]%10==0 causes no progress because data[0]=5. It prints nothing and loops indefinitely; changing <=10 to <10 alone does not repair progress.

Study-note section CP15

break exits the nearest enclosing loop or switch. continue skips the rest of the current loop iteration: a for loop then runs its update; a while loop goes directly to its condition. return leaves the current function and may supply a result. In main it ends the program normally.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 12 | lines 19-28

The for loop. Its format is: for (initialization; condition; increase) statement; 1, initialization is executed. Generally, it is a initial value setting for a counter variable. This is executed only once 2, condition is checked, if it is true the loop continues, otherwise the loop finishes and statement is skipped. 3, statement is executed. As usual, it can be either a single instruction or a block of instructions enclosed within curly brackets { }. 4, finally, whatever is specified in the increase field is executed and the loop gets back to step 2.

Computer Programming module | PDF page 13 | lines 30-35

Using continue and break Statements - The break statement skips the rest of the statements in the loop‟s block, jumping immediately to the next statement outside of the loop. - The continue statement is similar. It also skips the rest of the statements in the loop‟s block, but instead of terminating the loop, it transfers execution to the next iteration of the loop. It continues the loop after skipping the remaining statements in its current iteration.

Computer Programming module | PDF page 7 | lines 5-23

Assignment Operators (=) Example: int x=5; or used with a combination of other operators‟ example, x+=2;//x=x+2, x=y=10; Arithmetic Operators (+, -, *, /, %) E.g. Assume int X=9, Y=2 X+Y, Y-X, X%Y Relational operators (==,!=, <, <=,>,>=) Relational operators evaluate to 1 (representing the true outcome) or 0 (representing the false outcome). Assume int X=9, Y=2 X==Y, X!=Y, X>Y 'A' < 'F' // gives 1 (is like 65 < 70) Logical operators (! Negation, &&, ||) Like the relational operators, logical operators evaluate to 1 or 0. Example: 5 < 6 || 6 < 5 // gives 1 In general, any nonzero value can be used to represent the logical true, whereas only zero represents the logical false !12 // gives 0 10 && 5 // gives 1 Increment/decrement Operators The auto increment (++) and auto decrement (--) operators provide a convenient way of, respectively, adding and subtracting 1 from a numeric variable. Both operators can be used in prefix and postfix form.

Question 101 | SS160

For input b=4 and e=3, what numeric result is printed after the prompt by this repaired C++ program?

```
#include <iostream>
using namespace std;
int main(){
int b,e,r=1;
cout<<"Enter b and e";
cin>>b>>e;
for(int i=1;i<=e;i++){r=r*b;}
cout<<r;
return 0;
}
```

A. 81

B. 256

C. 12

D. 64

Hint

Fix the input case and cost model, then count dominant work or simultaneously live storage.

Answer D: D. 64

The accumulator r starts at one. With exponent e=3, the for loop executes for i=1, 2 and 3, multiplying by the base b=4 on each pass. Its successive values are 4, 16 and 64. The final insertion therefore prints 64 after the prompt. This is iterative exponentiation, rather than multiplying the base by the exponent or reversing their roles.

Why each choice is right or wrong

A - Incorrect: 81 is 3 raised to 4, reversing base and exponent.

B - Incorrect: 256 would require four multiplications by 4.

C - Incorrect: 12 multiplies base by exponent rather than computing the power.

D - Correct: Three multiplications by 4 starting at 1 give 64.

Primary note proof

Study-note section CP30

> C++ has no built-in exponentiation operator: ^ is bitwise XOR and ** is not a power operator. To compute b^e for a nonnegative integer e, start r=1 and repeat r*=b exactly e times; b=4,e=3 gives 64. Large powers and factorials can overflow fixed-width types; specify a valid input range.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Both operators can be used in prefix and postfix form.

Question sources

Computer Science model exam collection · Question 67

Question 102 | SS167

A program reads exactly 50 numbers and adds only positive values to a total. Which listed construct best expresses the known repetition count, while a separate if statement handles the positivity test?

A. for

B. break

C. jump

D. continue

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer A: A. for

The task has a counting responsibility and a filtering responsibility. A for loop naturally expresses the fixed total of 50 input attempts through its initialization, condition and update. The question assigns the positivity decision to a separate if, so it asks specifically about counting. continue can skip one contribution but cannot supply the repetition count; break would stop early, and jump is not a specific count-controlled construct.

Why each choice is right or wrong

A - Correct: for naturally expresses exactly 50 iterations.

B - Incorrect: break could stop processing before all 50 inputs.

C - Incorrect: Jump does not specify a count-controlled loop.

D - Incorrect: continue skips the rest of an iteration but does not establish 50 repetitions.

Primary note proof

Study-note section CP23

> For a sum, start total=0 and add each element once. For a maximum/minimum, initialize from a[0] only after confirming the array is nonempty. For 50 inputs where nonpositive values are skipped, use a count-controlled loop and either if(x>0) total+=x; or continue for x<=0. These constructs solve different parts of the task.

Study-note section CP14

> for(initialization; condition; update) executes initialization once, then condition → body → update → condition. A missing condition in for(;;) acts as true. A for loop is convenient for a known count but can also be condition controlled. To print indices 0 through n-1, use i=0; i<n; ++i. Starting i=0 with i<5 and i+=2 prints 0 2 4.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 12 | lines 19-28

> The for loop. Its format is: for (initialization; condition; increase) statement; 1, initialization is executed. Generally, it is a initial value setting for a counter variable. It continues the loop after skipping the remaining statements in its current iteration.

Question sources

Computer Science model exam collection · Question 74

Question 103 | SS173

Which sequence of array values is printed by this Java code? Ignore each println call's trailing space and line separator.

```
class PrintResult {
public static void main(String[] args){
int[] arr={3,4,5,6,7};
for(int i=0;i<arr.length-2;++i){
System.out.println(arr[i]+" ");
}
}
}
```

A. 3 4 5 6 7

B. 3 4 5 6

C. 3 4

D. 3 4 5

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer D: D. 3 4 5

The initializer contains five values, so arr.length-2 is 3. The loop starts at index zero and continues while i<3, visiting indices 0, 1 and 2. Those positions contain 3, 4 and 5. Each println also ends its line, but the question explicitly asks only for the value sequence.

Why each choice is right or wrong

A - Incorrect: The loop never reaches indices 3 and 4.

B - Incorrect: Four values would require the excluded index 3.

C - Incorrect: Index 2 also satisfies i<3, so a third value prints.

D - Correct: Indices 0,1,2 contain 3,4,5 in that order.

Primary note proof

Study-note section CP23

> In Java, length belongs to each array; a traversal ending at arr.length-2 visits fewer elements than a full traversal.

Study-note section CP22

> Valid indices are 0 through 3.

Study-note section CP14

> for(initialization; condition; update) executes initialization once, then condition → body → update → condition.

Study-note section CP-S04

Java System.out.print writes the supplied value without automatically ending the line. System.out.println writes its value and then a line separator. Successive println calls therefore place their values on separate lines, even when each printed expression also contains a trailing space.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 19 | lines 4-29

Arrays - an array is a collection of fixed-size number of elements of the same type stored sequentially in memory. - An individual element of an array is identified by its own unique index (or subscript). - The number of elements must be an integer. - The size of the array is referred to as its dimension - Array in C++ is Zero indexed. Declaring of one-dimensional Array Syntax: elementstype arrayname [size]; → You can use constants such as macro definitions or const ints as the sizes of arrays. Example: int num[5]; string fruit[3]; #define numstudents 100 or const int numstudents=100; double Score[numstudents] ; double Score[numstudents] ; Initialization of an Array - Arrays can be initialized at declaration time in two different ways: Syntax: elementstype arrayname[size] = {list each value separated by comma}; E.g int num[5]={1,2,3,4,5}; elementstype arrayname[ ] = { list with any number of values }; E.g int num[]={1,2,3,4,5}; string fruit[]={“Apple”,“orange”, “Mango”}; Accessing Array Elements - Each element could be accessed using an index into the array - When accessing an array, the index given must be a positive integer from 0 to n-1, where n is the dimension of the array.

Computer Programming module | PDF page 12 | lines 19-28

The for loop. Its format is: for (initialization; condition; increase) statement; 1, initialization is executed. Generally, it is a initial value setting for a counter variable. This is executed only once 2, condition is checked, if it is true the loop continues, otherwise the loop finishes and statement is skipped. 3, statement is executed. As usual, it can be either a single instruction or a block of instructions enclosed within curly brackets { }. 4, finally, whatever is specified in the increase field is executed and the loop gets back to step 2.

Question sources

Computer Science model exam collection · Question 80

Question 104 | SS177

Which activity comes last in fundamental program development in c++ ?

A. Compiling program

B. Writing program

C. Memory allocation for variables

D. Linking

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer D: Linking

Among the listed activities, linking comes after writing/editing and compilation in the module sequence edit source -> compile -> link -> execute (p.4). Memory allocation for variables is not the later named development phase. Execution/loading occurs afterward, but is not an offered option. Module support: PDF p. 4.

Why each choice is right or wrong

A - Incorrect: "Compiling program" does not match the rule or result derived here. Among the listed activities, linking comes after writing/editing and compilation in the module sequence edit source -> compile -> link -> execute (p.4). Memory allocation for variables is not the later named development phase. Execution/loading occurs afterward, but is not an offered option.

B - Incorrect: "Writing program" does not match the rule or result derived here. Among the listed activities, linking comes after writing/editing and compilation in the module sequence edit source -> compile -> link -> execute (p.4). Memory allocation for variables is not the later named development phase. Execution/loading occurs afterward, but is not an offered option.

C - Incorrect: "Memory allocation for variables" does not match the rule or result derived here. Among the listed activities, linking comes after writing/editing and compilation in the module sequence edit source -> compile -> link -> execute (p.4). Memory allocation for variables is not the later named development phase. Execution/loading occurs afterward, but is not an offered option.

D - Correct: "Linking" matches the derived result. Among the listed activities, linking comes after writing/editing and compilation in the module sequence edit source -> compile -> link -> execute (p.4). Memory allocation for variables is not the later named development phase. Execution/loading occurs afterward, but is not an offered option.

Primary note proof

Study-note section CP04

> In the conventional C++ toolchain: source → preprocessing → compilation proper → assembly → object files → linking → executable → loading → execution. Preprocessing handles directives such as #include; compilation may emit assembly; the assembler emits machine instructions in an object file. The linker resolves external symbols and combines object files and libraries. The loader places an executable and required components in memory and starts it.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 4 | lines 21-30

> The compilation process of C++ program consists of the following steps. • edit source code → compile → link → execute (Editor) (Compiler) (Linker) (Loader) I. Program source code is entered into a file using a text editor. II. After the code has been entered, a compiler program is started

that translates the source into an object code file. III. The object code file is linked with other object code files that come with the compiler and an executable file (or program) is created. IV. In order to execute the program, a program called the loader copies the executable file into the memory of the computer and sends an execute command to the CPU.

Question sources

Computer Science model exam collection · Question 84

Question 105 | SS179

The correct structure of the for loop statement is:
eooo
ao
5

A. for(condition, initialization, increment/decrement)

B. for(initialization; condition)

C. for(increment/decrement; initialization; condition)

D. for(initialization; condition; increment/decrement)

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer D: for(initialization; condition; increment/decrement)

The module gives for(initialization; condition; increase) statement (p.12). D has this order and two semicolons. A uses commas and wrong order, B omits the update field and its separator, and C reverses the roles. Module support: PDF p. 12.

Why each choice is right or wrong

A - Incorrect: "for(condition, initialization, increment/decrement)" does not match the rule or result derived here. The module gives for(initialization; condition; increase) statement (p.12). D has this order and two semicolons. A uses commas and wrong order, B omits the update field and its separator, and C reverses the roles.

B - Incorrect: "for(initialization; condition)" does not match the rule or result derived here. The module gives for(initialization; condition; increase) statement (p.12). D has this order and two semicolons. A uses commas and wrong order, B omits the update field and its separator, and C reverses the roles.

C - Incorrect: "for(increment/decrement; initialization; condition)" does not match the rule or result derived here. The module gives for(initialization; condition; increase) statement (p.12). D has this order and two semicolons. A uses commas and wrong order, B omits the update field and its separator, and C reverses the roles.

D - Correct: "for(initialization; condition; increment/decrement)" matches the derived result. The module gives for(initialization; condition; increase) statement (p.12). D has this order and two semicolons. A uses commas and wrong order, B omits the update field and its separator, and C reverses the roles.

Primary note proof

Study-note section CP14

> for(initialization; condition; update) executes initialization once, then condition → body → update → condition. A missing condition in for(;;) acts as true. A for loop is convenient for a known count but can also be condition controlled. To print indices 0 through n-1, use i=0; i<n; ++i. Starting i=0 with i<5 and i+=2 prints 0 2 4.

Module passages - related reading

As usual, it can be either a single instruction or a block of instructions enclosed within curly brackets { }. 4, finally, whatever is specified in the increase field is executed and the loop gets back to step 2.

Question sources

Computer Science model exam collection · Question 86

Question 106 | SS180

Which one of the following is the correct identifier in c++?

A. 7variable

B. 7VARIABLE

C. $variable

D. variable_1234

Hint

Apply the naming, type and syntax rules before deciding whether an option can be used as stated.

Answer D: variable_1234

variable_1234 begins with a letter and contains only letters, underscore and digits. A/B begin with 7, violating the initial-character rule, while C uses $, outside the permitted character set. Module support: PDF p. 5.

Why each choice is right or wrong

A - Incorrect: "7variable" does not match the rule or result derived here. variable_1234 begins with a letter and contains only letters, underscore and digits. A/B begin with 7, violating the initial-character rule, while C uses $, outside the permitted character set.

B - Incorrect: "7VARIABLE" does not match the rule or result derived here. variable_1234 begins with a letter and contains only letters, underscore and digits. A/B begin with 7, violating the initial-character rule, while C uses $, outside the permitted character set.

C - Incorrect: "$variable" does not match the rule or result derived here. variable_1234 begins with a letter and contains only letters, underscore and digits. A/B begin with 7, violating the initial-character rule, while C uses $, outside the permitted character set.

D - Correct: "variable_1234" matches the derived result. variable_1234 begins with a letter and contains only letters, underscore and digits. A/B begin with 7, violating the initial-character rule, while C uses $, outside the permitted character set.

Primary note proof

Study-note section CP05

> In the basic ASCII identifier rules, start with a letter or underscore; continue with letters, digits or underscores. Do not use a keyword. C++ is case sensitive: exitExam and ExitExam differ; delete and float are keywords, but FLOAT is a legal identifier. variable_1234 is valid; 4thInput, T-3 and names containing spaces are not single identifiers. Avoid reserved underscore patterns in application code.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 5 | lines 2-10

> 1. Keywords (reserved words) - Unique meaning within a C++ program and must not be used for any other purposes. E.g., if, namespace for, switch, continue, float, new, default, break Etc. 2. Identifiers - Name associated with a function or data object and used to refer to that function or data object. An identifier must: o Start with a letter or underscore o Consist only of letters, the digits 0-9, or the underscore symbol _ o Not be a reserved word

Question sources

Computer Science model exam collection · Question 87

Question 107 | AM0245

Which of the following is NOT a programming paradigm?

A. Procedural

B. Object-oriented

C. Functional

D. Conditional

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer D: Conditional is a construct rather than a programming paradigm.

CP02 distinguishes procedural, object oriented and functional programming as ways of organizing computation. A conditional is a selection construct used inside programs rather than a separate paradigm in this classification. Thus the first three options name paradigms, while Conditional is the requested exception.

Why each choice is right or wrong

A - Incorrect: Procedural programming is a paradigm organizing operations into procedures, as described in CP02.

B - Incorrect: Object oriented programming is a paradigm organizing state and behavior in objects.

C - Incorrect: Functional programming is a paradigm emphasizing function evaluation, as described in CP02.

D - Correct: Conditional denotes a selection construct used within paradigms rather than a separate paradigm here.

Primary note proof

Study-note section CP02

> Procedural programming organizes operations in procedures; structured programming combines sequence, selection and iteration; object oriented programming organizes state and behavior in objects; functional programming emphasizes function evaluation. A conditional statement is a construct, not a separate programming paradigm.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 4 | lines 4-19

> programming paradigm: provides the programmer's view of code execution. The most influential paradigms are: Procedural Programming Languages Procedural programming specifies a list of operations that the program must complete to reach the desired state. Each program has a starting state, a list of operations to complete, and an ending point. This approach is also known as imperative programming. Structured Programming Languages Structured programming is a special type of procedural programming. It provides additional tools to manage the problems that larger programs were creating. Structured programming requires that programmers break program structure into small pieces of code that are easily understood. One of the well-known features of structural programming is that it does not allow the use of the GOTO statement. It is often associated with a "top-down" approach to design. Object-Oriented Programming Languages Object-oriented programming is one the newest and most powerful paradigms. In object- oriented programs, the designer specifies both the data structures and the types of operations that can be applied to those data structures.

Question sources

Computer Science MCQ practice collection · Question 245

Question 108 | AM0246

What is the purpose of a compiler?

A. To execute programs

B. To debug programs

C. To translate source code into machine code

D. To optimize program performance

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer C: To translate source code into machine code

The module describes translating program source before execution, producing object code for linking and later loading. This supports source-to-machine translation as the compiler purpose. Execution belongs later in the pipeline; debugging and optimizing are not its defining role here. Module support: PDF p. 4, PDF p. 3.

Why each choice is right or wrong

A - Incorrect: "To execute programs" does not match the rule or result derived here. The module describes translating program source before execution, producing object code for linking and later loading. This supports source-to-machine translation as the compiler purpose. Execution belongs later in the pipeline; debugging and optimizing are not its defining role here.

B - Incorrect: "To debug programs" does not match the rule or result derived here. The module describes translating program source before execution, producing object code for linking and later loading. This supports source-to-machine translation as the compiler purpose. Execution belongs later in the pipeline; debugging and optimizing are not its defining role here.

C - Correct: "To translate source code into machine code" matches the derived result. The module describes translating program source before execution, producing object code for linking and later loading. This supports source-to-machine translation as the compiler purpose. Execution belongs later in the pipeline; debugging and optimizing are not its defining role here.

D - Incorrect: "To optimize program performance" does not match the rule or result derived here. The module describes translating program source before execution, producing object code for linking and later loading. This supports source-to-machine translation as the compiler purpose. Execution belongs later in the pipeline; debugging and optimizing are not its defining role here.

Primary note proof

Study-note section CP04

In the conventional C++ toolchain: source → preprocessing → compilation proper → assembly → object files → linking → executable → loading → execution. Preprocessing handles directives such as #include; compilation may emit assembly; the assembler emits machine instructions in an object file. The linker resolves external symbols and combines object files and libraries. The loader places an executable and required components in memory and starts it.

Computer Programming module | PDF page 3 | lines 8-17

Categories of programming language: - Low-level languages: - - are machine-dependent - They are designed to be run on a particular computer (not portable). Eg. Machine language and Assembly Language High-level languages - Are machine-independent - Can be run on a variety of computers. Programming language require translation source code to machine language before execution. This translation is accomplished by either a compiler or an interpreter. Compilers translate the entire source

Question sources

Computer Science MCQ practice collection · Question 246

Question 109 | AM0247

What is the main advantage of high-level programming languages?

A. They are easier to read and write than low-level languages.

B. They are faster and more efficient than low-level languages.

C. They provide direct control over hardware resources.

D. They are platform-specific and provide better compatibility.

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer A: High-level languages are easier to read and write.

CP03 says high-level source is easier to read and often portable after recompilation when platform assumptions are avoided. Readability is the advantage stated in A. The note does not promise universally faster execution or greater hardware control, and platform specificity conflicts with the portability advantage rather than explaining it.

Why each choice is right or wrong

A - Correct: Easier source reading and writing is the abstraction benefit directly supported by CP03.

B - Incorrect: The note gives no universal speed or efficiency guarantee for high-level languages over low-level ones.

C - Incorrect: Direct hardware control is not the high-level readability advantage described here.

D - Incorrect: Platform specificity contradicts the potential source portability discussed in CP03.

Primary note proof

Study-note section CP03

> Machine and assembly code depend on an instruction set. High-level source is easier to read and often portable after recompilation, provided it avoids platform assumptions. People can write both assembly and high-level programs. Python, Perl and PHP are commonly called scripting languages; C++ is conventionally compiled. These labels describe common use, not an absolute technical prohibition.

Compilers translate the entire source

Question sources

Computer Science MCQ practice collection · Question 247

Question 110 | AM0248

Which option most precisely states the information a C++ variable declaration introduces, independently of whether that declaration also defines storage or supplies an initializer?

A. To assign a value to a variable

B. To create a new variable

C. To specify the data type and name of a variable

D. To check the validity of a variable

Hint

Apply the naming, type and syntax rules before deciding whether an option can be used as stated.

Answer C: C. To specify the data type and name of a variable

Declaration introduces a variable's name and type into the program. Initialization is the separate act of supplying its initial value, and later assignment replaces a value. Describing a declaration merely as creating a variable does not precisely identify its information or distinguish it from an object definition. The question asks for that precise name-and-type purpose, which C directly states.

Why each choice is right or wrong

A - Incorrect: Assigning a value is a different operation from introducing a declaration.

B - Incorrect: Creating an object is less precise and can depend on whether the declaration is also a definition.

C - Correct: A declaration introduces the variable's name and type.

D - Incorrect: A declaration is not primarily a validity check on an existing variable.

Primary note proof

Study-note section CP06

> Write type name; or type name = value; for ordinary variables: int age = 20;. Declaration introduces a name and type; initialization gives its initial value; later assignment replaces a value. a=b copies a scalar value, so later changes to b do not change a. A pointer or Java object reference instead copies an address/reference.

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 5 | lines 24-33

> 5. Data Types, Variables, and Constants Variable: - Variable is a symbolic name for a memory location in which data can be stored. - Attribute of Variables: o A type, which is, established when the variable is defined (e.g., integer, float, character) o A value, which can be changed by assigning a new value to the variable Variable Declaration - Declaring a variable means defining (creating) a variable. - Syntax: data type variable name; e.g. int num; - We can create More Than One Variable at a Time e.g., int num1, num2, num3;

Question sources

Computer Science MCQ practice collection · Question 248

Question 111 | AM0249

What is the purpose of a loop in programming?

A. To perform mathematical calculations

B. To make decisions based on conditions

C. To store and retrieve data

D. To repeat a set of instructions

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer D: To repeat a set of instructions

Iteration repeats a statement or block, and loops specify computations repeated while/until a logical condition controls continuation (pp.9,11). Arithmetic, decision-making and storage describe different roles, so D is the specific loop purpose. Module support: PDF p. 9, PDF p. 11.

Why each choice is right or wrong

A - Incorrect: "To perform mathematical calculations" does not match the rule or result derived here. Iteration repeats a statement or block, and loops specify computations repeated while/until a logical condition controls continuation (pp.9,11). Arithmetic, decision-making and storage describe different roles, so D is the specific loop purpose.

B - Incorrect: "To make decisions based on conditions" does not match the rule or result derived here. Iteration repeats a statement or block, and loops specify computations repeated while/until a logical condition controls continuation (pp.9,11). Arithmetic, decision-making and storage describe different roles, so D is the specific loop purpose.

C - Incorrect: "To store and retrieve data" does not match the rule or result derived here. Iteration repeats a statement or block, and loops specify computations repeated while/until a logical condition controls continuation (pp.9,11). Arithmetic, decision-making and storage describe different roles, so D is the specific loop purpose.

D - Correct: "To repeat a set of instructions" matches the derived result. Iteration repeats a statement or block, and loops specify computations repeated while/until a logical condition controls continuation (pp.9,11). Arithmetic, decision-making and storage describe different roles, so D is the specific loop purpose.

Primary note proof

Study-note section CP14

while(condition) checks before each body execution and may run zero times. do {body;} while(condition); runs the body once before checking; it repeats while the condition remains true. Use it when a menu or input attempt must occur at least once.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 9 | lines 2-8

Control Statements Control statements or flow control determines what is executed during a run and what is not, therefore affecting the overall outcome of the program. C++ provides different forms of statements for different purposes. Declaration statements are used for defining variables. Assignment-like statements are used for simple, algebraic computations. Branching statements are used for specifying alternate paths of execution, depending on the outcome of a logical condition. Loop statements are used for specifying computations, which need to be repeated until a certain logical condition is satisfied

Computer Programming module | PDF page 11 | lines 5-13

Iteration/Looping Statement: Iteration is the repetition of a statement or block of statements in a program. - Loops have as objective to repeat a statement a certain number of times or while a condition is fulfilled. - C++ has three iteration statements: the while statement, the do. While statement, and the for statement. The while loop: Its format is: while (expression) {statement;} First expression (called the loop condition) is evaluated. If the outcome is nonzero then statement (called the loop body) is executed and the whole process is repeated. Otherwise, the loop is terminated.

Question sources

Computer Science MCQ practice collection · Question 249

Question 112 | AM0250

Which statement gives the defining relationship between a method and a function?

A. A method is a function associated with a class or object.

B. Functions return a value, while methods do not.

C. Functions can take parameters, while methods cannot.

D. There is no difference; the terms are used interchangeably.

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer A: A. A method is a function associated with a class or object.

The defining feature of a method is its association with a class or object. It is therefore a function with that association, rather than a fundamentally different operation with no return value or no parameters. Both functions and methods can return values or accept arguments according to their definitions. The two terms are related, but method adds the class/object qualification that ordinary function alone does not assert.

Why each choice is right or wrong

A - Correct: A method is a function associated with a class or object.

B - Incorrect: Methods can return values, and functions may return void.

C - Incorrect: Both ordinary functions and methods can take parameters.

D - Incorrect: Method adds a specific class/object association.

Primary note proof

Study-note section CP17

> A method is a function associated with a class or object; methods can return values. Modules group related responsibilities behind interfaces. Reuse reduces duplication; independent functions are easier to understand and test. A library provides reusable components; a framework also supplies an organizing structure and often calls application callbacks.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 14 | lines 21-33

> Function A function is a group of statements that structure our programs in a more modular way and executed when it is called from some point of the program. It is a block of code that performs a specific task. It is important to Dividing a complex problem into smaller chunks makes our program easy to understand and reusable. When we need function? - When you need to repeat the same process over and over in a program. - The function can be called many times but appears in the code once Function - Categories C++ functions can be divided into 2 categories: • pre-defined (standard function) / library function - Which is the definitions have been written and it is ready to be used. - User needs to include pre-defined header file (i.e., math.h, time.h,cmath) To use it: FunctionName (value) e.g., sqrt (4), floor (4.3)

Computer Programming module | PDF page 4 | lines 4-19

> programming paradigm: provides the programmer's view of code execution. The most influential paradigms are: Procedural Programming Languages Procedural programming specifies a list of operations that the program must complete to reach the desired state. GOTO statement. It is often associated with a "top-down" approach to design. Object-Oriented Programming Languages Object-oriented programming is one the newest and most powerful paradigms. In object- oriented programs, the designer specifies both the data structures and the types of operations that can be applied to those data structures.

Question sources

Computer Science MCQ practice collection · Question 250

Question 113 | AM0251

Which type of error occurs when the program violates the rules of the programming language?

A. Syntax error

B. Runtime error

C. Logic error

D. Semantic error

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer A: Syntax error

Syntax is defined as rules governing language symbols, whereas semantics deals with meaning of syntactically correct constructs (p.3). Therefore violating the stated language rules is a syntax error. Runtime and logic problems are not the rule category described. Module support: PDF p. 3.

Why each choice is right or wrong

A - Correct: "Syntax error" matches the derived result. Syntax is defined as rules governing language symbols, whereas semantics deals with meaning of syntactically correct constructs (p.3). Therefore violating the stated language rules is a syntax error. Runtime and logic problems are not the rule category described.

B - Incorrect: "Runtime error" does not match the rule or result derived here. Syntax is defined as rules governing language symbols, whereas semantics deals with meaning of syntactically correct constructs (p.3). Therefore violating the stated language rules is a syntax error. Runtime and logic problems are not the rule category described.

C - Incorrect: "Logic error" does not match the rule or result derived here. Syntax is defined as rules governing language symbols, whereas semantics deals with meaning of syntactically correct constructs (p.3). Therefore violating the stated language rules is a syntax error. Runtime and logic problems are not the rule category described.

D - Incorrect: "Semantic error" does not match the rule or result derived here. Syntax is defined as rules governing language symbols, whereas semantics deals with meaning of syntactically correct

constructs (p.3). Therefore violating the stated language rules is a syntax error. Runtime and logic problems are not the rule category described.

Primary note proof

Study-note section CP32

> A syntax error violates grammar; a type error can be syntactically well formed but rejected during semantic checking. A runtime error occurs during execution; a logic error gives the wrong behavior. A bug is a defect; debugging locates and corrects it. Read the first useful compiler diagnostic, inspect nearby tokens and declarations, repair and rebuild; a debugger is useful after a runnable program exists.

Computer Science MCQ practice collection · Question 251

Question 114 | AM0252

What is the purpose of debugging in programming?

A. To execute programs

B. To write programs

C. To optimize program performance

D. To find and fix errors in programs

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer D: Find and fix errors in programs.

A bug is a defect, and CP32 says debugging locates and corrects it. Executing or writing programs describes broader activities; optimizing performance has a different primary aim. Debugging can involve running code and editing it, but those steps serve its specific purpose of finding and fixing errors.

Why each choice is right or wrong

A - Incorrect: Execution can reveal defects, but simply running a program does not define debugging's purpose.

B - Incorrect: Writing programs is implementation; debugging specifically investigates and corrects defects in them.

C - Incorrect: Performance optimization aims at efficiency, whereas debugging aims at correcting erroneous behavior.

D - Correct: Finding and fixing program errors directly matches CP32's stated debugging purpose.

Primary note proof

Study-note section CP32

> A syntax error violates grammar; a type error can be syntactically well formed but rejected during semantic checking. A runtime error occurs during execution; a logic error gives the wrong behavior. A bug is a defect; debugging locates and corrects it. Read the first useful compiler diagnostic, inspect nearby tokens and declarations, repair and rebuild; a debugger is useful after a runnable program exists.

Computer Programming module | PDF page 2 | lines 2-18

> 1. Introduction to programming Computer programming is the process of writing, testing, debugging/troubleshooting, and maintaining the source code of computer programs. Programs are the instructions that tells the computer what to do .so, writing computer programs means writing instructions, that will make the computer follow and run a program based on those instructions. We are going to write computer programs to solve problems. Problem Solving Problem: gap between the existing and the desired or proposed situation where problem solving will try to fill this gap. Problem solving: The process of transforming the description of a problem into the solution by using our knowledge of the problem-solving strategies, techniques and tools. Problem solving techniques • Analyze the problem: Carefully understand the problem • Outline the problem requirements • Does program require user interaction? • Does program manipulate data? • What is the output? • Design steps (algorithm) to solve the problem

Question sources

Computer Science MCQ practice collection · Question 252

Question 115 | AM0253

What is the role of comments in programming?

A. To execute specific sections of code

B. To define variables and constants

C. To provide documentation and explanations within the code

D. To display output to the user

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer C: To provide documentation and explanations within the code

Comments are descriptive text explaining aspects of a program, ignored by the compiler and intended for human readers (p.5). Thus they document/explain code; they do not execute, declare variables by themselves or display text at runtime. Module support: PDF p. 5.

Why each choice is right or wrong

A - Incorrect: "To execute specific sections of code" does not match the rule or result derived here. Comments are descriptive text explaining aspects of a program, ignored by the compiler and intended for human readers (p.5). Thus they document/explain code; they do not execute, declare variables by themselves or display text at runtime.

B - Incorrect: "To define variables and constants" does not match the rule or result derived here. Comments are descriptive text explaining aspects of a program, ignored by the compiler and intended for human readers (p.5). Thus they document/explain code; they do not execute, declare variables by themselves or display text at runtime.

C - Correct: "To provide documentation and explanations within the code" matches the derived result. Comments are descriptive text explaining aspects of a program, ignored by the compiler and intended for human readers (p.5). Thus they document/explain code; they do not execute, declare variables by themselves or display text at runtime.

D - Incorrect: "To display output to the user" does not match the rule or result derived here. Comments are descriptive text explaining aspects of a program, ignored by the compiler and intended for human readers (p.5). Thus they document/explain code; they do not execute, declare variables by themselves or display text at runtime.

Primary note proof

Study-note section CP05

> Comments use // to the line end or /* ... */ for a block. They explain intent and assumptions for maintenance; ordinary comments do not execute or automatically improve speed, reliability or portability. main is the conventional entry function name, not a C++ keyword.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 5 | lines 18-20

> 4. Comments A comment is a piece of descriptive text which explains some aspect of a program. Program comments are totally ignored by the compiler and are only intended for human readers.

Computer Science MCQ practice collection · Question 253

Question 116 | AM0254

What is the purpose of version control in programming?

A. To write programs

B. To execute programs

C. To manage and track changes in code over time

D. To optimize program performance

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer C: Manage and track code changes over time.

CP32 says version control records changes and supports comparison and rollback. That is the management of code history described by C. A version-control system may support a development workflow, but it does not itself define the process of writing code, executing a program or optimizing its runtime performance.

Why each choice is right or wrong

A - Incorrect: Developers write programs; version control records and manages the resulting revisions rather than creating program logic.

B - Incorrect: Execution is performed by the program's runtime or machine, not by revision-history management.

C - Correct: Tracking revisions, comparing changes and rolling back are the version-control purposes explicitly stated in CP32.

D - Incorrect: Runtime performance optimization changes program efficiency; version control manages the history of such changes.

Primary note proof

Study-note section CP32

> Test ordinary, boundary and invalid inputs and trace the first point where actual state differs from expected state. Exceptions transfer control to a matching handler for exceptional conditions; they do not make arbitrary undefined behavior recoverable. Refactoring improves internal structure while preserving observable behavior. Version control records changes, supports comparison and rollback; documentation explains use, design and maintenance assumptions.

Computer Science MCQ practice collection · Question 254

Question 117 | AM0255

What is the difference between a parameter and an argument in programming?

A. Parameters are used in functions, while arguments are used in loops.

B. Parameters are passed to functions, while arguments are used to define functions.

C. Parameters are variables used to define a function, while arguments are the values passed to the function when it is called.

D. There is no difference; the terms are used interchangeably.

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer C: Parameters are variables used to define a function, while arguments are the values passed to the function when it is called.

The definition syntax has a Parameter List (p.15), whereas the call Addition(x,y) supplies values; the passing-by-value discussion calls the passed actual value an argument (p.16). This supports C. A assigns arguments to loops, B reverses definition/call roles, and D ignores the distinction illustrated. Module support: PDF p. 15, PDF p. 16.

Why each choice is right or wrong

A - Incorrect: "Parameters are used in functions, while arguments are used in loops." does not match the rule or result derived here. The definition syntax has a Parameter List (p.15), whereas the call Addition(x,y) supplies values; the passing-by-value discussion calls the passed actual value an argument (p.16). This supports C. A assigns arguments to loops, B reverses definition/call roles, and D ignores the distinction illustrated.

B - Incorrect: "Parameters are passed to functions, while arguments are used to define functions." does not match the rule or result derived here. The definition syntax has a Parameter List (p.15), whereas the call Addition(x,y) supplies values; the passing-by-value discussion calls the passed actual value an argument (p.16). This supports C. A assigns arguments to loops, B reverses definition/call roles, and D ignores the distinction illustrated.

C - Correct: "Parameters are variables used to define a function, while arguments are the values passed to
the function when it is called." matches the derived result. The definition syntax has a Parameter List (p.15), whereas the call Addition(x,y) supplies values; the passing-by-value discussion calls the passed actual value an argument (p.16). This supports C. A assigns arguments to loops, B reverses definition/call roles, and D ignores the distinction illustrated.

D - Incorrect: "There is no difference; the terms are used interchangeably." does not match the rule or result derived here. The definition syntax has a Parameter List (p.15), whereas the call Addition(x,y) supplies values; the passing-by-value discussion calls the passed actual value an argument (p.16). This supports C. A assigns arguments to loops, B reverses definition/call roles, and D ignores the distinction illustrated.

Primary note proof

Study-note section CP17

> A function groups a named task. C++ definition: int add(int a,int b){return a+b;}. Call it with add(x,y);, without parameter type declarations at the call site. Parameters are names in the definition; arguments are supplied expressions or values. A void function produces no return value but can have side effects and return; to exit early.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 15 | lines 29-46

> • User-defined - Function that been created by the user. - These functions need to be declared and defined by the user. Declaration of function Function defines using the following syntax: Function_type function_name (Parameter List) { ...function body } Example: void Addition(int num1,int num2) #include<iostream> using namespace std; void Addition(int num1,int num2) { int sum=num1+num2; cout<<"The sum is:"<<sum; } int main() { int x=10,y=20; Addition(x,y);

Computer Programming module | PDF page 16 | lines 13-20

> Passing by Value In call by value, the actual value that is passed as argument is not changed after performing some operation on it. it creates a copy of that variable into the stack section in memory. When the value is changed, it changes the value of that copy, the actual value remains the same Example: Passing by Reference: It allows a function to modify a variable without having to create a copy of it. We have to declare reference variables. The memory location of the passed variable and parameter is the same and therefore, any change to the parameter reflects in the variable as well.

Computer Science MCQ practice collection · Question 255

Question 118 | AM0256

What is the purpose of logical operators in programming?

A. To perform arithmetic calculations

B. To control the flow of program execution

C. To combine or manipulate boolean values

D. To create user interfaces

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer C: To combine or manipulate boolean values

The module lists !, && and || as logical operators producing 1/0 truth outcomes (p.7). They manipulate and combine truth values. Arithmetic operators perform numerical calculations; UI construction and flow control are broader/different roles. Module support: PDF p. 7.

Why each choice is right or wrong

A - Incorrect: "To perform arithmetic calculations" does not match the rule or result derived here. The module lists !, && and || as logical operators producing 1/0 truth outcomes (p.7). They manipulate and combine truth values. Arithmetic operators perform numerical calculations; UI construction and flow control are broader/different roles.

B - Incorrect: "To control the flow of program execution" does not match the rule or result derived here. The module lists !, && and || as logical operators producing 1/0 truth outcomes (p.7). They manipulate and combine truth values. Arithmetic operators perform numerical calculations; UI construction and flow control are broader/different roles.

C - Correct: "To combine or manipulate boolean values" matches the derived result. The module lists !, && and || as logical operators producing 1/0 truth outcomes (p.7). They manipulate and combine truth values. Arithmetic operators perform numerical calculations; UI construction and flow control are broader/different roles.

D - Incorrect: "To create user interfaces" does not match the rule or result derived here. The module lists !, && and || as logical operators producing 1/0 truth outcomes (p.7). They manipulate and combine truth values. Arithmetic operators perform numerical calculations; UI construction and flow control are broader/different roles.

Primary note proof

Study-note section CP10

> Relational and equality operators test values; && and || combine truth values; ! negates. In C++, zero converts to false and a nonzero number to true. Streams display bool as 0 or 1 unless boolalpha is set. With a=3,b=5, cout<<(a==b) prints 0.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 7 | lines 5-23

> Assignment Operators (=) Example: int x=5; or used with a combination of other operators‟ example, x+=2;//x=x+2, x=y=10; Arithmetic Operators (+, -, *, /, %) E.g. Assume int X=9, Y=2 X+Y, Y-X, X%Y Relational operators (==,!=, <, <=,>,>=) Relational operators evaluate to 1 (representing the true outcome) or 0 (representing the false outcome). Assume int X=9, Y=2 X==Y, X!=Y, X>Y 'A' < 'F' // gives 1 (is like 65 < 70) Logical operators (! Negation, &&, ||) Like the relational operators, logical operators evaluate to 1 or 0. Example: 5 < 6 || 6 < 5 // gives 1 In general, any nonzero value can be used to represent the logical true, whereas only zero represents the logical false !12 // gives 0 10 && 5 // gives 1 Increment/decrement Operators The auto increment (++) and auto decrement (--) operators provide a convenient way of, respectively, adding and subtracting 1 from a numeric variable. Both operators can be used in prefix and postfix form.

Question 119 | AM0257

What is the purpose of modular programming?

A. To create user interfaces

B. To write efficient code

C. To divide a program into separate, reusable modules

D. To optimize program performance

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer C: To divide a program into separate, reusable modules

The module says functions structure programs modularly, and dividing a complex problem into smaller chunks improves understanding and reuse (p.14). That directly supports separate reusable modules. Efficiency may benefit indirectly but is not the stated modular decomposition purpose. Module support: PDF p. 14.

Why each choice is right or wrong

A - Incorrect: "To create user interfaces" does not match the rule or result derived here. The module says functions structure programs modularly, and dividing a complex problem into smaller chunks improves understanding and reuse (p.14). That directly supports separate reusable modules. Efficiency may benefit indirectly but is not the stated modular decomposition purpose.

B - Incorrect: "To write efficient code" does not match the rule or result derived here. The module says functions structure programs modularly, and dividing a complex problem into smaller chunks improves understanding and reuse (p.14). That directly supports separate reusable modules. Efficiency may benefit indirectly but is not the stated modular decomposition purpose.

C - Correct: "To divide a program into separate, reusable modules" matches the derived result. The module says functions structure programs modularly, and dividing a complex problem into smaller chunks improves understanding and reuse (p.14). That directly supports separate reusable modules. Efficiency may benefit indirectly but is not the stated modular decomposition purpose.

D - Incorrect: "To optimize program performance" does not match the rule or result derived here. The module says functions structure programs modularly, and dividing a complex problem into smaller chunks improves understanding and reuse (p.14). That directly supports separate reusable modules. Efficiency may benefit indirectly but is not the stated modular decomposition purpose.

Primary note proof

Study-note section CP17

> A method is a function associated with a class or object; methods can return values. Modules group related responsibilities behind interfaces. Reuse reduces duplication; independent functions are easier to understand and test. A library provides reusable components; a framework also supplies an organizing structure and often calls application callbacks.

Computer Science MCQ practice collection · Question 257

Question 120 | AM0258

What is the role of data structures in programming?

A. To store and organize data efficiently

B. To control the flow of program execution

C. To define user interfaces

D. To perform input/output operations

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer A: To store and organize data efficiently

The module organizes homogeneous indexed values as arrays (p.19) and grouped fields as structures (pp.34-35). These are concrete ways of storing and organizing data, matching A. Flow control, interface definition and input/output are separate program operations, not the storage organization role. Module support: PDF p. 19, PDF p. 35.

Why each choice is right or wrong

A - Correct: "To store and organize data efficiently" matches the derived result. The module organizes homogeneous indexed values as arrays (p.19) and grouped fields as structures (pp.34-35). These are concrete ways of storing and organizing data, matching A. Flow control, interface definition and input/output are separate program operations, not the storage organization role.

B - Incorrect: "To control the flow of program execution" does not match the rule or result derived here. The module organizes homogeneous indexed values as arrays (p.19) and grouped fields as structures (pp.34-35). These are concrete ways of storing and organizing data, matching A. Flow control, interface definition and input/output are separate program operations, not the storage organization role.

C - Incorrect: "To define user interfaces" does not match the rule or result derived here. The module organizes homogeneous indexed values as arrays (p.19) and grouped fields as structures (pp.34-35). These are concrete ways of storing and organizing data, matching A. Flow control, interface definition and input/output are separate program operations, not the storage organization role.

D - Incorrect: "To perform input/output operations" does not match the rule or result derived here. The module organizes homogeneous indexed values as arrays (p.19) and grouped fields as structures (pp.34-35). These are concrete ways of storing and organizing data, matching A. Flow control, interface definition and input/output are separate program operations, not the storage organization role.

Primary note proof

Study-note section CP22

A built-in C++ array has a fixed number of same-type elements in contiguous storage: int a[4]={10,20,30,40};. Valid indices are 0 through 3. a[4] is outside the array; accessing it has undefined behavior. Java checks bounds and throws ArrayIndexOutOfBoundsException. Do not predict a C++ out-of-range value from nearby memory.

Study-note section CP27

A struct groups named members, possibly of different types. struct House{double price; int rooms;}; defines a type; House h{150000,3}; creates an object. h.rooms uses a dot. House* p=&h; p->rooms is equivalent to (*p).rooms. The pointer must refer to a live object before member access. A type definition alone does not create an ordinary instance.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 19 | lines 4-29

Arrays - an array is a collection of fixed-size number of elements of the same type stored sequentially in memory. - An individual element of an array is identified by its own unique index (or subscript). - The number of elements must be an integer. - The size of the array is referred to as its dimension - Array in C++ is Zero indexed. Declaring of one-dimensional Array Syntax: elementstype arrayname [size]; → You can use constants such as macro definitions or const ints as the sizes of arrays. Example: int num[5]; string fruit[3]; #define numstudents 100 or const int numstudents=100; double Score[numstudents] ; double Score[numstudents] ; Initialization of an Array - Arrays can be initialized at declaration time in two different ways: Syntax: elementstype arrayname[size] = {list each value separated by comma}; E.g int num[5]={1,2,3,4,5}; elementstype arrayname[ ] = { list with any number of values }; E.g int num[]={1,2,3,4,5}; string fruit[]={“Apple”,“orange”, “Mango”}; Accessing Array Elements - Each element could be accessed using an index into the array - When accessing an array, the index given must be a positive integer from 0 to n-1, where n is the dimension of the array.

Computer Programming module | PDF page 35 | lines 13-17

Accessing members of a structure variable A structure member can be accessed using dot operator’.’ notation syntax: structvariable.member; eg. st.id=4;

Computer Science MCQ practice collection · Question 258

Question 121 | AM0259

What is the purpose of exception handling in programming?

A. To perform input/output operations

B. To optimize program performance

C. To handle and recover from runtime errors

D. To define variables and constants

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer C: Handle exceptional runtime conditions and recover where appropriate.

CP32 describes exceptions as transferring control to a matching handler for exceptional conditions. This supports handling and possible recovery from runtime errors. It does not promise that every runtime fault is recoverable: arbitrary undefined behavior is specifically excluded. Input/output, optimization and declarations are not exception handling's defining purpose.

Why each choice is right or wrong

A - Incorrect: Input/output may raise exceptional conditions, but performing I/O is not the defining purpose of exception handling.

B - Incorrect: Exception handling routes exceptional control flow rather than being a mechanism for performance optimization.

C - Correct: Matching handlers support handling and possible recovery from runtime exceptions, subject to the note's stated limits.

D - Incorrect: Variables and constants are introduced by declarations, not by exception-handling control flow.

Primary note proof

Study-note section CP32

> Test ordinary, boundary and invalid inputs and trace the first point where actual state differs from expected state. Exceptions transfer control to a matching handler for exceptional conditions; they do not make arbitrary undefined behavior recoverable. Refactoring improves internal structure while preserving observable behavior. Version control records changes, supports comparison and rollback; documentation explains use, design and maintenance assumptions.

Computer Programming module | PDF page 9 | lines 2-8

> Control Statements Control statements or flow control determines what is executed during a run and what is not, therefore affecting the overall outcome of the program. C++ provides different forms of statements for different purposes. Declaration statements are used for defining variables. Assignment-like statements are used for simple, algebraic computations. Branching statements are used for specifying alternate paths of execution, depending on the outcome of a logical condition. Loop statements are used for specifying computations, which need to be repeated until a certain logical condition is satisfied

Question sources

Computer Science MCQ practice collection · Question 259

Question 122 | AM0260

Which statement accurately distinguishes static typing from dynamic typing? Consider type-checking time rather than mandatory annotations or programming paradigms.

A. Static typing is more efficient than dynamic typing.

B. Static typing checks types before execution, possibly using inferred types; dynamic typing checks operations using runtime values.

C. Static typing is used in object-oriented programming, while dynamic typing is used in procedural programming.

D. There is no difference; the terms are used interchangeably.

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer B: B. Static typing checks types before execution, possibly using inferred types; dynamic typing checks operations using runtime values.

Static typing checks types before execution, and the static type may be inferred rather than explicitly written. Dynamic typing checks operations using values at runtime. The difference is therefore about the typing/checking model, not a guarantee of execution speed or a choice between object-oriented and procedural programming. B states this distinction; static typing does not require explicitly written type declarations.

Why each choice is right or wrong

A - Incorrect: Typing discipline alone does not guarantee a universal efficiency ranking.

B - Correct: This correctly distinguishes before-execution checking from runtime checking and allows inference.

C - Incorrect: Object-oriented versus procedural organization does not determine typing discipline.

D - Incorrect: The two checking models have distinct meanings.

Primary note proof

Study-note section CP33

> Static typing checks types before execution; type inference can still infer a static type, as with C++ auto. Dynamic typing checks operations using runtime values; it does not mean variables must have explicit static declarations. Static typing does not always require explicit type annotations.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Question 123 | AM0261

What is the purpose of libraries and frameworks in programming?

A. To perform input/output operations

B. To optimize program performance

C. To provide reusable code and functionality

D. To create user interfaces

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer C: To provide reusable code and functionality

Library functions are described as predefined definitions ready to use, with headers required before calling them (p.14). This supplies reusable functionality rather than forcing users to implement it again. Input/output and UI are possible particular facilities, not the broad purpose; optimization is not the definition. Module support: PDF p. 14, PDF p. 15.

Why each choice is right or wrong

A - Incorrect: "To perform input/output operations" does not match the rule or result derived here. Library functions are described as predefined definitions ready to use, with headers required before calling them (p.14). This supplies reusable functionality rather than forcing users to implement it again. Input/output and UI are possible particular facilities, not the broad purpose; optimization is not the definition.

B - Incorrect: "To optimize program performance" does not match the rule or result derived here. Library functions are described as predefined definitions ready to use, with headers required before calling them (p.14). This supplies reusable functionality rather than forcing users to implement it again. Input/output and UI are possible particular facilities, not the broad purpose; optimization is not the definition.

C - Correct: "To provide reusable code and functionality" matches the derived result. Library functions are described as predefined definitions ready to use, with headers required before calling them (p.14). This supplies reusable functionality rather than forcing users to implement it

again. Input/output and UI are possible particular facilities, not the broad purpose; optimization is not the definition.

D - Incorrect: "To create user interfaces" does not match the rule or result derived here. Library functions are described as predefined definitions ready to use, with headers required before calling them (p.14). This supplies reusable functionality rather than forcing users to implement it again. Input/output and UI are possible particular facilities, not the broad purpose; optimization is not the definition.

Primary note proof

Study-note section CP17

A method is a function associated with a class or object; methods can return values. Modules group related responsibilities behind interfaces. Question 124 | AM0262

What is the purpose of code refactoring in programming?

A. To write efficient code

B. To optimize program performance

C. To improve the readability and maintainability of code

D. To handle and recover from runtime errors

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer C: Improve code readability and maintainability while preserving behavior.

CP32 defines refactoring as improving internal structure while preserving observable behavior. Better readability and maintainability are the offered purpose that matches this definition. Performance tuning can accompany other changes, but is not the defining aim; runtime-error recovery belongs to exception handling rather than refactoring.

Why each choice is right or wrong

A - Incorrect: Writing efficient code is broader than refactoring and does not specify preserving existing observable behavior.

B - Incorrect: Performance optimization has a different primary aim; refactoring concerns structure and maintainability.

C - Correct: Readability and maintainability improve through internal restructuring while observable program behavior is preserved.

D - Incorrect: Handling exceptional runtime conditions belongs to exception handling, not to refactoring's structural purpose.

Primary note proof

Study-note section CP32

> Test ordinary, boundary and invalid inputs and trace the first point where actual state differs from expected state. Exceptions transfer control to a matching handler for exceptional conditions; they do not make arbitrary undefined behavior recoverable. Refactoring improves internal structure while preserving observable behavior. Version control records changes, supports comparison and rollback; documentation explains use, design and maintenance assumptions.

Question 125 | AM0263

What is the role of algorithms in programming?

A. To store and organize data efficiently

B. To perform input/output operations

C. To define user interfaces

D. To provide step-by-step instructions for solving problems

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer D: To provide step-by-step instructions for solving problems

The module defines an algorithm as ordered unambiguous executable steps defining a terminating process (p.2). Therefore it supplies step-by-step problem-solving instructions. Storage organization, input/output and UI design are possible concerns of a program rather than this general definition. Module support: PDF p. 2.

Why each choice is right or wrong

A - Incorrect: "To store and organize data efficiently" does not match the rule or result derived here. The module defines an algorithm as ordered unambiguous executable steps defining a terminating process (p.2). Therefore it supplies step-by-step problem-solving instructions. Storage organization, input/output and UI design are possible concerns of a program rather than this general definition.

B - Incorrect: "To perform input/output operations" does not match the rule or result derived here. The module defines an algorithm as ordered unambiguous executable steps defining a terminating process (p.2). Therefore it supplies step-by-step problem-solving instructions. Storage organization, input/output and UI design are possible concerns of a program rather than this general definition.

C - Incorrect: "To define user interfaces" does not match the rule or result derived here. The module defines an algorithm as ordered unambiguous executable steps defining a terminating process (p.2). Therefore it supplies step-by-step problem-solving instructions. Storage organization, input/output and UI design are possible concerns of a program rather than this general definition.

D - Correct: "To provide step-by-step instructions for solving problems" matches the derived result. The module defines an algorithm as ordered unambiguous executable steps defining a terminating process (p.2). Therefore it supplies step-by-step problem-solving instructions. Storage organization, input/output and UI design are possible concerns of a program rather than this general definition.

Primary note proof

Study-note section CP02

> An algorithm gives precise, executable steps and terminates for every legal input. Definiteness means each step has an unambiguous meaning; effectiveness means a step can actually be performed. Inputs may be absent, but a useful algorithm specifies a result. Correctness means the result meets the specification. Efficiency is desirable and measurable, but an inefficient terminating algorithm is still an algorithm. Efficiency is also a desirable property of an algorithm.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 2 | lines 19-26

> Algorithm is an ordered set of unambiguous, executable steps, defining a terminating process. Important Properties of Algorithms - Correct: always returns the desired output for all legal instances of the problem. - Unambiguous: Each step must be clearly defined, having only one interpretation. - Precise: simple but efficient - Efficient: can be measured in terms of Time and Space - Finiteness: the execution of the algorithm must terminate in a finite amount of time for each possible set of input data/must have an end.

Computer Science MCQ practice collection · Question 263

Question 126 | AM0264

What is the purpose of documentation in programming?

A. To execute programs

B. To optimize program performance

C. To provide explanations and instructions for using and maintaining the code

D. To create user interfaces

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer C: To provide explanations and instructions for using and maintaining the code

The module defines comments as descriptive text explaining a program for human readers (p.5). Documentation serves this explanatory role; instructions for use and maintenance are a reasonable application of that role. Module support: PDF p. 5.

Why each choice is right or wrong

A - Incorrect: Execution follows program instructions, whereas explanatory comments are ignored by the compiler.

B - Incorrect: The cited purpose is human understanding, not performance optimization.

C - Correct: Explanations for readers support using and maintaining code.

D - Incorrect: Creating interfaces is not the descriptive role defined on p.5.

Primary note proof

Study-note section CP05

> Comments use // to the line end or /* ... */ for a block. They explain intent and assumptions for maintenance; ordinary comments do not execute or automatically improve speed, reliability or portability. main is the conventional entry function name, not a C++ keyword.

Study-note section CP32

> Test ordinary, boundary and invalid inputs and trace the first point where actual state differs from expected state. Exceptions transfer control to a matching handler for exceptional conditions; they do not make arbitrary undefined behavior recoverable. Refactoring improves internal structure while preserving observable behavior. Version control records changes, supports comparison and rollback; documentation explains use, design and maintenance assumptions.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 5 | lines 18-20

4. Comments A comment is a piece of descriptive text which explains some aspect of a program. Program comments are totally ignored by the compiler and are only intended for human readers.

Question 127 | AM0265

What does the cout object do in C++?

A. It reads input from the user.

B. It writes output to the console.

C. It performs mathematical calculations.

D. It declares variables.

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer B: It writes output to the console.

Page 6 explicitly calls cout the standard output stream and says it displays information for the user. Module support: PDF p. 6.

Why each choice is right or wrong

A - Incorrect: Input is assigned to cin on p.6.

B - Correct: This is the stated output role.

C - Incorrect: cout displays expressions; it is not the calculation operator.

D - Incorrect: Declarations use a data type and name (p.5), not cout.

Primary note proof

Study-note section CP28

> Include <iostream> and qualify std::cin/std::cout or introduce the names explicitly. cout is the standard output stream; << inserts values. cin is standard input; >> extracts formatted values. std::endl inserts a newline and flushes. C++ names are case sensitive: Cout, Int and std: :cout are not equivalent valid spellings of cout, int and std::cout.

Module passages - related reading

Computer Programming module | PDF page 6 | lines 4-15

> 6. Communication through console cout (the standard output stream) o used to display information for the user Syntax: cout<<object; • Object can be variable or literals Example: int x=5; cout<<x cout<< “Hello there”; cin(the standard input stream): o used to accept information from the user. Syntax: cin>>variable name; Eg. cin>>x;

Question sources

Computer Science MCQ practice collection · Question 265

Question 128 | AM0266

Without any user-defined type aliases, which option declares an ordinary C++ int variable named variableName?

A. variableName = value;

B. value = variableName;

C. int variableName;

D. variableName var;

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer C: C. int variableName;

An ordinary C++ variable declaration places a type specifier before the variable name. Option C uses int followed by variableName and a semicolon, so it introduces the requested integer variable. The assignment expressions in A and B do not introduce a type. D would require variableName to be a type, contrary to the stated requested variable name and absence of aliases.

Why each choice is right or wrong

A - Incorrect: An assignment does not declare the variable's type.

B - Incorrect: Reversing an assignment still does not introduce a declaration.

C - Correct: int variableName; has the required type-then-name form.

D - Incorrect: variableName is not a type under the stated assumptions.

Primary note proof

Study-note section CP06

> Write type name; or type name = value; for ordinary variables: int age = 20;. Declaration introduces a name and type; initialization gives its initial value; later assignment replaces a value. a=b copies a scalar value, so later changes to b do not change a. A pointer or Java object reference instead copies an address/reference.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 5 | lines 24-33

> 5. Data Types, Variables, and Constants Variable: - Variable is a symbolic name for a memory location in which data can be stored. - Attribute of Variables: o A type, which is, established when the variable is defined (e.g., integer, float, character) o A value, which can be changed by assigning a new value to the variable Variable Declaration - Declaring a variable means defining (creating) a variable. - Syntax: data type variable name; e.g. int num; - We can create More Than One Variable at a Time e.g., int num1, num2, num3;

Question sources

Computer Science MCQ practice collection · Question 266

Question 129 | AM0267

What is the purpose of the for loop in C++?

A. To perform conditional branching.

B. To read input from the user.

C. To execute a block of code repeatedly.

D. To declare variables.

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer C: To execute a block of code repeatedly.

The for syntax on p.12 checks a condition, executes the body, performs the increase, then returns to the condition. This gives repeated execution. Module support: PDF p. 12.

Why each choice is right or wrong

A - Incorrect: Branch selection is not the loop purpose.

B - Incorrect: Input uses cin.

C - Correct: The body repeats while the condition holds.

D - Incorrect: An initializer can declare a counter, but declaration is not the loop purpose.

Primary note proof

Study-note section CP14

> for(initialization; condition; update) executes initialization once, then condition → body → update → condition. A missing condition in for(;;) acts as true. A for loop is convenient for a known count but can also be condition controlled. To print indices 0 through n-1, use i=0; i<n; ++i. Starting i=0 with i<5 and i+=2 prints 0 2 4.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 12 | lines 19-28

> The for loop. Its format is: for (initialization; condition; increase) statement; 1, initialization is executed. Generally, it is a initial value setting for a counter variable. This is executed only once 2, condition is checked, if it is true the loop continues, otherwise the loop finishes and statement is skipped. 3, statement is executed. As usual, it can be either a single instruction or a block of instructions enclosed within curly brackets { }. 4, finally, whatever is specified in the increase field is executed and the loop gets back to step 2.

Question sources

Computer Science MCQ practice collection · Question 267

Question 130 | AM0268

What is the output of the following code snippet?

```
int x = 5;
cout << x++ << endl;
cout << x << endl;
```

A. 5, 6

B. 5, 5

C. 6, 6

D. 6, 5

Hint

Trace the initial state and each executed operation in order, preserving the requested output layout.

Answer A: 5, 6

With x initially 5, postfix x++ yields its old value and then increases x to 6; the next statement displays 6. The module operator example on p.8 contrasts postfix b++ and prefix ++a; its previously inspected output confirms this distinction. The two cout statements thus print 5 then 6 on separate lines. Module support: PDF p. 7, PDF p. 8, PDF p. 6.

Why each choice is right or wrong

A - Correct: Old value followed by updated value.

B - Incorrect: Fails to include the increment in the second output.

C - Incorrect: Treats postfix as prefix in the first output.

D - Incorrect: Reverses both the initial output and final state.

Primary note proof

Study-note section CP09

> Prefix ++x changes x and yields the new value; postfix x++ yields the previous value and also increments x. Separate the value used in the expression from the stored value after it. Starting a=8,b=5, a++ + --b uses 8+4, gives 12, and leaves a=9,b=4. Starting x=1,y=10,z=-3, (x++*y--)+ ++z gives 8 and leaves x=2,y=9,z=-2.

Study-note section CP28

> std::endl inserts a newline and flushes.

Question 131 | AM0269

What is the purpose of the switch statement in C++?

A. To perform mathematical calculations.

B. To read input from the user.

C. To execute a block of code repeatedly.

D. To perform different actions based on different conditions.

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer D: To perform different actions based on different conditions.

Page 10 defines switch as choosing among alternatives based on an expression value; p.11 describes matching that value to case labels. D is the matching description, with conditions understood as case matches. Module support: PDF p. 10.

Why each choice is right or wrong

A - Incorrect: Arithmetic is not switch selection.

B - Incorrect: Input is performed by cin.

C - Incorrect: Repetition belongs to loops.

D - Correct: Selecting actions by expression values matches the definition.

Primary note proof

Study-note section CP13

> A traditional C++ switch selects using an integral or enumeration value. case labels are constant expressions. Execution starts at the matching label, then continues through subsequent statements until a break, return or the end. default handles an unmatched value but need not be the last physical label.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 10 | lines 15-26

> switch Statement The switch statement provides a way of choosing between a set of alternatives, based on the value of an expression. The general form of the switch statement is: switch (expression) { caseconstant1: statements; ... caseconstantn: statements; default: statements; }

Question sources

Computer Science MCQ practice collection · Question 269

Question 132 | AM0270

With no user-defined return-type aliases, which C++ function definition can be called and then reach its closing brace normally without omitting a required return value? Assume this is an ordinary function other than main.

A. function myFunction() { }

B. void myFunction() { }

C. int myFunction() { }

D. myFunction() { }

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer B: B. void myFunction() { }

The void definition needs no result value and can safely finish at the end of its empty body. The int definition can be accepted as a definition, but reaching its end without returning a value has undefined behavior. The other forms omit a known return type. Specifying normal completion of an ordinary call distinguishes a safe complete definition from merely syntactically accepted but unsafe fall-through.

Why each choice is right or wrong

A - Incorrect: function is not a declared return type or C++ definition keyword here.

B - Correct: A void function can finish its empty body without returning a value.

C - Incorrect: Reaching the end of this int function omits a required return value.

D - Incorrect: An ordinary C++ function requires an explicit return type.

Primary note proof

Study-note section CP17

> A function groups a named task. C++ definition: int add(int a,int b){return a+b;}. Call it with add(x,y);, without parameter type declarations at the call site. Parameters are names in the definition; arguments are supplied expressions or values. A void function produces no return value but can have side effects and return; to exit early.

Study-note section CP35

> A void function definition can be complete without returning a value; int myFunction(){} can compile, but reaching its end is undefined behavior.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 15 | lines 29-46

• User-defined - Function that been created by the user. - These functions need to be declared and defined by the user. Declaration of function Function defines using the following syntax: Function_type function_name (Parameter List) { ...function body } Example: void Addition(int num1,int num2) #include<iostream> using namespace std; void Addition(int num1,int num2) { int sum=num1+num2; cout<<"The sum is:"<<sum; } int main() { int x=10,y=20; Addition(x,y);

Question sources

Computer Science MCQ practice collection · Question 270

Question 133 | AM0271

What is the purpose of the sizeof operator in C++?

A. To determine the memory size of a variable or data type.

B. To perform mathematical calculations.

C. To compare two variables.

D. To check the equality of two values.

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer A: To determine the memory size of a variable or data type.

Page 29 ties pointer scaling to the size in bytes of the pointed object, and its example labels sizeof(x) as size of int. This supports sizeof as memory-size measurement, rather than arithmetic or comparison. Module support: PDF p. 29.

Why each choice is right or wrong

A - Correct: Memory size is the role shown by size of int and sizeof(x).

B - Incorrect: The example measures storage rather than calculating an arithmetic expression.

C - Incorrect: Comparisons use relational operators, not sizeof.

D - Incorrect: Equality uses == (p.7), not sizeof.

Primary note proof

Study-note section CP07

Single quotes denote a character literal, such as 'A'; double quotes denote a string literal, such as "A". A string includes more storage than just its visible characters when a terminator is required. sizeof reports size in bytes, with sizeof(char)==1; the byte width and other sizes are implementation dependent. sizeof(array) gives total array storage before conversion to a pointer.

Study-note section CP10

Relational and equality operators test values; && and || combine truth values; ! negates.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 29 | lines 6-17

> Note that ptr + 1 does not return the memory address after ptr, but the memory address of the next object of the type that ptr points to. If ptr points to an integer (assuming 4 bytes), ptr + 3 means 3 integers (12 bytes) after ptr. If ptr points to a char, which is always 1 byte, ptr + 3 means 3 chars (3 bytes) after ptr. When calculating the result of a pointer arithmetic expression, the compiler always multiplies the integer operand by the size of the object being pointed to. This is called scaling. Example: #include <iostream> using namespace std; int main() { int x=7; int* ptr=&x; cout<<"size of int:"<<sizeof(x)<<endl;

Variant 1 | Alternative version 1

What is the purpose of the sizeof operator in C++?

A. To determine the size of a variable in bytes.

B. To perform mathematical calculations.

C. To compare two variables.

D. To check the equality of two values.

Answer A: To determine the size of a variable in bytes.

Apply the same study-note rule to this alternative source set; the choice contrasts below show the derivation.

Why each choice is right or wrong

A - Correct: The pointer-scaling discussion uses bytes and the example labels sizeof(x) as size of int (p.29), supporting size of a variable in bytes.

B - Incorrect: sizeof measures storage size in the example, not arithmetic.

C - Incorrect: Comparing values uses relational operators (p.7).

D - Incorrect: Equality uses ==, not sizeof (p.7).

Primary note proof

Study-note section CP07

> Single quotes denote a character literal, such as 'A'; double quotes denote a string literal, such as "A". A string includes more storage than just its visible characters when a terminator is required. sizeof reports size in bytes, with sizeof(char)==1; the byte width and other sizes are implementation dependent. sizeof(array) gives total array storage before conversion to a pointer.

Study-note section CP10

> Relational and equality operators test values; && and || combine truth values; ! negates.

Computer Science MCQ practice collection · Question 271

Computer Science MCQ practice collection · Question 278

Question 134 | AM0272

What does break do when executed inside a C++ loop or switch?

A. To terminate the program.

B. To exit the nearest enclosing loop or switch.

C. To repeat the loop from the beginning.

D. To execute a specific case in a switch statement.

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer B: B. To exit the nearest enclosing loop or switch.

break exits the nearest enclosing loop or switch and resumes control after that construct. It does not terminate the entire program merely because it leaves the construct. Skipping only the remainder of the current iteration is the role of continue, while selecting a case is the switch expression's role. Option B states the exact enclosing-construct exit behavior rather than confusing it with iteration skipping.

Why each choice is right or wrong

A - Incorrect: Leaving a loop or switch does not itself terminate the program.

B - Correct: break exits the nearest enclosing loop or switch.

C - Incorrect: break exits rather than restarting the loop.

D - Incorrect: The switch expression selects a case; break exits the switch.

Primary note proof

Study-note section CP15

> break exits the nearest enclosing loop or switch. continue skips the rest of the current loop iteration: a for loop then runs its update; a while loop goes directly to its condition. return leaves the current function and may supply a result. In main it ends the program normally.

Study-note section CP13

> A traditional C++ switch selects using an integral or enumeration value. case labels are constant expressions. Execution starts at the matching label, then continues through subsequent statements until a break, return or the end. default handles an unmatched value but need not be the last physical label.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 13 | lines 30-35

Using continue and break Statements - The break statement skips the rest of the statements in the loop‟s block, jumping immediately to the next statement outside of the loop. - The continue statement is similar. It also skips the rest of the statements in the loop‟s block, but instead of terminating the loop, it transfers execution to the next iteration of the loop. It continues the loop after skipping the remaining statements in its current iteration.

Question 135 | AM0273

What is the output of the following code snippet?

```
int i = 0;
while (i < 5) {
cout << i << " ";
i++;
}
```

A. 0 1 2 3 4

B. 1 2 3 4 5

C. 5 4 3 2 1

D. 0 0 0 0 0

Hint

Trace the initial state and each executed operation in order, preserving the requested output layout.

Answer A: 0 1 2 3 4

The loop prints i before incrementing. Values 0,1,2,3,4 pass i<5; after the last increment i=5 fails the test (p.11). Module support: PDF p. 11, PDF p. 7, PDF p. 6.

Why each choice is right or wrong

A - Correct: Lists the five values printed before increments.

B - Incorrect: Starts after the increment and includes the excluded endpoint.

C - Incorrect: The counter increases from zero, not decreases.

D - Incorrect: i++ prevents i remaining zero.

Primary note proof

Study-note section CP14

while(condition) checks before each body execution and may run zero times. do {body;} while(condition); runs the body once before checking; it repeats while the condition remains true. Use it when a menu or input attempt must occur at least once.

Study-note section CP09

Prefix ++x changes x and yields the new value; postfix x++ yields the previous value and also increments x. Separate the value used in the expression from the stored value after it. Starting a=8,b=5, a++ + --b uses 8+4, gives 12, and leaves a=9,b=4. Starting x=1,y=10,z=-3, (x++*y--)+ ++z gives 8 and leaves x=2,y=9,z=-2.

Question sources

Computer Science MCQ practice collection · Question 274

Computer Science MCQ practice collection · Question 275

Question 137 | AM0276

Under C++17, what does this fragment print? Assume cout is available.
int x=5;
cout<<x++<<" "<<++x;

A. 5 7

B. 5 5

C. 6 5

D. 6 6

Hint

Trace the initial state and each executed operation in order, preserving the requested output layout.

Answer A: A. 5 7

In C++17 the chained operator-form stream insertions are sequenced left to right. The postfix increment supplies the original value 5 to the first insertion and leaves x equal to 6. The later prefix increment changes x to 7 before supplying its value to the second insertion. The output is therefore 5 followed by a space and 7. Specifying the language version makes this a defined trace.

Why each choice is right or wrong

A - Correct: The postfix supplies 5 and the later prefix supplies 7.

B - Incorrect: The two increments prevent the second value from remaining 5.

C - Incorrect: The first postfix yields 5 rather than 6.

D - Incorrect: The first value is 5 and the second is 7, not two sixes.

Primary note proof

Study-note section CP09

> Precedence determines grouping, not a universal evaluation order. Avoid expressions that modify a variable multiple times without sequencing. In C++17 and later, chained operator-form stream insertions are sequenced left to right: with x=5, cout<<x++<<" "<<++x prints 5 7. Before C++17 this expression has undefined behavior. For the C++17 expression above, 5 6, 5 5, 6 5 and 6 6 are all incorrect outputs.

Module passages - related reading

Question sources

Computer Science MCQ practice collection · Question 276

Question 138 | AM0277

What does this C++ fragment print? Assume cout is available and execution reaches the fragment normally.

```
int total=0;
for(int i=1;i<=4;++i){
if(i==3) break;
total+=i;
}
cout<<total<<" done";
```

A. No output; the program terminates when i reaches 3.

B. 3 done

C. 7 done

D. 10 done

Hint

Trace the initial state and each executed operation in order, preserving the requested output layout.

Answer B: B. 3 done

At i=1 and i=2, the condition is false and total becomes 1 and then 3. At i=3, break exits the nearest enclosing loop before the addition, so neither 3 nor 4 is added. Control continues after the loop and the output statement prints 3 done. A total of 7 would result from skipping only the i=3 iteration with continue; 10 would require completing every addition.

Why each choice is right or wrong

A - Incorrect: break exits the loop, so execution still reaches the following cout statement.

B - Correct: Only 1 and 2 are added before loop exit, and cout then appends the literal space and done.

C - Incorrect: 7 would include 4 after skipping 3, which describes continue rather than break.

D - Incorrect: 10 adds all four loop values and ignores the exit at i=3.

Primary note proof

Study-note section CP15

> break exits the nearest enclosing loop or switch. continue skips the rest of the current loop iteration: a for loop then runs its update; a while loop goes directly to its condition. return leaves the current function and may supply a result. In main it ends the program normally.

Study-note section CP14

> for(initialization; condition; update) executes initialization once, then condition → body → update → condition. A missing condition in for(;;) acts as true. A for loop is convenient for a known count but can also be condition controlled. To print indices 0 through n-1, use i=0; i<n; ++i. Starting i=0 with i<5 and i+=2 prints 0 2 4.

Question 139 | AM0279

What is the purpose of the return statement in a function?

A. To terminate the program.

B. To declare variables.

C. To pass values to another function.

D. To return a value from the function.

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer D: To return a value from the function.

The sum function on p.17 returns x+y+z+w and its callers display the resulting values. This shows return delivering a value to the caller. Module support: PDF p. 17, PDF p. 14.

Why each choice is right or wrong

A - Incorrect: An ordinary function return need not terminate the program.

B - Incorrect: No variable is declared by return.

C - Incorrect: Arguments pass values into a function; the example return supplies its result back.

D - Correct: Matches the sum example and caller usage.

Primary note proof

Study-note section CP15

> break exits the nearest enclosing loop or switch. continue skips the rest of the current loop iteration: a for loop then runs its update; a while loop goes directly to its condition. return leaves the current function and may supply a result. In main it ends the program normally.

Study-note section CP17

> A function groups a named task. C++ definition: int add(int a,int b){return a+b;}. Call it with add(x,y);, without parameter type declarations at the call site. Parameters are names in the definition; arguments are supplied expressions or values. A void function produces no return value but can have side effects and return; to exit early.

> int sum(int x, int y, int z = 0, int w = 0) { return (x + y + z + w); } int main() { cout << sum(10, 15) << endl; cout << sum(10, 15, 25) << endl; cout << sum(10, 15, 25, 30) << endl;

Computer Programming module | PDF page 14 | lines 21-33

> Function A function is a group of statements that structure our programs in a more modular way and executed when it is called from some point of the program. It is a block of code that performs a specific task. It is important to Dividing a complex problem into smaller chunks makes our program easy to understand and reusable. When we need function? - When you need to repeat the same process over and over in a program. - The function can be called many times but appears in the code once Function - Categories C++ functions can be divided into 2 categories: • pre-defined (standard function) / library function - Which is the definitions have been written and it is ready to be used. - User needs to include pre-defined header file (i.e., math.h, time.h,cmath) To use it: FunctionName (value) e.g., sqrt (4), floor (4.3)

Question sources

Computer Science MCQ practice collection · Question 279

Question 140 | AM0280

Which options are valid definitions of an ordinary initialized constant integer x in C++? Treat each option independently and assume no custom macros or aliases. Select all that apply.

A. const int x=5;

B. final int x;

C. int const x=5;

D. int x;

Hint

Apply the naming, type and syntax rules before deciding whether an option can be used as stated.

Answer A, C: A. const int x=5;; C. int const x=5;

C++ permits const before or after the integer type specifier. Both const int x=5 and int const x=5 therefore define initialized constant integers. The initializer supplies the value required for the ordinary const object. final does not replace const in this declaration, and an unqualified int remains mutable. Treating the options independently avoids redeclaration conflicts while recognizing both equivalent const placements.

Why each choice is right or wrong

A - Correct: const int with an initializer defines the requested constant.

B - Incorrect: final is not the const qualifier in an ordinary integer declaration.

C - Correct: int const is equivalent to const int and has an initializer here.

D - Incorrect: An unqualified int variable remains mutable.

Primary note proof

Study-note section CP06

> Use int for whole numbers, float/double for fractional approximations, char for a character and bool for logical values in C++. Type sizes depend on the implementation; do not import Java widths into C++. short n, short int n and int short n denote the same signed short type. const int n=5 and int const n=5 are equivalent; an ordinary const int needs initialization. typedef creates an alias, not a distinct new type.

Computer Programming module | PDF page 8 | lines 27-33

> Constant: A constant is any expression that has a fixed value like integer, float, character and string Eg. 120, 15.2, „A‟, “Hello There” Generally, we have two ways to define constant: 1. Using Const Key word Syntax: const type constant name=value; e.g. const float PI=3.14; 2. Using #define Keyword Syntax: #define constant name value e.g. #define PI 3.14

Question sources

Computer Science MCQ practice collection · Question 280

Question 141 | AM0281

Which option describes the defining execution and test behavior of a C++ do-while loop?

A. To execute a block exactly once regardless of its condition.

B. To perform mathematical calculations.

C. To iterate over a collection of elements.

D. To execute the body before its first test and repeat while the continuation condition is true.

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer D: D. To execute the body before its first test and repeat while the continuation condition is true.

A do-while loop executes its body before the first condition test. It then repeats while its continuation condition is true and stops when that condition becomes false. Thus at least one body execution is guaranteed when the loop is reached, but exactly one is not guaranteed. Collection traversal and arithmetic can occur inside many constructs; neither describes this loop's distinctive control rule.

Why each choice is right or wrong

A - Incorrect: A do-while loop can repeat, so it is not limited to exactly one execution.

B - Incorrect: Arithmetic is possible in the body but is not the defining control behavior.

C - Incorrect: Collection traversal is an application rather than the defining test-and-repeat rule.

D - Correct: The body runs first and further iterations require a true continuation condition.

Primary note proof

Study-note section CP14

> while(condition) checks before each body execution and may run zero times. do {body;} while(condition); runs the body once before checking; it repeats while the condition remains true. Use it when a menu or input attempt must occur at least once.

Module passages - related reading

Question 142 | AM0282

What is the output of the following code snippet?

```
int i = 0;
while (i < 5) {
cout << i << " ";
i += 2;
}
```

A. 0 1 2 3 4

B. 0 2 4

C. 0 1 2 3 4 5

D. 1 3 5

Hint

Trace the initial state and each executed operation in order, preserving the requested output layout.

Answer B: 0 2 4

Starting at zero, printing precedes i+=2. The successive printed values are 0,2,4, followed by i=6 and a failed i<5 test. Page 7 explicitly illustrates compound addition assignment. Module support: PDF p. 11, PDF p. 7.

Why each choice is right or wrong

A - Incorrect: Would require unit increments.

B - Correct: Matches the traced states before each increment.

C - Incorrect: Includes intermediate values and 5 although the test excludes 5.

D - Incorrect: Starts at 1 instead of the specified 0.

Primary note proof

Study-note section CP14

while(condition) checks before each body execution and may run zero times. do {body;} while(condition); runs the body once before checking; it repeats while the condition remains true. Use it when a menu or input attempt must occur at least once.

Study-note section CP08

x+=y, x-=y, x*=y, x/=y and x%=y update x using the operation and conversion to its type. For simple variables, trace them as x=x op y. Starting p=q=n=8, p+=n gives 16 and p/=q gives 2. Starting x=10, x+=5 then x/=2 gives 7. x=x+x doubles; it does not generally add one.

Question 143 | AM0283

What is the purpose of the continue statement in a loop?

A. To terminate the program.

B. To skip the remaining code within the loop and move to the next iteration.

C. To repeat the loop from the beginning.

D. To execute a specific case in a switch statement.

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer B: To skip the remaining code within the loop and move to the next iteration.

Page 13 defines continue as skipping the remaining statements of the current iteration and transferring to the next iteration. Module support: PDF p. 13.

Why each choice is right or wrong

A - Incorrect: Does not terminate the program.

B - Correct: Exactly matches the cited definition.

C - Incorrect: Too broad: it proceeds through the loop continuation rules, rather than necessarily restarting all loop setup.

D - Incorrect: Does not select a switch case.

Primary note proof

Study-note section CP15

> break exits the nearest enclosing loop or switch. continue skips the rest of the current loop iteration: a for loop then runs its update; a while loop goes directly to its condition. return leaves the current function and may supply a result. In main it ends the program normally.

Question 144 | AM0284

What is the purpose of the modulo operator (%) in C++?

A. To perform addition.

B. To perform multiplication.

C. To perform division.

D. To calculate the remainder of integer division.

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer D: To calculate the remainder of integer division.

The arithmetic list on p.7 includes %, and p.8 evaluates c=a%b++ for a=10,b=3; the previously inspected output c=1 demonstrates the remainder interpretation. Module support: PDF p. 7, PDF p. 8.

Why each choice is right or wrong

A - Incorrect: Addition is +.

B - Incorrect: Multiplication is *.

C - Incorrect: The quotient operation is /; the example produces a remainder.

D - Correct: 10 divided by 3 leaves the illustrated remainder 1.

Primary note proof

Study-note section CP08

> Multiplication, division and remainder have higher precedence than addition and subtraction; equal-precedence arithmetic groups left to right. Integer division truncates toward zero. For integers, a == (a/b)*b + a%b when the division is valid. % requires integral operands in C++; (8.0*3)%5 is invalid. Division by zero and signed integer overflow cannot be given ordinary numeric outputs.

Computer Science MCQ practice collection · Question 284

Question 145 | AM0285

What is the output of the following code snippet?

```
int x = 10;
int y = 3;
cout << x / y;
```

A. 3.33333

B. 3

C. 3.0

D. 3.33333...

Hint

Trace the initial state and each executed operation in order, preserving the requested output layout.

Answer B: 3.

Both x and y have type int, so CP08's integer-division rule applies: 10/3 truncates toward zero to 3. The stream prints that integer value. No floating conversion occurs before division, and no decimal formatting is requested, so neither a fractional quotient nor the literal output 3.0 is correct.

Why each choice is right or wrong

A - Incorrect: 3.33333 is a fractional approximation, but division of these int operands discards the fractional part.

B - Correct: Integer division gives 3, and cout prints the resulting integer without a decimal suffix.

C - Incorrect: 3.0 is not the printed representation of the int quotient in this code.

D - Incorrect: An indefinitely repeating decimal is not produced by integer division or this stream insertion.

Primary note proof

Study-note section CP08

Multiplication, division and remainder have higher precedence than addition and subtraction; equal-precedence arithmetic groups left to right. Integer division truncates toward zero. For integers, a == (a/b)*b + a%b when the division is valid. % requires integral operands in C++; (8.0*3)%5 is invalid. Division by zero and signed integer overflow cannot be given ordinary numeric outputs.

Study-note section CP28

Read a full line with getline(cin,text). After formatted numeric extraction, consume the pending newline before a line read when required. Input failure must be tested before trusting a value. Console output formatting matters: by default a double storing an exact 4 may print 4 rather than 4.0. Text, spaces and newlines are part of an output trace.

Computer Science MCQ practice collection · Question 285

Question 146 | AM0286

Which listed C++ construct computes a number raised to a power, using the standard mathematical library?

A. ^

B. **

C. pow()

D. ^=

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer C: C. pow()

C++ supplies pow as a mathematical library function for exponentiation. It is a function call rather than a built-in exponentiation operator. The caret denotes bitwise XOR, and ** is not a C++ power operator; ^= consequently does not provide exponentiation assignment. With the required mathematical declarations available, pow is the construct matching the requested operation, so the intended C key remains valid.

Why each choice is right or wrong

A - Incorrect: ^ is bitwise XOR rather than exponentiation.

B - Incorrect: ** is not a C++ exponentiation operator.

C - Correct: The standard-library pow function computes powers.

D - Incorrect: ^= uses the bitwise operation, not exponentiation.

Primary note proof

Study-note section CP30

> C++ has no built-in exponentiation operator: ^ is bitwise XOR and ** is not a power operator. To compute b^e for a nonnegative integer e, start r=1 and repeat r*=b exactly e times; b=4,e=3 gives 64. Large powers and factorials can overflow fixed-width types; specify a valid input range.

Question 147 | AM0287

What is the output of the following code snippet?

```
double result = sqrt(16);
cout << result;
```

A. 2

B. 4

C. 8

D. 16

Hint

Trace the initial state and each executed operation in order, preserving the requested output layout.

Answer B: 4

Page 15 defines sqrt as square root. Since 4 multiplied by 4 is 16, sqrt(16) is 4. Its worked example also displays sqrt(25) as 5, supporting the plain integral-looking output format. Module support: PDF p. 15, PDF p. 15.

Why each choice is right or wrong

A - Incorrect: 2 squared is 4, not 16.

B - Correct: 4 squared equals 16.

C - Incorrect: 8 squared is 64.

D - Incorrect: 16 is the argument, not its square root.

Primary note proof

Study-note section CP30

> Use <cmath> for sqrt, pow, floor and ceil; integer abs is also provided by <cstdlib>. sqrt(16)=4; pow(3,4)=81; abs(-7)=7. ceil(x) is the least integer-valued result >=x; floor(x) the greatest <=x. Thus ceil(-2.7)=-2 and floor(-2.7)=-3; truncation toward zero differs from floor for negatives.

Study-note section CP28

> Read a full line with getline(cin,text). After formatted numeric extraction, consume the pending newline before a line read when required. Input failure must be tested before trusting a value. Console output formatting matters: by default a double storing an exact 4 may print 4 rather than 4.0. Text, spaces and newlines are part of an output trace.

Question 148 | AM0288

Which header file should be included to use mathematical functions in C++?

A. <iostream>

B. <cmath>

C. <string>

D. <iomanip>

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer B: <cmath>

The module math-function example on p.15 includes <cmath> before using fabs, floor, ceil and sqrt. This directly supports B among these headers. Module support: PDF p. 15.

Why each choice is right or wrong

A - Incorrect: The example also includes iostream for streams; the math header is cmath.

B - Correct: This is the demonstrated math header.

C - Incorrect: string is not the math header in the cited example.

D - Incorrect: iomanip is not the math header demonstrated here.

Primary note proof

Study-note section CP30

> Use <cmath> for sqrt, pow, floor and ceil; integer abs is also provided by <cstdlib>. sqrt(16)=4; pow(3,4)=81; abs(-7)=7. ceil(x) is the least integer-valued result >=x; floor(x) the greatest <=x. Thus ceil(-2.7)=-2 and floor(-2.7)=-3; truncation toward zero differs from floor for negatives.

Trace the initial state and each executed operation in order, preserving the requested output layout.

Answer D: 81

The p.15 definition of pow gives 3 raised to 4: 3*3*3*3=81. Module support: PDF p. 15.

Why each choice is right or wrong

A - Incorrect: 7 is addition of the arguments.

B - Incorrect: 12 is multiplication of the arguments.

C - Incorrect: 27 uses exponent 3 instead of 4.

D - Correct: 81 is the fourth power.

Primary note proof

Study-note section CP30

> Use <cmath> for sqrt, pow, floor and ceil; integer abs is also provided by <cstdlib>. sqrt(16)=4; pow(3,4)=81; abs(-7)=7. ceil(x) is the least integer-valued result >=x; floor(x) the greatest <=x. Thus ceil(-2.7)=-2 and floor(-2.7)=-3; truncation toward zero differs from floor for negatives.

Study-note section CP28

> Read a full line with getline(cin,text). After formatted numeric extraction, consume the pending newline before a line read when required. Input failure must be tested before trusting a value. Console output formatting matters: by default a double storing an exact 4 may print 4 rather than 4.0. Text, spaces and newlines are part of an output trace.

Question sources

Computer Science MCQ practice collection · Question 290

Question 151 | AM0291

What is the purpose of the abs() function in C++?

A. To calculate the absolute value of a number.

B. To calculate the average of two numbers.

C. To round a floating-point number to the nearest integer.

D. To compare two numbers for equality.

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer A: To calculate the absolute value of a number.

Page 14 distinguishes fabs for a floating-point absolute value and abs for an integer. Thus abs supplies the integer absolute value. Module support: PDF p. 14.

Why each choice is right or wrong

A - Correct: Matches the stated integer absolute-value role.

B - Incorrect: No averaging role is given.

C - Incorrect: Rounding is not the abs role; floor and ceil are separate.

D - Incorrect: Equality is a relational operation, not abs.

Primary note proof

Study-note section CP30

> Use <cmath> for sqrt, pow, floor and ceil; integer abs is also provided by <cstdlib>. sqrt(16)=4; pow(3,4)=81; abs(-7)=7. ceil(x) is the least integer-valued result >=x; floor(x) the greatest <=x. Thus ceil(-2.7)=-2 and floor(-2.7)=-3; truncation toward zero differs from floor for negatives.

Question 152 | AM0292

What is the output of the following code snippet?

```
int x = -7;
cout << abs(x);
```

A. -7

B. 7

C. 0

D. Undefined

Hint

Trace the initial state and each executed operation in order, preserving the requested output layout.

Answer B: 7

Page 14 identifies abs for integers. The absolute value is distance from zero, so -7 gives 7. Module support: PDF p. 14.

Why each choice is right or wrong

A - Incorrect: Keeps the negative sign instead of taking magnitude.

B - Correct: Magnitude of -7 is 7.

C - Incorrect: Only zero has zero magnitude.

D - Incorrect: No undefined input is present for this small integer under the stated function assumption.

Primary note proof

Study-note section CP30

> Use <cmath> for sqrt, pow, floor and ceil; integer abs is also provided by <cstdlib>. sqrt(16)=4; pow(3,4)=81; abs(-7)=7. ceil(x) is the least integer-valued result >=x; floor(x) the greatest <=x. Thus ceil(-2.7)=-2 and floor(-2.7)=-3; truncation toward zero differs from floor for negatives.

Question 153 | AM0293

What is the purpose of the ceil() function in C++?

A. To calculate the ceiling value of a floating-point number.

B. To calculate the factorial of an integer.

C. To round a floating-point number down to the nearest integer.

D. To perform bitwise complement on an integer.

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer A: To calculate the ceiling value of a floating-point number.

Page 15 defines ceil as the smallest integral value not less than x. This is the ceiling operation. Module support: PDF p. 15.

Why each choice is right or wrong

A - Correct: Matches the exact ceiling definition.

B - Incorrect: Factorial is unrelated to the cited definition.

C - Incorrect: Rounding downward corresponds to floor, not ceil.

D - Incorrect: No bitwise operation appears in the definition.

Primary note proof

Study-note section CP30

> Use <cmath> for sqrt, pow, floor and ceil; integer abs is also provided by <cstdlib>. sqrt(16)=4; pow(3,4)=81; abs(-7)=7. ceil(x) is the least integer-valued result >=x; floor(x) the greatest <=x. Thus ceil(-2.7)=-2 and floor(-2.7)=-3; truncation toward zero differs from floor for negatives.

Computer Science MCQ practice collection · Question 293

Question 154 | AM0294

Which of the following data types in C++ can store fractional values?

A. int

B. char

C. float

D. bool

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer C: C. float

The float type represents fractional numeric approximations, so it can retain a fractional component. int represents whole numbers; converting a fractional value to it does not preserve that component. char represents a character, and bool represents the logical values true and false. These different value domains make float the unique listed type intended for fractional quantities, without implying that every real number is represented exactly.

Why each choice is right or wrong

A - Incorrect: An int stores a whole-number result rather than a retained fractional component.

B - Incorrect: A char represents a character, not the listed fractional numeric type.

C - Correct: A float represents fractional numeric approximations.

D - Incorrect: A bool represents logical true/false values rather than fractional magnitudes.

Primary note proof

Study-note section CP06

> Use int for whole numbers, float/double for fractional approximations, char for a character and bool for logical values in C++. Type sizes depend on the implementation; do not import Java widths into C++. short n, short int n and int short n denote the same signed short type. const int n=5 and int const n=5 are equivalent; an ordinary const int needs initialization. typedef creates an alias, not a distinct new type.

Question sources

Computer Science MCQ practice collection · Question 294

Question 155 | AM0295

What is the result of the expression 5 / 2 in C++?

A. 2

B. 2.5

C. 2.0

D. 2.25

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer A: The integer value 2.

Both literals in 5/2 are integers. CP07 states that the integer quotient is 2, and even assigning that already-computed quotient to double would not restore the lost fraction. The question asks for the expression's result, so the integer 2 is the precise choice rather than a floating representation or fractional quotient.

Why each choice is right or wrong

A - Correct: Two integer operands produce the integer quotient 2 after truncating the fractional part.

B - Incorrect: 2.5 requires floating division, which these uncast integer literals do not perform.

C - Incorrect: 2.0 is a floating representation, while this expression itself has an integer result.

D - Incorrect: 2.25 follows neither integer truncation nor the ordinary mathematical quotient of five divided by two.

Primary note proof

Study-note section CP07

With int x=5,y=2, x/y is 2. Assigning that quotient to double gives 2.0, not 2.5. static_cast<double>(x)/y performs floating division and yields 2.5. Converting an in-range fractional floating value to int truncates toward zero. Cast before the operation if a fractional result is needed.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 7 | lines 5-23

> Assignment Operators (=) Example: int x=5; or used with a combination of other operators‟ example, x+=2;//x=x+2, x=y=10; Arithmetic Operators (+, -, *, /, %) E.g. Assume int X=9, Y=2 X+Y, Y-X, X%Y Relational operators (==,!=, <, <=,>,>=) Relational operators evaluate to 1 (representing the true outcome) or 0 (representing the false outcome). Assume int X=9, Y=2 X==Y, X!=Y, X>Y 'A' < 'F' // gives 1 (is like 65 < 70) Logical operators (! Negation, &&, ||) Like the relational operators, logical operators evaluate to 1 or 0. Example: 5 < 6 || 6 < 5 // gives 1 In general, any nonzero value can be used to represent the logical true, whereas only zero represents the logical false !12 // gives 0 10 && 5 // gives 1 Increment/decrement Operators The auto increment (++) and auto decrement (--) operators provide a convenient way of, respectively, adding and subtracting 1 from a numeric variable. Both operators can be used in prefix and postfix form.

Question sources

Computer Science MCQ practice collection · Question 295

Question 156 | AM0296

What is the output of the following code snippet?

```
int x = 5;
int y = 2;
double result = static_cast<double>(x) / y;
cout << result;
```

A. 2

B. 2.5

C. 2.0

D. 2.25

Hint

Trace the initial state and each executed operation in order, preserving the requested output layout.

Answer B: 2.5.

static_cast<double>(x) converts 5 to a floating value before the division takes place. CP07 explicitly gives this form as yielding 2.5 when x=5 and y=2. The result therefore retains the fractional part; storing it in double does not first perform an integer quotient.

Why each choice is right or wrong

A - Incorrect: Casting x before division prevents the integer truncation that would have produced 2.

B - Correct: The converted floating operand makes the quotient 2.5, which is stored and printed.

C - Incorrect: 2.0 would result from first computing the integer quotient and then converting it, unlike this code.

D - Incorrect: The floating quotient of 5 by 2 is 2.5, not 2.25.

Primary note proof

Study-note section CP07

With int x=5,y=2, x/y is 2. Assigning that quotient to double gives 2.0, not 2.5. static_cast<double>(x)/y performs floating division and yields 2.5. Converting an in-range fractional floating value to int truncates toward zero. Cast before the operation if a fractional result is needed.

Computer Science MCQ practice collection · Question 296

Question 157 | AM0297

What is the value of x after executing the following code snippet?

```
int x = 10;
x += 5;
x /= 2;
```

A. 5

B. 7

C. 8

D. 10

Hint

Trace the initial state and each executed operation in order, preserving the requested output layout.

Answer B: x becomes 7.

The initial x is 10. x+=5 updates it to 15; x/=2 then performs integer division because x is int, truncating 15/2 toward zero to 7. CP08 provides this exact sequence and result. The updates happen in order, so the second operation acts on 15 rather than the original 10.

Why each choice is right or wrong

A - Incorrect: Five divides the original value by two and ignores the preceding addition of five.

B - Correct: The sequence gives 10+5=15, then integer 15/2=7.

C - Incorrect: Integer division truncates 7.5 to 7 rather than rounding it to 8.

D - Incorrect: Both compound assignments update x; it does not retain its initial value of 10.

Primary note proof

Study-note section CP08

> x+=y, x-=y, x*=y, x/=y and x%=y update x using the operation and conversion to its type. For simple variables, trace them as x=x op y. Starting p=q=n=8, p+=n gives 16 and p/=q gives 2. Starting x=10, x+=5 then x/=2 gives 7. x=x+x doubles; it does not generally add one.

Question 158 | AM0298

What is the result of the following expression?

bool result = (5 > 3) && (10 < 8);

A. true

B. false

C. compilation error

D. runtime error

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer B: false

Page 7 lists relational and logical operators and represents true and false as 1 and 0. Here 5>3 is true and 10<8 is false; logical AND requires both, so result is false. Module support: PDF p. 7.

Why each choice is right or wrong

A - Incorrect: Would require both comparisons to be true.

B - Correct: The second comparison is false, making the conjunction false.

C - Incorrect: The operators are listed module constructs, and the declaration follows the taught type-name form.

D - Incorrect: No runtime failure is implied by either simple comparison.

Primary note proof

Study-note section CP10

> Relational and equality operators test values; && and || combine truth values; ! negates. In C++, zero converts to false and a nonzero number to true. Streams display bool as 0 or 1 unless boolalpha is set. With a=3,b=5, cout<<(a==b) prints 0.

Question 159 | AM0299

What is the output of the following code snippet?

```
int x = 3;
int y = 5;
cout << (x == y);
```

A. 1

B. 0

C. true

D. false

Hint

Trace the initial state and each executed operation in order, preserving the requested output layout.

Answer B: 0

Page 7 explicitly says relational operators evaluate to 1 for true or 0 for false. Since 3 and 5 differ, x==y evaluates to 0; cout displays that result (p.6). Module support: PDF p. 7, PDF p. 6.

Why each choice is right or wrong

A - Incorrect: 1 would mean equality is true.

B - Correct: 0 represents the false equality.

C - Incorrect: The equality is not true.

D - Incorrect: This names the logical result but differs from the numeric representation taught by the module.

Primary note proof

Study-note section CP10

Relational and equality operators test values; && and || combine truth values; ! negates. In C++, zero converts to false and a nonzero number to true. Streams display bool as 0 or 1 unless boolalpha is set. With a=3,b=5, cout<<(a==b) prints 0.

Question 160 | AM0300

What is the value of result after executing the following code snippet?

```
int a = 3;
int b = 2;
int result = pow(a, b);
```

A. 6

B. 9

C. 8

D. 5

Hint

Trace the initial state and each executed operation in order, preserving the requested output layout.

Answer B: 9

The module defines pow as raising a number to a power (p.15). With a=3 and b=2, it computes 3*3=9; this whole-number value is the intended integer result. Module support: PDF p. 15.

Why each choice is right or wrong

A - Incorrect: 6 multiplies base and exponent.

B - Correct: 9 is 3 squared.

C - Incorrect: 8 is 2 cubed, reversing arguments.

D - Incorrect: 5 adds the arguments.

Primary note proof

Study-note section CP30

> Use <cmath> for sqrt, pow, floor and ceil; integer abs is also provided by <cstdlib>. sqrt(16)=4; pow(3,4)=81; abs(-7)=7. ceil(x) is the least integer-valued result >=x; floor(x) the greatest <=x. Thus ceil(-2.7)=-2 and floor(-2.7)=-3; truncation toward zero differs from floor for negatives.

Study-note section CP07

> With int x=5,y=2, x/y is 2. Assigning that quotient to double gives 2.0, not 2.5. static_cast<double>(x)/y performs floating division and yields 2.5. Converting an in-range fractional floating value to int truncates toward zero. Cast before the operation if a fractional result is needed.

Question 162 | AM0302

What is the value of result after executing the following code snippet?

```
double pi = 3.14159;
int result = floor(pi);
```

A. 3

B. 4

C. 3.14

D. 3.14159

Hint

Trace the initial state and each executed operation in order, preserving the requested output layout.

Answer A: 3

Page 14 defines floor as the largest integral value not greater than x. For 3.14159 that value is 3, because 3<=3.14159<4. Module support: PDF p. 14.

Why each choice is right or wrong

A - Correct: 3 is the greatest integer not exceeding pi.

B - Incorrect: 4 is greater than pi and would be a ceiling.

C - Incorrect: 3.14 remains fractional and is not floor.

D - Incorrect: 3.14159 is the original argument, not its floor.

Primary note proof

Study-note section CP30

> Use <cmath> for sqrt, pow, floor and ceil; integer abs is also provided by <cstdlib>. sqrt(16)=4; pow(3,4)=81; abs(-7)=7. ceil(x) is the least integer-valued result >=x; floor(x) the greatest <=x. Thus ceil(-2.7)=-2 and floor(-2.7)=-3; truncation toward zero differs from floor for negatives.

Question 163 | AM0303

What is the output of the following code snippet?

```
int x = 4;
int y = 2;
cout << (x % y);
```

A. 0

B. 1

C. 2

D. 4

Hint

Trace the initial state and each executed operation in order, preserving the requested output layout.

Answer A: 0

The remainder operation illustrated on p.8 gives 4%2=0 because 4=2*2+0. Module support: PDF p. 8.

Why each choice is right or wrong

A - Correct: Exact divisibility leaves zero remainder.

B - Incorrect: A remainder of 1 would represent an odd dividend.

C - Incorrect: 2 is the quotient and cannot be the remainder for positive divisor 2.

D - Incorrect: 4 is the original dividend, not its remainder.

Primary note proof

Study-note section CP08

> Multiplication, division and remainder have higher precedence than addition and subtraction; equal-precedence arithmetic groups left to right. Integer division truncates toward zero. For integers, a == (a/b)*b + a%b when the division is valid. % requires integral operands in C++; (8.0*3)%5 is invalid. Division by zero and signed integer overflow cannot be given ordinary numeric outputs.

Question 164 | CS0086

What is the output of the following C++ fragment code? int x = 15, y = 2; int z = x / y; cout << z;

A. 7.5

B. 7

C. 3

D. 12.5

Hint

Trace the initial state and each executed operation in order, preserving the requested output layout.

Answer B: 7.

x and y are int variables with values 15 and 2. Their division therefore produces integer 7 before assignment to z, as CP08 specifies truncation toward zero. z also has type int and cout prints 7. None of the fractional or unrelated numerical options follows from this expression.

Why each choice is right or wrong

A - Incorrect: 7.5 is the mathematical fractional quotient, but these int operands produce an integer quotient.

B - Correct: The integer quotient 15/2 truncates toward zero to 7, which z stores and cout prints.

C - Incorrect: Three is not the quotient obtained by dividing the stated values 15 and 2.

D - Incorrect: 12.5 is neither the integer quotient nor the fractional quotient of 15 divided by 2.

Primary note proof

Study-note section CP08

> Multiplication, division and remainder have higher precedence than addition and subtraction; equal-precedence arithmetic groups left to right. Integer division truncates toward zero. For integers, a == (a/b)*b + a%b when the division is valid. % requires integral operands in C++; (8.0*3)%5 is invalid. Division by zero and signed integer overflow cannot be given ordinary numeric outputs.

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 7 | lines 5-23

Assignment Operators (=) Example: int x=5; or used with a combination of other operators‟ example, x+=2;//x=x+2, x=y=10; Arithmetic Operators (+, -, *, /, %) E.g. Assume int X=9, Y=2 X+Y, Y-X, X%Y Relational operators (==,!=, <, <=,>,>=) Relational operators evaluate to 1 (representing the true outcome) or 0 (representing the false outcome). Assume int X=9, Y=2 X==Y, X!=Y, X>Y 'A' < 'F' // gives 1 (is like 65 < 70) Logical operators (! Negation, &&, ||) Like the relational operators, logical operators evaluate to 1 or 0. Example: 5 < 6 || 6 < 5 // gives 1 In general, any nonzero value can be used to represent the logical true, whereas only zero represents the logical false !12 // gives 0 10 && 5 // gives 1 Increment/decrement Operators The auto increment (++) and auto decrement (--) operators provide a convenient way of, respectively, adding and subtracting 1 from a numeric variable. Both operators can be used in prefix and postfix form.

Computer Programming module | PDF page 5 | lines 24-33

5. Data Types, Variables, and Constants Variable: - Variable is a symbolic name for a memory location in which data can be stored. - Attribute of Variables: o A type, which is, established when the variable is defined (e.g., integer, float, character) o A value, which can be changed by assigning a new value to the variable Variable Declaration - Declaring a variable means defining (creating) a variable. - Syntax: data type variable name; e.g. int num; - We can create More Than One Variable at a Time e.g., int num1, num2, num3;

Computer Science Exit Exam practice collection · Question 86

Question 165 | CS0087

Writing comments in between our C++ program makes our program _____.

A. Portable

B. Maintainable

C. Reliable

D. Efficient

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer B: Maintainable

Page 5 says comments explain aspects of a program for human readers and are ignored by the compiler. Explanations help a maintainer understand and change code, so maintainable is the best fit. Module support: PDF p. 5.

Why each choice is right or wrong

A - Incorrect: Human explanatory text does not establish cross-platform compatibility.

B - Correct: Explanatory text helps people understand code during maintenance.

C - Incorrect: Comments alone do not establish correctness or reliable execution.

D - Incorrect: Ignored comments do not establish runtime efficiency.

Primary note proof

Study-note section CP05

> Comments use // to the line end or /* ... */ for a block. They explain intent and assumptions for maintenance; ordinary comments do not execute or automatically improve speed, reliability or portability. main is the conventional entry function name, not a C++ keyword.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 5 | lines 18-20

> 4. Comments A comment is a piece of descriptive text which explains some aspect of a program. Program comments are totally ignored by the compiler and are only intended for human readers.

Question sources

Computer Science Exit Exam practice collection · Question 87

Question 166 | CS0088

What is the output of the following C++ fragment code? int data[10] = {5,10,15,20,25,30,35,40,45,50}; int i = 0; while (i <= 10) { if(data[i] % 10 == 0) { cout << data[i] << " "; i = i + 2; } }

A. 5 15 25 35 45 55

B. 10 20 30 40 50

C. 5 10 15 20 25 30 35 40 45 50

D. No output

Hint

Trace the initial state and each executed operation in order, preserving the requested output layout.

Answer D: No output

Arrays are zero indexed (p.19), so initially data[0]=5. Its remainder on division by 10 is 5, not zero, so the if body is skipped. The only increment of i lies inside that skipped body. Therefore i stays zero, i<=10 remains true, and no cout is ever reached. The loop runs indefinitely with no output; it never reaches the potentially invalid index 10. Module support: PDF p. 19, PDF p. 11, PDF p. 8, PDF p. 9.

Why each choice is right or wrong

A - Incorrect: No print occurs at the first iteration or later, so this odd-value sequence cannot appear.

B - Incorrect: The loop never advances to data[1]=10.

C - Incorrect: No array traversal occurs because i never changes.

D - Correct: Correct: nothing is printed, and the loop does not terminate.

Primary note proof

Study-note section CP16

> For n=1; n<=18; n+=2, print n unless n%7==0 then break: output is 1 3 5. A while(a>b) with fixed a=6,b=5 never changes its true condition. In data[10]={5,10,...,50}, i=0, advancing i only if data[i]%10==0 causes no progress because data[0]=5. It prints nothing and loops indefinitely; changing <=10 to <10 alone does not repair progress.

Study-note section CP22

> A built-in C++ array has a fixed number of same-type elements in contiguous storage: int a[4]={10,20,30,40};. Valid indices are 0 through 3. a[4] is outside the array; accessing it has undefined behavior. Java checks bounds and throws ArrayIndexOutOfBoundsException. Do not predict a C++ out-of-range value from nearby memory.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 19 | lines 4-29

Arrays - an array is a collection of fixed-size number of elements of the same type stored sequentially in memory. - An individual element of an array is identified by its own unique index (or subscript). - The number of elements must be an integer. - The size of the array is referred to as its dimension - Array in C++ is Zero indexed. Declaring of one-dimensional Array Syntax: elementstype arrayname [size]; → You can use constants such as macro definitions or const ints as the sizes of arrays. Example: int num[5]; string fruit[3]; #define numstudents 100 or const int numstudents=100; double Score[numstudents] ; double Score[numstudents] ; Initialization of an Array - Arrays can be initialized at declaration time in two different ways: Syntax: elementstype arrayname[size] = {list each value separated by comma}; E.g int num[5]={1,2,3,4,5}; elementstype arrayname[ ] = { list with any number of values }; E.g int num[]={1,2,3,4,5}; string fruit[]={“Apple”,“orange”, “Mango”}; Accessing Array Elements - Each element could be accessed using an index into the array - When accessing an array, the index given must be a positive integer from 0 to n-1, where n is the dimension of the array.

Computer Programming module | PDF page 11 | lines 5-13

Iteration/Looping Statement: Iteration is the repetition of a statement or block of statements in a program. - Loops have as objective to repeat a statement a certain number of times or while a condition is fulfilled. - C++ has three iteration statements: the while statement, the do. While statement, and the for statement. The while loop: Its format is: while (expression) {statement;} First expression (called the loop condition) is evaluated. If the outcome is nonzero then statement (called the loop body) is executed and the whole process is repeated. Otherwise, the loop is terminated.

Computer Programming module | PDF page 8 | lines 12-23

{int a=10,b=3,c,d,e,f; c=a%b++; cout<<"c="<<c<<endl; b+=2; cout<<"b="<<b<<endl; d=++a+b; cout<<"d="<<d<<endl; e=a>b?a:b; e++; cout<<"e="<<e++<<endl; f=a+b+c+d+e; cout<<"f="<<f;

Computer Programming module | PDF page 9 | lines 9-21

Conditional Statements A. The if Statement Syntax: if (expression) statement; First expression is evaluated. If the outcome is nonzero (true) then statement is executed. Otherwise, nothing happens. if-else statement Syntax: if (expression) statement1; else statement2; First expression is evaluated. If the outcome is nonzero (true) then statement1 is executed. Otherwise, statement2 is executed.

Computer Science Exit Exam practice collection · Question 88

Question 167 | CS0092

After a compiler reports a syntax error and before rebuilding, which action directly helps locate and repair its cause?

A. Rewrite the entire program

B. Ignore the error and continue execution

C. Use a debugger tool

D. Check the code for typos or incorrect syntax

Hint

Apply the naming, type and syntax rules before deciding whether an option can be used as stated.

Answer D: D. Check the code for typos or incorrect syntax

A syntax error violates the language grammar, so inspecting the relevant tokens and nearby declarations is the direct diagnostic step. The note recommends starting with the first useful compiler diagnostic, repairing the code and rebuilding afterward. Rewriting everything is unnecessary, ignoring the diagnostic leaves the defect in place, and a debugger is useful after a runnable program exists. The revised timing asks for inspection rather than the final verification step.

Why each choice is right or wrong

A - Incorrect: A complete rewrite is unnecessary for locating a local grammar mistake.

B - Incorrect: Ignoring a compiler error leaves the cause unresolved.

C - Incorrect: A debugger is useful after a runnable program exists.

D - Correct: Inspecting nearby tokens and declarations helps locate and correct grammar mistakes.

Primary note proof

Study-note section CP32

> A syntax error violates grammar; a type error can be syntactically well formed but rejected during semantic checking. A runtime error occurs during execution; a logic error gives the wrong behavior. A bug is a defect; debugging locates and corrects it. Read the first useful compiler diagnostic, inspect nearby tokens and declarations, repair and rebuild; a debugger is useful after a runnable program exists.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Programming module | PDF page 4 | lines 21-30

> The compilation process of C++ program consists of the following steps. • edit source code → compile → link → execute (Editor) (Compiler) (Linker) (Loader) I. Program source code is entered into a file using a text editor. II. After the code has been entered, a compiler program is started that translates the source into an object code file. III. The object code file is linked with other

object code files that come with the compiler and an executable file (or program) is created. IV. In order to execute the program, a program called the loader copies the executable file into the memory of the computer and sends an execute command to the CPU.

Computer Programming module | PDF page 2 | lines 2-18

1. Introduction to programming Computer programming is the process of writing, testing, debugging/troubleshooting, and maintaining the source code of computer programs. Programs are the instructions that tells the computer what to do .so, writing computer programs means writing instructions, that will make the computer follow and run a program based on those instructions. We are going to write computer programs to solve problems. Problem Solving Problem: gap between the existing and the desired or proposed situation where problem solving will try to fill this gap. Problem solving: The process of transforming the description of a problem into the solution by using our knowledge of the problem-solving strategies, techniques and tools. Problem solving techniques • Analyze the problem: Carefully understand the problem • Outline the problem requirements • Does program require user interaction? • Does program manipulate data? • What is the output? • Design steps (algorithm) to solve the problem

Question sources

Computer Science Exit Exam practice collection · Question 92

Question 168 | NS0278

What is the difference between a compiler and an interpreter? Which is Java?

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer: Compilers translate representations; interpreters execute them. Java uses bytecode compilation and JVM interpretation/JIT.

CP04 says javac produces bytecode, then a JVM interprets or compiles it at runtime. A compiler translates rather than necessarily producing a complete native executable, while an interpreter executes a program representation. Java therefore cannot be reduced to exclusively compiled or interpreted.

Primary note proof

Study-note section CP04

> In the conventional C++ toolchain: source → preprocessing → compilation proper → assembly → object files → linking → executable → loading → execution. Preprocessing handles directives such as #include; compilation may emit assembly; the assembler emits machine instructions in an object file. The linker resolves external symbols and combines object files and libraries. The loader places an executable and required components in memory and starts it.

Study-note section CP04

> GCC documents the first four stages explicitly. A compiler need not emit a complete executable or even native machine code. Java javac produces bytecode, which a JVM interprets or compiles at runtime. Interpreters execute a program representation; “one source line at a time” is a beginner approximation. Compilation uses multiple passes, so “whole program in one step” is not literally universal.

Computer Programming review questions · Question 1

Question 169 | NS0279

What is the difference between = (assignment) and == (comparison)? Why is this a common mistake?

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer: = assigns a value; == compares values for equality.

CP06 describes assignment as replacing a variable's value; CP10 describes equality as a value test. Confusing them can change state instead of testing it. In C++ a numeric assigned result can also convert to a condition, allowing an unintended assignment to alter control flow.

Primary note proof

Study-note section CP-S05

> In C++, simple assignment changes its left-hand object, and the assignment expression refers to that updated object. When an ordinary numeric assignment is used as a condition, the newly assigned value is converted to truth: zero is false and nonzero is true. Equality testing with == instead produces a Boolean result without assigning either operand. Confusing the two can both change program state and choose an unintended branch.

Study-note section CP10

> Relational and equality operators test values; && and || combine truth values; ! negates. In C++, zero converts to false and a nonzero number to true. Streams display bool as 0 or 1 unless boolalpha is set. With a=3,b=5, cout<<(a==b) prints 0.

Question sources

Computer Programming review questions · Question 2

Question 170 | NS0280

What is the difference between while and do-while loops? When would you use do-while?

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer: while tests first; do-while runs once before testing. Use do-while for a mandatory first menu/input attempt.

CP14 allows a while body to execute zero times because its condition is checked first. A do-while body executes before its first check, making it suitable for a menu or input attempt that must happen at least once.

Primary note proof

Study-note section CP14

> while(condition) checks before each body execution and may run zero times. do {body;} while(condition); runs the body once before checking; it repeats while the condition remains true. Use it when a menu or input attempt must occur at least once.

Question sources

Computer Programming review questions · Question 3

Question 171 | NS0281

What happens if you try to access array index array[5] when the array has 5 elements (indices 0-4)?

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer: Index 5 is out of bounds: Java throws; C++ access has undefined behavior.

Five elements occupy indices 0 through 4, so array[5] is outside the array. CP22 distinguishes Java's bounds exception from C++ undefined behavior; an adjacent-memory value must not be guessed. The question does not specify a language, so both consequences are stated.

Primary note proof

Study-note section CP22

> A built-in C++ array has a fixed number of same-type elements in contiguous storage: int a[4]={10,20,30,40};. Valid indices are 0 through 3. a[4] is outside the array; accessing it has undefined behavior. Java checks bounds and throws ArrayIndexOutOfBoundsException. Do not predict a C++ out-of-range value from nearby memory.

Question sources

Computer Programming review questions · Question 4

Question 172 | NS0282

Why do we use functions? What are the benefits?

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer: Functions decompose named tasks, enable reuse, reduce duplication and simplify understanding/testing.

CP17 defines a function as grouping a named task and explains that reuse reduces duplication while independent functions are easier to understand and test. Decomposition localizes responsibilities and supports maintenance through those clearer units.

Primary note proof

Study-note section CP17

> A function groups a named task. C++ definition: int add(int a,int b){return a+b;}. Call it with add(x,y);, without parameter type declarations at the call site. Parameters are names in the definition; arguments are supplied expressions or values. A void function produces no return value but can have side effects and return; to exit early.

Question sources

Computer Programming review questions · Question 5

Question 173 | NS0283

What is the difference between pass-by-value and pass-by-reference?

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer: C++ value parameters copy; reference parameters alias caller variables. Java passes copied values, including references.

CP18 makes a value parameter a separate initialized object, while int& aliases the caller variable and can change it directly. Passing a pointer copies an address and can change its target without rebinding the caller's pointer. Java copies object references by value.

Primary note proof

Study-note section CP18

> A C++ value parameter is a separate object initialized from the argument. In func(int a,int b){a*=5;b+=5;return a+b;}, calling func(9,3) returns 53 and leaves the caller values 9 and 3 unchanged.

Study-note section CP18

> An int& parameter aliases the caller variable, so swap(int& a,int& b) changes both originals. An int* parameter copies an address; *p=value changes the pointed-to object, but p=anotherAddress only changes the local pointer. An array parameter int a[] is adjusted to int*: elements can change, and the length must be passed separately. Java always passes by value, including a copy of an object reference; it does not pass caller variables by reference.

Question sources

Computer Programming review questions · Question 6

Question 174 | NS0301

What does this C++ fragment print? Assume cout is available.

```
int a=6,b=8;
int x=2,y=4;
int c(x>y ? (a--,x) : (b--,y));
cout<<"a="<<a;
cout<<" b="<<b;
cout<<" c="<<c;
```

A. a=6 b=5 c=4

B. a=6 b=7 c=5

C. a=8 b=6 c=5

D. a=6 b=7 c=4

Hint

Trace the initial state and each executed operation in order, preserving the requested output layout.

Answer D: D. a=6 b=7 c=4

The condition x>y compares 2 with 4 and is false. Only the false branch is evaluated. Its comma expression first decrements b from 8 to 7 and then yields y, which is 4, for initializing c. The true branch does not execute, so a remains 6. With valid stream spelling, comma operators and ordinary string delimiters, the output is a=6 b=7 c=4.

Why each choice is right or wrong

A - Incorrect: b decreases once from 8 to 7, not to 5.

B - Incorrect: The comma expression yields y=4, not 5.

C - Incorrect: The false branch leaves a=6 and produces b=7,c=4.

D - Correct: Only b decrements; the branch yields y=4 and a remains 6.

Primary note proof

Study-note section CP11

> condition ? yes : no evaluates the condition and exactly one alternative. The comma operator evaluates its left expression, then its right, and yields the right value. Do not confuse it with commas separating function arguments.

Study-note section CP09

> Prefix ++x changes x and yields the new value; postfix x++ yields the previous value and also increments x. Separate the value used in the expression from the stored value after it. Starting a=8,b=5, a++ + --b uses 8+4, gives 12, and leaves a=9,b=4. Starting x=1,y=10,z=-3, (x++*y--)+ ++z gives 8 and leaves x=2,y=9,z=-2.

Question sources

Computer Science Exit Exam · 2018 · Question 19

Question 175 | NS0325

Assume that you are computer science expert and you need to develop large programs within short period of time. Finally, you have planned to provide portable program to the concerned body. Which type of programming language is preferable for the above scenario?

A. Low level

B. Machine level

C. High level

D. Assembly

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer C: A high-level language, with portability constraints checked.

CP03 says high-level source is easier to read and often portable after recompilation if platform assumptions are avoided. That fits rapid development of a large program and a portable result better than instruction-set-dependent machine or assembly code. Portability remains conditional on the target environment; the answer is a preference, not an unconditional guarantee.

Why each choice is right or wrong

A - Incorrect: Low-level code retains instruction-set details and does not best match the stated readability/development and portability goals.

B - Incorrect: Machine-level code depends directly on the instruction set, opposing the requested portable-source preference.

C - Correct: High-level source offers the note's readability and conditional portability advantages for the stated scenario.

D - Incorrect: Assembly depends on the instruction set and is not the preferred abstraction for these development goals.

Primary note proof

Study-note section CP03

> Machine and assembly code depend on an instruction set. High-level source is easier to read and often portable after recompilation, provided it avoids platform assumptions. People can write both assembly and high-level programs. Python, Perl and PHP are commonly called scripting languages; C++ is conventionally compiled. These labels describe common use, not an absolute technical prohibition.

Question sources

Computer Science Exit Exam · 2018 · Question 51

Question 176 | NS0346

Which one of the following identifier name is INVALID in C++ programming language?

A. delete

B. for_cpp

C. jan2025

D. Hello

Hint

Apply the naming, type and syntax rules before deciding whether an option can be used as stated.

Answer A: delete is a reserved keyword.

delete is a C++ keyword and cannot be used as an ordinary identifier. for_cpp is not the keyword for, and jan2025 and Hello use letters followed only by permitted letters or digits.

Why each choice is right or wrong

A - Correct: delete is a reserved C++ keyword and therefore invalid as an ordinary identifier.

B - Incorrect: for_cpp is a distinct permitted name containing letters and underscore, rather than the keyword for.

C - Incorrect: jan2025 begins with a letter and contains only permitted letters and trailing digits.

D - Incorrect: Hello contains permitted letters and is not a reserved keyword identified by the question.

Primary note proof

Study-note section CP05

> In the basic ASCII identifier rules, start with a letter or underscore; continue with letters, digits or underscores. Do not use a keyword. C++ is case sensitive: exitExam and ExitExam differ; delete and float are keywords, but FLOAT is a legal identifier. variable_1234 is valid; 4thInput, T-3 and names containing spaces are not single identifiers. Avoid reserved underscore patterns in application code.

Question sources

Computer Science Exit Exam · 2018 · Question 79

Question 177 | NS0358

Which of the following statement about function overloading is TRUE?

A. Overload function have same name but different parameters/type

B. Overload function is not supported

C. Overload function must have different return type

D. Overload function must have the same number of parameters

Hint

Use the cited language rules to separate the purpose of each construct from its implementation details.

Answer A: Overloads share a name and differ in their parameter lists.

CP19 requires a shared name with differences in parameter count or types/order. A states that relationship. Return type alone does not distinguish overloads, and neither different return types nor equal parameter counts are mandatory. Thus the other statements either deny supported overloading or impose restrictions contradicted here.

Why each choice is right or wrong

A - Correct: This states the shared-name and differing-parameter-list relationship required by CP19.

B - Incorrect: CP19 explicitly describes supported C++ function overloading, contradicting this blanket denial.

C - Incorrect: Different return types are not required and return type alone cannot distinguish overloads.

D - Incorrect: Parameter count may differ between overloads, so equal counts are not mandatory.

Primary note proof

Study-note section CP19

> Overloads share a name but differ in parameter count or types/order. Return type alone cannot distinguish them. Choose a candidate using argument types, then required conversions; report ambiguity if there is no unique best match. int sum(int x,int y,int z=0) allows two or three arguments; defaults occupy trailing positions in ordinary declarations.

Fundamental of Database Systems

Questions & Worked Answers

226 questions + 2 source variants

Question 1 | Q00021

Which one of the following is not correct when mapping ER diagrams to relational tables?

A. Multi-valued attributes are mapped to new tables

B. Foreign key are used to map relationships to create relation between tables

C. Table names are directly mapped from entity names

D. Composite attribute are mapped as it is

Hint

Apply the ER mapping rule for the given attribute or entity type.

Answer D: Composite attribute are mapped as it is

Atomic relational values exclude storing an undecomposed composite attribute. Relation names need not differ from entity names.

Why each choice is right or wrong

A - Incorrect: Multivalues are separated to remove repeating groups (PDF 12, 17.)

B - Incorrect: Foreign-key mapping is explicitly described (PDF 12, 17.)

C - Incorrect: Naming a relation after its entity is compatible with the mapping (PDF 12, 17.)

D - Correct: Keeping a composite value unchanged violates atomicity (PDF 12, 17.)

Primary note proof

Study-note section FDB10

> Create one relation per strong entity type, preserve its simple attributes and select a candidate key. Expand composite attributes into their useful simple components; do not copy a composite ER structure unchanged into a flat atomic design. Derived values can usually be calculated, avoiding stale stored copies.

Study-note section FDB10

> Table names may follow entity names; naming does not invalidate a mapping.

Study-note section FDB10

> Map each multivalued attribute to a separate relation containing the owner key and one value.

Related reading (context, not primary note proof)

Study-note section FDB11

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 12 | lines 9-24

> 1. For each strong entity type E, create a relation R that includes all the attributes of E. 2. Choose one of the key attributes of E as the primary key for R. For each weak entity type W with owner entity type E (which is a strong entity), create a relation R & include all attributes of _W‘ as attributes of R. Also, include the primary key attribute of the relation that correspond to the owner entity type as foreign key attributes of R . 3. For each binary 1:1 relationship type R in the ER schema, identify the relations S and T that correspond to the entity types participating in R. Foreign Key approach: Choose one of the relations-say S-and include a foreign key in S the primary key of T. It is better to choose an entity type with total participation in R in the role of S. 4. For each binary 1:N relationship type R, identify the relation S that represent the participating entity type at the N-side of the relationship type. Include the primary key of the relation T as foreign key in S that represents the other entity type participating in R. Include any attributes of the 1:N relation type as attributes of S. 5. For each n-ary relationship type R, where n>2, create a new relationship S to represent R. Include the primary keys of the relations that represent the participating entity types as foreign key attributes in S. Also include any attributes of the n-ary relationship type as attributes of S.

Fundamental of Database Systems module | PDF page 17 | lines 2-9

> First normal form (1NF) A relation (table) R is in 1NF if and only if (iff) all underlying domains of attributes contain only atomic (simple or indivisible) values. i.e. The value of any attribute in a tuple (row) must be a single value from the domain of their attribute. It is defined to disallow multivalued attributes, composite attributes, and their combinations. In other words, 1NF disallows relations within relations or relations as attribute values within tuples. It must be remove repeating groups (values) in a single field. The primary key with repeating group attributes are moved into a new table. When a relation contains no repeating groups (values), it is in first normal form (1NF).

MOE Computer Science Exit Exam · 2016 · Question 21

Question 2 | Q00038

In DBMS-independent logical relational design, before vendor-specific refinement, which statement is NOT correct?

A. It consider a particular DBMS

B. Normalization is undertaken in logical phase

C. It is based on specific data model

D. It is independent from physical considerations

Hint

Identify the design phase from its inputs and intended deliverable.

Answer A: A. It consider a particular DBMS

Logical design maps the conceptual model into relations, keys and constraints and checks normalization. It therefore uses a particular data model while separating storage decisions from logical structure. Under the stated DBMS-independent methodology, considering a particular vendor's DBMS is the false claim. Normalization, a chosen model and independence from physical storage are all consistent with this phase.

Why each choice is right or wrong

A - Correct: False in the stated phase: particular-DBMS implementation choices are deferred.

B - Incorrect: True: normalization checks the mapped relations.

C - Incorrect: True: relational logical design uses a specific data model.

D - Incorrect: True: file layouts and indexes belong to physical design.

Primary note proof

Study-note section FDB05

> First collect business facts, required transactions, reports, volumes, privacy rules and quality targets. Conceptual design turns them into an ER/EER model. Logical design maps the conceptual model to relations, keys and constraints and checks normalization. Physical design chooses file organization, indexes and storage. Implementation creates and loads the actual objects; testing checks requirements.

Study-note section FDB05

> Whether logical design is DBMS-dependent depends on the stated design methodology.

Study-note section FDB05

> Logical relational design is tied to a data model but can remain independent of a particular DBMS.

MOE Computer Science Exit Exam · 2016 · Question 38

Question 3 | Q00040

Which SQL command would you use if you want to specify constraints to be applied on tuples?

A. GRANT

B. SELECT

C. REVOKE

D. CHECK

Hint

Read each SQL constraint's scope and enforcement rule.

Answer D: CHECK

CHECK verifies criteria on attribute values within rows; GRANT and REVOKE control permission, and SELECT retrieves data.

Why each choice is right or wrong

A - Incorrect: Permission grant is not a tuple predicate (PDF 49, 54.)

B - Incorrect: Retrieval is not constraint specification (PDF 49, 54.)

C - Incorrect: Permission removal is not a tuple predicate (PDF 49, 54.)

D - Correct: CHECK is explicitly shown verifying criteria (PDF 49, 54.)

Primary note proof

Study-note section FDB16

> Example: CREATE TABLE Enrollment (StudentID INTEGER NOT NULL REFERENCES Student(StudentID), CourseID INTEGER NOT NULL REFERENCES Course(CourseID), Grade INTEGER CHECK (Grade BETWEEN 0 AND 100), PRIMARY KEY (StudentID,CourseID)); Each column declaration gives its name then type, with commas between declarations. CHECK is a constraint clause, not a standalone GRANT-like statement. POSITIVE is not a general SQL constraint keyword; CHECK (Amount > 0) expresses positivity.

Study-note section FDB16

> A CHECK can pass when its result is unknown, so add NOT NULL if missing values must be forbidden.

Study-note section FDB26

> DML retrieves or changes data: SELECT, INSERT, UPDATE, DELETE.

● CREATE TABLE table-name (attr2 attr-type NOT NULL, forbids NULL values attrN attr-type CHECK (attrN = UPPER(attrN) verifies that the data meets certain criteria attrO attr-type DEFAULT default_value); Supplies default values

Fundamental of Database Systems module | PDF page 54 | lines 6-18

2.2.3 Authorization Rules ● Most current DBMS permit the DBA to define —access permissions‖ on a table by table basis (at least) using the GRANT and REVOKE SQL commands ● Some systems permit finer grained authorization (most use GRANT and REVOKE on variant views 2.2.4 Privileges in SQL GRANT <privileges> ON <object> TO <users> [WITH GRANT OPTION] • <privileges> is a list of SELECT <columns>, INSERT <columns>, DELETE, and UPDATE <columns>, or simply ALL

Fundamental of Database Systems module | PDF page 26 | lines 10-11

7.1.2 DML (data manipulation language) Basic DDL commands are: SELECT, PROJECT, JOIN, INSERT, DELETE, and UPDATE

Question sources

MOE Computer Science Exit Exam · 2016 · Question 40

Question 4 | Q00041

Which data management approach allows application programs to define and manage their own data?

A. Manual approach

B. Database approach

C. Hierarchical approach

D. Traditional file based approach

Hint

Review the database approach and match each claimed benefit or cost to its mechanism.

Answer D: Traditional file based approach

The file approach lacks the database approach separation between programs and data; application-owned data corresponds to traditional file processing. B reverses that distinction.

Why each choice is right or wrong

A - Incorrect: Manual records do not describe application-owned files (PDF 5, 6.)

B - Incorrect: Program/data insulation contradicts the stem (PDF 5, 6.)

C - Incorrect: Hierarchical is a model rather than this processing distinction (PDF 5, 6.)

D - Correct: Traditional file processing matches the contrast (PDF 5, 6.)

Primary note proof

Study-note section FDB01

A database is a coherent collection of related facts with meaning for an application. A DBMS is software that defines, stores, retrieves, updates, protects and shares that data. The database is the content; the DBMS manages it. A database system also includes applications, people and infrastructure.

Study-note section FDB01

Traditional file applications define their own formats and access procedures.

Study-note section FDB04

Data abstraction hides irrelevant details; program-data insulation separates data definitions from application code.

Related reading (context, not primary note proof)

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 5 | lines 17-25

1.2 Database System versus File System The traditional file processing system is file-directory structure supported by a conventional operating system. A file system organization of data lucks a number of major features of a database system, such as Data redundancy and inconsistency, Difficulty in accessing data, Data isolation, Integrity problems, Atomicity problems, Concurrent access anomalies. 1.3 Characteristics of the Database Approach The main characteristics of the database approach are Self-describing nature, Data abstraction and Insulation between programs and data, Support of multiple views of the data, sharing of data and multiuser transaction processing.

Fundamental of Database Systems module | PDF page 6 | lines 2-4

Data abstraction and Insulation between programs and data- Data Abstraction is a process of hiding unwanted or irrelevant details from the end user. It provides a different view and helps in achieving data independence which is used to enhance the security of data.

Question sources

MOE Computer Science Exit Exam · 2016 · Question 41

Question 5 | Q00043

Which database constraints are specified in the data definition language?

A. Implicit or inherent model based constraints

B. Semantic constraints

C. Application based constraints

D. Schema based constraints

Hint

Match the validity requirement to the appropriate constraint definition.

Answer D: Schema-based constraints.

The question asks how constraints are specified, rather than which business meaning they express. FDB15 distinguishes constraints inherent in a data model from constraints explicitly declared in schema DDL. That second category is schema-based. Semantic or application rules may require triggers or application code when ordinary DDL cannot express them.

Why each choice is right or wrong

A - Incorrect: Inherent model constraints follow from the data model rather than explicit schema declarations.

B - Incorrect: Semantic rules express application meaning and may exceed what ordinary schema DDL can enforce.

C - Incorrect: Application-based constraints may require program logic rather than declarations in the database definition.

D - Correct: Schema-based constraints are explicitly specified in data definition language declarations.

Primary note proof

Study-note section FDB15

> Inherent constraints come from the data model; schema-based constraints are declared through the DDL; semantic/application rules may need triggers or application logic when DDL cannot express them. Integrity improves data validity; authorization controls who may access it. Uniqueness and domain validation are both integrity mechanisms. If a Department primary key is NULL and Manager=107 lacks a referenced employee, entity integrity certainly fails and referential integrity also fails if that foreign key is declared. One INSERT can violate multiple constraints.

Question sources

MOE Computer Science Exit Exam · 2016 · Question 43

Question 6 | Q00080

Which SQL command removes an existing relation's table object, including its definition?

A. Delete

B. Drop

C. Remove

D. UPDATE

Hint

Classify each SQL command by the kind of change it performs.

Answer B: B. Drop

Removing a relation object means removing its definition as well as its contents. DROP TABLE performs that operation. DELETE affects rows while retaining the table, and UPDATE changes values within rows. REMOVE is not the SQL table-removal command. The distinction is between schema removal and operations on data in an existing schema.

Why each choice is right or wrong

A - Incorrect: DELETE removes rows and retains the table definition.

B - Correct: DROP TABLE removes the table object and its definition.

C - Incorrect: REMOVE is not the SQL command for dropping a table.

D - Incorrect: UPDATE changes existing row values.

Primary note proof

Study-note section FDB26

> DELETE removes rows and keeps the table; DROP TABLE removes the table object; ALTER changes its definition. TRUNCATE empties a table using implementation-specific mechanisms. PostgreSQL allows transactional rollback of TRUNCATE, so no rollback information is retained is not a universal SQL property. SQL Server permits DROP DATABASE Sales, suppliers; that comma-list syntax is vendor-specific. SQLite's .databases lists attached names/files in its command-line shell; .database is not the documented command.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 26 | lines 8-9

> Basic DDL commands we usually use are: CREATE, DROP, ALTER, TRUNCATE and RENAME

Fundamental of Database Systems module | PDF page 26 | lines 11-11

> Basic DDL commands are: SELECT, PROJECT, JOIN, INSERT, DELETE, and UPDATE

MOE Computer Science Exit Exam · 2016 · Question 80

Question 7 | Q00106

Which of the following statement best describe relational data model?

A. It is a database model that allows multiple records to be linked to the same owner file.

B. It structures data in a tree like structure using parent to child relationship.

C. It is a database model to manage data as tuples grouped into relations

D. It is a model that use concepts such as entities, attributes, and relationships

E. Describe how data is stored in the computer, representing information such as record structures, record ordering, and access paths.

Hint

Compare the data models by how they organize records and relationships.

Answer C: It is a database model to manage data as tuples grouped into relations

A relational database consists of relations with tuple rows and attribute columns.

Why each choice is right or wrong

A - Incorrect: Owner-file links do not define tuple relations (PDF 13, 7.)

B - Incorrect: A tree is not the stated relational representation (PDF 13, 7.)

C - Correct: Tuple rows in relations match the definition (PDF 13, 7.)

D - Incorrect: Entities and relationships describe conceptual ER modeling (PDF 13, 7.)

E - Incorrect: Storage details define the physical model (PDF 13, 7.)

Primary note proof

Study-note section FDB02

> A data model supplies concepts for structure, relationships, constraints and operations. Conceptual ER models describe entities and relationships. Relational models use tables; hierarchical models organize records in a parent-child tree; classic network models connect records through pointer-based owner/member links, allowing multiple parents. Object models represent objects with identity, state and behavior. A physical model specifies record layouts and access paths. These are different representation choices, not stages of one query.

Study-note section FDB03

> Degree counts columns; cardinality counts rows.

Study-note section FDB03

> A tuple/row/record contains related attribute values; an attribute/column/field describes a property.

> 2. Low-level or physical data models provide concepts that describe the details of how data is stored on the computer storage media. Concepts provided by physical data models are generally meant

Question sources

Addis Ababa University mock exam · Question 8

Question 8 | Q00107

Department(Dept_Name, Manager) has primary key Dept_Name and foreign key Manager referencing Employee(Emp_ID). Employee contains IDs 101-105 only. Consider INSERT INTO Department (Dept_Name, Manager) VALUES (NULL, 107); Which named integrity rules are violated? Select all that apply. Treat key integrity as uniqueness and domain integrity as type/allowed-value checks.

A. Domain constraint

B. Key constraint

C. Entity Integrity constraint

D. Referential Integrity constraint

Hint

Match the validity requirement to the appropriate constraint definition.

Answer C, D: C. Entity Integrity constraint; D. Referential Integrity constraint

The inserted row has two independent defects. Dept_Name is the primary key, so NULL violates entity integrity. Manager is a non-NULL foreign key, yet employee 107 is absent, violating referential integrity. These are separate requirements and the same insertion fails both. Under the question's taxonomy, neither a duplicate-key violation nor an incompatible-domain value is being asserted.

Why each choice is right or wrong

A - Incorrect: The stated domain checks are satisfied; primary-key NULL is classified separately.

B - Incorrect: No duplicate key value is inserted; this category tests uniqueness.

C - Correct: NULL in the primary key violates entity integrity.

D - Correct: Manager 107 has no referenced employee and violates referential integrity.

Primary note proof

Study-note section FDB15

> Domain integrity restricts type and allowed values. Key integrity enforces uniqueness. Entity integrity requires every primary-key component to be non-NULL. Referential integrity requires a non-NULL foreign-key value to match an eligible referenced unique/candidate key; self-references are allowed. A parent need not have a child.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

> • A —foreign key‖ links each occurrence in a relation representing a child entity to the occurrence of the parent entity containing the matching candidate (usually primary) key

Question sources

Addis Ababa University mock exam · Question 9

Question 9 | Q00108

Assume atomic attribute values. Consider R(A,B,C,D) with functional dependencies F = {C→D, C→B, B→C}. Which statement about R is true?

A. The relation R is in second normal form

B. The relation R is in third normal form

C. The candidate key for R is BC

D. The relation R is in Boyce-Codd normal form

E. None of the other statements is true

Hint

Derive every candidate key before testing dependency-based normal forms.

Answer E: None of the other statements is true

Every candidate key must contain A because no dependency derives it. Both AB and AC determine all attributes and are minimal; BC determines only B, C and D. The nonprime attribute D depends on B or C alone, a proper subset of either composite key, so 2NF fails. The dependency C→D also violates 3NF and BCNF because C is not a superkey and D is nonprime. None of the other statements is true.

Why each choice is right or wrong

A - Incorrect: False: D depends on a proper subset of a candidate key, violating 2NF.

B - Incorrect: False: C→D has a nonsuperkey determinant and a nonprime dependent attribute, violating 3NF.

C - Incorrect: False: $(BC)^+ = \{B,C,D\}$, so BC cannot determine A and is not a key.

D - Incorrect: False: C determines D but is not a superkey, violating BCNF.

E - Correct: Correct: each of the other four claims is false.

Primary note proof

Study-note section FDB18

> For R(A,B,C,D), let C→D, C→B and B→C. A never appears on a right-hand side, so every key needs A. $(AB)^+$ gives ABCD through B→C→D; $(AC)^+$ also gives ABCD. AB and AC are minimal keys. BC cannot derive A and is not a key. A, B and C are prime; D is nonprime.

Study-note section FDB20

> 2NF requires 1NF and no nonprime attribute partially dependent on any candidate key.

Study-note section FDB21

> For every nontrivial FD X→A, 3NF permits it when X is a superkey or A is prime. BCNF requires X to be a superkey.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 15 | lines 5-17

> A functional dependency is a constraint between two attributes or sets of attributes of entities in a database. A functional dependency is denoted by X → Y, between two sets of attributes X and Y that are subsets of relation R. The constraint is that, the values of Y component of a tuple in r depend on, or are determined by the values of X component. Alternatively, the values of X component of a tuple uniquely (or functionally) determine the values of Y component. 4.2 Types of Functional Dependency Partial Dependency - If an attribute which is not a member of the key is dependent on some part of the key (if we have composite/candidate key) then that attribute is partially functionally dependent on the key. Let {A, B} is the key set and C is no key attribute, then if {A, B} → C and [B → C or A → C] holds. We say C is partially functionally dependent on {A, B}. Partial dependency occurs when a non-prime attribute is functionally dependent on part of a candidate/composite key.

Fundamental of Database Systems module | PDF page 17 | lines 10-15

> Second normal form (2NF) Second normal form (2NF) is based on the concept of full functional dependency. A relation schema R is in 2NF if it is in 1NF and every non-prime attribute A in R is fully functionally dependent on the primary key (i.e. the non-prime attributes are not partially dependent on key attributes). Remove any partially dependent attributes and place them in another relation. A partial dependency is when the attribute(s) is/are dependent on a part of a key.

Fundamental of Database Systems module | PDF page 18 | lines 5-8

> Third Normal Form (3NF) A relation schema R is in third normal form (3NF) if it is in 2NF and every non-prime attribute of _R‘ are fully functionally dependent on every key of R and non-transitively dependent on every key of R.

Question sources

Addis Ababa University mock exam · Question 10

Question 10 | Q00109

Which schema of the three-schema Architecture describe the structure of the whole database?

A. Internal schema

B. Conceptual schema

C. External schema

D. schema

Hint

Trace which schema levels a proposed change affects.

Answer B: Conceptual schema

The conceptual schema describes the whole database while internal describes storage and external describes each user view.

Why each choice is right or wrong

A - Incorrect: Internal covers physical storage (PDF 8.)

B - Correct: Conceptual explicitly covers the whole database (PDF 8.)

C - Incorrect: External covers a user subset (PDF 8.)

D - Incorrect: Generic schema does not identify the required level (PDF 8.)

Primary note proof

Study-note section FDB04

> The external level gives each user group a selected view. The conceptual level describes the whole logical database: entity types, relationships, data types and constraints. The

internal/physical level describes files, record placement and access paths. These are abstraction levels, distinct from client/server deployment tiers.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 7 | lines 25-30

2.3 Three-schema Architecture and Data Independence The goal of the three-schema architecture is to separate the user applications from the physical database. In this architecture, schemas can be defined at the following three levels: 1. The internal level has an internal schema, which describes the physical storage structure of the database. The internal schema uses a physical data model and describes the complete details of data storage and access paths for the database.

Fundamental of Database Systems module | PDF page 8 | lines 2-7

2. The conceptual level has a conceptual schema, which describes the structure of the whole database for users. The conceptual schema hides the details of physical storage structures and concentrates on describing entities, data types, relationships, user operations, and constraints. 3. The external or view level includes a number of external schemas or user views. Each external schema describes the part of the database that a particular user group is interested in and hides the rest of the database from that user group.

Question sources

Addis Ababa University mock exam · Question 11

Question 11 | Q00110

Which of the following is the disadvantage of a database approach?

A. Data consistency

B. Sharing of data

C. Improved data integrity

D. Increased concurrency

E. Enforcement of standards

F. Complexity

G. None

Hint

Review the database approach and match each claimed benefit or cost to its mechanism.

Answer F: Complexity is a database-approach disadvantage.

FDB01 identifies complexity and administration costs as possible disadvantages of a DBMS. Consistency, sharing, integrity and centrally supported standards are benefits. Increased concurrency means useful concurrent access here; only uncontrolled concurrent access causes anomalies. Thus complexity is the sole listed disadvantage, even though database management can improve the other listed properties.

Why each choice is right or wrong

A - Incorrect: Data consistency is improved by shared definitions and controlled updates, making it a benefit.

B - Incorrect: Sharing data is a purpose and benefit of the database approach.

C - Incorrect: Improved integrity means better enforcement of valid data and is a benefit.

D - Incorrect: Concurrent access is useful; uncontrolled interference, rather than increased concurrency itself, causes problems.

E - Incorrect: Central management supports consistent definitions and standards, which is a benefit.

F - Correct: A DBMS introduces administrative and technical complexity that can outweigh benefits for small applications.

G - Incorrect: A listed disadvantage exists: the complexity of database management.

Primary note proof

Study-note section FDB01

> A database is a coherent collection of related facts with meaning for an application. A DBMS is software that defines, stores, retrieves, updates, protects and shares that data. The database is the content; the DBMS manages it. A database system also includes applications, people and infrastructure.

Study-note section FDB01

> Concurrent access itself is useful; uncontrolled concurrent access causes anomalies.

Study-note section FDB01

> Separate files can repeat facts, disagree after updates, isolate useful data and make shared integrity or concurrent updates difficult.

Question sources

Addis Ababa University mock exam · Question 12

Question 12 | Q00111

Which of the following is a correct statement about relation? (Choose all that applies)

A. Values of each columns is a repeating group/array

B. Values in a column can be from different domain

C. A relation is in the INF

D. Two rows in a relational table can be identical

E. The sequence of columns and rows is insignificant

F. None

Hint

Distinguish a relation's structure from its current contents and its descriptive metadata.

Answer C, E: A relation is in the INF; The sequence of columns and rows is insignificant

Read INF as 1NF. Relations have atomic cells rather than repeating groups; the relational representation is independent of tuple sequence. The column sequence likewise does not alter named attributes. Distinct tuples and typed attribute domains rule out A,B,D.

Why each choice is right or wrong

A - Incorrect: Repeating arrays violate atomicity (PDF 14, 17.)

B - Incorrect: An attribute has a constrained domain (PDF 14, 17.)

C - Correct: Atomic relation values satisfy 1NF (PDF 14, 17.)

D - Incorrect: Duplicate tuples conflict with relation uniqueness (PDF 14, 17.)

E - Correct: Presentation order does not change named tuple values (PDF 14, 17.)

F - Incorrect: C and E already supply valid statements (PDF 14, 17.)

Primary note proof

Study-note section FDB03

A relation is a set of tuples, represented as a table. A tuple/row/record contains related attribute values; an attribute/column/field describes a property. Degree counts columns; cardinality counts rows. Classical relations have distinct tuples, atomic cells and domains for attributes; row order has no meaning. Column order has no logical meaning when attributes are identified by name. SQL tables can contain duplicate rows unless constrained.

Study-note section FDB20

1NF requires atomic values in the chosen relational domains and no repeating groups in cells.

Study-note section FDB20

A mapped ER design that correctly splits composite and multivalued structures gives ordinary 1NF tables; ER drawing alone guarantees no higher form.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 14 | lines 4-20

Properties of Relations • Name of the relation is distinct from all other relations. • Each relation cell contains exactly one atomic (single) value. • Each attribute contains a distinct name. • Each tuple has no duplicate value. • Order of tuple can have a different sequence. 3.8 Relational Constraints Relational constraints in DBMS are referred to conditions which must be present for a valid relation. These Relational constraints in DBMS are derived from the rules in the system that the database represents. There are many types of Constraints in DBMS. Domain Constraints - Every domain (cell in the table or attribute value) must contain atomic values (smallest indivisible units). We perform data type check here, which means we need to assign a data type to a column and limit the values that it can contain. Key Constraints- These are called uniqueness constraints since it ensures that every tuple in the relation should be unique. An attribute that can uniquely identify a tuple in a relation is called the key or primary key of the table. The value of the attribute for different tuples in the relation has to be unique. Primary keys must be unique and cannot be null.

Fundamental of Database Systems module | PDF page 17 | lines 2-9

First normal form (1NF) A relation (table) R is in 1NF if and only if (iff) all underlying domains of attributes contain only atomic (simple or indivisible) values. i.e. The value of any attribute in a tuple (row) must be a single value from the domain of their attribute. It is defined to disallow multivalued attributes, composite attributes, and their combinations. In other words, 1NF disallows relations within relations or relations as attribute values within tuples. It must be remove repeating groups (values) in a single field. The primary key with repeating group attributes are moved into a new table. When a relation contains no repeating groups (values), it is in first normal form (1NF).

Question sources

Addis Ababa University mock exam · Question 13

Question 13 | Q00112

Which of the following statement is correct about executing the following SQL query on the employee database given in question 2? (Choose all that applies)
SELECT Emp_ID, First_Name, Last_Name
FROM Employee E, Department D
WHERE Department <> Sales' and AVG (salary) > 35000 and
E.Department=D.Dept_Name
GROUP BY Department;

A. the query will execute successfully and will obtain all departments with an average salary higher than 35,000

B. the query will not execute because Department attribute in Group by statement was not included in the select statement list

C. the query will not execute because we can't include aggregate function in the where statement

D. the query will execute successfully and will obtain employees of all departments with an average salary higher than 35,000

Hint

Apply grouping before filtering groups and computing aggregate output.

Answer C: AVG(salary) cannot be used directly in WHERE.

The query places AVG(salary) > 35000 in WHERE. FDB32 requires ordinary aggregate predicates in HAVING. Omitting Department from SELECT is not itself an error. Selecting ungrouped employee details is another defect unless functional dependence is established. The query therefore does not successfully produce either claimed result.

Why each choice is right or wrong

A - Incorrect: The aggregate predicate in WHERE prevents this query from successfully producing department averages.

B - Incorrect: A grouping column need not appear in SELECT; that omission is not the stated error.

C - Correct: WHERE filters individual rows before grouping, so the ordinary AVG predicate belongs in HAVING.

D - Incorrect: The invalid aggregate predicate prevents execution; employee columns also require valid grouping or functional dependence.

Primary note proof

Study-note section FDB32

> COUNT(*) counts rows, COUNT(x) counts non-NULL x values; SUM and AVG summarize non-NULL numeric values. SQL's usual average function is AVG, not AVERAGE. GROUP BY creates one group per distinct grouping value; HAVING tests aggregate groups after WHERE has filtered individual rows.

Study-note section FDB32

> The grouping column need not itself appear in SELECT; check the functional dependence of other selected columns.

Study-note section FDB32

> SELECT Department, AVG(Salary) FROM Employee WHERE Department <> 'Sales' GROUP BY Department HAVING AVG(Salary) > 35000; lists qualifying department averages.

Question sources

Addis Ababa University mock exam · Question 14

Question 14 | Q00219

Which of the following keys is generally used to represent the relationships between the tables?

A. None of the choices is correct

B. Secondary key

C. Primary key

D. Foreign key

Hint

Match the validity requirement to the appropriate constraint definition.

Answer D: Foreign key

A foreign key is the child-side reference linking to an existing parent candidate key.

Why each choice is right or wrong

A - Incorrect: A named key does supply the link (PDF 48.)

B - Incorrect: Secondary key is not the child reference (PDF 48.)

C - Incorrect: Primary key is the target identifier (PDF 48.)

D - Correct: Foreign key is the explicit link (PDF 48.)

Primary note proof

Study-note section FDB15

Domain integrity restricts type and allowed values. Key integrity enforces uniqueness. Entity integrity requires every primary-key component to be non-NULL. Referential integrity requires a non-NULL foreign-key value to match an eligible referenced unique/candidate key; self-references are allowed. A parent need not have a child.

Study-note section FDB07

A primary key is one selected candidate key; remaining candidates are alternate keys.

Study-note section FDB25

Secondary indexes provide other access paths and must represent all searchable values with record pointers or pointer lists.

> 2. Low-level or physical data models provide concepts that describe the details of how data is stored on the computer storage media. Concepts provided by physical data models are generally meant

Question sources

Mock exam 4 · Question 22

Question 16 | Q00221

Which one of the following given statements possibly contains the error?

A. select empid where empid = 1009 and Lastname = 'ADDIS';

B. select empid from emp where empid = 10006;

C. select empid from emp;

D. select * from emp where empid = 10003;

Hint

Trace how SELECT forms its result columns and rows.

Answer A: The first SELECT is missing its FROM source.

The first query reads empid and Lastname but never names a table in FROM. FDB27 allows literal-only SELECT statements without FROM, but this statement is not literal-only. The other three statements include emp as their source and use ordinary valid selection syntax, assuming those table and column names exist.

Why each choice is right or wrong

A - Correct: It refers to table columns without a FROM clause identifying their source.

B - Incorrect: It selects empid from emp with a syntactically ordinary equality predicate.

C - Incorrect: It supplies emp as the table source and validly selects its empid column.

D - Incorrect: It supplies a table source, selects all columns, and filters by empid.

Primary note proof

Study-note section FDB27

> SELECT Name,Address FROM Customer; produces only those mailing-label fields. SELECT * selects all columns; DISTINCT removes duplicate result rows; AS supplies an alias; ALL permits duplicates and does not mean all columns. SQL normally preserves duplicates without DISTINCT. A query reading table columns needs an appropriate FROM source. A literal-only query such as SELECT 1 may legally omit FROM.

Study-note section FDB27

> SELECT alone normally reads without changing the database state.

Study-note section FDB27

> Typical written clause order is SELECT ... FROM ... WHERE ... GROUP BY ... HAVING ... ORDER BY ....

> Basic DDL commands are: SELECT, PROJECT, JOIN, INSERT, DELETE, and UPDATE

Question sources

Mock exam 4 · Question 23

Question 17 | Q00222

Which one of the following is a type of Data Manipulation Command?

A. Delete

B. Alter

C. All choices are correct

D. Create

Hint

Classify each SQL command by the kind of change it performs.

Answer A: Delete

DELETE is explicitly DML; ALTER and CREATE are DDL.

Why each choice is right or wrong

A - Correct: DELETE is in DML list (PDF 26, 26.)

B - Incorrect: ALTER is in DDL list (PDF 26, 26.)

C - Incorrect: Other choices include DDL (PDF 26, 26.)

D - Incorrect: CREATE is in DDL list (PDF 26, 26.)

Primary note proof

Study-note section FDB26

> DDL changes structure: CREATE, ALTER, DROP, commonly RENAME and TRUNCATE in textbook classifications. DML retrieves or changes data: SELECT, INSERT, UPDATE, DELETE. Some texts separate SELECT as DQL. DCL manages privileges through GRANT and REVOKE. TCL includes COMMIT, ROLLBACK and SAVEPOINT. Classify a statement by its effect, not its length.

> Basic DDL commands are: SELECT, PROJECT, JOIN, INSERT, DELETE, and UPDATE

Question sources

Mock exam 4 · Question 24

Question 18 | Q00223

Which one of the following refers to the "data about data"?

A. Warehouse

B. Directory

C. Sub Data

D. Meta Data

Hint

Distinguish a relation's structure from its current contents and its descriptive metadata.

Answer D: Meta Data

The description of database structure and constraints is metadata.

Why each choice is right or wrong

A - Incorrect: Warehouse is not this term (PDF 5.)

B - Incorrect: Directory is not this term (PDF 5.)

C - Incorrect: Sub Data is not this term (PDF 5.)

D - Correct: Meta-data describes the data structure (PDF 5.)

Primary note proof

Study-note section FDB03

> A schema describes names, structures and constraints; an instance, state or snapshot is the data at a particular time. Inserting a student changes the state, while adding a column changes the schema. Metadata is data describing data. The catalog or data dictionary records table definitions, types, constraints and often access privileges and optimizer statistics. A schema diagram draws tables and key references; labels such as database diagram can overlap.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

> description of the database structure and constraints. This information is called meta-data, and it describes the structure of the database.

Question sources

Mock exam 4 · Question 25

Question 19 | Q00298

A language that used to formulate the schema of database structure is_____.

A. Data Manipulation language

B. Data Definition Language

C. Transaction Control Language

D. Data Control Language

Hint

Classify each SQL command by the kind of change it performs.

Answer B: Data Definition Language

DDL supplies definitions, while DML handles data operations.

Why each choice is right or wrong

A - Incorrect: Manipulates contents (PDF 26.)

B - Correct: Defines database structure (PDF 26.)

C - Incorrect: Controls transactions (PDF 26.)

D - Incorrect: Controls privileges (PDF 26.)

Primary note proof

Study-note section FDB26

> DDL changes structure: CREATE, ALTER, DROP, commonly RENAME and TRUNCATE in textbook classifications. DML retrieves or changes data: SELECT, INSERT, UPDATE, DELETE. Some texts separate SELECT as DQL. DCL manages privileges through GRANT and REVOKE. TCL includes COMMIT, ROLLBACK and SAVEPOINT. Classify a statement by its effect, not its length.

> has statements for data definitions, and updates. Hence, it is both a DDL (Data Definition language) and a DML (Data Manipulation Language).

Question sources

Computer Science model exam · Question 29

University of Gondar model exam · Question 29

Question 20 | Q00299

A table can have only one

A. Unique Key

B. Candidate key

C. Primary key

D. Foreign key

Hint

Test uniqueness and minimality separately when classifying keys.

Answer C: Primary key

One candidate is selected as the primary key; multiple candidates and multiple inter-table references can coexist.

Why each choice is right or wrong

A - Incorrect: Uniqueness need not be the selected identifier (PDF 11, 11.)

B - Incorrect: Several candidates are explicitly allowed (PDF 11, 11.)

C - Correct: Primary key is the selected candidate (PDF 11, 11.)

D - Incorrect: Separate relationships can use separate foreign keys (PDF 11, 11.)

Primary note proof

Study-note section FDB07

> A superkey uniquely identifies a tuple. A candidate key is a minimal superkey: removing any component loses uniqueness. Minimal means no unnecessary attribute, not necessarily the fewest columns among all keys. A primary key is one selected candidate key; remaining candidates are alternate keys. A composite key contains multiple attributes and need not be the chosen primary key.

Study-note section FDB07

> A table can have several candidates and foreign keys but at most one declared primary-key constraint, possibly containing several columns.

Study-note section FDB07

> Prefer stable, compact identifiers when practical, but Email, SSN or EmployeeID is a candidate only if business rules guarantee uniqueness.

Module passages - related reading

Question 21 | Q00301

When the values in one or more attributes being used as a foreign key must exist there must be a corresponding primary key value in another table in the database, we have

created

A. Domain Integrity constraint

B. Referential Integrity Constraint

C. Transitive Dependency

D. Entity Integrity Constraints

Hint

Match the validity requirement to the appropriate constraint definition.

Answer B: Referential Integrity Constraint

Matching foreign-key values to existing parent occurrences is the referential-integrity rule.

Why each choice is right or wrong

A - Incorrect: Domain checks legal attribute values (PDF 48.)

B - Correct: Matches the explicit parent-reference rule (PDF 48.)

C - Incorrect: Transitivity is functional dependency (PDF 48.)

D - Incorrect: Entity integrity constrains the primary key itself (PDF 48.)

Primary note proof

Study-note section FDB15

> Domain integrity restricts type and allowed values. Key integrity enforces uniqueness. Entity integrity requires every primary-key component to be non-NULL. Referential integrity requires a non-NULL foreign-key value to match an eligible referenced unique/candidate key; self-references are allowed. A parent need not have a child.

Study-note section FDB17

> Full dependency requires all determinant attributes; partial dependency holds through a proper subset.

Study-note section FDB17

A prime attribute belongs to some candidate key; a nonprime attribute belongs to none.

Module passages - related reading

University of Gondar model exam · Question 32

Question 22 | Q00302

Which of the following is not a feature of DBMS?

A. Support ACID Property

B. Single-user Access only

C. High Level of Security

D. Minimum Duplication and Redundancy of Data

Hint

Review the database approach and match each claimed benefit or cost to its mechanism.

Answer B: Single-user Access only

Single-user-only contradicts the explicit multiuser DBMS requirement.

Why each choice is right or wrong

A - Incorrect: ACID is a requirement (PDF 6, 66.)

B - Correct: Multiuser support disproves only (PDF 6, 66.)

C - Incorrect: Security is supported (PDF 6, 66.)

D - Incorrect: Normalization aims to reduce redundancy (PDF 6, 66.)

Primary note proof

Study-note section FDB01

A DBMS centralizes metadata and supports multiple views, authorization, transactions, backup and recovery. It controls redundancy rather than guaranteeing zero duplication.

Study-note section FDB37

A transaction groups operations into one logical unit. Atomicity applies all its effects or none. Consistency means a correct transaction preserves declared invariants. Isolation controls interference between concurrent transactions; serializable isolation provides behavior equivalent to some serial execution. Durability preserves committed effects after a crash, typically through durable logging rather than forcing every data page immediately.

Study-note section FDB01

Concurrent access itself is useful; uncontrolled concurrent access causes anomalies.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

University of Gondar model exam · Question 33

Question 23 | Q00303

Which of the following is not a function of the database?

A. Analyzing code

B. Provide Backup and recovery

C. Manipulating data

D. Managing stored data

Hint

Review the database approach and match each claimed benefit or cost to its mechanism.

Answer A: Analyzing code

Data definition, manipulation and recovery are database responsibilities. Arbitrary program-code analysis is not a listed database function; parsing database queries is a narrower task.

Why each choice is right or wrong

A - Correct: General code analysis is outside the stated functions (PDF 5, 97.)

B - Incorrect: Recovery is expressly covered (PDF 5, 97.)

C - Incorrect: Manipulation is expressly covered (PDF 5, 97.)

D - Incorrect: DBMS manages databases (PDF 5, 97.)

Primary note proof

Study-note section FDB01

> A database is a coherent collection of related facts with meaning for an application. A DBMS is software that defines, stores, retrieves, updates, protects and shares that data. The database is the content; the DBMS manages it. A database system also includes applications, people and infrastructure.

Study-note section FDB01

> A DBMS centralizes metadata and supports multiple views, authorization, transactions, backup and recovery.

Computer Science model exam · Question 34

University of Gondar model exam · Question 34

Question 24 | Q00307

Read each pair left→right. Buildings and locations are 1:1; each employee belongs to one department and a department may have many employees; a hospital serves many patients, each registered at one hospital; authors and books are M:N. Which pair is many-to-one?

A. [Building - Location]

B. [Employee - Department]

C. [Hospital - Patient]

D. [Author - Book]

Hint

Read the relationship in both directions and check participation constraints.

Answer B: B. [Employee - Department]

Many-to-one means several left-side entities may share a right-side entity while each left entity has at most one right partner. Employees share departments under the stated assignment rule. Building→Location is one-to-one, Hospital→Patient is one-to-many and Author→Book is many-to-many. Reading the direction and both maximum counts determines the answer rather than the entity names.

Why each choice is right or wrong

A - Incorrect: Building→Location is explicitly 1:1.

B - Correct: Many employees can share one department; each employee has one department.

C - Incorrect: Hospital→Patient is 1:N under the registration rule.

D - Incorrect: Author→Book is explicitly M:N.

Primary note proof

Study-note section FDB09

> Cardinality specifies maximum associated occurrences: 1:1, 1:N or M:N. Minimum cardinality specifies optional/partial participation (zero permitted) or mandatory/total participation (at least one). A maximum of one does not mean participation is compulsory. Relationship degree counts participating entity roles: unary recursive, binary or ternary.

Study-note section FDB09

> If each employee belongs to one department and each department has many employees, Employee→Department is N:1; Department→Employee is 1:N.

Study-note section FDB09

> Building→Location could also be N:1, so names alone cannot select a unique example.

Question sources

Computer Science model exam · Question 38

University of Gondar model exam · Question 38

Question 25 | Q00374

_____ is a single elementary unit of information representing an attribute of an entity.

A. Entity Set

B. Record

C. File

D. Field

Hint

Distinguish a relation's structure from its current contents and its descriptive metadata.

Answer D: Field.

A field corresponds to one attribute rather than the collection of attributes describing a whole record. FDB03 equates attribute, column and field, while tuple, row and record refer to related attribute values together. An entity set groups entities, and a file groups stored records, so both are larger collections.

Why each choice is right or wrong

A - Incorrect: An entity set collects entities of one type rather than representing a single attribute.

B - Incorrect: A record contains related values for multiple attributes, rather than one elementary field.

C - Incorrect: A file groups records and is not an elementary attribute unit.

D - Correct: A field represents one attribute or property within a record.

Primary note proof

Study-note section FDB03

> A relation is a set of tuples, represented as a table. A tuple/row/record contains related attribute values; an attribute/column/field describes a property. Degree counts columns; cardinality counts rows. Classical relations have distinct tuples, atomic cells and domains for attributes; row order has no meaning. Column order has no logical meaning when attributes are identified by name. SQL tables can contain duplicate rows unless constrained.

Study-note section FDB06

> An entity type describes common properties; its current collection of entities is an entity set.

Study-note section FDB06

> In Chen notation rectangles represent entity types, diamonds relationships and ellipses attributes; double ellipses denote multivalued attributes and dashed ellipses derived attributes.

entities. A table has two properties rows and columns. Rows represent records and columns represent attributes.

Question sources

Data Structures & Algorithms practice questions · Question 4

Question 26 | Q00548

An ER model has entity types A and B connected by an attribute-free relationship R. Cardinalities are read A→B. Which conditions allow R to be represented by a single B-key foreign-key column in A, permitting NULL for partial participation? Select all that apply.

A. Relationship R is one -to -many and the participation of A in R is Total.

B. Relationship R is one -to -many and the participation of A in R is Partial.

C. Relationship R is many -to -one and the participation of A in R is Total.

D. Relationship R is many --to -one and the participation of A in R is Partial.

Hint

Locate the relationship's cardinality and participation before placing a foreign key.

Answer C, D: C. Relationship R is many -to -one and the participation of A in R is Total.; D. Relationship R is many --to -one and the participation of A in R is Partial.

A single foreign-key column in A can represent R whenever each A is related to at most one B. This is exactly the many-to-one direction. Total participation makes the reference mandatory; partial participation permits NULL. One-to-many in the opposite direction needs the reference on B or another representation, because one A may have multiple related B values.

Why each choice is right or wrong

A - Incorrect: For A→B one-to-many, B normally holds A's key; total participation does not reverse that mapping.

B - Incorrect: Partial participation does not make a one-to-many collection fit a single ordinary foreign key in A.

C - Correct: Many-to-one with total A participation stores a non-NULL B reference in A.

D - Correct: Many-to-one with partial A participation stores a nullable B reference in A.

Primary note proof

Study-note section FDB11

For 1:N, place the one-side key as a foreign key in the many-side table; store relationship attributes there. Department(DeptID) and Employee(EmpID,DeptID,HireDate) implement many employees per department. If participation is total, make the reference NOT NULL. If partial, a nullable reference can represent no assignment.

Study-note section FDB11

For A→B many-to-one, A can absorb the relationship reference under either total or partial participation; requiring total participation as the only possible case overstates the rule.

Study-note section FDB11

Prefer the totally participating side to reduce NULLs; NOT NULL enforces that side's mandatory reference.

4. For each binary 1:N relationship type R, identify the relation S that represent the participating entity type at the N-side of the relationship type. Include the primary key of the relation T as

Question sources

Computer Science model exam · 2015 · Question 17

Question 27 | Q00567

Under set relational algebra, which listed operation is not commutative? Interpret Join as an inner join, adjust its predicate when swapping inputs, and ignore attribute order.

A. Union

B. Join

C. Intersection

D. None

Hint

Apply each algebra operator to the input relations step by step.

Answer D: D. None

Union and intersection give the same tuple sets when their inputs are exchanged. An inner join also gives corresponding matches after the predicate is adjusted for the swapped inputs; the question explicitly ignores attribute order. Thus none of the three named operations lacks commutativity here. This conclusion depends on the stated inner-join interpretation; preservation of one designated outer side would use a different rule.

Why each choice is right or wrong

A - Incorrect: Union is commutative on union-compatible relations.

B - Incorrect: Inner join is commutative under the stated predicate and schema convention.

C - Incorrect: Intersection is commutative on union-compatible relations.

D - Correct: All three named operators are commutative under these assumptions.

Primary note proof

Study-note section FDB35

> Selection σ filters tuples; projection π retains attributes and removes duplicate tuples under set semantics. Rename ρ changes relation or attribute names. Union, difference and intersection require union-compatible schemas. Difference R−S is not commutative; union and intersection are. Inner joins are commutative up to attribute order when predicates are adjusted; left outer joins are not generally commutative. Identify the join variant before predicting its behavior.

Question sources

Computer Science model exam · 2015 · Question 36

Question 28 | Q00595

Which of the following is a benefit of normalization rather than a potential cost or disadvantage?

A. May require joins to reconstruct decomposed records

B. May reduce system performance

C. Time consuming

D. Reduce duplicate data

Hint

Distinguish dependency-based design problems from the contents of one sample table.

Answer D: Reduce duplicate data

Normalization organizes facts according to their dependencies to reduce avoidable duplication and update anomalies. That reduction is a benefit. Decomposing a table may require joins when an application needs the original combined information, which can increase retrieval cost for some workloads. Dependency analysis and schema design also take time. These are possible costs, not claims that normalization always slows a system. Declared dependencies suffice for normalization even when the current sample data shows no errors.

Why each choice is right or wrong

A - Incorrect: A possible cost: reconstructing information from decomposed tables may require joins.

B - Incorrect: A possible cost: additional joins can reduce performance for some workloads, although this is not inevitable.

C - Incorrect: A possible cost: analyzing dependencies and designing a decomposition takes time.

D - Correct: Correct: reducing duplicate facts is a principal benefit, rather than a disadvantage.

Primary note proof

Study-note section FDB19

> Normalization separates facts according to their determinants, reducing avoidable repetition and associated anomalies. It does not require seeing bad current data: declared dependencies suffice. Adding a generated row ID may make insertion technically possible, but does not remove repeated facts or fix the dependency design. Reduced redundancy can improve integrity and storage use, but extra keys and joins mean neither storage savings nor faster retrieval is guaranteed.

Module passages - related reading

> Normalization is a process of organizing the data in database to avoid data redundancy, insertion anomaly, update anomaly & deletion anomaly. It is a technique of organizing the data in the

Question sources

Computer Science model exam · 2015 · Question 64

Question 29 | Q00617

Let you have two relations A and B, each table has 200 and 100 rows of records respectively. So after applying cross product on those tables, how many rows of records you will have?

A. 300

B. 20000

C. 2000

D. 100

Hint

Apply each algebra operator to the input relations step by step.

Answer B: 20000

The Cartesian-product example explicitly creates 1000*50 tuples from inputs of sizes 1000 and 50 (PDF p.28, lines 6-8). Applying the same all-pairs construction to 200 and 100 rows yields 200*100 = 20000. Each of the 200 rows is paired with each of the 100 rows; no filtering or duplicate-eliminating projection is specified.

Why each choice is right or wrong

A - Incorrect: 300 adds input sizes instead of counting pairs (PDF p.28).

B - Correct: 20000 is 200*100, the illustrated Cartesian pair-count rule (PDF p.28).

C - Incorrect: 2000 is ten times too small for the all-pairs count (PDF p.28).

D - Incorrect: 100 counts only one input and omits its 200 pairings per row (PDF p.28).

Primary note proof

Study-note section FDB35

> A Cartesian product has |R|×|S| tuples and degree degree(R)+degree(S), renaming conflicting attributes if necessary. Thus 200×100=20,000 and 5×7=35. Join equals selection over a product; intersection can be derived from difference. A common minimal basis contains selection, projection, union, difference, product and rename. Assignment is a useful notation, not an indispensable primitive; lists of basic operations vary across textbooks.

Computer Science model exam · 2015 · Question 86

Question 30 | Q00675

_____It defines how and where data are organized in physical data storage

A. Internal Schema

B. Conceptual Schema

C. External Schema

D. External and Conceptual Schema

Hint

Trace which schema levels a proposed change affects.

Answer A: Internal Schema

Internal schema specifies physical structure and access paths.

Why each choice is right or wrong

A - Correct: Exact storage schema (PDF 7.)

B - Incorrect: Conceptual hides physical detail (PDF 7.)

C - Incorrect: External is user view (PDF 7.)

D - Incorrect: Neither listed user-level schema defines storage (PDF 7.)

Primary note proof

Study-note section FDB04

> The external level gives each user group a selected view. The conceptual level describes the whole logical database: entity types, relationships, data types and constraints. The internal/physical level describes files, record placement and access paths. These are abstraction levels, distinct from client/server deployment tiers.

Question sources

Computer Science model exam 2 · Question 16

Question 31 | Q00676

Which database-design stage primarily builds an ER model from the users' requirements?

A. Applications and security

B. Physical refinement

C. Conceptual database

D. Schema refinement

Hint

Identify the design phase from its inputs and intended deliverable.

Answer C: Conceptual database

Conceptual design represents the required entities, attributes and relationships in an ER model. Logical design later maps that conceptual model into relations, keys and constraints and checks normalization. Physical refinement chooses storage organizations and access paths, while application and security work concerns behavior and protection rather than the modeling stage requested. The stem asks for the primary stage building the ER model, not every later activity that might consult it.

Why each choice is right or wrong

A - Incorrect: Incorrect: application and security work addresses behavior and protection, rather than building the conceptual ER model.

B - Incorrect: Incorrect: physical refinement chooses storage organization and access paths.

C - Correct: Correct: conceptual design turns requirements into the ER model.

D - Incorrect: Incorrect: schema refinement checks or improves a logical schema, rather than naming the initial ER-model stage.

Primary note proof

Study-note section FDB05

> First collect business facts, required transactions, reports, volumes, privacy rules and quality targets. Conceptual design turns them into an ER/EER model. Logical design maps the conceptual model to relations, keys and constraints and checks normalization. Physical design chooses file organization, indexes and storage. Implementation creates and loads the actual objects; testing checks requirements.

Module passages - related reading

Employee(empid, ...) already exists, has no primary key, and empid values are unique and non-NULL. Which SQL statement adds a primary key on empid?

A. ADD TABLE Employee ADD PRIMARY KEY (empid)

B. ATTACH TABLE Employee ADD PRIMARY KEY (empid)

C. ADD TABLE Employee ATTACH PRIMARY KEY (empid)

D. ALTER TABLE Employee ADD PRIMARY KEY (empid);

Hint

Distinguish table definition changes from changes to stored rows.

Answer D: D. ALTER TABLE Employee ADD PRIMARY KEY (empid);

Adding a constraint to an existing table uses ALTER TABLE, followed by ADD PRIMARY KEY and the parenthesized key column. The existing unique, non-NULL empid values satisfy the prerequisite for the constraint. Option D has this structure. ADD TABLE and ATTACH TABLE do not perform this alteration, and ATTACH PRIMARY KEY is not the required constraint clause.

Why each choice is right or wrong

A - Incorrect: ADD TABLE does not modify an existing table's constraints.

B - Incorrect: ATTACH TABLE is not the required table-alteration syntax.

C - Incorrect: Neither ADD TABLE nor ATTACH PRIMARY KEY forms this SQL alteration.

D - Correct: The corrected ALTER TABLE statement adds the primary-key constraint.

Primary note proof

Study-note section FDB30

> CREATE TABLE Employee (EmpID INTEGER PRIMARY KEY, Name VARCHAR(80)); declares two columns. The name and its type stay together; the comma separates whole column declarations. To add a primary key later: ALTER TABLE Employee ADD PRIMARY KEY (EmpID); existing data must be unique and non-NULL. A table cannot gain a second primary key without replacing the existing constraint.

> Basic DDL commands we usually use are: CREATE, DROP, ALTER, TRUNCATE and RENAME

Question sources

Computer Science model exam 2 · Question 19

Question 33 | Q00679

While checking normalization process, the problem that doesn't exist on transitive dependency is

A. Modification Anomaly

B. Revoke Anomaly

C. Insertion Anomaly

D. Deletion Anomaly

Hint

Distinguish dependency-based design problems from the contents of one sample table.

Answer B: Revoke Anomaly

The defined anomalies are insertion, deletion and update; revoke concerns privileges.

Why each choice is right or wrong

A - Incorrect: Modification means update (PDF 16.)

B - Correct: Revoke is not a normalization anomaly (PDF 16.)

C - Incorrect: Insertion is defined (PDF 16.)

D - Incorrect: Deletion is defined (PDF 16.)

Primary note proof

Study-note section FDB19

> Suppose Enrollment repeats StudentName for every course. An update anomaly requires changing every copy of the student's name; missed copies disagree. An insertion anomaly prevents recording a new student until some enrollment exists. A deletion anomaly loses the only record of a student's details when their last enrollment is deleted. Revoke anomaly is not a normalization anomaly.

Study-note section FDB19

> Normalization separates facts according to their determinants, reducing avoidable repetition and associated anomalies.

Study-note section FDB19

> Adding a generated row ID may make insertion technically possible, but does not remove repeated facts or fix the dependency design.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 16 | lines 8-9

data. Types of database anomalies are Insertion anomaly, Deletion anomaly, and Update anomaly. Insertion Anomaly - occurs when the entire primary key is not known and the database cannot

Question sources

Computer Science model exam 2 · Question 20

Question 34 | Q00680

You need to produce a report for mailing labels for customers. The mailing label must have only the customer name and address. The CUSTOMERS table has these columns, ID ,NAME,ADDRESS,PHONE ,the SELECT statement to accomplishes this task?
*

A. SELECT name, address FROM customers;

B. SELECT*FROM customers;

C. SELECT id, name, address, phone FROM customers;

D. SELECT cust_name, cust_address FROM customers;

Hint

Trace how SELECT forms its result columns and rows.

Answer A: SELECT name, address FROM customers;

The required output contains exactly NAME and ADDRESS from the listed schema. FDB27 distinguishes naming specific columns from selecting all columns with *. A names the two available columns explicitly. B and C include unwanted ID and PHONE fields, while D uses column names not supplied by the question.

Why each choice is right or wrong

A - Correct: It selects exactly the two existing columns required for the mailing label.

B - Incorrect: The wildcard also includes ID and PHONE, exceeding the required output.

C - Incorrect: It explicitly includes ID and PHONE in addition to the requested label fields.

D - Incorrect: The supplied schema names NAME and ADDRESS, not CUST_NAME and CUST_ADDRESS.

Primary note proof

Study-note section FDB27

SELECT Name,Address FROM Customer; produces only those mailing-label fields. SELECT * selects all columns; DISTINCT removes duplicate result rows; AS supplies an alias; ALL permits duplicates and does not mean all columns. SQL normally preserves duplicates without DISTINCT. A query reading table columns needs an appropriate FROM source. A literal-only query such as SELECT 1 may legally omit FROM.

Study-note section FDB27

> Typical written clause order is SELECT ... FROM ... WHERE ... GROUP BY ... HAVING ... ORDER BY ....

Study-note section FDB27

> SELECT alone normally reads without changing the database state.

Question sources

Computer Science model exam 2 · Question 21

Question 35 | Q00681

If the maximum cardinality is equal to 1 in both directions of a relationship, then it is classified as:

A. Optional

B. Many-to-many

C. One-to-one

D. One-to-many

Hint

Read the relationship in both directions and check participation constraints.

Answer C: One-to-one

At most one related entity on each side is the one-to-one case.

Why each choice is right or wrong

A - Incorrect: Optional describes minimum participation (PDF 11.)

B - Incorrect: Many-to-many allows multiple (PDF 11.)

C - Correct: Both maxima match one-to-one (PDF 11.)

D - Incorrect: One-to-many permits multiple on one side (PDF 11.)

Primary note proof

Study-note section FDB09

> Cardinality specifies maximum associated occurrences: 1:1, 1:N or M:N. Minimum cardinality specifies optional/partial participation (zero permitted) or mandatory/total participation (at least one). A maximum of one does not mean participation is compulsory. Relationship degree counts participating entity roles: unary recursive, binary or ternary.

Study-note section FDB09

> Read business rules in both directions.

Study-note section FDB09

> If each employee belongs to one department and each department has many employees, Employee→Department is N:1; Department→Employee is 1:N.

> One to one (1-1) - When each entity in each entity set can take part only once in the relationship, the cardinality is one to one.

Question sources

Computer Science model exam 2 · Question 22

Question 36 | Q00682

Which SQL statement sets PRICE to 600 in BOOK for rows whose ID is 'B001'?

A. CHANGE BOOK SET PRICE =600 Where ID ='B001';

B. UPDATE TO CHANGE BOOK SET PRICE =600 Where ID ='B001';

C. UPDATE BOOK SET PRICE =600 Where ID ='B001';

D. GRANT BOOK SET PRICE =600 Where ID ='B001';

Hint

Track which rows each data-changing command affects.

Answer C: UPDATE BOOK SET PRICE =600 Where ID ='B001';

UPDATE changes existing row values. The table name follows UPDATE, SET supplies the assignment and WHERE restricts the rows. C therefore assigns 600 only where ID equals the quoted string B001. CHANGE is not the row-update command, the extra TO CHANGE words break the required UPDATE structure, and GRANT controls privileges rather than performing a row assignment. These malformed alternatives are definite incorrect selections.

Why each choice is right or wrong

A - Incorrect: Incorrect: the required row-change statement begins UPDATE, not CHANGE BOOK SET.

B - Incorrect: Incorrect: UPDATE must be followed by its target table, not TO CHANGE.

C - Correct: Correct: the statement assigns 600 to PRICE for precisely the matching ID rows.

D - Incorrect: Incorrect: GRANT manages privileges; it cannot perform this SET assignment.

Primary note proof

Study-note section FDB29

> UPDATE Book SET Price = 600 WHERE ID = 'B001'; changes matching rows. UPDATE without WHERE targets every row. DELETE FROM Publisher WHERE Name = 'XWZ'; deletes matching publisher rows, subject to reference policies. DELETE FROM r; removes every row but leaves r defined. Both clear relation entries and delete rows describe that effect. Several UPDATE statements can all be valid while performing different tasks; most appropriate requires a requested change and a specified quoting dialect.

Study-note section FDB26

> DCL manages privileges through GRANT and REVOKE.

> has statements for data definitions, and updates. Hence, it is both a DDL (Data Definition language) and a DML (Data Manipulation Language).

Question sources

Computer Science model exam 2 · Question 23

Question 37 | Q00683

While listing limitation of File Processing System identify the wrong statement?

A. Difficult in accessing data

B. Data isolation and integrity.

C. Data redundancy & inconsistency available.

D. Concurrent access is possible.

Hint

Review the database approach and match each claimed benefit or cost to its mechanism.

Answer D: Concurrent access is possible.

The file-system limitation is concurrent-access anomalies; merely allowing concurrent access is not itself the listed limitation.

Why each choice is right or wrong

A - Incorrect: Access difficulty is listed (PDF 5.)

B - Incorrect: Isolation and integrity problems are listed (PDF 5.)

C - Incorrect: Redundancy and inconsistency are listed (PDF 5.)

D - Correct: Possibility of access does not name the anomaly (PDF 5.)

Primary note proof

Study-note section FDB01

> A database is a coherent collection of related facts with meaning for an application. A DBMS is software that defines, stores, retrieves, updates, protects and shares that data. The database is the content; the DBMS manages it. A database system also includes applications, people and infrastructure.

Study-note section FDB01

> Concurrent access itself is useful; uncontrolled concurrent access causes anomalies.

Study-note section FDB01

> Traditional file applications define their own formats and access procedures.

Computer Science model exam 2 · Question 24

Question 38 | Q00684

The Entity Relationship (E-R) Model

A. Entities are represented by circle

B. Attributes are represented by rectangle

C. It represents conceptual view

D. It corresponds to row

Hint

Review entity, attribute and relationship notation before interpreting the model.

Answer C: It represents conceptual view

ER depicts the conceptual database schema and entity rectangles.

Why each choice is right or wrong

A - Incorrect: Entity uses rectangle (PDF 9, 10.)

B - Incorrect: Attribute is a property rather than an entity rectangle (PDF 9, 10.)

C - Correct: Conceptual depiction matches ER (PDF 9, 10.)

D - Incorrect: A model is not one tuple (PDF 9, 10.)

Primary note proof

Study-note section FDB06

> An entity is a distinguishable real or conceptual thing, such as one student or one course. An entity type describes common properties; its current collection of entities is an entity set. A relationship associates entities. In Chen notation rectangles represent entity types, diamonds relationships and ellipses attributes; double ellipses denote multivalued attributes and dashed ellipses derived attributes. Always inspect the diagram legend.

Study-note section FDB05

> Conceptual design turns them into an ER/EER model.

Study-note section FDB05

> Logical design maps the conceptual model to relations, keys and constraints and checks normalization.

Question sources

Computer Science model exam 2 · Question 25

Question 39 | Q00685

Removal of transitivity property should be full filled in

A. First Normal form

B. Fourth Normal form

C. Third Normal form

D. Second Normal form

Hint

Check atomicity, candidate keys and partial dependencies in that order.

Answer C: Third Normal form

3NF requires nonprime attributes to depend nontransitively on keys after reaching 2NF.

Why each choice is right or wrong

A - Incorrect: 1NF requires atomicity (PDF 18.)

B - Incorrect: 4NF is not the stated rule (PDF 18.)

C - Correct: 3NF explicitly removes transitive dependence (PDF 18.)

D - Incorrect: 2NF removes partial dependence (PDF 18.)

Primary note proof

Study-note section FDB20

> 2NF requires 1NF and no nonprime attribute partially dependent on any candidate key. For Enrollment(SID,CID,SName,CTitle,Grade), assume key (SID,CID), SID→SName and CID→CTitle. Split into Student(SID,SName), Course(CID,CTitle) and Enrollment(SID,CID,Grade). Grade still depends on the whole pair. A relation whose every candidate key is single-attribute has no nonprime partial-key dependency. Higher forms inherit 2NF, so no partial dependencies establishes the minimum guaranteed stage only when 1NF is also assumed.

Study-note section FDB21

> With atomic values the highest form is 1NF, even though a transitive dependency also exists.

Study-note section FDB21

> The mnemonic whole key and nothing but the key describes the common single-key case; it cannot replace the full tests when keys overlap.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

> _R‘ are fully functionally dependent on every key of R and non-transitively dependent on every key of R.

Question sources

Computer Science model exam 2 · Question 26

Question 40 | Q00686

If relation R has 5 tuples and relation S has also 7 tuples, then Cartesian product of R and S will have

A. 5+7 tuples

B. 7-5 tuples

C. 5X7 tuples

D. 5/7 tuples

Hint

Apply each algebra operator to the input relations step by step.

Answer C: 5X7 tuples

The module explicitly multiplies input tuple counts for a Cartesian product (PDF p.28, lines 6-8). Hence 5 rows paired with 7 rows give 5*7 = 35 distinct concatenated tuples, before any filtering/projection.

Why each choice is right or wrong

A - Incorrect: 5+7 is the sum, not all pair combinations (PDF p.28).

B - Incorrect: 7-5 is the size difference, not the pair count (PDF p.28).

C - Correct: 5*7 gives the 35 combinations required by the product construction (PDF p.28).

D - Incorrect: 5/7 is not even an integer tuple count and is not pair enumeration (PDF p.28).

Primary note proof

Study-note section FDB35

> A Cartesian product has |R|×|S| tuples and degree degree(R)+degree(S), renaming conflicting attributes if necessary. Thus 200×100=20,000 and 5×7=35. Join equals selection over a product; intersection can be derived from difference. A common minimal basis contains selection, projection, union, difference, product and rename. Assignment is a useful notation, not an indispensable primitive; lists of basic operations vary across textbooks.

> Selection (σ) - Selects a subset of rows from relation. Projection (π) - Deletes unwanted columns from relation. Cross-product (x) - Allows us to combine two relations. Set-difference (-) - Tuples in relation 1, but not in relation 2.

Fundamental of Database Systems module | PDF page 28 | lines 6-8

◦ Requires (1000+50) disk accesses to read from Staff and Branch relations ◦ Creates temporary relation of Cartesian Product (1000*50) tuples ◦ Requires (1000*50) disk access to read in temporary relation and test predicate

Question sources

Computer Science model exam 2 · Question 27

Question 41 | Q00688

The language associated with a database management system that is employed by end users and programmers to alter data values in the database is the:

A. Data translation language.

B. Data definition language.

C. Data manipulation language.

D. Data presentation language.

Hint

Classify each SQL command by the kind of change it performs.

Answer C: Data manipulation language.

The language for INSERT, UPDATE and DELETE is DML.

Why each choice is right or wrong

A - Incorrect: Not a defined language category (PDF 26.)

B - Incorrect: DDL defines structure (PDF 26.)

C - Correct: DML changes stored data (PDF 26.)

D - Incorrect: Not a defined language category (PDF 26.)

Primary note proof

Study-note section FDB26

> DDL changes structure: CREATE, ALTER, DROP, commonly RENAME and TRUNCATE in textbook classifications. DML retrieves or changes data: SELECT, INSERT, UPDATE, DELETE. Some texts separate SELECT as DQL. DCL manages privileges through GRANT and REVOKE. TCL includes COMMIT, ROLLBACK and SAVEPOINT. Classify a statement by its effect, not its length.

> language) and a DML (Data Manipulation Language). 7.1.1 DDL (data definition language)

Question sources

Computer Science model exam 2 · Question 29

Question 42 | Q00730

Using standard SQL string literals, which update changes only the name of the student whose ID is '123' to 'abel'?

A. UPDATE student ID='123';

B. UPDATE student SET ID='123';

C. UPDATE student SET name='abel' WHERE ID='123';

D. UPDATE student SET name='abel';

Hint

Track which rows each data-changing command affects.

Answer C: C. UPDATE student SET name='abel' WHERE ID='123';

UPDATE needs SET to state the assignment and WHERE to restrict the target rows. C assigns the desired name only to the student with ID '123'. B changes IDs in every row, while D changes every student's name because it has no filter. A omits SET and is malformed. Correct syntax and the requested scope both matter.

Why each choice is right or wrong

A - Incorrect: SET is missing before the assignment.

B - Incorrect: This sets every student's ID and does not change the name.

C - Correct: SET changes name and WHERE restricts the operation to ID '123'.

D - Incorrect: Without WHERE, every name is changed.

Primary note proof

Study-note section FDB29

> INSERT INTO Hotel(HotelID,HotelName,SubCity) VALUES (1,'Hilton','Yeka'); pairs each named column with a compatible value. Counts and types must match; keys and other constraints still apply. Without a column list, values must follow the table's declared column order.

Study-note section FDB29

> UPDATE Book SET Price = 600 WHERE ID = 'B001'; changes matching rows.

Study-note section FDB28

> Use single quotes for SQL string literals: WHERE ID = 'B001'.

> has statements for data definitions, and updates. Hence, it is both a DDL (Data Definition language) and a DML (Data Manipulation Language).

Question sources

Computer Science model exam 2 · Question 71

Question 43 | Q00899

A weak entity is identified by its partial key together with the key of an independently keyed associated entity. Which listed terms describe that associated entity set? Select all that apply.

A. Identifying set

B. Strong entity set

C. Neighbor set

D. Owner set

Hint

Check how a dependent entity obtains its complete identity.

Answer B, D: B. Strong entity set; D. Owner set

A weak entity cannot identify itself using its own attributes alone. Its owner contributes the missing key component, and in the specified case that owner has an independent key, so it is a strong entity set. Both owner set and strong entity set describe it. The identifying relationship connects the sets; neighbor does not identify the required ownership role.

Why each choice is right or wrong

A - Incorrect: Identifying normally names the owner relationship rather than the defined owner entity-set role.

B - Correct: The owner supplying the independent key is normally a strong entity set.

C - Incorrect: Neighbor does not express the ownership and identification needed for a weak entity.

D - Correct: Owner set names the entity set whose key contributes to weak-entity identification.

Primary note proof

Study-note section FDB08

> A weak entity lacks a complete independent key. Its owner is normally a strong entity, so owner entity set and strong entity set may both describe the associated set. Its partial key, also called discriminator, distinguishes weak entities of the same owner. Identification combines the owner key and partial key.

Study-note section FDB08

> The weak entity participates totally in its identifying relationship.

Study-note section FDB08

> Chen notation uses a double rectangle, double identifying diamond and dashed underline for a partial key.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 10 | lines 6-10

> Each entity has attributes, the particular properties that describe it. Entities that do not have key attributes of their own are called weak entity. The regular entity types that have a key attribute are called strong entity types. Weak entities are identified by being related to specific strong entities in combination with one of their attribute values. A weak entity type has a partial key, which is the attribute that can uniquely identify weak entities that are related to the same owner entity.

Fundamental of Database Systems module | PDF page 12 | lines 10-13

> 2. Choose one of the key attributes of E as the primary key for R. For each weak entity type W with owner entity type E (which is a strong entity), create a relation R & include all attributes of ‗W‘ as attributes of R. Also, include the primary key attribute of the relation that correspond to the owner entity type as foreign key attributes of R .

Computer Science Exit Exam · 2018 · Question 12

Question 44 | Q00901

A language that allows the DBA or user to describe and name the entities, attributes, and relationships required for the application is

A. Transaction control language (TCL)

B. Data control language (DCL)

C. .
Data Manipulation Language (DML)

D. Data Definition Language (DDL)

Hint

Classify each SQL command by the kind of change it performs.

Answer D: Data Definition Language (DDL)

Defining schema objects belongs to DDL.

Why each choice is right or wrong

A - Incorrect: Transaction control is a different task (PDF 26.)

B - Incorrect: Privileges are a different task (PDF 26.)

C - Incorrect: Manipulation operates on contents (PDF 26.)

D - Correct: DDL supplies definitions (PDF 26.)

Primary note proof

Study-note section FDB26

> DDL changes structure: CREATE, ALTER, DROP, commonly RENAME and TRUNCATE in textbook classifications. DML retrieves or changes data: SELECT, INSERT, UPDATE, DELETE. Some texts separate SELECT as DQL. DCL manages privileges through GRANT and REVOKE. TCL includes COMMIT, ROLLBACK and SAVEPOINT. Classify a statement by its effect, not its length.

> has statements for data definitions, and updates. Hence, it is both a DDL (Data Definition language) and a DML (Data Manipulation Language).

Question sources

Computer Science Exit Exam · 2018 · Question 14

Question 45 | Q00907

In relational-table terminology, which listed terms name a unit of related field values treated together by an application? Select all that apply.

A. Rows

B. Field

C. Record

D. Database

Hint

Distinguish a relation's structure from its current contents and its descriptive metadata.

Answer A, C: A. Rows; C. Record

A relational tuple groups related attribute values into one unit. Row and record are names for that same unit, so both options qualify even though one is plural. A field refers to one property rather than the whole grouping. A database is the larger coherent collection containing tables and their data, rather than one individual tuple.

Why each choice is right or wrong

A - Correct: A relational row groups related field values and is synonymous with a record.

B - Incorrect: A field represents one attribute, not the collection of related fields in the definition.

C - Correct: A record is the unit containing related fields described by the stem.

D - Incorrect: A database contains a larger coherent collection, rather than this single field grouping.

Primary note proof

Study-note section FDB03

> A relation is a set of tuples, represented as a table. A tuple/row/record contains related attribute values; an attribute/column/field describes a property. Degree counts columns; cardinality counts rows. Classical relations have distinct tuples, atomic cells and domains for attributes; row order has no meaning. Column order has no logical meaning when attributes are identified by name. SQL tables can contain duplicate rows unless constrained.

Study-note section FDB01

> A database is a coherent collection of related facts with meaning for an application.

Study-note section FDB01

> It controls redundancy rather than guaranteeing zero duplication.

entities. A table has two properties rows and columns. Rows represent records and columns represent attributes.

Question sources

Computer Science Exit Exam · 2018 · Question 20

Question 46 | Q00927

Which template correctly creates a table with one column? Treat table_name, column_name and column_type as placeholders for valid identifiers and a data type.

A. CREATE table_name (column_name, column type);

B. CREATE table_name (column_type, column name);

C. CREATE TABLE table_name (column_name column_type);

D. CREATE TABLE table_name (column_type, column_name);

Hint

Distinguish table definition changes from changes to stored rows.

Answer C: C. CREATE TABLE table_name (column_name column_type);

A column declaration places its name immediately before its data type. Commas separate complete declarations when more than one column is present. The corrected C uses CREATE TABLE and a properly paired name and type. A and B omit TABLE, while D separates and reverses the name/type parts rather than declaring the intended column.

Why each choice is right or wrong

A - Incorrect: TABLE is missing and the name/type pair is split by a comma.

B - Incorrect: TABLE is missing and the type/name order is wrong.

C - Correct: CREATE TABLE is followed by one correctly ordered name/type declaration.

D - Incorrect: A comma separates type from name and no valid intended declaration is formed.

Primary note proof

Study-note section FDB30

> CREATE TABLE Employee (EmpID INTEGER PRIMARY KEY, Name VARCHAR(80)); declares two columns. The name and its type stay together; the comma separates whole column declarations. To add a primary key later: ALTER TABLE Employee ADD PRIMARY KEY (EmpID); existing data must be unique and non-NULL. A table cannot gain a second primary key without replacing the existing constraint.

Question sources

Computer Science Exit Exam · 2018 · Question 40

Question 47 | Q00932

From the following alternatives which one is FALSE about database system?

A. " I is very difficult to protect a file under the system

B. * iy database system the user is not required to write the procedures

C. « tn database system, DBMS provides a good protection mechanism.

D. ° i contains a wide variety of sophisticated techniques to store and retrieve the data.

Hint

Review the database approach and match each claimed benefit or cost to its mechanism.

Answer A: " I is very difficult to protect a file under the system

DBMS permission and authentication support contradicts the claim of poor protection; B is interpreted as nonprocedural querying rather than no application code ever.

Why each choice is right or wrong

A - Correct: Contradicts described protection (PDF 53.)

B - Incorrect: Nonprocedural retrieval is supported (PDF 53.)

C - Incorrect: Matches security support (PDF 53.)

D - Incorrect: Storage and indexes support retrieval (PDF 53.)

Primary note proof

Study-note section FDB01

> A database is a coherent collection of related facts with meaning for an application. A DBMS is software that defines, stores, retrieves, updates, protects and shares that data. The database is the content; the DBMS manages it. A database system also includes applications, people and infrastructure.

Study-note section FDB25

> B/B+ trees support ordered and range search; hashing targets equality; bitmap indexes suit some analytic workloads.

Study-note section FDB01

> Complexity, administration, storage and licensing can outweigh benefits for a tiny fixed application; lightweight embedded DBMSs also exist.

Question sources

Computer Science Exit Exam · 2018 · Question 45

Question 48 | Q00943

Consider a directed line(->) from the relationship set advisor to both entity sets instructor and student. This indicates cardinality

A. Many to one

B. Many to many

C. ¢.
One to one

D. One to many

Hint

Read the relationship in both directions and check participation constraints.

Answer C: One-to-one, under the common relationship-arrow convention.

FDB09 explicitly states the convention used for this example: arrows from advisor toward both Instructor and Student impose maximum-one at both ends. Each instructor can therefore be associated with at most one student and each student with at most one instructor. That is 1:1, without implying mandatory participation. A different notation would need an explicit legend.

Why each choice is right or wrong

A - Incorrect: Many-to-one constrains only one end to maximum one, whereas both ends have arrows here.

B - Incorrect: Many-to-many permits multiple associations at both ends, contrary to both maximum-one arrows.

C - Correct: Maximum one at each end yields a one-to-one relationship under the stated common convention.

D - Incorrect: One-to-many allows multiple associations at one end, which the second arrow rules out.

Primary note proof

Study-note section FDB09

Read business rules in both directions. If each employee belongs to one department and each department has many employees, Employee→Department is N:1; Department→Employee is 1:N. Building→Location could also be N:1, so names alone cannot select a unique example. Under the common arrow convention, arrows from advisor to both Instructor and Student impose maximum-one at both ends, giving 1:1. Without a notation convention, arrows are unsafe evidence.

Fundamental of Database Systems module | PDF page 11 | lines 27-28

> One to one (1-1) - When each entity in each entity set can take part only once in the relationship, the cardinality is one to one.

Question sources

Computer Science Exit Exam · 2018 · Question 56

Question 49 | Q00957

What is the basic goal of Normalization?

A. To decrease data integrity

B. To reduce redundancy

C. ¢.
To maximize transitive dependency

D. To increase dependency

Hint

Distinguish dependency-based design problems from the contents of one sample table.

Answer B: To reduce redundancy

Normalization reduces repeated data and resulting anomalies.

Why each choice is right or wrong

A - Incorrect: Integrity is protected (PDF 16.)

B - Correct: Redundancy reduction is explicit (PDF 16.)

C - Incorrect: 3NF removes transitive dependence (PDF 16.)

D - Incorrect: Increasing dependency is not the goal (PDF 16.)

Primary note proof

Study-note section FDB19

> Suppose Enrollment repeats StudentName for every course. An update anomaly requires changing every copy of the student's name; missed copies disagree. An insertion anomaly prevents recording a new student until some enrollment exists. A deletion anomaly loses the only record of a student's details when their last enrollment is deleted. Revoke anomaly is not a normalization anomaly.

Study-note section FDB19

> Reduced redundancy can improve integrity and storage use, but extra keys and joins mean neither storage savings nor faster retrieval is guaranteed.

Study-note section FDB19

> Adding a generated row ID may make insertion technically possible, but does not remove repeated facts or fix the dependency design.

Related reading (context, not primary note proof)

Study-note section FDB21

> database design technique that minimizes redundancy from a relation or a set of relations. Normalization rules divides larger tables into smaller tables and links them using relationship.

Question sources

Computer Science Exit Exam · 2018 · Question 70

Question 50 | Q00964

For a relation with attributes ID, CITY and NAME, ID is guaranteed unique and non-NULL; CITY and NAME are not unique. Which listed attribute sets are superkeys? Select all that apply.

A. NAME

B. ID

C. CITY

D. CITY, ID

Hint

Test uniqueness and minimality separately when classifying keys.

Answer B, D: B. ID; D. CITY, ID

A superkey is any attribute set guaranteed to identify a tuple; it need not be minimal. ID has the stated uniqueness guarantee, and adding CITY cannot destroy it. Thus ID and (CITY, ID) are superkeys. CITY and NAME individually lack uniqueness guarantees. Only ID is a minimal candidate key among the two qualifying choices, but minimality is not required here.

Why each choice is right or wrong

A - Incorrect: Repeated names are permitted, so NAME is not a guaranteed identifier.

B - Correct: ID is guaranteed unique and identifies each tuple.

C - Incorrect: Repeated cities are permitted, so CITY alone is not a superkey.

D - Correct: The set includes unique ID and therefore retains uniqueness.

Primary note proof

Study-note section FDB07

A superkey uniquely identifies a tuple. A candidate key is a minimal superkey: removing any component loses uniqueness. Minimal means no unnecessary attribute, not necessarily the fewest columns among all keys. A primary key is one selected candidate key; remaining candidates are alternate keys. A composite key contains multiple attributes and need not be the chosen primary key.

Study-note section FDB07

If ID is unique, both {ID} and {ID,City} are superkeys, but only {ID} is minimal.

Study-note section FDB07

Prefer stable, compact identifiers when practical, but Email, SSN or EmployeeID is a candidate only if business rules guarantee uniqueness.

Super Key − A set of attributes (one or more) that collectively identifies an entity in an entity set. Candidate Key − A minimal super key is called a candidate key.

Question sources

Computer Science Exit Exam · 2018 · Question 77

Question 51 | Q00982

is one of the candidate keys chosen by the database designer to uniquely identify the entity set.

A. Super key

B. Candidate key

C. Social security key

D. Primary key

Hint

Test uniqueness and minimality separately when classifying keys.

Answer D: Primary key

A primary key is the candidate selected by the designer.

Why each choice is right or wrong

A - Incorrect: Superkey need not be minimal (PDF 11.)

B - Incorrect: Candidate need not be selected (PDF 11.)

C - Incorrect: Example identifier is not this role (PDF 11.)

D - Correct: Exact selected-key definition (PDF 11.)

Primary note proof

Study-note section FDB07

> A superkey uniquely identifies a tuple. A candidate key is a minimal superkey: removing any component loses uniqueness. Minimal means no unnecessary attribute, not necessarily the fewest columns among all keys. A primary key is one selected candidate key; remaining candidates are alternate keys. A composite key contains multiple attributes and need not be the chosen primary key.

Computer Science Exit Exam · 2018 · Question 95

Question 52 | Q01151

12.
is a collection of concepts thatcan be used to describe the structure of a database.

A. a | Data Architecture

B. i? | Data Model

C. oO Data client

D. | All of the above

Hint

Compare the data models by how they organize records and relationships.

Answer B: i? | Data Model

The defined collection of concepts describing database structure is a data model.

Why each choice is right or wrong

A - Incorrect: Architecture is not the defined term (PDF 7.)

B - Correct: Exact definition (PDF 7.)

C - Incorrect: Client is an application role (PDF 7.)

D - Incorrect: Other choices do not match (PDF 7.)

Primary note proof

Study-note section FDB02

> A data model supplies concepts for structure, relationships, constraints and operations. Conceptual ER models describe entities and relationships. Relational models use tables; hierarchical models organize records in a parent-child tree; classic network models connect records through pointer-based owner/member links, allowing multiple parents. Object models represent objects with identity, state and behavior. A physical model specifies record layouts and access paths. These are different representation choices, not stages of one query.

> A data model a collection of concepts that can be used to describe the structure of a database and provides the necessary means to achieve data abstraction. By structure of a database we mean the

Question sources

Computer Science Exit Exam practice questions · Question 12

Question 53 | Q01152

The description of a database is called

A. a | Database snapshot

B. i? | Database instances

C. @) Database schema

D. | All of the above

Hint

Distinguish a relation's structure from its current contents and its descriptive metadata.

Answer C: @) Database schema

Schema describes the designed database; instance and snapshot describe current data.

Why each choice is right or wrong

A - Incorrect: Current contents (PDF 7.)

B - Incorrect: Current occurrences (PDF 7.)

C - Correct: Designed structure (PDF 7.)

D - Incorrect: Other choices are different concepts (PDF 7.)

Primary note proof

Study-note section FDB03

> A schema describes names, structures and constraints; an instance, state or snapshot is the data at a particular time. Inserting a student changes the state, while adding a column changes the schema. Metadata is data describing data. The catalog or data dictionary records table definitions, types, constraints and often access privileges and optimizer statistics. A schema diagram draws tables and key references; labels such as database diagram can overlap.

Fundamental of Database Systems module | PDF page 7 | lines 21-22

> The description of a database is called the database schema, which is specified during database design and is not expected to change frequently. The data in the database at a particular moment

Question sources

Computer Science Exit Exam practice questions · Question 13

Question 54 | Q01153

Which listed terms denote database contents at one particular moment, rather than the database definition? Select all that apply.

A. Database instance

B. Database state / snapshot

C. Database schema

D. None of the above

Hint

Distinguish a relation's structure from its current contents and its descriptive metadata.

Answer A, B: A. Database instance; B. Database state / snapshot

An instance, state or snapshot describes the actual data at a selected time. Those contents can change after an insertion or update without changing the database definition. A schema describes names, structures and constraints instead. Therefore both the instance option and the state/snapshot option fit, while none of the above cannot be selected because these matching terms are present.

Why each choice is right or wrong

A - Correct: A database instance denotes its data at a particular time.

B - Correct: State and snapshot are synonyms for the same time-specific database contents.

C - Incorrect: A schema describes structure and constraints rather than current data values.

D - Incorrect: Both instance and state/snapshot are provided and correctly fit the definition.

Primary note proof

Study-note section FDB03

> A schema describes names, structures and constraints; an instance, state or snapshot is the data at a particular time. Inserting a student changes the state, while adding a column changes the schema. Metadata is data describing data. The catalog or data dictionary records table definitions, types, constraints and often access privileges and optimizer statistics. Question sources

Computer Science Exit Exam practice questions · Question 14

Question 55 | Q01154

What is the capacity to change the conceptual schema while preserving affected external schemas and application interfaces?

A. Logical data independence

B. Physical data independence

C. Conceptual database

D. All of the above

Hint

Trace which schema levels a proposed change affects.

Answer A: Logical data independence

Logical data independence allows changes to the conceptual schema while preserving the external views and application interfaces that depend on it. Physical data independence instead concerns changing internal storage without changing the conceptual schema. A conceptual database or schema describes the logical structure itself; naming that structure does not express the ability to preserve external interfaces during a change. Consequently A names the requested property and the all-of-the-above choice is false.

Why each choice is right or wrong

A - Correct: Correct: logical data independence preserves external interfaces across conceptual-schema changes.

B - Incorrect: Incorrect: physical data independence concerns internal-storage changes while preserving the conceptual schema.

C - Incorrect: Incorrect: conceptual database names the logical structure, not the property preserving external interfaces when that structure changes.

D - Incorrect: Incorrect: physical independence and the conceptual database are not the requested change-preservation property.

Primary note proof

Study-note section FDB04

> The external level gives each user group a selected view. The conceptual level describes the whole logical database: entity types, relationships, data types and constraints.

Study-note section FDB04

> Physical data independence permits changing internal storage without changing the conceptual schema, for example adding an index. Logical data independence permits conceptual changes while preserving affected external views and application interfaces, for example splitting a table while maintaining a compatible view.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 8 | lines 12-13

1. Logical data independence is the capacity to change the conceptual schema without having to change external schemas or application programs.

Question sources

Computer Science Exit Exam practice questions · Question 15

Question 56 | Q01155

is language used to define the database conceptual schema

A. a | Data Manipulation Language (DML) x

B. ? | Data Definition Langugae (DDL) v

C. /@| Transaction Query Language (TQL) x

D. | None of the above x

Hint

Classify each SQL command by the kind of change it performs.

Answer B: ? | Data Definition Langugae (DDL) v

Defining a schema is definition rather than manipulation. DDL commands define structure, while DML commands manipulate data.

Why each choice is right or wrong

A - Incorrect: DML covers retrieval and updates, not schema definition. (PDF pp. 26.)

B - Correct: DDL is the definition-language category. (PDF pp. 26.)

C - Incorrect: TQL is not the module's schema language. (PDF pp. 26.)

D - Incorrect: The definition-language choice is present. (PDF pp. 26.)

Primary note proof

Study-note section FDB26

> DDL changes structure: CREATE, ALTER, DROP, commonly RENAME and TRUNCATE in textbook classifications. DML retrieves or changes data: SELECT, INSERT, UPDATE, DELETE. Some texts separate SELECT as DQL. DCL manages privileges through GRANT and REVOKE. TCL includes COMMIT, ROLLBACK and SAVEPOINT. Classify a statement by its effect, not its length.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 26 | lines 4-11

> SQL represents Structured Query Language. SQL is a comprehensive database language: It has statements for data definitions, and updates. Hence, it is both a DDL (Data Definition language) and a DML (Data Manipulation Language). 7.1.1 DDL (data definition language) Basic DDL commands we usually use are: CREATE, DROP, ALTER, TRUNCATE and RENAME 7.1.2 DML (data manipulation language) Basic DDL commands are: SELECT, PROJECT, JOIN, INSERT, DELETE, and UPDATE

Question sources

Computer Science Exit Exam practice questions · Question 16

Question 57 | Q01157

Common functions applied to collections of numeric values: SUM, AVERAGE, COUNT. This function belongs to

A. Ww Grouping x

B. i? | Aggregate functions 4

C. |@| All of the above x

D. | None of the above ><

Hint

Apply grouping before filtering groups and computing aggregate output.

Answer B: Aggregate functions.

SUM, average and COUNT summarize collections into values, which is aggregation. GROUP BY instead partitions rows into groups for those summaries. SQL normally spells the average function AVG; the conceptual use of AVERAGE here still describes aggregation.

Why each choice is right or wrong

A - Incorrect: Grouping partitions rows; it is not the function category containing SUM and COUNT.

B - Correct: These functions summarize a collection of values into a count, total or average.

C - Incorrect: Grouping and aggregate functions are distinct concepts, so all listed categories cannot be correct.

D - Incorrect: Aggregate functions is present and correctly describes the functions in the stem.

Primary note proof

Study-note section FDB32

> COUNT(*) counts rows, COUNT(x) counts non-NULL x values; SUM and AVG summarize non-NULL numeric values. SQL's usual average function is AVG, not AVERAGE. GROUP BY creates one group per distinct grouping value; HAVING tests aggregate groups after WHERE has filtered individual rows.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Science Exit Exam practice questions · Question 18

Question 58 | Q01158

Entity types that do not have key attributes of their own are called

A. a | Entity

B. i? | Strong Entity

C. @) Weak Entity

D. | Foreign Entity

Hint

Check how a dependent entity obtains its complete identity.

Answer C: @) Weak Entity

Weak entities lack their own key attributes, while strong entities have their own keys. Their partial keys identify them only within an owner.

Why each choice is right or wrong

A - Incorrect: Entity is the broader category and does not identify the missing-key subtype. (PDF pp. 10.)

B - Incorrect: Strong entities have their own key, the opposite condition. (PDF pp. 10.)

C - Correct: Weak entity matches the exact definition. (PDF pp. 10.)

D - Incorrect: Foreign entity is not the defined subtype; foreign keys concern table references. (PDF pp. 10.)

Primary note proof

Study-note section FDB08

> A weak entity lacks a complete independent key. Its owner is normally a strong entity, so owner entity set and strong entity set may both describe the associated set. Its partial key, also called discriminator, distinguishes weak entities of the same owner. Identification combines the owner key and partial key.

Study-note section FDB08

> A weak entity is not merely any table with a foreign key.

Study-note section FDB08

> Then (EmployeeID,DependentName) is the key, and EmployeeID is a foreign key.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 10 | lines 6-10

> Each entity has attributes, the particular properties that describe it. Entities that do not have key attributes of their own are called weak entity. The regular entity types that have a key attribute are called strong entity types. Weak entities are identified by being related to specific strong entities in combination with one of their attribute values. A weak entity type has a partial key, which is the attribute that can uniquely identify weak entities that are related to the same owner entity.

Question sources

Computer Science Exit Exam practice questions · Question 19

Question 59 | Q01159

The partial key is sometimes called

A. a | Dominant Entity

B. i? | Child Entity Type

C. @) Subordinate Entity Type

D. | Discriminator

Hint

Check how a dependent entity obtains its complete identity.

Answer D: Discriminator.

A partial key distinguishes weak entities belonging to the same owner; the owner key is still needed for global identification. FDB08 explicitly calls that partial key a discriminator. The other choices describe entity roles or types rather than the identifying attribute.

Why each choice is right or wrong

A - Incorrect: An entity role is not the name of the identifying partial-key attribute.

B - Incorrect: A child entity type describes a type of entity rather than its partial identifier.

C - Incorrect: A subordinate entity type is not a synonym for a partial key.

D - Correct: Discriminator is the partial key that distinguishes weak entities within the same owner.

Primary note proof

Study-note section FDB08

> A weak entity lacks a complete independent key. Its owner is normally a strong entity, so owner entity set and strong entity set may both describe the associated set. Its partial key, also called discriminator, distinguishes weak entities of the same owner. Identification combines the owner key and partial key.

Study-note section FDB08

The weak entity participates totally in its identifying relationship.

Study-note section FDB08

Chen notation uses a double rectangle, double identifying diamond and dashed underline for a partial key.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 10 | lines 6-13

Each entity has attributes, the particular properties that describe it. Entities that do not have key attributes of their own are called weak entity. The regular entity types that have a key attribute are called strong entity types. Weak entities are identified by being related to specific strong entities in combination with one of their attribute values. A weak entity type has a partial key, which is the attribute that can uniquely identify weak entities that are related to the same owner entity. In ER diagrams, both a weak entity type and its identifying relationship are distinguished by surrounding their boxes and diamonds with double lines. The partial key attribute is underlined with a dashed or dotted line.

Question sources

Computer Science Exit Exam practice questions · Question 20

Question 60 | Q01162

A real-world physical or logical object is called:

A. Attributes

B. Relationship

C. Entity

D. All of the above

Hint

Review entity, attribute and relationship notation before interpreting the model.

Answer C: Entity

An entity may have physical existence or conceptual existence. Attributes describe an entity; relationships associate entity types. The stem asks for the object itself.

Why each choice is right or wrong

A - Incorrect: An attribute is a property of the object. (PDF pp. 10, 11.)

B - Incorrect: A relationship associates objects rather than naming the object. (PDF pp. 10, 11.)

C - Correct: Entity covers both physical and conceptual objects. (PDF pp. 10, 11.)

D - Incorrect: The other categories have different roles, so all is false. (PDF pp. 10, 11.)

Primary note proof

Study-note section FDB06

An entity is a distinguishable real or conceptual thing, such as one student or one course. An entity type describes common properties; its current collection of entities is an entity set. A relationship associates entities. In Chen notation rectangles represent entity types, diamonds relationships and ellipses attributes; double ellipses denote multivalued attributes and dashed ellipses derived attributes. Always inspect the diagram legend.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 10 | lines 3-8

An entity may be an object with a physical existence (for example, a particular person, car, house, or employee) or it may be an object with a conceptual existence (for instance, a company, a job, or a university course). In ER diagrams, an entity is placed in a rectangle. Each entity has attributes, the particular properties that describe it. Entities that do not have key attributes of their own are called weak entity. The regular entity types that have a key attribute are called strong entity types. Weak entities are identified by being related to specific strong entities

Fundamental of Database Systems module | PDF page 11 | lines 13-15

A relationship type represents the association between entity types. For example, _Enrolled in‘ is a relationship type that exists between entity Student and Course. In ER diagram, relationship is represented by a diamond and connecting the entities with lines.

Question sources

Computer Science Exit Exam practice questions · Question 23

Question 61 | Q01163

In the usual normalization sequence, which is the first normal form that excludes partial dependencies of nonprime attributes on any candidate key?

A. First Normal Form (1NF)

B. Third Normal Form (3NF)

C. Second Normal Form (2NF)

D. Boyce-Codd Normal Form (BCNF)

Hint

Check atomicity, candidate keys and partial dependencies in that order.

Answer C: Second Normal Form (2NF)

Second normal form is the first stage requiring atomic relations to have no nonprime attribute partially dependent on any candidate key. First normal form addresses atomic values, so it does not impose that dependency rule. Third normal form and BCNF are stronger stages that inherit the absence of partial dependencies, but they are not the first stage introducing it. BCNF specifically requires every nontrivial functional-dependency determinant to be a superkey.

Why each choice is right or wrong

A - Incorrect: Incorrect: 1NF requires atomic values but does not exclude partial dependencies.

B - Incorrect: Incorrect: 3NF inherits 2NF and imposes its additional determinant/prime-attribute condition; it is not the first stage.

C - Correct: Correct: 2NF is the first stage excluding nonprime partial dependencies on candidate keys.

D - Incorrect: Incorrect: BCNF requires every nontrivial determinant to be a superkey; it is stronger than the first stage imposing the partial-dependency rule.

Primary note proof

Study-note section FDB20

> 1NF requires atomic values in the chosen relational domains and no repeating groups in cells.

Study-note section FDB20

> 2NF requires 1NF and no nonprime attribute partially dependent on any candidate key.

Study-note section FDB21

> For every nontrivial FD X→A, 3NF permits it when X is a superkey or A is prime. BCNF requires X to be a superkey. The mnemonic whole key and nothing but the key describes the common single-key case; it cannot replace the full tests when keys overlap. Remove dependencies of nonprime facts on nonkey determinants.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 17 | lines 2-15

> First normal form (1NF) A relation (table) R is in 1NF if and only if (iff) all underlying domains of attributes contain only atomic (simple or indivisible) values. i.e. The value of any attribute in a tuple (row) must be a single value from the domain of their attribute. It is defined to disallow multivalued attributes, composite attributes, and their combinations. In other words, 1NF disallows relations within relations or relations as attribute values within tuples. It must be remove repeating groups (values) in a single field. The primary key with repeating group attributes are moved into a new table. When a relation contains no repeating groups (values), it is in first normal form (1NF). Second normal form (2NF) Second normal form (2NF) is based on the concept of full functional dependency. A relation schema R is in 2NF if it is in 1NF and every non-prime attribute A in R is fully functionally dependent on the primary key (i.e. the non-prime attributes are not partially dependent on key attributes). Remove any partially dependent

attributes and place them in another relation. A partial dependency is when the attribute(s) is/are dependent on a part of a key.

Fundamental of Database Systems module | PDF page 18 | lines 5-8

Third Normal Form (3NF) A relation schema R is in third normal form (3NF) if it is in 2NF and every non-prime attribute of _R‘ are fully functionally dependent on every key of R and non-transitively dependent on every key of R.

Question sources

Computer Science Exit Exam practice questions · Question 24

Question 62 | Q01164

In the usual normalization sequence, which is the first normal form that excludes transitive dependence of nonprime attributes on a key through a nonkey determinant?

A. Third Normal Form (3NF)

B. Fourth Normal Form (4NF)

C. First Normal Form (1NF)

D. All of the above

Hint

Check atomicity, candidate keys and partial dependencies in that order.

Answer A: Third Normal Form (3NF)

In the stated single-key teaching case, 2NF excludes partial dependencies but can still allow a nonprime fact to depend on the key through a nonkey determinant. The next defining stage is 3NF, summarized by the whole-key-and-nothing-but-the-key mnemonic. BCNF strengthens the determinant rule, and 4NF addresses multivalued dependencies. Stronger forms inherit earlier conditions, so the explicit first-stage scope makes 3NF the unique selection rather than treating inherited properties as rival answers.

Why each choice is right or wrong

A - Correct: Correct: 3NF is the first stage imposing the specified nonprime transitive-dependency restriction in this teaching case.

B - Incorrect: Incorrect: 4NF addresses multivalued dependencies and is a later stage; it is not the first stage imposing the 3NF condition.

C - Incorrect: Incorrect: 1NF concerns atomic values and does not eliminate the specified transitive dependencies.

D - Incorrect: Incorrect: Not all options identify the requested first stage: 1NF does not eliminate the specified transitive dependency and 4NF is later.

Primary note proof

Study-note section FDB20

1NF requires atomic values in the chosen relational domains and no repeating groups in cells.

Study-note section FDB20

2NF requires 1NF and no nonprime attribute partially dependent on any candidate key.

Study-note section FDB21

For every nontrivial FD X→A, 3NF permits it when X is a superkey or A is prime. BCNF requires X to be a superkey. The mnemonic whole key and nothing but the key describes the common single-key case; it cannot replace the full tests when keys overlap. Remove dependencies of nonprime facts on nonkey determinants.

Study-note section FDB21

4NF addresses nontrivial multivalued dependencies with nonsuperkey determinants; 5NF addresses join dependencies.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Science Exit Exam practice questions · Question 25

Question 63 | Q01217

A conceptual level refers to:

A. Describes the represents global view of the entire database

B. Describes the part of the database that a particular user group views of the data environment

C. Describes how data is actually stored on disk

D. Describes the physical storage structure of the database

Hint

Trace which schema levels a proposed change affects.

Answer A: Describes the represents global view of the entire database

The conceptual schema describes the whole database while hiding storage details. External views show a particular group's part, and internal schema describes storage.

Why each choice is right or wrong

A - Correct: Whole-database structure is conceptual. (PDF pp. 7, 8.)

B - Incorrect: A user-group subset is external. (PDF pp. 7, 8.)

C - Incorrect: Actual storage is internal. (PDF pp. 7, 8.)

D - Incorrect: Physical storage structure is internal. (PDF pp. 7, 8.)

Primary note proof

Study-note section FDB04

> The external level gives each user group a selected view. The conceptual level describes the whole logical database: entity types, relationships, data types and constraints. The internal/physical level describes files, record placement and access paths. These are abstraction levels, distinct from client/server deployment tiers.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 7 | lines 25-30

> 2.3 Three-schema Architecture and Data Independence The goal of the three-schema architecture is to separate the user applications from the physical database. In this architecture, schemas can be defined at the following three levels: 1. The internal level has an internal schema, which describes the physical storage structure of the database. The internal schema uses a physical data model and describes the complete details of data storage and access paths for the database.

Fundamental of Database Systems module | PDF page 8 | lines 2-7

> 2. The conceptual level has a conceptual schema, which describes the structure of the whole database for users. The conceptual schema hides the details of physical storage structures and

concentrates on describing entities, data types, relationships, user operations, and constraints. 3. The external or view level includes a number of external schemas or user views. Each external schema describes the part of the database that a particular user group is interested in and hides the rest of the database from that user group.

Question sources

Computer Science model exam 2 · Question 38

Question 64 | Q01226

Suppose you want to design a database for a certain company after you know the need of all users of the database. What is the next step you are expected to do?

A. Logical design

B. Normalization

C. Query Processing

D. Conceptual design

Hint

Identify the design phase from its inputs and intended deliverable.

Answer D: Conceptual design

After collecting users' information requirements, conceptual design develops the ER/EER model that represents those needs. Logical design then maps that model to relations, keys and constraints and checks normalization. Normalization refines dependency structure rather than replacing the initial conceptual modeling step. Query processing evaluates database requests instead of defining the initial enterprise model. D is therefore the next step under the stated sequence, rather than a claim that design can never iterate.

Why each choice is right or wrong

A - Incorrect: Incorrect: logical design maps an already developed conceptual model into relations and constraints.

B - Incorrect: Incorrect: normalization refines relation dependencies during logical design; the initial conceptual model must first be developed.

C - Incorrect: Incorrect: query processing evaluates requests rather than creating the initial model from requirements.

D - Correct: Correct: conceptual design follows the collection of requirements in the stated sequence.

Primary note proof

Study-note section FDB05

First collect business facts, required transactions, reports, volumes, privacy rules and quality targets. Conceptual design turns them into an ER/EER model. Logical design maps the conceptual model to relations, keys and constraints and checks normalization. Physical design chooses file organization, indexes and storage. Implementation creates and loads the actual objects; testing checks requirements.

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 9 | lines 10-26

Requirement Analysis The most important step in implementing a database system is to find out what is needed i.e what type of a database is required for the business organization, daily volume of data, how much data needs to be stored in the master files etc. In order to collect all this information, a database analyst spends a lot of time within the business organization talking to people, end users and getting acquainted with the day-to-day process. Conceptual Database Design In this phase the database designers will make a decision on the database model that perfectly suits the organization‘s requirement. The database designers will study the documents prepared by the analysis in the requirement analysis stage and then start development of a system model that fulfils the needs. Logical database design (Data model mapping) The conceptual design is translated into internal model which includes mapping of all objects i.e design of tables, indexes, views, transaction, access privileges etc. Physical Design Physical design or Database implementation needs the formation of special storage related constructs. These constructs consist of storage groups, table spaces, data files, tables etc.

Question sources

Computer Science model exam 2 · Question 47

Question 65 | Q01278

All are true about the Database except:

A. Program data independence.

B. Self-describing nature

C. Sharing of data and multi-user transaction processing

D. Support of single views of the data

Hint

Review the database approach and match each claimed benefit or cost to its mechanism.

Answer D: Support of single views of the data

The listed characteristics include insulation between data and programs, self-description, sharing, and multiple views. The exception is single views, interpreted as support restricted to one view; a DBMS can of course also display a single view.

Why each choice is right or wrong

A - Incorrect: Program/data insulation is expressly a characteristic. (PDF pp. 5, 6.)

B - Incorrect: Self-description is expressly listed. (PDF pp. 5, 6.)

C - Incorrect: Sharing and multiuser transactions are expressly listed. (PDF pp. 5, 6.)

D - Correct: The stated characteristic is multiple views, rather than restriction to a single view. (PDF pp. 5, 6.)

Primary note proof

Study-note section FDB01

> A database is a coherent collection of related facts with meaning for an application. A DBMS is software that defines, stores, retrieves, updates, protects and shares that data. The database is the content; the DBMS manages it. A database system also includes applications, people and infrastructure.

Study-note section FDB01

> A DBMS centralizes metadata and supports multiple views, authorization, transactions, backup and recovery.

Study-note section FDB04

> The external level gives each user group a selected view.

Related reading (context, not primary note proof)

Fundamental of Database Systems module | PDF page 5 | lines 22-29

> 1.3 Characteristics of the Database Approach The main characteristics of the database approach are Self-describing nature, Data abstraction and Insulation between programs and data, Support of multiple views of the data, sharing of data and multiuser transaction processing.
> Self-describing nature - A fundamental characteristic of the database approach is that the database system contains not only the database itself (data) but also a complete definition or description of the database structure and constraints. This information is called meta-data, and it describes the structure of the database.

Fundamental of Database Systems module | PDF page 6 | lines 2-9

> Data abstraction and Insulation between programs and data- Data Abstraction is a process of hiding unwanted or irrelevant details from the end user. It provides a different view and helps

in achieving data independence which is used to enhance the security of data. Support of multiple views of the data - A view may be a subset of the database or it may contain virtual data that is derived from the database files but is not explicitly stored. Sharing of data and multiuser transaction processing - A multiuser DBMS must allow multiple users to access the database at the same time. This is essential if data for multiple applications is to be integrated and maintained in a single database.

Question sources

Computer Science model exam 2 · Question 99

Question 66 | Q01326

Which one of the following provides the ability to query information from the database and to insert tuples into, delete tuples from, and modify tuples in the database?

A. DML(Data Manipulation Langauge)

B. DDL(Data Definition Langauge)

C. Query

D. Relational Schema

Hint

Classify each SQL command by the kind of change it performs.

Answer A: DML(Data Manipulation Langauge)

DML includes SELECT, INSERT, DELETE, UPDATE and therefore covers both retrieval and tuple changes. The second list is misprinted as Basic DDL commands but sits under the DML heading; the heading and separation resolve that typo.

Why each choice is right or wrong

A - Correct: DML is the category covering all named operations. (PDF pp. 26.)

B - Incorrect: DDL describes structural commands. (PDF pp. 26.)

C - Incorrect: A query is a request, not the complete language category for all modifications. (PDF pp. 26.)

D - Incorrect: A relational schema describes structure rather than performing operations. (PDF pp. 26.)

Primary note proof

Study-note section FDB26

DDL changes structure: CREATE, ALTER, DROP, commonly RENAME and TRUNCATE in textbook classifications. DML retrieves or changes data: SELECT, INSERT, UPDATE, DELETE. Some texts separate SELECT as DQL. DCL manages privileges through GRANT and REVOKE. TCL includes COMMIT, ROLLBACK and SAVEPOINT. Classify a statement by its effect, not its length.

Module passages - related reading

> SQL represents Structured Query Language. SQL is a comprehensive database language: It has statements for data definitions, and updates. Hence, it is both a DDL (Data Definition language) and a DML (Data Manipulation Language). 7.1.1 DDL (data definition language) Basic DDL commands we usually use are: CREATE, DROP, ALTER, TRUNCATE and RENAME 7.1.2 DML (data manipulation language) Basic DDL commands are: SELECT, PROJECT, JOIN, INSERT, DELETE, and UPDATE

Question sources

Database Fundamentals practice questions · Question 1

Question 67 | Q01327

Which command is used to modifies an existing database object, such as a table?

A. Create

B. Alter

C. Drop

D. Modify

Hint

Distinguish table definition changes from changes to stored rows.

Answer B: ALTER.

ALTER changes the definition of an existing database object. FDB30 demonstrates adding or removing columns and adding constraints with ALTER TABLE. CREATE establishes an object and DROP removes it. MODIFY can occur within some vendor-specific alteration syntax, but it is not the general top-level command requested here.

Why each choice is right or wrong

A - Incorrect: CREATE defines a new object rather than altering the definition of an existing one.

B - Correct: ALTER is the command used to change an existing database object definition.

C - Incorrect: DROP removes the object instead of modifying its existing definition.

D - Incorrect: MODIFY is not the general standalone command; some dialects use it inside ALTER syntax.

Primary note proof

Study-note section FDB30

> ALTER TABLE Employee ADD COLUMN Email VARCHAR(120); adds a column in PostgreSQL-style syntax. ALTER TABLE Employee DROP COLUMN Email; removes it. ALTER TABLE Employee ADD

CONSTRAINT uq_email UNIQUE (Email); adds a named constraint. Use ALTER rather than DALTER, and do not separate column_name and column_type with a comma; validate the resulting SQL before execution.

Study-note section FDB26

DDL changes structure: CREATE, ALTER, DROP, commonly RENAME and TRUNCATE in textbook classifications.

Study-note section FDB26

Some texts separate SELECT as DQL.

7.1.1 DDL (data definition language) Basic DDL commands we usually use are: CREATE, DROP, ALTER, TRUNCATE and RENAME 7.1.2 DML (data manipulation language) Basic DDL commands are: SELECT, PROJECT, JOIN, INSERT, DELETE, and UPDATE

Question sources

Database Fundamentals practice questions · Question 2

Question 68 | Q01328

Which command is used to modifies records?

A. Insert

B. Update

C. Delete

D. Modify

Hint

Track which rows each data-changing command affects.

Answer B: Update

The module puts UPDATE in DML (PDF p.26). Its UPDATE(Salary) privilege example explicitly permits the Finance user to change Salary values (PDF pp.54-55), grounding UPDATE as the command for modifying existing record values.

Why each choice is right or wrong

A - Incorrect: INSERT is a separate DML operation, illustrated as adding VALUES rows on PDF p.77.

B - Correct: UPDATE is explicitly tied to changing Salary values on PDF p.55.

C - Incorrect: DELETE is a separate operation illustrated with a row predicate on PDF p.77.

D - Incorrect: MODIFY is not the command used for the demonstrated change-value privilege on PDF pp.54-55.

Primary note proof

Study-note section FDB29

> INSERT INTO Hotel(HotelID,HotelName,SubCity) VALUES (1,'Hilton','Yeka'); pairs each named column with a compatible value. Counts and types must match; keys and other constraints still apply. Without a column list, values must follow the table's declared column order.

Study-note section FDB29

> UPDATE without WHERE targets every row.

Study-note section FDB29

> DELETE FROM r; removes every row but leaves r defined.

> Example 1: Commit Transaction BEGIN TRANSACTION; DELETE FROM HumanResources.JobCandidate WHERE JobCandidateID = 13; COMMIT; Example 2: Rollback Transaction CREATE TABLE ValueTable (id int); BEGIN TRANSACTION; INSERT INTO ValueTable VALUES(1); INSERT INTO ValueTable VALUES(2); ROLLBACK;

Question sources

Database Fundamentals practice questions · Question 3

Question 69 | Q01329

In the SQLite command-line shell, which command lists the names and files of attached databases?

A. db

B. use

C. .databases

D. database

Hint

Classify each SQL command by the kind of change it performs.

Answer C: C. .databases

The command belongs to the SQLite shell rather than ordinary SQL statement syntax. Its documented spelling is .databases, including the leading dot and final s, and it lists attached database names and files. The corrected C has that spelling. The alternatives db, use and database do not form this SQLite attached-database listing command.

Why each choice is right or wrong

A - Incorrect: db is not the SQLite shell listing command.

B - Incorrect: use does not list SQLite attached names and files.

C - Correct: The .databases command performs the requested listing.

D - Incorrect: database lacks the required shell-command spelling.

Primary note proof

Study-note section FDB26

DELETE removes rows and keeps the table; DROP TABLE removes the table object; ALTER changes its definition. TRUNCATE empties a table using implementation-specific mechanisms. PostgreSQL allows transactional rollback of TRUNCATE, so no rollback information is retained is not a universal SQL property. SQL Server permits DROP DATABASE Sales, suppliers; that comma-list syntax is vendor-specific. SQLite's .databases lists attached names/files in its command-line shell; .database is not the documented command.

Module passages - related reading

Question sources

Database Fundamentals practice questions · Question 4

Question 70 | Q01330

What is an RDBMS?

A. Database that stores data elements that are not linked

B. Database that accesses data elements that are not linked

C. Database that stores and allows access to data elements that are linked

D. None of the mentioned

Hint

Compare the data models by how they organize records and relationships.

Answer C: Database that stores and allows access to data elements that are linked

A relational DBMS manages a database represented by relations/tables, with references maintaining relationships between tuples. Among these broad descriptions C is closest, although linked data alone is not a complete definition distinguishing relational from other models.

Why each choice is right or wrong

A - Incorrect: A description excluding links omits the relationships modeled by references. (PDF pp. 5, 13, 14.)

B - Incorrect: Accessing only unlinked elements also omits those relationships. (PDF pp. 5, 13, 14.)

C - Correct: Storage and access to related elements agrees with tables and relational constraints. (PDF pp. 5, 13, 14.)

D - Incorrect: C supplies the compatible broad description, though it is not a formal definition. (PDF pp. 5, 13, 14.)

Primary note proof

Study-note section FDB02

> A data model supplies concepts for structure, relationships, constraints and operations. Conceptual ER models describe entities and relationships. Relational models use tables; hierarchical models organize records in a parent-child tree; classic network models connect records through pointer-based owner/member links, allowing multiple parents. Object models represent objects with identity, state and behavior. A physical model specifies record layouts and access paths. These are different representation choices, not stages of one query.

Study-note section FDB03

> A relation is a set of tuples, represented as a table.

Study-note section FDB03

Classical relations have distinct tuples, atomic cells and domains for attributes; row order has no meaning.

Fundamental of Database Systems module | PDF page 5 | lines 14-16

Database Management System (DBMS) is then a tool for creating and managing databases. DBMS is a software that facilities the processes of defining, constructing, manipulating, and sharing databases. Example: MySQL server, MS ACESS, Microsoft SQL server.

Fundamental of Database Systems module | PDF page 13 | lines 18-27

3.6 The Relational Database Model The relational model represents the database as a collection of relations. A table is represented with columns and rows. Each table is an entity in the ER diagram. Each row is known as a tuple. Each table of the column has a name or attribute of the entity. 3.7 Relational Model Concepts in DBMS Attribute: Each column in a Table. Attributes are the properties which define a relation Tables - In the Relational model, relations are saved in the table format. It is stored along with its entities. A table has two properties rows and columns. Rows represent records and columns represent attributes. Tuple - It is a single row of a table, which contains a single record.

Fundamental of Database Systems module | PDF page 14 | lines 21-26

Referential Integrity Constraints - The Referential integrity constraints is specified between two relations or tables and used to maintain the consistency among the tuples in two relations. Referential Integrity constraints in DBMS are based on the concept of Foreign Keys. A foreign key is an important attribute of a relation which should be referred to in other relationships. Referential integrity constraint state happens where relation refers to a key attribute of a different or same relation. However, that key element must exist in the table.

Question sources

Database Fundamentals practice questions · Question 5

Question 71 | Q01331

What is a relation in RDBMS?

A. Key

B. Table

C. Row

D. Data Types

Hint

Distinguish a relation's structure from its current contents and its descriptive metadata.

Answer B: Table

The relational model represents relations in table format. A tuple is one row; a key identifies tuples rather than being the relation itself.

Why each choice is right or wrong

A - Incorrect: A key is an identifying attribute set. (PDF pp. 13.)

B - Correct: A relation is represented as a table. (PDF pp. 13.)

C - Incorrect: A row is a tuple within the relation. (PDF pp. 13.)

D - Incorrect: Data types constrain values rather than constituting a relation. (PDF pp. 13.)

Primary note proof

Study-note section FDB03

> A relation is a set of tuples, represented as a table. A tuple/row/record contains related attribute values; an attribute/column/field describes a property. Degree counts columns; cardinality counts rows. Classical relations have distinct tuples, atomic cells and domains for attributes; row order has no meaning. Column order has no logical meaning when attributes are identified by name. SQL tables can contain duplicate rows unless constrained.

Study-note section FDB07

> A superkey uniquely identifies a tuple.

Study-note section FDB07

> A primary key is one selected candidate key; remaining candidates are alternate keys.

Module passages - related reading

Question sources

Database Fundamentals practice questions · Question 6

Question 72 | Q01332

Relational Algebra is a _____ query language that takes two relations as input and produces another relation as an output of the query.

A. Relational

B. Structural

C. Procedural

D. Fundamental

Hint

Distinguish a declarative condition from a prescribed evaluation procedure.

Answer C: Procedural

Relational algebra is procedural because it specifies a sequence of operations. The stem overgeneralizes arity: operations can take one or more input relations, not always two.

Why each choice is right or wrong

A - Incorrect: Relational describes the model but misses the procedural/calculus distinction. (PDF pp. 24, 24.)

B - Incorrect: Structural is not the stated classification. (PDF pp. 24, 24.)

C - Correct: Procedural is expressly justified by the required sequence. (PDF pp. 24, 24.)

D - Incorrect: Fundamental is not the procedural classification used in the definition. (PDF pp. 24, 24.)

Primary note proof

Study-note section FDB36

> Relational algebra specifies a sequence of operations and is procedural at the logical level. Relational calculus specifies a predicate describing desired results and is declarative/nonprocedural. A tuple variable ranges over tuples; a domain variable ranges over individual attribute values. Safe/range-restricted expressions produce results bounded by the database's active domain.

Study-note section FDB35

> Rename ρ changes relation or attribute names.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 24 | lines 5-9

> Relational algebra is the basic set of operations for the relational model. These operations enable a user to specify basic retrieval requests (or queries). The result of an operation is a new relation, which may have been formed from one or more input relations. The algebra operations thus

produce new relations. Since each operation returns a relation, operations can be composed (Algebra is —closed‖.)

Fundamental of Database Systems module | PDF page 24 | lines 21-26

In a calculus expression, there is no order of operations to specify how to retrieve the query result. A calculus expression specifies only what information the result should contain. This is the main distinguishing feature between relational algebra and relational calculus. Relational calculus is considered to be a nonprocedural language. This differs from relational algebra, where we must write a sequence of operations to specify a retrieval request; hence relational algebra can be considered as a procedural way of stating a query.

Question sources

Database Fundamentals practice questions · Question 7

Question 73 | Q01333

Which of the following is a fundamental operation in relational algebra?

A. Set intersection

B. Natural join

C. Assignment

D. None of the mentioned

Hint

Use the operator convention stated in the question and distinguish membership from derivability.

Answer A: Set intersection

Under the stated Basic operations list, intersection is basic. A smaller primitive basis may instead treat intersection as derived; the answer uses the stated list.

Why each choice is right or wrong

A - Correct: Intersection is explicitly under Basic operations. (PDF pp. 24.)

B - Incorrect: Natural join is absent from this basic list. (PDF pp. 24.)

C - Incorrect: Assignment is absent from this basic list. (PDF pp. 24.)

D - Incorrect: False because intersection is listed as basic. (PDF pp. 24.)

Primary note proof

Study-note section FDB-S01

A list of basic relational-algebra operators is a teaching convention, distinct from a claim that every listed operation is logically indispensable. The course module uses selection, projection, Cartesian product, set difference, union and intersection as its basic-operation list. Natural join and assignment are not members of that particular list.

Study-note section FDB-S01

A smaller primitive basis may therefore omit intersection even when it is introduced as a basic operation.

Study-note section FDB-S01

Under set semantics, union includes tuples from either compatible input, intersection retains tuples common to both, and difference keeps first-input tuples absent from the second.

Related reading (context, not primary note proof)

Study-note section FDB35

Fundamental of Database Systems module | PDF page 24 | lines 10-16

Basic operations: Selection (σ) - Selects a subset of rows from relation. Projection (π) - Deletes unwanted columns from relation. Cross-product (x) - Allows us to combine two relations. Set-difference (-) - Tuples in relation 1, but not in relation 2. Union (U) - Tuples in relation 1 and in relation 2. Intersection (∩) - Only tuples in relation 1 and in relation 2 (only the common tuples).

Question sources

Database Fundamentals practice questions · Question 8

Question 74 | Q01334

Which of the following is used to denote the selection operation in relational algebra?

A. Pi (Greek)

B. Sigma (Greek)

C. Lambda (Greek)

D. Omega (Greek)

Hint

Apply each algebra operator to the input relations step by step.

Answer B: Sigma (Greek)

Selection filters tuples and is conventionally denoted by sigma, σ. Projection keeps attributes and is denoted by pi, π. Lambda and omega are different Greek symbols and therefore cannot identify the requested sigma operation under this notation. This is a question about the operator's conventional symbol, rather than whether another symbol could be assigned a new meaning in a custom notation. B is the unique selection symbol among the choices.

Why each choice is right or wrong

A - Incorrect: Incorrect: pi, π, denotes projection, which retains attributes.

B - Correct: Correct: sigma, σ, denotes selection, which filters tuples.

C - Incorrect: Incorrect: lambda, λ, is a different symbol from the conventional selection symbol σ.

D - Incorrect: Incorrect: omega, ω, is a different symbol from the conventional selection symbol σ.

Primary note proof

Study-note section FDB35

> Selection σ filters tuples; projection π retains attributes and removes duplicate tuples under set semantics.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 24 | lines 10-16

> Basic operations: Selection (σ) - Selects a subset of rows from relation. Projection (π) - Deletes unwanted columns from relation. Cross-product (x) - Allows us to combine two relations. Set-difference (-) - Tuples in relation 1, but not in relation 2. Union (U) - Tuples in relation 1 and in relation 2. Intersection (∩) - Only tuples in relation 1 and in relation 2 (only the common tuples).

Question sources

Database Fundamentals practice questions · Question 9

Question 75 | Q01335

For union-compatible relations, which listed names denote the minus operation R−S, returning tuples in R but not S? Select all that apply.

A. Union

B. Set-difference

C. Difference

D. Intersection

Hint

Use the operator convention stated in the question and distinguish membership from derivability.

Answer B, C: B. Set-difference; C. Difference

R−S tests membership asymmetrically: a tuple must occur in R and must not occur in S. Difference and set-difference are names for this same operator, so both should be selected. Union combines membership from either input, whereas intersection requires membership in both. Swapping the inputs to difference can change the result because the exclusion direction matters.

Why each choice is right or wrong

A - Incorrect: Union combines compatible input tuples rather than retaining only first-input tuples absent from the second.

B - Correct: Set-difference returns tuples in the first relation that do not occur in the second.

C - Correct: Difference is the same minus operator as set-difference.

D - Incorrect: Intersection keeps tuples common to both relations, the opposite membership condition.

Primary note proof

Study-note section FDB-S01

> Under set semantics, union includes tuples from either compatible input, intersection retains tuples common to both, and difference keeps first-input tuples absent from the second. Intersection can be expressed using difference, while a matching join can be expressed as selection over a Cartesian product. A smaller primitive basis may therefore omit intersection even when it is introduced as a basic operation.

Study-note section FDB35

> Union, difference and intersection require union-compatible schemas.

Study-note section FDB35

> Rename ρ changes relation or attribute names.

Question sources

Database Fundamentals practice questions · Question 10

Question 76 | Q01336

Which one of the following is used to define the structure of the relation, deleting relations and relating schemas?

A. DML(Data Manipulation Langauge)

B. DDL(Data Definition Langauge)

C. Query

D. Relational Schema

Hint

Classify each SQL command by the kind of change it performs.

Answer B: DDL(Data Definition Langauge)

Defining and deleting relation structures are schema operations in DDL. DML operates on their data. Relating schemas here is interpreted as defining schema structure rather than retrieving joins.

Why each choice is right or wrong

A - Incorrect: DML is for data operations. (PDF pp. 26.)

B - Correct: DDL is the schema-definition category. (PDF pp. 26.)

C - Incorrect: A query request is not the schema language category. (PDF pp. 26.)

D - Incorrect: A schema is a description, not a language for changing it. (PDF pp. 26.)

Primary note proof

Study-note section FDB26

> DDL changes structure: CREATE, ALTER, DROP, commonly RENAME and TRUNCATE in textbook classifications. DML retrieves or changes data: SELECT, INSERT, UPDATE, DELETE. Some texts separate SELECT as DQL. DCL manages privileges through GRANT and REVOKE. TCL includes COMMIT, ROLLBACK and SAVEPOINT. Classify a statement by its effect, not its length.

SQL represents Structured Query Language. SQL is a comprehensive database language: It has statements for data definitions, and updates. Hence, it is both a DDL (Data Definition language) and a DML (Data Manipulation Language). 7.1.1 DDL (data definition language) Basic DDL commands we usually use are: CREATE, DROP, ALTER, TRUNCATE and RENAME 7.1.2 DML (data manipulation language) Basic DDL commands are: SELECT, PROJECT, JOIN, INSERT, DELETE, and UPDATE

Question sources

Database Fundamentals practice questions · Question 11

Question 77 | Q01337

CREATE TABLE employee (name VARCHAR(80), id INTEGER); What kind of SQL statement is this?

A. DML

B. DDL

C. View

D. Integrity constraint

Hint

Classify each SQL command by the kind of change it performs.

Answer B: DDL

CREATE TABLE defines a new table and its columns, so it is a data-definition-language statement. DML instead retrieves or changes stored rows. A view is a query-based logical object, while this statement creates a base table. Integrity constraints can be included inside a table definition, but this whole statement is not merely a constraint expression. VARCHAR has the stated length in this table definition.

Why each choice is right or wrong

A - Incorrect: Incorrect: DML acts on stored data, whereas this statement defines a table.

B - Correct: Correct: creating a table and declaring its columns is DDL.

C - Incorrect: Incorrect: CREATE TABLE defines a table rather than a view.

D - Incorrect: Incorrect: the statement defines an entire table, not just an integrity-constraint expression.

Primary note proof

Study-note section FDB26

DDL changes structure: CREATE, ALTER, DROP, commonly RENAME and TRUNCATE in textbook classifications. DML retrieves or changes data: SELECT, INSERT, UPDATE, DELETE. Some texts separate SELECT as DQL. DCL manages privileges through GRANT and REVOKE. TCL includes COMMIT, ROLLBACK and SAVEPOINT. Classify a statement by its effect, not its length.

Study-note section FDB30

CREATE TABLE Employee (EmpID INTEGER PRIMARY KEY, Name VARCHAR(80)); declares two columns. The name and its type stay together; the comma separates whole column declarations.

SQL represents Structured Query Language. SQL is a comprehensive database language: It has statements for data definitions, and updates. Hence, it is both a DDL (Data Definition language) and a DML (Data Manipulation Language). 7.1.1 DDL (data definition language) Basic DDL commands we usually use are: CREATE, DROP, ALTER, TRUNCATE and RENAME 7.1.2 DML (data manipulation language) Basic DDL commands are: SELECT, PROJECT, JOIN, INSERT, DELETE, and UPDATE

Question sources

Database Fundamentals practice questions · Question 12

Question 78 | Q01338

SELECT * FROM employee
What type of statement is this?

A. DML

B. DDL

C. View

D. Integrity constraint

Hint

Classify each SQL command by the kind of change it performs.

Answer A: DML

SELECT is in the list under the DML heading. The line's repeated DDL word is a typographical error in that DML subsection, as shown by the preceding separate DDL list.

Why each choice is right or wrong

A - Correct: SELECT is classified under DML. (PDF pp. 26.)

B - Incorrect: SELECT is not in the preceding DDL list. (PDF pp. 26.)

C - Incorrect: No view is defined by this standalone retrieval. (PDF pp. 26.)

D - Incorrect: The retrieval is not an integrity constraint. (PDF pp. 26.)

Primary note proof

Study-note section FDB26

DDL changes structure: CREATE, ALTER, DROP, commonly RENAME and TRUNCATE in textbook classifications. DML retrieves or changes data: SELECT, INSERT, UPDATE, DELETE. Some texts separate SELECT as DQL. Database Fundamentals practice questions · Question 13

Question 79 | Q01339

The basic data type char(n) is a _____ length character string and varchar(n) is _____ length character.

A. Fixed, equal

B. Equal, variable

C. Fixed, variable

D. Variable, equal

Hint

Relate the value domain and access requirements to storage and type choices.

Answer C: Fixed, variable

The attribute-type section directly defines CHAR as fixed-length and VARCHAR as variable-length. Neither blank means equal length.

Why each choice is right or wrong

A - Incorrect: Fixed is right for CHAR but equal is wrong for VARCHAR. (PDF pp. 19.)

B - Incorrect: Variable is right for VARCHAR but equal is not the stated CHAR class. (PDF pp. 19.)

C - Correct: Fixed followed by variable matches both definitions. (PDF pp. 19.)

D - Incorrect: Both descriptions miss the given definitions. (PDF pp. 19.)

Primary note proof

Study-note section FDB23

> CHAR(n) is fixed length; VARCHAR(n) has variable length up to a limit. DATE represents a date and BLOB binary content such as images. INTEGER represents whole numbers; DECIMAL(p,s) represents exact decimal values, making it suitable for money when scale is specified. FLOAT/REAL/DOUBLE are approximate; names, widths and precision depend on the DBMS. Numeric type widths depend on the DBMS and type; do not assume one universal width.

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 19 | lines 11-15

> 5.2 Choosing Attribute Data Types CHAR - fixed-length character VARCHAR() - variable-length characters DATE - actual date BLOB - binary large object (good for graphics images, audio, sound clips, etc.)

Question sources

Database Fundamentals practice questions · Question 14

Question 80 | Q01340

To remove a relation from an SQL database, we use the _____ comman
d.

A. Delete

B. Purge

C. Remove

D. Drop table

Hint

Classify each SQL command by the kind of change it performs.

Answer D: DROP TABLE.

Removing a relation means removing the table object, rather than just its tuples. FDB26 distinguishes DROP TABLE from DELETE: DELETE preserves the table definition while removing rows. DROP TABLE removes the object itself. PURGE and REMOVE are not the general SQL command specified here for this task.

Why each choice is right or wrong

A - Incorrect: DELETE removes tuples while preserving the relation definition, so it does not remove the relation.

B - Incorrect: PURGE is not the general table-removal command established here.

C - Incorrect: REMOVE is not the SQL command used here to remove a relation object.

D - Correct: DROP TABLE removes the table object, including its relation definition.

Primary note proof

Study-note section FDB26

> DELETE removes rows and keeps the table; DROP TABLE removes the table object; ALTER changes its definition. TRUNCATE empties a table using implementation-specific mechanisms. PostgreSQL allows transactional rollback of TRUNCATE, so no rollback information is retained is not a universal SQL property. SQL Server permits DROP DATABASE Sales, suppliers; that comma-list syntax is vendor-specific. SQLite's .databases lists attached names/files in its command-line shell; .database is not the documented command.

Fundamental of Database Systems module | PDF page 26 | lines 7-11

> 7.1.1 DDL (data definition language) Basic DDL commands we usually use are: CREATE, DROP, ALTER, TRUNCATE and RENAME 7.1.2 DML (data manipulation language) Basic DDL commands are: SELECT, PROJECT, JOIN, INSERT, DELETE, and UPDATE

Question sources

Database Fundamentals practice questions · Question 15

Question 81 | Q01341

Assume constraints permit the deletion. Which descriptions apply to executing DELETE FROM r; on an existing table r? Select all that apply.

A. Remove relation

B. Clear relation entries

C. Delete fields

D. Delete rows

Hint

Track which rows each data-changing command affects.

Answer B, D: B. Clear relation entries; D. Delete rows

Without WHERE, DELETE targets every row in r. If the operation succeeds, the table's entries are cleared but its column definitions and table object remain. Clear relation entries and delete rows describe this same effect. Removing the relation itself requires a schema operation such as DROP TABLE, while deleting fields would change columns rather than row contents.

Why each choice is right or wrong

A - Incorrect: The table definition remains; DELETE does not remove the relation object.

B - Correct: Without WHERE, every relation entry is removed while the table remains available.

C - Incorrect: Fields are columns; DELETE removes rows rather than column definitions.

D - Correct: Every row is targeted because the statement contains no filtering WHERE clause.

Primary note proof

Study-note section FDB29

> INSERT INTO Hotel(HotelID,HotelName,SubCity) VALUES (1,'Hilton','Yeka'); pairs each named column with a compatible value. Counts and types must match; keys and other constraints still apply. Without a column list, values must follow the table's declared column order.

Study-note section FDB29

> Both clear relation entries and delete rows describe that effect.

Study-note section FDB29

> DELETE FROM r; removes every row but leaves r defined.

Question sources

Database Fundamentals practice questions · Question 16

Question 82 | Q01342

INSERT INTO instructor VALUES (10211, 'Smith', 'Biology', 66000);
What type of statement is this?

A. Query

B. DML

C. Relational

D. DDL

Hint

Classify each SQL command by the kind of change it performs.

Answer B: DML

INSERT belongs to the DML list. Classification follows from the operation name; it does not require assuming an instructor schema or proving that these particular values satisfy its constraints.

Why each choice is right or wrong

A - Incorrect: Query is a generic request rather than the displayed language category. (PDF pp. 26.)

B - Correct: INSERT is expressly a DML command. (PDF pp. 26.)

C - Incorrect: Relational names a model, not this statement class. (PDF pp. 26.)

D - Incorrect: INSERT is not in the DDL list. (PDF pp. 26.)

Primary note proof

Study-note section FDB26

> DDL changes structure: CREATE, ALTER, DROP, commonly RENAME and TRUNCATE in textbook classifications. DML retrieves or changes data: SELECT, INSERT, UPDATE, DELETE. Question sources

Database Fundamentals practice questions · Question 17

Question 83 | Q01343

Which joins discard unmatched tuples from both inputs? Interpret Natural join as an ordinary natural inner join. Select all that apply.

A. Left outer join

B. Right outer join

C. Inner join

D. Natural join

Hint

Compute matching pairs, then account for any preserved unmatched rows.

Answer C, D: C. Inner join; D. Natural join

An inner join returns only pairs that satisfy its matching condition, so unmatched tuples from either input disappear. An ordinary natural join is an inner equality join using all common column names and has the same preservation behavior. Left and right outer joins instead preserve unmatched tuples from their designated side by adding NULLs for the other side.

Why each choice is right or wrong

A - Incorrect: A left outer join preserves unmatched left rows, filling right-side columns with NULL.

B - Incorrect: A right outer join preserves unmatched right rows, filling left-side columns with NULL.

C - Correct: An inner join returns matching pairs only, so unmatched tuples do not survive.

D - Correct: An ordinary natural join is an inner equality join and discards unmatched tuples.

Primary note proof

Study-note section FDB31

An inner join returns matching pairs satisfying ON. An equijoin uses equality; a theta join permits another comparison. A natural join is ordinarily an inner equality join on every same-named column and merges those duplicate columns. JOIN ... USING (DeptID) specifies shared join columns explicitly. CROSS JOIN forms every pair without a matching condition.

Study-note section FDB31

LEFT OUTER JOIN also preserves unmatched left rows, padding right columns with NULL; RIGHT preserves right rows and FULL preserves both.

Study-note section FDB31

Therefore inner and natural inner joins both discard unmatched rows.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Basic operations: Selection (σ) - Selects a subset of rows from relation. Projection (π) - Deletes unwanted columns from relation. Cross-product (x) - Allows us to combine two relations. Set-difference (-) - Tuples in relation 1, but not in relation 2. Union (U) - Tuples in relation 1 and in relation 2. Intersection (∩) - Only tuples in relation 1 and in relation 2 (only the common tuples).

Fundamental of Database Systems module | PDF page 28 | lines 17-24

Query 2 (Better) (position=„Manager“)^(city=„London“) (Staff Staff.branchNo = Branch.branchNo Branch) - Again requires (1000+50) disk accesses to read from Staff and Branch - Joins Staff and Branch on branchNo with 1000 tuples (1 employee : 1 branch) - Requires (1000) disk access to read in joined relation and check predicate Total Work = (1000+50) + 2*(1000) = 3050 I/O operations

Question sources

Database Fundamentals practice questions · Question 18

Question 84 | Q01344

What type of join is needed when you wish to include rows that do not have matching values?

A. Equi-join

B. Natural join

C. Outer join

D. All of the mentioned

Hint

Compute matching pairs, then account for any preserved unmatched rows.

Answer C: Outer join.

An outer join retains unmatched rows from one or both inputs and fills the missing side with NULL. FDB31 contrasts that behavior with ordinary matching-only joins. Equijoin describes an equality condition, and an ordinary natural join is an inner equality join; neither alone guarantees unmatched-row preservation. Therefore all of the mentioned is false.

Why each choice is right or wrong

A - Incorrect: An equality condition alone does not retain rows that fail to match.

B - Incorrect: An ordinary natural join uses matching shared-column values and discards unmatched rows.

C - Correct: Outer joins preserve unmatched rows from the left, right or both inputs.

D - Incorrect: The other named joins do not all guarantee preservation of unmatched rows.

Primary note proof

Study-note section FDB31

> An inner join returns matching pairs satisfying ON. An equijoin uses equality; a theta join permits another comparison. A natural join is ordinarily an inner equality join on every same-named column and merges those duplicate columns. JOIN ... USING (DeptID) specifies shared join columns explicitly. CROSS JOIN forms every pair without a matching condition.

Study-note section FDB31

> Therefore inner and natural inner joins both discard unmatched rows.

read in joined relation and check predicate Total Work = (1000+50) + 2*(1000) = 3050 I/O operations

Question sources

Database Fundamentals practice questions · Question 19

Question 85 | Q01345

How many input relations does one ordinary binary join operator combine? Count operator inputs, not distinct base tables used by a complete query.

A. One

B. Two

C. Three

D. All of the mentioned

Hint

Compute matching pairs, then account for any preserved unmatched rows.

Answer B: B. Two

One binary join operator combines two input relations. Either input may itself be the output of an earlier join, so the complete query can involve more base tables. A self-join can refer twice to one base table, but still supplies two relation occurrences to the operator. The question fixes the count at the operator level, making two the unique choice.

Why each choice is right or wrong

A - Incorrect: One distinct base table can support a self-join, but the operator still has two inputs.

B - Correct: A binary join operator has exactly two inputs.

C - Incorrect: Three base tables require a chain of binary joins, not one operator.

D - Incorrect: The input count of the specified binary operator is fixed, so all counts do not apply.

Primary note proof

Study-note section FDB31

An inner join returns matching pairs satisfying ON. An equijoin uses equality; a theta join permits another comparison. A natural join is ordinarily an inner equality join on every same-named column and merges those duplicate columns. JOIN ... USING (DeptID) specifies shared join columns explicitly. CROSS JOIN forms every pair without a matching condition.

Study-note section FDB31

Each ordinary join operator combines two inputs, but its inputs can be earlier joins, so one query can join many tables.

Study-note section FDB31

Distinguish base-table count, table occurrences and binary operator arity.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 24 | lines 5-9

Relational algebra is the basic set of operations for the relational model. These operations enable a user to specify basic retrieval requests (or queries). The result of an operation is a new relation, which may have been formed from one or more input relations. The algebra operations thus produce new relations. Since each operation returns a relation, operations can be composed (Algebra is —closed‖.)

Fundamental of Database Systems module | PDF page 28 | lines 17-24

Query 2 (Better) (position=„Manager“)^(city=„London“) (Staff Staff.branchNo = Branch.branchNo Branch) - Again requires (1000+50) disk accesses to read from Staff and Branch - Joins Staff and Branch on branchNo with 1000 tuples (1 employee : 1 branch) - Requires (1000) disk access to read in joined relation and check predicate Total Work = (1000+50) + 2*(1000) = 3050 I/O operations

Question sources

Database Fundamentals practice questions · Question 20

Question 86 | Q01346

Which option gives the complete set of valid SQL join forms among the listed alternatives? Choose the most complete single answer.

A. Cross join

B. Natural join

C. Join with USING clause

D. All of the mentioned

Hint

Compute matching pairs, then account for any preserved unmatched rows.

Answer D: All of the mentioned

CROSS JOIN forms every pair of input rows without a matching predicate. NATURAL JOIN matches all same-named columns and merges the duplicate join columns. JOIN USING explicitly names shared equality columns. All three are valid join forms, although they do not all express a join condition in the same way. The revised stem requests the complete single answer, so the aggregate D is selected; each individually true alternative is incomplete on its own.

Why each choice is right or wrong

A - Incorrect: Incorrect as the complete selection: CROSS JOIN is a valid join form without a matching condition, but B and C also qualify.

B - Incorrect: Incorrect as the complete selection: NATURAL JOIN is valid and matches same-named columns, but A and C also qualify.

C - Incorrect: Incorrect as the complete selection: JOIN USING is valid and names shared equality columns, but A and B also qualify.

D - Correct: Correct: all three named constructs are valid SQL join forms, so the aggregate is the complete answer.

Primary note proof

Study-note section FDB31

> An inner join returns matching pairs satisfying ON. An equijoin uses equality; a theta join permits another comparison. A natural join is ordinarily an inner equality join on every same-named column and merges those duplicate columns. JOIN ... USING (DeptID) specifies shared join columns explicitly. CROSS JOIN forms every pair without a matching condition.

> Query 2 (Better) (position=„Manager“)^(city=„London“) (Staff Staff.branchNo = Branch.branchNo Branch) - Again requires (1000+50) disk accesses to read from Staff and Branch - Joins Staff and Branch on branchNo with 1000 tuples (1 employee : 1 branch) - Requires (1000) disk access to read in joined relation and check predicate Total Work = (1000+50) + 2*(1000) = 3050 I/O operations

Question sources

Database Fundamentals practice questions · Question 21

Question 87 | Q01347

The operation which is not considered a basic operation of relational algebra is

A. Join

B. Selection

C. Union

D. Cross product

Hint

Use the operator convention stated in the question and distinguish membership from derivability.

Answer A: Join

The stated basic-operation list contains selection, union, cross-product, projection, difference, and intersection. Join is not included, even though it appears in later execution-plan examples.

Why each choice is right or wrong

A - Correct: Join is absent from the basic list and is the requested exception. (PDF pp. 24.)

B - Incorrect: Selection is explicitly basic. (PDF pp. 24.)

C - Incorrect: Union is explicitly basic. (PDF pp. 24.)

D - Incorrect: Cross-product is explicitly basic. (PDF pp. 24.)

Primary note proof

Study-note section FDB-S01

> A list of basic relational-algebra operators is a teaching convention, distinct from a claim that every listed operation is logically indispensable. The course module uses selection, projection, Cartesian product, set difference, union and intersection as its basic-operation list. Natural join and assignment are not members of that particular list.

Study-note section FDB-S01

> A smaller primitive basis may therefore omit intersection even when it is introduced as a basic operation.

Study-note section FDB-S01

> Intersection can be expressed using difference, while a matching join can be expressed as selection over a Cartesian product.

Question sources

Database Fundamentals practice questions · Question 22

Question 88 | Q01348

A many to many relationship between two entities usually results in how many tables?

A. One

B. Two

C. Three

D. Four

Hint

Identify relationship degree and cardinality before choosing a relational mapping.

Answer C: Three tables: two entity tables and one association table.

Each of the two entity types normally has its own relation. Their many-to-many relationship requires an additional association relation holding references to both entities and any relationship attributes. FDB12 illustrates Student, Course and Enrollment. Thus the usual total is three, rather than only the one new association table.

Why each choice is right or wrong

A - Incorrect: One counts only the association table and omits the two participating entity tables.

B - Incorrect: Two entity tables alone do not record arbitrary many-to-many pairs.

C - Correct: The two entity tables plus their association table produce the usual total of three.

D - Incorrect: No fourth table is required by the ordinary binary many-to-many mapping.

Primary note proof

Study-note section FDB12

> A binary M:N relationship needs an association table in addition to the two entity tables. Enrollment(StudentID,CourseID,Grade) references Student and Course; (StudentID,CourseID) is a key if one enrollment per pair is allowed. Repeated attempts require Term or AttemptNo in the key. This ordinarily produces three tables.

Question 89 | Q01349

An _____ is a set of entities of the same type that share the same properties, or attributes.

A. Entity set

B. Attribute set

C. Relation set

D. Entity model

Hint

Review entity, attribute and relationship notation before interpreting the model.

Answer A: Entity set.

FDB06 distinguishes an individual entity from the type describing its properties and the set containing the current entities of that type. The stem asks for that collection of similarly described entities, which is an entity set. Attributes describe properties; a model describes representation rather than the current collection itself.

Why each choice is right or wrong

A - Correct: An entity set is the collection of entities belonging to one common entity type.

B - Incorrect: An attribute set groups properties, rather than the entities possessing those properties.

C - Incorrect: Relation set is not the ER term for the stated collection of entities.

D - Incorrect: An entity model describes structures, rather than naming the current set of entity instances.

Primary note proof

Study-note section FDB06

An entity is a distinguishable real or conceptual thing, such as one student or one course. An entity type describes common properties; its current collection of entities is an entity set. A relationship associates entities. In Chen notation rectangles represent entity types, diamonds relationships and ellipses attributes; double ellipses denote multivalued attributes and dashed ellipses derived attributes. Always inspect the diagram legend.

Study-note section FDB03

A relation is a set of tuples, represented as a table.

Study-note section FDB03

A tuple/row/record contains related attribute values; an attribute/column/field describes a property.

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 11 | lines 2-9

An important constraint on the entities of an entity type is the key or uniqueness constraint on attributes. An entity type usually has one or more attributes whose values are distinct for each individual entity in the entity set. Such an attribute is called a key attribute, and its values can be used to identify each entity uniquely. Key Super Key − A set of attributes (one or more) that collectively identifies an entity in an entity set. Candidate Key − A minimal super key is called a candidate key. An entity set may have more than one candidate key.

Fundamental of Database Systems module | PDF page 11 | lines 16-18

Degree of a relationship The number of different entity sets participating in a relationship set is called as degree of a relationship set.

Question sources

Database Fundamentals practice questions · Question 24

Question 90 | Q01350

Entity is a _____

A. Object of relation

B. Present working model

C. Thing in real world

D. Model of relation

Hint

Review entity, attribute and relationship notation before interpreting the model.

Answer C: Thing in real world

An entity is an object with physical or conceptual existence. It need not be a physical thing; the real-world thing option includes conceptual objects such as a course.

Why each choice is right or wrong

A - Incorrect: Object of relation is not the module's definition. (PDF pp. 10.)

B - Incorrect: A present working model is not an entity definition. (PDF pp. 10.)

C - Correct: Thing in the real world matches physical or conceptual objects. (PDF pp. 10.)

D - Incorrect: A model describes entities rather than being the object described. (PDF pp. 10.)

Primary note proof

Study-note section FDB06

> An entity is a distinguishable real or conceptual thing, such as one student or one course. An entity type describes common properties; its current collection of entities is an entity set. A relationship associates entities. In Chen notation rectangles represent entity types, diamonds relationships and ellipses attributes; double ellipses denote multivalued attributes and dashed ellipses derived attributes. Always inspect the diagram legend.

Database Fundamentals practice questions · Question 25

Question 91 | Q01351

E-R modeling technique is a :

A. Top-down approach

B. Bottom-up approach

C. Left-right approach

D. None of the above

Hint

Identify the design phase from its inputs and intended deliverable.

Answer A: Top-down is the usual conceptual ER approach.

FDB05 describes conceptual design as usually starting with an enterprise view and working downward into entity and relationship details. This is the usual top-down classification of ER modeling. Bottom-up refinement is associated here with normalization from dependencies. This is a useful conventional approach, rather than a claim that every ER modeling activity must follow one direction.

Why each choice is right or wrong

A - Correct: Conceptual ER modeling usually moves from an overall enterprise view toward detailed entities and relationships.

B - Incorrect: Bottom-up dependency refinement describes normalization here, rather than the usual ER conceptual approach.

C - Incorrect: Left-right is not a database design methodology identified here.

D - Incorrect: Top-down is an available and appropriate description of the usual conceptual ER approach.

Primary note proof

Study-note section FDB05

> First collect business facts, required transactions, reports, volumes, privacy rules and quality targets. Conceptual design turns them into an ER/EER model. Logical design maps the conceptual model to relations, keys and constraints and checks normalization. Physical design chooses file organization, indexes and storage. Implementation creates and loads the actual objects; testing checks requirements.

Study-note section FDB05

> Conceptual design usually proceeds from a whole enterprise view downward; normalization can refine structures from dependencies upward.

Study-note section FDB05

> These are useful approaches rather than mandatory directions for every modeling activity.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 9 | lines 3-6

> 3.1 Database Modeling High-level conceptual data models provide concepts for presenting data in ways that are close to the way people perceive data. A typical example is the entity relationship model, which uses main concepts like entities, attributes and relationships.

Fundamental of Database Systems module | PDF page 9 | lines 27-31

> 3.3 ERD (Entity Relationship Diagram) ERD a graphical technique for representing a database schema. It is a modeling tool used to depict graphically a DB design before it is actually implemented. It shows the various entities being modeled and the important relationships among them. ERD has three basic components Entity, Relationship and Attribute.

Question sources

Database Fundamentals practice questions · Question 26

Question 92 | Q01352

The number of entities to which another entity can be associated via a relationship set is expressed as :

A. Entity

B. Cardinality

C. Schema

D. Attributes

Hint

Read the relationship in both directions and check participation constraints.

Answer B: Cardinality

Cardinality measures how often an entity participates and distinguishes one-to-one, one-to-many, and many-to-many. That is the number of possible associations asked about.

Why each choice is right or wrong

A - Incorrect: Entity is a participating object. (PDF pp. 11, 12.)

B - Correct: Cardinality is the association-count constraint. (PDF pp. 11, 12.)

C - Incorrect: Schema describes structure rather than the count. (PDF pp. 11, 12.)

D - Incorrect: Attributes are properties, not the association-count classification. (PDF pp. 11, 12.)

Primary note proof

Study-note section FDB09

Cardinality specifies maximum associated occurrences: 1:1, 1:N or M:N. Minimum cardinality specifies optional/partial participation (zero permitted) or mandatory/total participation (at least one). A maximum of one does not mean participation is compulsory. Relationship degree counts participating entity roles: unary recursive, binary or ternary.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 11 | lines 24-31

Cardinality The number of times an entity of an entity set participates in a relationship set is known as cardinality. Cardinality can be of different types: One to one (1-1) - When each entity in each entity set can take part only once in the relationship, the cardinality is one to one. One to many(1-M)- When entities in one entity set can take part only once in the relationship set and entities in other entity set can take part more than once in the relationship set, cardinality is many to one.

Fundamental of Database Systems module | PDF page 12 | lines 2-7

Many to many (M-M) - When entities in all entity sets can take part more than once in the relationship cardinality is many to many. The participation constraint specifies whether the existence of an entity depends on its being related to another entity via the relationship type. This constraint specifies the minimum number of relationship instances that each entity can participate in and is sometimes called the minimum cardinality constraint. There are two types of participation constraints, total and partial.

Database Fundamentals practice questions · Question 27

Question 93 | Q01353

Relations produced from an E-R model will always be in :

A. First normal form

B. Second normal form

C. Third normal form

D. Fourth normal form

Hint

Check atomicity, candidate keys and partial dependencies in that order.

Answer A: First normal form, assuming correct ER-to-relational mapping.

FDB20 states that properly splitting composite and multivalued ER structures produces ordinary 1NF relations. Nothing in an ER drawing alone proves absence of partial, transitive or multivalued dependencies needed for higher forms. Thus A is the guaranteed level under correct relational mapping; the word always must not be read as excusing an incorrect mapping.

Why each choice is right or wrong

A - Correct: Correctly mapped atomic relations are in 1NF; this is the guaranteed level described here.

B - Incorrect: An ER model alone does not rule out partial dependencies on a composite candidate key.

C - Incorrect: An ER model alone does not establish the full dependency conditions required for 3NF.

D - Incorrect: An ER model alone does not rule out the nontrivial multivalued dependencies addressed by 4NF.

Primary note proof

Study-note section FDB20

> 1NF requires atomic values in the chosen relational domains and no repeating groups in cells. It does not mean merely declaring a primary key. A mapped ER design that correctly splits composite and multivalued structures gives ordinary 1NF tables; ER drawing alone guarantees no higher form.

Study-note section FDB20

> Higher forms inherit 2NF, so no partial dependencies establishes the minimum guaranteed stage only when 1NF is also assumed.

Study-note section FDB20

> A relation whose every candidate key is single-attribute has no nonprime partial-key dependency.

Related reading (context, not primary note proof)

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 12 | lines 8-24

> 3.4 Mapping ER-models to relational tables 1. For each strong entity type E, create a relation R that includes all the attributes of E. 2. Choose one of the key attributes of E as the primary key for R. For each weak entity type W with owner entity type E (which is a strong entity), create a relation R & include all attributes of ‗W‘ as attributes of R. Also, include the primary key attribute of the relation that correspond to the owner entity type as foreign key attributes of R . 3. For each binary 1:1 relationship type R in the ER schema, identify the relations S and T that correspond to the entity types participating in R. Foreign Key approach: Choose one of the relations-say S-and include a foreign key in S the primary key of T. It is better to choose an entity type with total participation in R in the role of S. 4. For each binary 1:N relationship type R, identify the relation S that represent the participating entity type at the N-side of the relationship type. Include the primary key of the relation T as foreign key in S that represents the other entity type participating in R. Include any attributes of the 1:N relation type as attributes of S. 5. For each

n-ary relationship type R, where n>2, create a new relationship S to represent R. Include the primary keys of the relations that represent the participating entity types as foreign key attributes in S. Also include any attributes of the n-ary relationship type as attributes of S.

Fundamental of Database Systems module | PDF page 17 | lines 2-15

First normal form (1NF) A relation (table) R is in 1NF if and only if (iff) all underlying domains of attributes contain only atomic (simple or indivisible) values. i.e. The value of any attribute in a tuple (row) must be a single value from the domain of their attribute. It is defined to disallow multivalued attributes, composite attributes, and their combinations. In other words, 1NF disallows relations within relations or relations as attribute values within tuples. It must be remove repeating groups (values) in a single field. The primary key with repeating group attributes are moved into a new table. When a relation contains no repeating groups (values), it is in first normal form (1NF). Second normal form (2NF) Second normal form (2NF) is based on the concept of full functional dependency. A relation schema R is in 2NF if it is in 1NF and every non-prime attribute A in R is fully functionally dependent on the primary key (i.e. the non-prime attributes are not partially dependent on key attributes). Remove any partially dependent attributes and place them in another relation. A partial dependency is when the attribute(s) is/are dependent on a part of a key.

Fundamental of Database Systems module | PDF page 18 | lines 5-8

Third Normal Form (3NF) A relation schema R is in third normal form (3NF) if it is in 2NF and every non-prime attribute of _R‘ are fully functionally dependent on every key of R and non-transitively dependent on every key of R.

Database Fundamentals practice questions · Question 28

Question 94 | Q01354

In ER model the details of the entities are hidden from the user. This process is called :

A. generalization

B. specialization

C. abstraction

D. none of these above

Hint

Trace which schema levels a proposed change affects.

Answer C: abstraction

Abstraction hides unwanted or irrelevant details. Generalization groups subclasses; specialization divides a superclass. Thus hiding entity details describes abstraction.

Why each choice is right or wrong

A - Incorrect: Generalization combines common characteristics, rather than the general detail-hiding process. (PDF pp. 6, 13.)

B - Incorrect: Specialization separates narrower classes. (PDF pp. 6, 13.)

C - Correct: Abstraction is explicitly the process of hiding details. (PDF pp. 6, 13.)

D - Incorrect: The required term is present. (PDF pp. 6, 13.)

Primary note proof

Study-note section FDB04

> The external level gives each user group a selected view. The conceptual level describes the whole logical database: entity types, relationships, data types and constraints. The internal/physical level describes files, record placement and access paths. These are abstraction levels, distinct from client/server deployment tiers.

Study-note section FDB13

> Specialization divides Student into Undergraduate and Graduate; generalization combines common properties into Student.

Study-note section FDB13

> EER extends ER with superclass/subclass structure.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 6 | lines 2-4

> Data abstraction and Insulation between programs and data- Data Abstraction is a process of hiding unwanted or irrelevant details from the end user. It provides a different view and helps in achieving data independence which is used to enhance the security of data.

Fundamental of Database Systems module | PDF page 13 | lines 9-14

> Specialization is the process of dividing a parent-level entity (super-class) into narrower categories (sub-classes) accordingly to all the possible child categories. Specialization requires the separation of entities based on certain uncommon attributes. The process of extracting common characteristics from two or more classes (sub-classes) and combining them into a generalized superclass is called Generalization. It is the process that does the grouping entities into broader or distributed categories based on certain common attributes.

Question sources

Database Fundamentals practice questions · Question 29

Question 95 | Q01355

The attributes made up of more than one single attributes are called

A. Composite attribute

B. Derived attribute

C. Single value attribute

D. Multi value attribute

Hint

Review entity, attribute and relationship notation before interpreting the model.

Answer A: Composite attribute

Composite attributes have smaller meaningful subparts. This differs from multiple values of one attribute and from calculating a value from another.

Why each choice is right or wrong

A - Correct: Composite is the stated divisible structure. (PDF pp. 10, 10.)

B - Incorrect: Derived concerns computation from stored attributes. (PDF pp. 10, 10.)

C - Incorrect: Single-valued concerns count of values, not internal composition. (PDF pp. 10, 10.)

D - Incorrect: Multivalued concerns a set of values rather than components of one value. (PDF pp. 10, 10.)

Primary note proof

Study-note section FDB06

> Simple versus composite asks whether a value has meaningful components: Address may split into City and Street. Single-valued versus multivalued asks how many values one entity may have: a student may have several phone numbers. These dimensions differ: one address may be composite and single-valued. Age derived from birth date is derived, even if also single-valued. Attribute names alone do not establish multiplicity.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 10 | lines 15-24

> Composite and Simple (Atomic) Attributes Composite attributes can be divided into smaller subparts, which represent more basic attributes with independent meanings. Attributes that are not divisible are called simple or atomic attributes. Multivalued Attributes Most attributes have a single value for a particular entity; such attributes are called single-valued. For example, Age is a single-valued attribute of a person. In some cases an attribute can have a set of values for the same entity. For instance, a College_degrees attribute for a person. Similarly, one person may not have any college degrees, another person may have one, and a third person may have two or more degrees; therefore, different people can have different numbers of values for the College_degrees attribute. Such attributes are called multivalued.

Fundamental of Database Systems module | PDF page 10 | lines 25-30

> Derived Attributes In some cases, two (or more) attribute values are related. For example, the Age and Birth_date attributes of a person. For a particular person entity, the value of Age can be determined from the current (today‘s) date and the value of that person‘s Birth_date. The Age attribute is hence called a derived attribute and is said to be derivable from the Birth_date attribute, which is called a stored attribute.

Question sources

Database Fundamentals practice questions · Question 30

Question 96 | Q01356

The attribute AGE is calculated from DATE_OF_BIRTH. The attribute AGE is

A. Single valued

B. Multi valued

C. Composite

D. Derived

Hint

Review entity, attribute and relationship notation before interpreting the model.

Answer D: Derived

The exact Age/Birth_date example identifies Age as derived. Age can also be single-valued, but the stem asks the classification indicated by calculating it from another attribute; D describes that dependency, while A describes a different axis.

Why each choice is right or wrong

A - Incorrect: Age can be single-valued, but that does not express the calculation relationship asked for. (PDF pp. 10, 10.)

B - Incorrect: No set of ages per person is described. (PDF pp. 10, 10.)

C - Incorrect: No meaningful component attributes of Age are specified. (PDF pp. 10, 10.)

D - Correct: Derived directly matches the module's example and the calculation clause. (PDF pp. 10, 10.)

Primary note proof

Study-note section FDB06

> Simple versus composite asks whether a value has meaningful components: Address may split into City and Street. Single-valued versus multivalued asks how many values one entity may have: a student may have several phone numbers. These dimensions differ: one address may be composite and single-valued. Age derived from birth date is derived, even if also single-valued. Attribute names alone do not establish multiplicity.

The Age attribute is hence called a derived attribute and is said to be derivable from the Birth_date attribute, which is called a stored attribute.

Question sources

Database Fundamentals practice questions · Question 31

Question 97 | Q01357

A student has one official Name and one Date_of_birth, but may have several Phone_number values. Which listed attribute is multivalued for a student?

A. Phone_number

B. Name

C. Date_of_birth

D. All of the mentioned

Hint

Review entity, attribute and relationship notation before interpreting the model.

Answer A: A. Phone_number

Multiplicity asks how many values of one attribute may belong to the same entity. The student may have several phone numbers, making Phone_number multivalued. The stated rules allow one official name and one birth date, so those attributes are single-valued. These classifications follow the supplied requirements rather than the names or internal structure of the values.

Why each choice is right or wrong

A - Correct: Several phone values are permitted for one student.

B - Incorrect: The model permits one official name per student.

C - Incorrect: One birth date is permitted per student.

D - Incorrect: Name and birth date are single-valued under the stated rules.

Primary note proof

Study-note section FDB06

Simple versus composite asks whether a value has meaningful components: Address may split into City and Street. Single-valued versus multivalued asks how many values one entity may have: a student may have several phone numbers. These dimensions differ: one address may be composite and single-valued. Age derived from birth date is derived, even if also single-valued. Attribute names alone do not establish multiplicity.

Database Fundamentals practice questions · Question 32

Question 98 | Q01358

For each student, Register_number has one value; Address records all residences and permits several values; SUBJECT_TAKEN permits several subjects; Reference permits several referees. Which listed attribute is single-valued?

A. Register_number

B. Address

C. SUBJECT_TAKEN

D. Reference

Hint

Review entity, attribute and relationship notation before interpreting the model.

Answer A: A. Register_number

Single-valued means one value per entity, independently of whether that value can be broken into components. Register_number is single-valued under the stated student rule. Address, SUBJECT_TAKEN and Reference each explicitly permit multiple values for one student. An address can be composite without necessarily being multivalued, but this particular model permits multiple residences.

Why each choice is right or wrong

A - Correct: One register number is assigned per student.

B - Incorrect: Several residence addresses are permitted.

C - Incorrect: Several subjects can be taken by one student.

D - Incorrect: Several referee references are permitted.

Primary note proof

Study-note section FDB06

> Simple versus composite asks whether a value has meaningful components: Address may split into City and Street. Single-valued versus multivalued asks how many values one entity may have: a student may have several phone numbers. These dimensions differ: one address may be composite and single-valued. Age derived from birth date is derived, even if also single-valued. Attribute names alone do not establish multiplicity.

Database Fundamentals practice questions · Question 33

Question 99 | Q01359

An association of several entities in an Entity-Relation model is called :

A. Tuple

B. Record

C. Relationship

D. Field

Hint

Review entity, attribute and relationship notation before interpreting the model.

Answer C: Relationship

A relationship represents an association between entity types. Tuples and records instead represent individual table rows.

Why each choice is right or wrong

A - Incorrect: Tuple is a row. (PDF pp. 11, 13.)

B - Incorrect: Record is row data, not the ER association category. (PDF pp. 11, 13.)

C - Correct: Relationship is the explicit association term. (PDF pp. 11, 13.)

D - Incorrect: Field is an attribute component, not the association. (PDF pp. 11, 13.)

Primary note proof

Study-note section FDB06

> An entity is a distinguishable real or conceptual thing, such as one student or one course. An entity type describes common properties; its current collection of entities is an entity set. A relationship associates entities. In Chen notation rectangles represent entity types, diamonds relationships and ellipses attributes; double ellipses denote multivalued attributes and dashed ellipses derived attributes. Always inspect the diagram legend.

Study-note section FDB03

> A tuple/row/record contains related attribute values; an attribute/column/field describes a property.

Study-note section FDB03

> A relation is a set of tuples, represented as a table.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 11 | lines 13-15

> A relationship type represents the association between entity types. For example, _Enrolled in‘ is a relationship type that exists between entity Student and Course. In ER diagram, relationship is represented by a diamond and connecting the entities with lines.

Fundamental of Database Systems module | PDF page 13 | lines 24-27

> Tables - In the Relational model, relations are saved in the table format. It is stored along with its entities. A table has two properties rows and columns. Rows represent records and columns represent attributes. Tuple - It is a single row of a table, which contains a single record.

Question sources

Database Fundamentals practice questions · Question 34

Question 100 | Q01360

To include integrity constraint in an existing relation use:

A. Modify table

B. Drop table

C. Alter table

D. Create table

Hint

Distinguish table definition changes from changes to stored rows.

Answer C: Alter table

Adding an integrity constraint to an existing table changes its definition, so ALTER TABLE is the appropriate command family. It can add a named constraint or a primary key, provided existing data satisfies the rule. DROP TABLE removes the object, and CREATE TABLE defines a new one. MODIFY TABLE does not follow the ALTER TABLE command form required for this structural change. The remaining constraint clause depends on the integrity rule to be enforced.

Why each choice is right or wrong

A - Incorrect: Incorrect: the required command family for this definition change is ALTER TABLE, not MODIFY TABLE.

B - Incorrect: Incorrect: DROP TABLE removes the existing object instead of adding a constraint.

C - Correct: Correct: ALTER TABLE can add a constraint to an existing table definition.

D - Incorrect: Incorrect: CREATE TABLE defines a new table rather than changing this existing one.

Primary note proof

Study-note section FDB30

> ALTER TABLE Employee ADD COLUMN Email VARCHAR(120); adds a column in PostgreSQL-style syntax. ALTER TABLE Employee DROP COLUMN Email; removes it. ALTER TABLE Employee ADD CONSTRAINT uq_email UNIQUE (Email); adds a named constraint. Use ALTER rather than DALTER, and do not separate column_name and column_type with a comma; validate the resulting SQL before execution.

Study-note section FDB26

DDL changes structure: CREATE, ALTER, DROP, commonly RENAME and TRUNCATE in textbook classifications.

Fundamental of Database Systems module | PDF page 26 | lines 7-11

7.1.1 DDL (data definition language) Basic DDL commands we usually use are: CREATE, DROP, ALTER, TRUNCATE and RENAME 7.1.2 DML (data manipulation language) Basic DDL commands are: SELECT, PROJECT, JOIN, INSERT, DELETE, and UPDATE

Fundamental of Database Systems module | PDF page 49 | lines 16-28

Data and Domain Integrity • This is now increasing handled by the database. In Oracle, for example, when defining a table you can specify: • CREATE TABLE table-name (attr2 attr-type NOT NULL, forbids NULL values attrN attr-type CHECK (attrN = UPPER(attrN) verifies that the data meets certain criteria attrO attr-type DEFAULT default_value); Supplies default values Referential Integrity • Ensures that dependent relationships in the data are maintained. In Oracle, for example: • CREATE TABLE table-name (attr1 attr-type PRIMARY KEY, attr2 attr-type NOT NULL, ..., attrM attr-type REFERENCES owner.tablename(attrname) ON DELETE CASCADE, ...

Question sources

Database Fundamentals practice questions · Question 35

Question 101 | Q01361

Which option is not a general SQL integrity-constraint keyword or clause? Distinguish a constraint clause from a business condition that could be expressed inside one.

A. Not null

B. Positive

C. Unique

D. Check predicate

Hint

Read each SQL constraint's scope and enforcement rule.

Answer B: Positive

NOT NULL forbids missing values, UNIQUE enforces uniqueness under the DBMS's NULL rules, and CHECK evaluates a declared predicate. POSITIVE by itself is not a general SQL constraint keyword. A positivity requirement is still a valid business rule and can be written as a CHECK predicate such as CHECK (Amount > 0). The question therefore distinguishes clause syntax from the meaning of a possible rule, making B the unique incorrect keyword rather than rejecting positivity as an integrity requirement.

Why each choice is right or wrong

A - Incorrect: Incorrect selection: NOT NULL is a constraint that forbids NULL values.

B - Correct: Correct selection: POSITIVE is not the standalone constraint keyword; a CHECK predicate can enforce positivity.

C - Incorrect: Incorrect selection: UNIQUE is a constraint enforcing uniqueness.

D - Incorrect: Incorrect selection: CHECK is the clause for enforcing a declared predicate.

Primary note proof

Study-note section FDB16

> Example: CREATE TABLE Enrollment (StudentID INTEGER NOT NULL REFERENCES Student(StudentID), CourseID INTEGER NOT NULL REFERENCES Course(CourseID), Grade INTEGER CHECK (Grade BETWEEN 0 AND 100), PRIMARY KEY (StudentID,CourseID)); Each column declaration gives its name then type, with commas between declarations. CHECK is a constraint clause, not a standalone GRANT-like statement. POSITIVE is not a general SQL constraint keyword; CHECK (Amount > 0) expresses positivity.

Study-note section FDB16

> PRIMARY KEY implies uniqueness and non-NULL. UNIQUE does not generally imply NOT NULL; NULL treatment differs by DBMS.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 14 | lines 17-20

> Key Constraints- These are called uniqueness constraints since it ensures that every tuple in the relation should be unique. An attribute that can uniquely identify a tuple in a relation is called the key or primary key of the table. The value of the attribute for different tuples in the relation has to be unique. Primary keys must be unique and cannot be null.

Fundamental of Database Systems module | PDF page 47 | lines 20-27

> • Five types i. Required data ii. attribute domain constraints iii. entity integrity iv. referential integrity v. enterprise constraints i. Required Data • Some attributes must always contain a value -- they cannot have a NULL value

Fundamental of Database Systems module | PDF page 49 | lines 19-22

> • CREATE TABLE table-name (attr2 attr-type NOT NULL, forbids NULL values attrN attr-type CHECK (attrN = UPPER(attrN) verifies that the data meets certain criteria attrO attr-type DEFAULT default_value); Supplies default values

Question sources

Database Fundamentals practice questions · Question 36

Question 102 | Q01362

Foreign key is the one in which the _____ of one relation is referenced in another relation.

A. Foreign key

B. Primary key

C. References

D. Check constraint

Hint

Match the validity requirement to the appropriate constraint definition.

Answer B: Primary key

A foreign key references a matching candidate, usually primary, key in the parent. B is the offered conventional primary-key case; the definition also permits a candidate key, so primary is not an exclusive universal requirement.

Why each choice is right or wrong

A - Incorrect: An arbitrary foreign key is not the required parent unique target. (PDF pp. 48.)

B - Correct: Primary key is the listed usual referenced key. (PDF pp. 48.)

C - Incorrect: References names a mechanism rather than the key category. (PDF pp. 48.)

D - Incorrect: A CHECK predicate is not the referenced key. (PDF pp. 48.)

Primary note proof

Study-note section FDB15

> Domain integrity restricts type and allowed values. Key integrity enforces uniqueness. Entity integrity requires every primary-key component to be non-NULL. Referential integrity requires a non-NULL foreign-key value to match an eligible referenced unique/candidate key; self-references are allowed. A parent need not have a child.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 48 | lines 13-17

> iv. Referential Integrity • A —foreign key‖ links each occurrence in a relation representing a child entity to the occurrence of the parent entity containing the matching candidate (usually primary) key • Referential Integrity means that if the foreign key contains a value, that value must refer to an existing occurrence in the parent entity

Question sources

Database Fundamentals practice questions · Question 37

Question 103 | Q01363

Which are uses of data integrity constraints, rather than access authorization? Select all that apply.

A. Control who is allowed access to the data

B. Ensure that duplicate records are not entered into the table

C. Improve the quality of data entered for a specific property (i.e., table column)

D. Prevent users from changing the values stored in the table

Hint

Match the validity requirement to the appropriate constraint definition.

Answer B, C: B. Ensure that duplicate records are not entered into the table; C. Improve the quality of data entered for a specific property (i.e., table column)

Integrity constraints test whether data is valid according to the schema's rules. Uniqueness constraints can reject duplicate keyed records, while domain constraints reject inappropriate values for a column. These support the two selected purposes. Authorization controls who may access the data. Integrity rejects invalid changes rather than prohibiting all changes, so it does not imply that every stored value is immutable.

Why each choice is right or wrong

A - Incorrect: Controlling who may access data is authorization rather than data integrity itself.

B - Correct: Key or uniqueness constraints prevent duplicate keyed records.

C - Correct: Domain constraints validate types and allowed values for a specific column.

D - Incorrect: Integrity permits valid updates; it does not prohibit every change to stored values.

Primary note proof

Study-note section FDB15

> Domain integrity restricts type and allowed values. Key integrity enforces uniqueness. Entity integrity requires every primary-key component to be non-NULL. Referential integrity requires a non-NULL foreign-key value to match an eligible referenced unique/candidate key; self-references are allowed. A parent need not have a child.

Fundamental of Database Systems module | PDF page 47 | lines 4-19

> ● Security vs Integrity ◦ Database security makes sure that the user is authorised to access information ◦ Database integrity makes sure that (authorised) users use that information correctly ● Integrity constraints ◦ Domain constraints apply to data types ◦ Attribute constraints apply to columns ◦ Relation constraints apply to rows in a single table ◦ Database constraints apply between tables ● Intrarecord integrity (enforcing constraints on contents of fields, etc.) ● Referential Integrity (enforcing the validity of references between records in the database) ●

Concurrency control (ensuring the validity of database updates in a shared multiuser environment) ● The constraints we wish to impose in order to protect the database from becoming inconsistent.

Fundamental of Database Systems module | PDF page 48 | lines 4-12

ii. Attribute domain constraints ● Every attribute has a domain, that is a set of values that are legal for it to use ● For example: ◦ The domain of sex in the employee relation is —M‖ or —F‖ ● Domain ranges can be used to validate input to the database iii. Entity integrity ● The primary key of any entity: ◦ Must be Unique ◦ Cannot be NULL

Question sources

Database Fundamentals practice questions · Question 38

Question 104 | Q01364

The relationship between the two tables are created using _____

A. Candidate Key

B. Primary Key

C. Foreign Key

D. Check Constraint

Hint

Match the validity requirement to the appropriate constraint definition.

Answer C: Foreign Key

A foreign key links child occurrences to the matching parent candidate key. Primary/candidate keys identify the target, but foreign-key referencing creates the intertable link.

Why each choice is right or wrong

A - Incorrect: Candidate keys identify potential reference targets rather than expressing the link alone. (PDF pp. 48.)

B - Incorrect: A primary key identifies a row; a foreign key expresses the reference. (PDF pp. 48.)

C - Correct: The foreign key is explicitly the linking mechanism. (PDF pp. 48.)

D - Incorrect: CHECK restricts values rather than defining this intertable reference. (PDF pp. 48.)

Primary note proof

Study-note section FDB15

Domain integrity restricts type and allowed values. Key integrity enforces uniqueness. Entity integrity requires every primary-key component to be non-NULL. Referential integrity requires a non-NULL foreign-key value to match an eligible referenced unique/candidate key; self-references are allowed. A parent need not have a child.

Study-note section FDB07

A primary key is one selected candidate key; remaining candidates are alternate keys.

Study-note section FDB16

POSITIVE is not a general SQL constraint keyword; CHECK (Amount > 0) expresses positivity.

Fundamental of Database Systems module | PDF page 48 | lines 13-17

iv. Referential Integrity • A —foreign key‖ links each occurrence in a relation representing a child entity to the occurrence of the parent entity containing the matching candidate (usually primary) key • Referential Integrity means that if the foreign key contains a value, that value must refer to an existing occurrence in the parent entity

Question sources

Database Fundamentals practice questions · Question 39

Question 105 | Q01365

Customer has candidate keys CustId, Email and ContactNo. CustId is an immutable compact generated identifier; Email and ContactNo may change. A policy prefers stable compact candidate keys. Which is the best primary key under that policy?

A. CustId

B. Email

C. ContactNo

D. CustId and ContactNo

Hint

Test uniqueness and minimality separately when classifying keys.

Answer A: A. CustId

Every candidate key is eligible for primary-key selection, but the policy gives a reason to prefer one. CustId is explicitly stable and compact, while the contact attributes may change. Choosing CustId follows that policy without denying the uniqueness of the other candidates. Combining CustId and ContactNo is nonminimal because CustId alone already identifies each customer.

Why each choice is right or wrong

A - Correct: Its stated stability and compactness satisfy the preference policy.

B - Incorrect: Email is eligible but may change, so it loses under this policy.

C - Incorrect: ContactNo is eligible but may change, so it loses under this policy.

D - Incorrect: Adding ContactNo to an already unique CustId is unnecessary and nonminimal.

Primary note proof

Study-note section FDB07

A superkey uniquely identifies a tuple. A candidate key is a minimal superkey: removing any component loses uniqueness. Minimal means no unnecessary attribute, not necessarily the fewest columns among all keys. A primary key is one selected candidate key; remaining candidates are alternate keys. A composite key contains multiple attributes and need not be the chosen primary key.

Study-note section FDB07

Prefer stable, compact identifiers when practical, but Email, SSN or EmployeeID is a candidate only if business rules guarantee uniqueness.

Study-note section FDB07

A table can have several candidates and foreign keys but at most one declared primary-key constraint, possibly containing several columns.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 11 | lines 7-11

Super Key − A set of attributes (one or more) that collectively identifies an entity in an entity set. Candidate Key − A minimal super key is called a candidate key. An entity set may have more than one candidate key. Primary Key − A primary key is one of the candidate keys chosen by the database designer to uniquely identify the entity set.

Question sources

Database Fundamentals practice questions · Question 40

Question 106 | Q01366

Which of the following statement(s) is/are FALSE about primary key?

A. There can be more than one primary key for a table

B. Columns with string data types cannot be made Primary Key because they are large

C. Both A and B

D. None of the above

Hint

Test uniqueness and minimality separately when classifying keys.

Answer C: Both A and B

The designer selects one candidate key as the primary key; a composite primary key is still one key. No numeric-only restriction appears: a key is defined by uniqueness, not by a prohibition on string type. Thus both A and B are false claims.

Why each choice is right or wrong

A - Incorrect: False: several candidate keys do not mean several primary keys. (PDF pp. 11, 14.)

B - Incorrect: False: the definition imposes uniqueness, not a ban on strings. (PDF pp. 11, 14.)

C - Correct: Both preceding claims conflict with the key definition. (PDF pp. 11, 14.)

D - Incorrect: There are false claims, so none is not correct. (PDF pp. 11, 14.)

Primary note proof

Study-note section FDB07

> A superkey uniquely identifies a tuple. A candidate key is a minimal superkey: removing any component loses uniqueness. Minimal means no unnecessary attribute, not necessarily the fewest columns among all keys. A primary key is one selected candidate key; remaining candidates are alternate keys. A composite key contains multiple attributes and need not be the chosen primary key.

Study-note section FDB07

> A table can have several candidates and foreign keys but at most one declared primary-key constraint, possibly containing several columns.

Study-note section FDB16

> PRIMARY KEY implies uniqueness and non-NULL.

Module passages - related reading

> Super Key − A set of attributes (one or more) that collectively identifies an entity in an entity set. Candidate Key − A minimal super key is called a candidate key. An entity set may have more than one candidate key. Primary Key − A primary key is one of the candidate keys chosen by the database designer to uniquely identify the entity set.

Fundamental of Database Systems module | PDF page 14 | lines 17-20

> Key Constraints- These are called uniqueness constraints since it ensures that every tuple in the relation should be unique. An attribute that can uniquely identify a tuple in a relation is called the key or primary key of the table. The value of the attribute for different tuples in the relation has to be unique. Primary keys must be unique and cannot be null.

Question sources

Database Fundamentals practice questions · Question 41

Question 107 | Q01367

Which is the subset of SQL commands used to manipulate Oracle Database structures, including tables?

A. Data Definition Language(DDL)

B. Data Manipulation Language(DML)

C. DML and DDL

D. None of the Mentioned

Hint

Classify each SQL command by the kind of change it performs.

Answer A: Data Definition Language(DDL)

Schema-structure manipulation falls under definition language, despite the everyday word manipulate. DML is the separate category for data manipulation.

Why each choice is right or wrong

A - Correct: DDL contains the structural commands. (PDF pp. 26.)

B - Incorrect: DML concerns data operations. (PDF pp. 26.)

C - Incorrect: The asked subset for structures is DDL, not a combined category. (PDF pp. 26.)

D - Incorrect: DDL is offered. (PDF pp. 26.)

Primary note proof

Study-note section FDB26

> DDL changes structure: CREATE, ALTER, DROP, commonly RENAME and TRUNCATE in textbook classifications. DML retrieves or changes data: SELECT, INSERT, UPDATE, DELETE. Some texts separate SELECT as DQL. DCL manages privileges through GRANT and REVOKE. TCL includes COMMIT, ROLLBACK and SAVEPOINT. Classify a statement by its effect, not its length.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 26 | lines 4-11

> SQL represents Structured Query Language. SQL is a comprehensive database language: It has statements for data definitions, and updates. Hence, it is both a DDL (Data Definition language) and a DML (Data Manipulation Language). 7.1.1 DDL (data definition language) Basic DDL commands we usually use are: CREATE, DROP, ALTER, TRUNCATE and RENAME 7.1.2 DML (data manipulation language) Basic DDL commands are: SELECT, PROJECT, JOIN, INSERT, DELETE, and UPDATE

Question sources

Database Fundamentals practice questions · Question 42

Question 108 | Q01368

Using the course's textbook SQL command categories, with RENAME treated as DDL, which listed commands are outside DDL? Select all that apply.

A. RENAME

B. REVOKE

C. GRANT

D. UPDATE

Hint

Classify each SQL command by the kind of change it performs.

Answer B, C, D: B. REVOKE; C. GRANT; D. UPDATE

DDL concerns structural definitions and includes RENAME in this course classification. GRANT and REVOKE manage privileges, placing them in DCL, while UPDATE changes existing data and belongs to DML. All three are consequently outside DDL. Classifying by each statement's effect distinguishes schema operations, access permissions and data changes even though all are expressed using SQL.

Why each choice is right or wrong

A - Incorrect: RENAME is commonly classified as DDL in the note's textbook taxonomy.

B - Correct: REVOKE removes privileges and is DCL rather than DDL.

C - Correct: GRANT assigns privileges and is DCL rather than DDL.

D - Correct: UPDATE changes data and is DML rather than DDL.

Primary note proof

Study-note section FDB26

> DDL changes structure: CREATE, ALTER, DROP, commonly RENAME and TRUNCATE in textbook classifications. DML retrieves or changes data: SELECT, INSERT, UPDATE, DELETE. Some texts separate SELECT as DQL. DCL manages privileges through GRANT and REVOKE. TCL includes COMMIT, ROLLBACK and SAVEPOINT. Classify a statement by its effect, not its length.

> 7.1.1 DDL (data definition language) Basic DDL commands we usually use are: CREATE, DROP, ALTER, TRUNCATE and RENAME 7.1.2 DML (data manipulation language) Basic DDL commands are: SELECT, PROJECT, JOIN, INSERT, DELETE, and UPDATE

Fundamental of Database Systems module | PDF page 54 | lines 6-10

2.2.3 Authorization Rules • Most current DBMS permit the DBA to define —access permissions‖ on a table by table basis (at least) using the GRANT and REVOKE SQL commands • Some systems permit finer grained authorization (most use GRANT and REVOKE on variant views

Question sources

Database Fundamentals practice questions · Question 43

Question 109 | Q01369

Which command empties an existing table while retaining its definition, using DBMS-specific table-emptying mechanisms rather than asserting that rollback is impossible?

A. TRUNCATE command

B. Create command

C. Drop table command

D. Alter table command

Hint

Classify each SQL command by the kind of change it performs.

Answer A: A. TRUNCATE command

TRUNCATE empties a table while retaining the table object. Its implementation, logging and transaction behavior depend on the DBMS, so the answer does not rely on a claim that rollback is impossible. CREATE defines an object, DROP TABLE removes it, and ALTER changes its definition. Only TRUNCATE has the requested table-emptying role among these choices.

Why each choice is right or wrong

A - Correct: TRUNCATE empties the table and keeps its definition.

B - Incorrect: CREATE defines objects rather than emptying an existing table.

C - Incorrect: DROP TABLE removes the definition as well as the table.

D - Incorrect: ALTER changes the table definition rather than serving as the table-emptying command.

Primary note proof

Study-note section FDB26

DELETE removes rows and keeps the table; DROP TABLE removes the table object; ALTER changes its definition. TRUNCATE empties a table using implementation-specific mechanisms. PostgreSQL allows transactional rollback of TRUNCATE, so no rollback information is retained is not a universal SQL property. SQL Server permits DROP DATABASE Sales, suppliers; that comma-list syntax is vendor-specific. SQLite's .databases lists attached names/files in its command-line shell; .database is not the documented command.

Question sources

Database Fundamentals practice questions · Question 44

Question 110 | Q01370

Which SQL command form removes a database object together with its contained database objects?

A. DROP DATABASE

B. DELETE DATABASE

C. REMOVE DATABASE

D. None of the mentioned

Hint

Classify each SQL command by the kind of change it performs.

Answer A: DROP DATABASE

DROP removes a database object, whereas DELETE removes rows from an existing table. DROP DATABASE is consequently the correct command form for removing a database and its contained objects. DELETE DATABASE does not express that structural operation, and REMOVE DATABASE does not follow the taught DROP syntax. Since the correct DROP DATABASE form is one of the options, the none-of-the-mentioned alternative is also incorrect.

Why each choice is right or wrong

A - Correct: Correct: DROP DATABASE removes the database object and its contained objects.

B - Incorrect: Incorrect: DELETE is row removal; deleting rows does not remove the database object.

C - Incorrect: Incorrect: the database-removal command form uses DROP, not REMOVE.

D - Incorrect: Incorrect: DROP DATABASE is present and performs the requested structural operation.

Primary note proof

Study-note section FDB26

> DDL changes structure: CREATE, ALTER, DROP, commonly RENAME and TRUNCATE in textbook classifications. DML retrieves or changes data: SELECT, INSERT, UPDATE, DELETE. Some texts separate SELECT as DQL. DCL manages privileges through GRANT and REVOKE. TCL includes COMMIT, ROLLBACK and SAVEPOINT. Classify a statement by its effect, not its length.

Study-note section FDB26

Question sources

Database Fundamentals practice questions · Question 45

Question 111 | Q01371

In SQL Server, which statement drops the two databases named Sales and suppliers? Assume permissions and database state allow the operation.

A. DROP DATABASE Sales, NewSales

B. DROP DATABASE Sales, suppliers

C. DROP DATABASE Sales and suppliers

D. DROP DATABASE Sales-suppliers

Hint

Classify each SQL command by the kind of change it performs.

Answer B: B. DROP DATABASE Sales, suppliers

SQL Server permits a comma-separated list of database names after DROP DATABASE. B names exactly Sales and suppliers using that syntax. A names a different second database, while AND and a hyphen do not form the required two-name list. The answer is specific to SQL Server and does not assert that the same multi-database syntax works in every SQL dialect.

Why each choice is right or wrong

A - Incorrect: The second target is NewSales rather than suppliers.

B - Correct: The supported comma list names both required databases.

C - Incorrect: AND is not the separator in this DROP DATABASE syntax.

D - Incorrect: A hyphen does not separate these two database names.

Primary note proof

Study-note section FDB26

DELETE removes rows and keeps the table; DROP TABLE removes the table object; ALTER changes its definition. TRUNCATE empties a table using implementation-specific mechanisms. PostgreSQL allows transactional rollback of TRUNCATE, so no rollback information is retained is not a universal SQL property. SQL Server permits DROP DATABASE Sales, suppliers; that comma-list syntax is vendor-specific. SQLite's .databases lists attached names/files in its command-line shell; .database is not the documented command.

7.1.1 DDL (data definition language) Basic DDL commands we usually use are: CREATE, DROP, ALTER, TRUNCATE and RENAME 7.1.2 DML (data manipulation language) Basic DDL commands are: SELECT, PROJECT, JOIN, INSERT, DELETE, and UPDATE

Question sources

Database Fundamentals practice questions · Question 46

Question 112 | Q01372

Command that is used to add attributes to an existing relation, is said to be

A. Alter

B. Modify

C. Tailor

D. Eliminate

Hint

Distinguish table definition changes from changes to stored rows.

Answer A: ALTER.

Adding attributes changes a relation schema. FDB30 demonstrates ALTER TABLE Employee ADD COLUMN Email VARCHAR(120), keeping the column name next to its type. ALTER is therefore the required command family. The remaining alternatives do not name the general SQL schema-change command shown by the complete note.

Why each choice is right or wrong

A - Correct: ALTER changes an existing relation definition and supports adding a column.

B - Incorrect: MODIFY alone is not the general command for adding attributes to an existing relation.

C - Incorrect: TAILOR is not an SQL schema-change command established here.

D - Incorrect: ELIMINATE is not the SQL command for adding a relation attribute.

Primary note proof

Study-note section FDB30

> ALTER TABLE Employee ADD COLUMN Email VARCHAR(120); adds a column in PostgreSQL-style syntax. ALTER TABLE Employee DROP COLUMN Email; removes it. ALTER TABLE Employee ADD CONSTRAINT uq_email UNIQUE (Email); adds a named constraint. Use ALTER rather than DALTER, and do not separate column_name and column_type with a comma; validate the resulting SQL before execution.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 26 | lines 7-11

> 7.1.1 DDL (data definition language) Basic DDL commands we usually use are: CREATE, DROP, ALTER, TRUNCATE and RENAME 7.1.2 DML (data manipulation language) Basic DDL commands are: SELECT, PROJECT, JOIN, INSERT, DELETE, and UPDATE

Question sources

Database Fundamentals practice questions · Question 47

Question 113 | Q01373

Which keyword pair changes a table definition to remove a specified column, rather than changing or deleting row values? Treat the comma in an option as separating keyword names.

A. UPDATE TABLE

B. TRUNCATE COLUMN

C. ALTER, DROP

D. DELETE COLUMN

Hint

Distinguish table definition changes from changes to stored rows.

Answer C: ALTER, DROP

Removing a column changes the table's definition. The appropriate form is ALTER TABLE followed by DROP COLUMN, so the keyword pair represented by C is correct. Its comma separates the two keyword names rather than belonging in executable SQL. UPDATE changes stored row values, DELETE removes rows, and TRUNCATE empties a table while retaining its definition; none of those operations removes the specified column definition.

Why each choice is right or wrong

A - Incorrect: Incorrect: UPDATE changes row values rather than removing a column definition.

B - Incorrect: Incorrect: TRUNCATE empties a table; TRUNCATE COLUMN is not the column-removal form.

C - Correct: Correct: ALTER TABLE ... DROP COLUMN removes a column definition.

D - Incorrect: Incorrect: DELETE removes rows, not a column from the schema.

Primary note proof

Study-note section FDB30

> ALTER TABLE Employee ADD COLUMN Email VARCHAR(120); adds a column in PostgreSQL-style syntax. ALTER TABLE Employee DROP COLUMN Email; removes it. ALTER TABLE Employee ADD CONSTRAINT uq_email UNIQUE (Email); adds a named constraint. Use ALTER rather than DALTER, and do not separate column_name and column_type with a comma; validate the resulting SQL before execution.

Study-note section FDB26

> DELETE removes rows and keeps the table; DROP TABLE removes the table object; ALTER changes its definition.

Study-note section FDB26

> TRUNCATE empties a table using implementation-specific mechanisms.

Study-note section FDB29

UPDATE Book SET Price = 600 WHERE ID = 'B001'; changes matching rows. UPDATE without WHERE targets every row.

7.1.1 DDL (data definition language) Basic DDL commands we usually use are: CREATE, DROP, ALTER, TRUNCATE and RENAME 7.1.2 DML (data manipulation language) Basic DDL commands are: SELECT, PROJECT, JOIN, INSERT, DELETE, and UPDATE

Question sources

Database Fundamentals practice questions · Question 48

Question 114 | Q01374

Which one of these is used with SELECT clause to fetch all columns from a table?

A. ALL

B. *

C. DISTINCT

D. AS

Hint

Trace how SELECT forms its result columns and rows.

Answer B: The asterisk (*).

FDB27 explicitly says SELECT * selects all columns. ALL and DISTINCT instead govern duplicate result rows, so neither means every column. AS introduces an alias. A query still needs the appropriate FROM source for table columns; the question asks only which SELECT-list symbol requests them all.

Why each choice is right or wrong

A - Incorrect: ALL permits duplicate result rows and does not expand the result to every column.

B - Correct: The wildcard * requests every column from the selected table source.

C - Incorrect: DISTINCT removes duplicate result rows rather than selecting all available columns.

D - Incorrect: AS supplies an alias for a result expression or source, not a wildcard column list.

Primary note proof

Study-note section FDB27

SELECT Name,Address FROM Customer; produces only those mailing-label fields. SELECT * selects all columns; DISTINCT removes duplicate result rows; AS supplies an alias; ALL permits duplicates and does not mean all columns. SQL normally preserves duplicates without DISTINCT.

A query reading table columns needs an appropriate FROM source. A literal-only query such as SELECT 1 may legally omit FROM.

Study-note section FDB27

WHERE alone is a clause rather than a complete read-only statement, so it cannot be compared as an equivalent executable command.

Study-note section FDB27

Typical written clause order is SELECT … FROM … WHERE … GROUP BY … HAVING … ORDER BY ….

● SET TRANSACTION READ ONLY; ● SELECT NAME, ADDRESS FROM WORKERS; ● SELECT MANAGER, ADDRESS FROM PLACES;

Question sources

Database Fundamentals practice questions · Question 49

Question 115 | Q01375

A parent table has a DATE column, a nullable data column and a primary-key column referenced by existing child rows with ON UPDATE RESTRICT. Which column's change to a different otherwise valid value is blocked specifically because the old key is still referenced? No other constraints or triggers block changes.

A. DATE type columns in the table

B. Columns which allows NULL values in the table

C. A primary key column which also serves as foreign key reference in another table

D. All of the above

Hint

Read each SQL constraint's scope and enforcement rule.

Answer C: C. A primary key column which also serves as foreign key reference in another table

The stated restrictive action prevents changing the parent key while existing children still refer to its old value. This is a consequence of the particular reference state and action, rather than inherent immutability of every primary key. DATE and nullable columns can accept otherwise valid changes. Therefore only the referenced primary-key column has the specified update block.

Why each choice is right or wrong

A - Incorrect: DATE values can be changed to other permitted dates.

B - Incorrect: Allowing NULL does not itself block valid updates.

C - Correct: Existing child references plus ON UPDATE RESTRICT block this key change.

D - Incorrect: The date and nullable columns are not blocked under the given conditions.

Primary note proof

Study-note section FDB16

> PRIMARY KEY implies uniqueness and non-NULL. UNIQUE does not generally imply NOT NULL; NULL treatment differs by DBMS. A CHECK can pass when its result is unknown, so add NOT NULL if missing values must be forbidden. Parent updates/deletes may use NO ACTION/RESTRICT, CASCADE or SET NULL. A referenced key is not inherently unchangeable: legality depends on matching children and the declared action.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 48 | lines 13-17

> iv. Referential Integrity ● A —foreign key‖ links each occurrence in a relation representing a child entity to the occurrence of the parent entity containing the matching candidate (usually primary) key ● Referential Integrity means that if the foreign key contains a value, that value must refer to an existing occurrence in the parent entity

Fundamental of Database Systems module | PDF page 49 | lines 4-11

> Deletion rules ● A row should not be deleted from the referenced table (parent) if there are matching rows in the referencing table (child) ● Three ways to handle this ◦ Restrict -- disallow the delete ◦ Nullify -- reset the foreign keys in the child to some NULL or dummy value ◦ Cascade -- Delete all rows in the child where there is a foreign key matching the key in the parent row being deleted

Fundamental of Database Systems module | PDF page 26 | lines 10-11

> 7.1.2 DML (data manipulation language) Basic DDL commands are: SELECT, PROJECT, JOIN, INSERT, DELETE, and UPDATE

Question sources

Database Fundamentals practice questions · Question 50

Question 116 | Q01376

Using the course classification that includes SELECT in DML, which listed language terms can describe application requests to retrieve database data? Select all that apply.

A. DML

B. DDL

C. Query language

D. All of the Mentioned

Hint

Classify each SQL command by the kind of change it performs.

Answer A, C: A. DML; C. Query language

A query language expresses requests for data. The course also includes SELECT retrieval within DML, alongside insertion, update and deletion. Both terms can therefore describe the application's retrieval request at different levels of terminology. DDL changes structural definitions instead of expressing the requested retrieval. Since DDL does not fit, the aggregate all-of-the-mentioned choice is also false.

Why each choice is right or wrong

A - Correct: DML includes retrieval with SELECT in the note's classification.

B - Incorrect: DDL changes schema structure rather than expressing ordinary data retrieval requests.

C - Correct: A query language expresses requests for data, directly matching the stem.

D - Incorrect: DDL does not fit the retrieval role, so the inclusive choice is false.

Primary note proof

Study-note section FDB26

> DDL changes structure: CREATE, ALTER, DROP, commonly RENAME and TRUNCATE in textbook classifications. DML retrieves or changes data: SELECT, INSERT, UPDATE, DELETE. Some texts separate SELECT as DQL. DCL manages privileges through GRANT and REVOKE. TCL includes COMMIT, ROLLBACK and SAVEPOINT. Classify a statement by its effect, not its length.

Database Fundamentals practice questions · Question 52

Question 118 | Q01378

In the course's SQL command taxonomy, how is TRUNCATE classified?

A. DDL

B. DML

C. DCL

D. TCL

Hint

Classify each SQL command by the kind of change it performs.

Answer A: DDL

The course groups TRUNCATE with DDL commands. It empties a table through mechanisms that depend on the implementation, but that fact does not turn it into a privilege-management or transaction-boundary command. DML covers commands such as INSERT, UPDATE and DELETE; DCL covers GRANT and REVOKE; TCL covers COMMIT, ROLLBACK and SAVEPOINT. The requested classification is the course convention, not a claim that TRUNCATE has identical recovery behavior in every DBMS.

Why each choice is right or wrong

A - Correct: Correct: the course's textbook classification includes TRUNCATE under DDL.

B - Incorrect: Incorrect: DML includes row operations such as INSERT, UPDATE and DELETE; TRUNCATE is assigned to DDL in this taxonomy.

C - Incorrect: Incorrect: DCL manages privileges through commands such as GRANT and REVOKE.

D - Incorrect: Incorrect: TCL controls transaction boundaries or rollback points, unlike TRUNCATE.

Primary note proof

Study-note section FDB26

> DDL changes structure: CREATE, ALTER, DROP, commonly RENAME and TRUNCATE in textbook classifications. DML retrieves or changes data: SELECT, INSERT, UPDATE, DELETE. Some texts separate SELECT as DQL. DCL manages privileges through GRANT and REVOKE. TCL includes COMMIT, ROLLBACK and SAVEPOINT. Classify a statement by its effect, not its length.

> 7.1.1 DDL (data definition language) Basic DDL commands we usually use are: CREATE, DROP, ALTER, TRUNCATE and RENAME 7.1.2 DML (data manipulation language) Basic DDL commands are: SELECT, PROJECT, JOIN, INSERT, DELETE, and UPDATE

Question sources

Database Fundamentals practice questions · Question 53

Question 119 | Q01379

A type of query that is placed within a WHERE or HAVING clause of another query is called

A. Master query

B. Sub query

C. Super query

D. Multi-query

Hint

Distinguish a stored query definition from stored data and trace subquery scope.

Answer B: Sub query

The optimization section identifies nested queries as separate query blocks, and the view example places a SELECT inside an outer WHERE. Subquery is the offered name matching this inner/nested query; WHERE or HAVING placement does not define every possible subquery location.

Why each choice is right or wrong

A - Incorrect: Master describes neither the inner query nor the module's nesting distinction. (PDF pp. 34, 58.)

B - Correct: Subquery corresponds to the nested inner SELECT demonstrated. (PDF pp. 34, 58.)

C - Incorrect: Super query does not name the inner block. (PDF pp. 34, 58.)

D - Incorrect: Multi-query does not identify the nesting relationship. (PDF pp. 34, 58.)

Primary note proof

Study-note section FDB33

> A subquery is a SELECT nested inside another statement. It may appear in WHERE, HAVING or FROM, not only the first two. IN tests membership; EXISTS tests whether at least one qualifying row exists. Correlated subqueries refer to the outer row. A scalar subquery must produce an appropriate single value. Beware NOT IN when its subquery can return NULL; NOT EXISTS often expresses the intended absence more safely.

Study-note section FDB33

> CREATE VIEW CSStudent AS SELECT StudentID,Name FROM Student WHERE Major = 'CS'; stores a query definition and presents a virtual table.

Study-note section FDB33

> An ordinary view does not necessarily store its result; a materialized view does.

Fundamental of Database Systems module | PDF page 34 | lines 12-16

> • Query block: The basic unit that can be translated into the algebraic operators and optimized. • A query block contains a single SELECT-FROM-WHERE expression, as well as GROUP BY and HAVING clause if these are part of the block. • Nested queries within a query are identified as separate query blocks.

Fundamental of Database Systems module | PDF page 58 | lines 15-20

> View example CREATE VIEW OwnDept AS SELECT Name, Phone FROM Employee WHERE Department = (SELECT Department FROM Employee WHERE name = USER)

Question sources

Database Fundamentals practice questions · Question 54

Question 120 | Q01380

A data manipulation command the combines the records from one or more tables is called

A. SELECT

B. PROJECT

C. JOIN

D. PRODUCT

Hint

Compute matching pairs, then account for any preserved unmatched rows.

Answer C: JOIN

The DML list contains JOIN, and the query-plan example describes joining Staff and Branch into a joined relation. This directly matches combining records rather than selecting columns alone.

Why each choice is right or wrong

A - Incorrect: SELECT can retrieve data, but JOIN names the combining operation illustrated. (PDF pp. 26, 28.)

B - Incorrect: PROJECT selects columns rather than linking records by the illustrated condition. (PDF pp. 26, 28.)

C - Correct: JOIN is explicitly used to combine the example relations. (PDF pp. 26, 28.)

D - Incorrect: PRODUCT combines all pairs; it is the broader Cartesian operation rather than the illustrated join command. (PDF pp. 26, 28.)

Primary note proof

Study-note section FDB31

An inner join returns matching pairs satisfying ON. An equijoin uses equality; a theta join permits another comparison. A natural join is ordinarily an inner equality join on every same-named column and merges those duplicate columns. JOIN ... USING (DeptID) specifies shared join columns explicitly. CROSS JOIN forms every pair without a matching condition.

Study-note section FDB35

Rename ρ changes relation or attribute names.

Study-note section FDB35

Identify the join variant before predicting its behavior.

Question 121 | Q01382

Data manipulation language (DML) includes statements that modify the _____ of a database.

A. Structure

B. Data

C. User

D. Size

Hint

Classify each SQL command by the kind of change it performs.

Answer B: Data

Data-definition commands are distinct from data-manipulation commands such as INSERT, DELETE and UPDATE. Their category concerns the stored data, while SELECT is also included as a retrieval command that need not modify state.

Why each choice is right or wrong

A - Incorrect: Structure belongs to definition language. (PDF pp. 26.)

B - Correct: Data is the manipulated content. (PDF pp. 26.)

C - Incorrect: User administration is not the target category here. (PDF pp. 26.)

D - Incorrect: Size can change as a consequence, not the category manipulated. (PDF pp. 26.)

Primary note proof

Study-note section FDB26

> DDL changes structure: CREATE, ALTER, DROP, commonly RENAME and TRUNCATE in textbook classifications. DML retrieves or changes data: SELECT, INSERT, UPDATE, DELETE. Question sources

Database Fundamentals practice questions · Question 57

Question 122 | Q01383

Which listed term names the standard SQL expression form for converting a value to a requested data type, rather than vendor-specific conversion syntax?

A. Cast

B. Drop type

C. Alter type

D. Convert

Hint

Check set membership, duplicates and compatible result types.

Answer A: A. Cast

CAST is the standard expression form that requests conversion of a value to a target type. CONVERT can also perform conversions in supporting vendor dialects, but the question specifically excludes vendor-specific syntax. DROP TYPE and ALTER TYPE act on type definitions rather than converting one expression value. The target value must still be representable in the requested type.

Why each choice is right or wrong

A - Correct: CAST supplies the requested standard expression conversion.

B - Incorrect: DROP TYPE removes a type definition.

C - Incorrect: ALTER TYPE changes a type definition.

D - Incorrect: CONVERT is vendor-specific in the supplied course distinction.

Primary note proof

Study-note section FDB34

> CAST('42' AS INTEGER) converts an expression to a requested type if the value permits it. CONVERT is vendor-specific and can also perform type conversion; specify the SQL dialect when comparing it with CAST. In SELECT xyz FROM table1 UNION xyz FROM table2, the second SELECT is missing. In the corrected query, xyz is a selected column/expression, not a table name.

Question sources

Database Fundamentals practice questions · Question 58

Question 123 | Q01384

Which SQL keyword combines the rows returned by two compatible SELECT statements into one result set, removing duplicates by default?

A. COMBINE

B. CONCAT

C. JOIN

D. UNION

Hint

Check set membership, duplicates and compatible result types.

Answer D: UNION

UNION combines the rows of compatible query results and removes duplicates by default. It is written between the SELECT statements. JOIN instead combines input rows through matching or product behavior within a query, rather than taking the set union of completed results. CONCAT concerns concatenation of values, and COMBINE does not form the required SQL set-operation syntax. D is therefore the unique correct selection for this result-set operation.

Why each choice is right or wrong

A - Incorrect: Incorrect: COMBINE is not the UNION set-operation keyword required between these SELECT statements.

B - Incorrect: Incorrect: concatenating values does not perform the requested union of query-result rows.

C - Incorrect: Incorrect: JOIN forms combinations of input rows rather than this union of compatible SELECT results.

D - Correct: Correct: UNION combines compatible query results and removes duplicates by default.

Primary note proof

Study-note section FDB34

SELECT ID FROM A UNION SELECT ID FROM B; combines compatible result columns and removes duplicate rows by default. UNION ALL retains duplicates. Explicit UNION DISTINCT is accepted in some dialects, including PostgreSQL; it is not a separate algebra rule. INTERSECT returns common rows; EXCEPT returns first-result rows absent from the second. Inputs need the same column count and compatible corresponding types.

Question sources

Database Fundamentals practice questions · Question 59

Question 124 | Q01385

What is xyz in the following SQL statement? SELECT xyz FROM table1 UNION xyz FROM table2;

A. row name

B. column name

C. table name

D. database name

Hint

Check set membership, duplicates and compatible result types.

Answer B: xyz denotes a selected column/expression; the second SELECT is missing.

The printed statement is malformed because the second branch says UNION xyz rather than UNION SELECT xyz. Nevertheless, the role of xyz in the first SELECT list is clear: it is a column or expression, not a row, table or database name. FDB34 explicitly identifies that role and the required repair, so the terminology question remains answerable.

Why each choice is right or wrong

A - Incorrect: SQL does not select a row by placing its row name in this SELECT-list position.

B - Correct: xyz occupies the selected-column position; the second branch needs its missing SELECT keyword.

C - Incorrect: The table sources are table1 and table2, which follow FROM rather than SELECT.

D - Incorrect: No database identifier occupies xyz's SELECT-list position in this statement.

Primary note proof

Study-note section FDB34

> SELECT ID FROM A UNION SELECT ID FROM B; combines compatible result columns and removes duplicate rows by default. UNION ALL retains duplicates. Explicit UNION DISTINCT is accepted in some dialects, including PostgreSQL; it is not a separate algebra rule. INTERSECT returns common rows; EXCEPT returns first-result rows absent from the second. Question sources

Database Fundamentals practice questions · Question 60

Question 125 | Q01386

In a dialect that accepts explicit UNION DISTINCT, which listed modifier requests duplicate elimination when used with UNION?

A. ALL

B. NARROW

C. STRICT

D. DISTINCT

Hint

Check set membership, duplicates and compatible result types.

Answer D: DISTINCT

UNION eliminates duplicate result rows by default. In the stated dialect, DISTINCT explicitly requests that same behavior, while ALL retains duplicates. NARROW and STRICT are not modifiers in the UNION [ALL | DISTINCT] form being tested. This classification does not imply that every DBMS accepts the explicit DISTINCT spelling: the question states that support, and bare UNION remains sufficient to request duplicate elimination.

Why each choice is right or wrong

A - Incorrect: Incorrect: ALL retains duplicates, the opposite of the requested behavior.

B - Incorrect: Incorrect: NARROW is not an ALL or DISTINCT modifier in the stated UNION form.

C - Incorrect: Incorrect: STRICT is not an ALL or DISTINCT modifier in the stated UNION form.

D - Correct: Correct: DISTINCT explicitly requests duplicate elimination in the stated dialect.

Primary note proof

Study-note section FDB34

> SELECT ID FROM A UNION SELECT ID FROM B; combines compatible result columns and removes duplicate rows by default. UNION ALL retains duplicates. Question sources

Database Fundamentals practice questions · Question 61

Question 126 | Q01387

The database design prevents some data from being stored due to _____.

A. Deletion anomalies

B. Insertion anomalies

C. Update anomalies

D. Selection anomalies

Hint

Distinguish dependency-based design problems from the contents of one sample table.

Answer B: Insertion anomalies

Insertion anomaly is explicitly the inability to insert a new record properly when the whole primary key is unknown. The other anomalies concern losing information on deletion or inconsistent/multiple updates.

Why each choice is right or wrong

A - Incorrect: Deletion anomaly loses existing related information. (PDF pp. 16.)

B - Correct: Insertion anomaly prevents a proper new insertion. (PDF pp. 16.)

C - Incorrect: Update anomaly concerns changing existing values. (PDF pp. 16.)

D - Incorrect: Selection anomaly is not among the module's stated three types. (PDF pp. 16.)

Primary note proof

Study-note section FDB19

Normalization separates facts according to their determinants, reducing avoidable repetition and associated anomalies. It does not require seeing bad current data: declared dependencies suffice. Adding a generated row ID may make insertion technically possible, but does not remove

repeated facts or fix the dependency design. Reduced redundancy can improve integrity and storage use, but extra keys and joins mean neither storage savings nor faster retrieval is guaranteed.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 16 | lines 5-16

4.3 Database Anomalies Database Anomalies are the flaws in databases which occurs because of poor database design and storing everything in a single flat database. They are problems that are caused usually by redundant data. Types of database anomalies are Insertion anomaly, Deletion anomaly, and Update anomaly. Insertion Anomaly - occurs when the entire primary key is not known and the database cannot insert a new record properly. This would violate entity integrity. It can be avoided by using a sequence number for the primary key. Deletion Anomaly - happens when a record is deleted that results in the loss of other related data. It can be avoided by normalizing tables in a database to minimize their dependency. Update Anomaly - occurs when a change to one attribute value causes the database to either contain inconsistent data or causes multiple records to need changing. It may be prevented by making sure tables are in third normal form.

Question sources

Database Fundamentals practice questions · Question 62

Question 127 | Q01388

In the course terminology, which labels can name a drawing of relational tables and their primary-key/foreign-key references? Select all that apply. ER Diagram means a conceptual entity/relationship drawing; Relational Schema means a textual table definition here.

A. ER Diagram

B. Database Diagram

C. Schema Diagram

D. Relational Schema

Hint

Distinguish a relation's structure from its current contents and its descriptive metadata.

Answer B, C: B. Database Diagram; C. Schema Diagram

A schema diagram draws relational tables and their key references. Database diagram is also used for that depiction in the course terminology, so both labels qualify. The question explicitly distinguishes a conceptual ER drawing and a textual relational schema from the requested table-reference drawing. This makes the two accepted names compatible without treating every representation of a database as the same artifact.

Why each choice is right or wrong

A - Incorrect: A conceptual ER diagram represents entities and relationships rather than specifically depicting mapped table key references.

B - Correct: Database diagram can denote the table-and-key depiction also called a schema diagram.

C - Correct: A schema diagram explicitly draws tables and their primary/foreign-key references.

D - Incorrect: A relational schema defines structures and constraints but need not itself be a diagram.

Primary note proof

Study-note section FDB03

> A schema describes names, structures and constraints; an instance, state or snapshot is the data at a particular time. Inserting a student changes the state, while adding a column changes the schema. Metadata is data describing data. The catalog or data dictionary records table definitions, types, constraints and often access privileges and optimizer statistics. A schema diagram draws tables and key references; labels such as database diagram can overlap.

Study-note section FDB06

> An entity is a distinguishable real or conceptual thing, such as one student or one course.

Study-note section FDB06

> In Chen notation rectangles represent entity types, diamonds relationships and ellipses attributes; double ellipses denote multivalued attributes and dashed ellipses derived attributes.

> 3.3 ERD (Entity Relationship Diagram) ERD a graphical technique for representing a database schema. It is a modeling tool used to depict graphically a DB design before it is actually implemented. It shows the various entities being modeled and the important relationships among them. ERD has three basic components Entity, Relationship and Attribute.

Fundamental of Database Systems module | PDF page 14 | lines 2-3

> Relation Schema: A relation schema represents the name of the relation with its attributes (columns).

Fundamental of Database Systems module | PDF page 48 | lines 13-17

> iv. Referential Integrity ● A —foreign key‖ links each occurrence in a relation representing a child entity to the occurrence of the parent entity containing the matching candidate (usually primary) key ● Referential Integrity means that if the foreign key contains a value, that value must refer to an existing occurrence in the parent entity

Question sources

Database Fundamentals practice questions · Question 63

Question 128 | Q01389

R(A,B,C) has atomic attributes and exactly the dependencies implied by A→B and B→C. A is the sole candidate key; B is not a superkey and C is nonprime. Moving upward through 1NF, 2NF, 3NF and BCNF, which listed normal form is the first that R fails?

A. BCNF

B. 1NF

C. 2NF

D. 3NF

Hint

Check atomicity, candidate keys and partial dependencies in that order.

Answer D: D. 3NF

The atomic relation satisfies 1NF. Its only candidate key is the single attribute A, so no nonprime dependency can involve a proper part of that key, and 2NF holds. However, B→C has a determinant that is not a superkey and a dependent that is nonprime. This violates the stated 3NF test, so 3NF is the listed form it fails.

Why each choice is right or wrong

A - Incorrect: BCNF also fails, but 3NF is the earlier failed level in the stated hierarchy.

B - Incorrect: Atomic values satisfy 1NF.

C - Incorrect: A single-attribute candidate key has no nonprime partial-key dependency.

D - Correct: B→C violates 3NF because B is not a superkey and C is nonprime.

Primary note proof

Study-note section FDB20

> 2NF requires 1NF and no nonprime attribute partially dependent on any candidate key. For Enrollment(SID,CID,SName,CTitle,Grade), assume key (SID,CID), SID→SName and CID→CTitle. Split into Student(SID,SName), Course(CID,CTitle) and Enrollment(SID,CID,Grade). Grade still depends on the whole pair. A relation whose every candidate key is single-attribute has no nonprime partial-key dependency. Higher forms inherit 2NF, so no partial dependencies establishes the minimum guaranteed stage only when 1NF is also assumed.

Study-note section FDB17

> Full dependency requires all determinant attributes; partial dependency holds through a proper subset.

Study-note section FDB21

With atomic values the highest form is 1NF, even though a transitive dependency also exists.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 15 | lines 25-28

Transitive Dependency - In mathematics and logic, a transitive relationship is a relationship of the following form: —If A → B, and if also B → C, then A → C.‖ Example: If X >Y and Y >Z then X >Z. Generalized way of describing transitive dependency is that:

Fundamental of Database Systems module | PDF page 16 | lines 2-4

If A functionally governs B, AND If B functionally governs C THEN _A‘ functionally governs _C‘, provided that neither C nor B determines A. A functional dependency is said to be transitive if it is indirectly formed by two functional dependencies.

Fundamental of Database Systems module | PDF page 18 | lines 5-8

Third Normal Form (3NF) A relation schema R is in third normal form (3NF) if it is in 2NF and every non-prime attribute of _R‘ are fully functionally dependent on every key of R and non-transitively dependent on every key of R.

Question sources

Database Fundamentals practice questions · Question 64

Question 129 | Q01390

Consider the relation Sale(Date, Customer, Product, Vendor, VendorCity, SalesRep){Date, Customer, Product} is the composite candidate key and the following functional dependencies are also given:Vendor => VendorCity, Product => VendorWhat is the highest normal form of the sale relation?

A. 0NF

B. 1NF

C. 2NF

D. 3NF

Hint

Test determinants and prime attributes against the stated normal-form rules.

Answer B: 1NF

Assuming atomic values as customary for a relation, Product is a proper subset of the stated composite key and determines non-prime Vendor. Vendor→VendorCity adds another non-key dependency. Product→Vendor alone violates 2NF, so the highest supported form is 1NF. No stated dependency makes these non-prime attributes alternative keys.

Why each choice is right or wrong

A - Incorrect: 0NF is not warranted when attributes are atomic. (PDF pp. 15, 17.)

B - Correct: 1NF is the highest form under the explicit atomicity assumption. (PDF pp. 15, 17.)

C - Incorrect: 2NF fails because Vendor depends on Product alone. (PDF pp. 15, 17.)

D - Incorrect: 3NF requires 2NF, which already fails. (PDF pp. 15, 17.)

Primary note proof

Study-note section FDB21

In Sale(Date,Customer,Product,Vendor,VendorCity,SalesRep), assume key (Date,Customer,Product), Product→Vendor and Vendor→VendorCity. Product is a proper subset of the key, so Vendor and VendorCity violate 2NF. With atomic values the highest form is 1NF, even though a transitive dependency also exists. 4NF addresses nontrivial multivalued dependencies with nonsuperkey determinants; 5NF addresses join dependencies. Do not confuse a multivalued dependency with a list stored inside a cell.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 15 | lines 11-17

Partial Dependency - If an attribute which is not a member of the key is dependent on some part of the key (if we have composite/candidate key) then that attribute is partially functionally dependent on the key. Let {A, B} is the key set and C is no key attribute, then if {A, B} → C and [B → C or A → C] holds. We say C is partially functionally dependent on {A, B}. Partial dependency occurs when a non-prime attribute is functionally dependent on part of a candidate/composite key.

Fundamental of Database Systems module | PDF page 17 | lines 2-15

First normal form (1NF) A relation (table) R is in 1NF if and only if (iff) all underlying domains of attributes contain only atomic (simple or indivisible) values. i.e. The value of any attribute in a tuple (row) must be a single value from the domain of their attribute. It is defined to disallow multivalued attributes, composite attributes, and their combinations. In other words, 1NF disallows relations within relations or relations as attribute values within tuples. It must be remove repeating groups (values) in a single field. The primary key with repeating group attributes are moved into a new table. When a relation contains no repeating groups (values), it is in first normal form (1NF). Second normal form (2NF) Second normal form (2NF) is based on the concept of full functional dependency. A relation schema R is in 2NF if it is in 1NF and every non-prime attribute A in R is fully functionally dependent on the primary key (i.e. the non-prime attributes are not partially dependent on key attributes). Remove any partially dependent attributes and place them in another relation. A partial dependency is when the attribute(s) is/are dependent on a part of a key.

Question sources

Database Fundamentals practice questions · Question 65

Question 130 | Q01391

Third normal form is based on the concept of _____

A. Closure Dependency

B. Transitive Dependency

C. Normal Dependency

D. Functional Dependency

Hint

Test determinants and prime attributes against the stated normal-form rules.

Answer B: Transitive Dependency

The defining extra condition of 3NF over 2NF is non-transitive dependence of non-prime attributes on keys. Functional dependency is the broader framework, but transitive dependency is the particular concept distinguishing this stage.

Why each choice is right or wrong

A - Incorrect: Closure dependency is not the stated criterion. (PDF pp. 18.)

B - Correct: Transitive dependency is the specific concept addressed. (PDF pp. 18.)

C - Incorrect: Normal dependency is not a defined dependency category. (PDF pp. 18.)

D - Incorrect: Functional dependency is broader and does not identify the distinctive 3NF condition. (PDF pp. 18.)

Primary note proof

Study-note section FDB21

> For every nontrivial FD X→A, 3NF permits it when X is a superkey or A is prime. BCNF requires X to be a superkey. The mnemonic whole key and nothing but the key describes the common single-key case; it cannot replace the full tests when keys overlap. Remove dependencies of nonprime facts on nonkey determinants.

Study-note section FDB21

> With atomic values the highest form is 1NF, even though a transitive dependency also exists.

Study-note section FDB21

> Do not confuse a multivalued dependency with a list stored inside a cell.

Fundamental of Database Systems module | PDF page 18 | lines 5-8

> Third Normal Form (3NF) A relation schema R is in third normal form (3NF) if it is in 2NF and every non-prime attribute of _R‘ are fully functionally dependent on every key of R and non-transitively dependent on every key of R.

Question sources

Database Fundamentals practice questions · Question 66

Question 131 | Q01392

Which of the following statements does not change the state of the database?

A. Where

B. Select

C. Insert

D. Drop

Hint

Trace how SELECT forms its result columns and rows.

Answer B: Select

The read-only transaction example uses SELECT to retrieve rows from two tables. SELECT is the complete retrieval statement among these choices; WHERE is only a clause and not a standalone SQL statement. The question is read as asking about valid statements.

Why each choice is right or wrong

A - Incorrect: WHERE alone is not a complete statement, so it cannot be the requested statement. (PDF pp. 52, 26.)

B - Correct: SELECT is demonstrated in a read-only transaction. (PDF pp. 52, 26.)

C - Incorrect: INSERT is a manipulation command, not the demonstrated read-only request. (PDF pp. 52, 26.)

D - Incorrect: DROP is a structural DDL command, not the demonstrated retrieval. (PDF pp. 52, 26.)

Primary note proof

Study-note section FDB27

> SELECT Name,Address FROM Customer; produces only those mailing-label fields. SELECT * selects all columns; DISTINCT removes duplicate result rows; AS supplies an alias; ALL permits duplicates and does not mean all columns. SQL normally preserves duplicates without DISTINCT. A query reading table columns needs an appropriate FROM source. A literal-only query such as SELECT 1 may legally omit FROM.

Study-note section FDB27

> WHERE alone is a clause rather than a complete read-only statement, so it cannot be compared as an equivalent executable command.

Study-note section FDB27

Typical written clause order is SELECT ... FROM ... WHERE ... GROUP BY ... HAVING ... ORDER BY ....

Fundamental of Database Systems module | PDF page 52 | lines 4-11

• SET TRANSACTION READ ONLY; • SELECT NAME, ADDRESS FROM WORKERS; • SELECT MANAGER, ADDRESS FROM PLACES; • COMMIT; • Freezes the data for the user in both tables before either select retrieves any rows, so that changes that occur concurrently will not show up • Commits before and after ensure any uncompleted transactions are finish, and then release the frozen data when done

Fundamental of Database Systems module | PDF page 26 | lines 7-11

7.1.1 DDL (data definition language) Basic DDL commands we usually use are: CREATE, DROP, ALTER, TRUNCATE and RENAME 7.1.2 DML (data manipulation language) Basic DDL commands are: SELECT, PROJECT, JOIN, INSERT, DELETE, and UPDATE

Question sources

Database Fundamentals practice questions · Question 67

Question 132 | Q01500

A relation is in 1NF and has no nonprime attribute partially dependent on any candidate key. What is the strongest normal form guaranteed by these facts alone?

A. First

B. BCNF

C. Third

D. Second

Hint

Check atomicity, candidate keys and partial dependencies in that order.

Answer D: D. Second

The two stated conditions are exactly the requirements for 2NF: 1NF plus the absence of nonprime partial dependencies on candidate keys. First normal form is also true but is a weaker guarantee. Third normal form and BCNF need additional conditions on other functional dependencies. The relation might satisfy those higher forms, but the given facts alone establish only 2NF.

Why each choice is right or wrong

A - Incorrect: 1NF is given, but 2NF is the stronger guaranteed form.

B - Incorrect: BCNF additionally requires all nontrivial determinants to be superkeys.

C - Incorrect: 3NF needs further checks on determinants and prime dependents.

D - Correct: The conditions directly establish 2NF as the strongest guaranteed form.

Primary note proof

Study-note section FDB20

> 1NF requires atomic values in the chosen relational domains and no repeating groups in cells. It does not mean merely declaring a primary key. A mapped ER design that correctly splits composite and multivalued structures gives ordinary 1NF tables; ER drawing alone guarantees no higher form.

Study-note section FDB20

> 2NF requires 1NF and no nonprime attribute partially dependent on any candidate key.

Study-note section FDB20

> A relation whose every candidate key is single-attribute has no nonprime partial-key dependency.

Related reading (context, not primary note proof)

Study-note section FDB21

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 17 | lines 2-15

> First normal form (1NF) A relation (table) R is in 1NF if and only if (iff) all underlying domains of attributes contain only atomic (simple or indivisible) values. i.e. The value of any attribute in a tuple (row) must be a single value from the domain of their attribute. It is defined to disallow multivalued attributes, composite attributes, and their combinations. In other words, 1NF disallows relations within relations or relations as attribute values within tuples. It must be remove repeating groups (values) in a single field. The primary key with repeating group attributes are moved into a new table. When a relation contains no repeating groups (values), it is in first normal form (1NF). Second normal form (2NF) Second normal form (2NF) is based on the concept of full functional dependency. A relation schema R is in 2NF if it is in 1NF and every non-prime attribute A in R is fully functionally dependent on the primary key (i.e. the non-prime attributes are not partially dependent on key attributes). Remove any partially dependent attributes and place them in another relation. A partial dependency is when the attribute(s) is/are dependent on a part of a key.

Fundamental of Database Systems module | PDF page 18 | lines 5-8

> Third Normal Form (3NF) A relation schema R is in third normal form (3NF) if it is in 2NF and every non-prime attribute of ‗R' are fully functionally dependent on every key of R and non-transitively dependent on every key of R.

Question sources

Mock exam 1 · Question 16

Question 133 | Q01502

The minimal set of super key is called

A. Foreign key

B. None of the choices is correct

C. Candidate key

D. Primary key

Hint

Test uniqueness and minimality separately when classifying keys.

Answer C: Candidate key

A candidate key is a minimal superkey. Minimal means no removable attribute while retaining uniqueness, not necessarily the fewest attributes among all keys.

Why each choice is right or wrong

A - Incorrect: Foreign key links relations, not the minimal-superkey definition. (PDF pp. 11.)

B - Incorrect: A matching definition is offered. (PDF pp. 11.)

C - Correct: Candidate key is the exact definition. (PDF pp. 11.)

D - Incorrect: Primary key is the selected candidate key rather than the category of every minimal superkey. (PDF pp. 11.)

Primary note proof

Study-note section FDB07

> A superkey uniquely identifies a tuple. A candidate key is a minimal superkey: removing any component loses uniqueness. Minimal means no unnecessary attribute, not necessarily the fewest columns among all keys. A primary key is one selected candidate key; remaining candidates are alternate keys. A composite key contains multiple attributes and need not be the chosen primary key.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 11 | lines 7-11

> Super Key − A set of attributes (one or more) that collectively identifies an entity in an entity set. Candidate Key − A minimal super key is called a candidate key. An entity set may have more than one candidate key. Primary Key − A primary key is one of the candidate keys chosen by the database designer to uniquely identify the entity set.

Question sources

Mock exam 1 · Question 18

Question 134 | Q01581

Assume every foreign-key column is NOT NULL and references a declared primary key. Which statement expresses referential integrity under these assumptions?

A. Every primary-key value must match a primary-key value in an associated table

B. Every primary-key value must match a foreign-key value in an associated table

C. Every foreign-key value must match a primary-key value in an associated table

D. Every foreign-key value must match a foreign-key value in an associated table

Hint

Match the validity requirement to the appropriate constraint definition.

Answer C: C. Every foreign-key value must match a primary-key value in an associated table

A foreign key is a reference from a child row to an eligible key in the parent. Because the question makes every reference non-NULL and targets primary keys, each foreign-key value must match a primary-key value. A parent row need not have children, and primary keys do not themselves have to reference another table. Merely matching a foreign-key column is not sufficient.

Why each choice is right or wrong

A - Incorrect: A primary key can exist without referencing another table.

B - Incorrect: A parent can have no child references.

C - Correct: Every non-NULL child reference must match its targeted parent primary key.

D - Incorrect: The target must be an eligible referenced key, not an arbitrary foreign-key column.

Primary note proof

Study-note section FDB15

> Domain integrity restricts type and allowed values. Key integrity enforces uniqueness. Entity integrity requires every primary-key component to be non-NULL. Referential integrity requires a non-NULL foreign-key value to match an eligible referenced unique/candidate key; self-references are allowed. A parent need not have a child.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 48 | lines 13-17

> iv. Referential Integrity • A —foreign key‖ links each occurrence in a relation representing a child entity to the occurrence of the parent entity containing the matching candidate (usually primary) key • Referential Integrity means that if the foreign key contains a value, that value must refer to an existing occurrence in the parent entity

Fundamental of Database Systems module | PDF page 49 | lines 2-3

- Sometimes a special NULL value may be used to create child entries without a parent or with a —dummy‖ parent

Question sources

Mock exam 3 · Question 13

Question 135 | Q01582

Which of the following is generally used for performing tasks like creating the structure of the relations, deleting relation?

A. DML(Data Manipulation Language)

B. Query

C. Relational Schema

D. DDL(Data Definition Language)

Hint

Classify each SQL command by the kind of change it performs.

Answer D: DDL(Data Definition Language)

Creating/deleting relation structure falls under DDL's structural command category. It is distinguished from data manipulation and from the schema description itself.

Why each choice is right or wrong

A - Incorrect: DML is the data-operation category. (PDF pp. 26.)

B - Incorrect: Query is not the schema-definition category. (PDF pp. 26.)

C - Incorrect: A relational schema is a description, not a command language. (PDF pp. 26.)

D - Correct: DDL is the named structural-language category. (PDF pp. 26.)

Primary note proof

Study-note section FDB26

> DDL changes structure: CREATE, ALTER, DROP, commonly RENAME and TRUNCATE in textbook classifications. DML retrieves or changes data: SELECT, INSERT, UPDATE, DELETE. Some texts separate SELECT as DQL. DCL manages privileges through GRANT and REVOKE. TCL includes COMMIT, ROLLBACK and SAVEPOINT. Classify a statement by its effect, not its length.

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 26 | lines 4-11

> SQL represents Structured Query Language. SQL is a comprehensive database language: It has statements for data definitions, and updates. Hence, it is both a DDL (Data Definition language) and a DML (Data Manipulation Language). 7.1.1 DDL (data definition language) Basic DDL commands we usually use are: CREATE, DROP, ALTER, TRUNCATE and RENAME 7.1.2 DML (data manipulation language) Basic DDL commands are: SELECT, PROJECT, JOIN, INSERT, DELETE, and UPDATE

Question sources

Mock exam 3 · Question 14

Question 136 | Q01583

Which of the following is used in the application programs to request data from the database management system?

A. Data Manipulation language

B. Data Definition Language

C. Data Control Language

D. All choices are correct

Hint

Classify each SQL command by the kind of change it performs.

Answer A: Data Manipulation language

DML is the offered language category that includes retrieval requests such as SELECT. DDL handles definition, while authorization is separate from retrieval commands.

Why each choice is right or wrong

A - Correct: DML includes retrieval. (PDF pp. 26, 24.)

B - Incorrect: DDL is definition rather than ordinary data requests. (PDF pp. 26, 24.)

C - Incorrect: Access-control language is not the category that retrieves the requested data. (PDF pp. 26, 24.)

D - Incorrect: DDL and control are not all retrieval categories. (PDF pp. 26, 24.)

Primary note proof

Study-note section FDB26

> DDL changes structure: CREATE, ALTER, DROP, commonly RENAME and TRUNCATE in textbook classifications. DML retrieves or changes data: SELECT, INSERT, UPDATE, DELETE. Some texts separate SELECT as DQL. DCL manages privileges through GRANT and REVOKE. TCL includes COMMIT, ROLLBACK and SAVEPOINT. Classify a statement by its effect, not its length.

Relational algebra is the basic set of operations for the relational model. These operations enable a user to specify basic retrieval requests (or queries). The result of an operation is a new relation, which may have been formed from one or more input relations. The algebra operations thus produce new relations. Since each operation returns a relation, operations can be composed (Algebra is —closed‖.)

Question sources

Mock exam 3 · Question 15

Question 137 | Q01331B

Which single choice completely identifies the relational DBMS products in the list?

A. Oracle Database

B. Microsoft SQLServer

C. IBM Db2

D. All of the mentioned

Hint

Compare the data models by how they organize records and relationships.

Answer D: D. All of the mentioned

Oracle Database, Microsoft SQL Server and IBM Db2 are all relational DBMS products named in the note. Replacing the vendor-only IBM label with IBM Db2 makes every product entry well-defined. The question asks for the complete set, so All of the mentioned is the best answer. Each individual product is genuinely relational but identifies only part of the full set.

Why each choice is right or wrong

A - Incorrect: Oracle Database is relational, but this alone is an incomplete set.

B - Incorrect: SQL Server is relational, but this alone is an incomplete set.

C - Incorrect: IBM Db2 is relational, but this alone is an incomplete set.

D - Correct: The aggregate choice includes all three relational products.

Primary note proof

Study-note section FDB02

PostgreSQL, MySQL, Oracle Database, Microsoft SQL Server and IBM Db2 are relational DBMS products. MongoDB is a document DBMS. Java is a programming language. IBM alone names a vendor, not a database product. Distinguish a vendor such as IBM from a specific database product.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 5 | lines 14-16

Database Management System (DBMS) is then a tool for creating and managing databases. DBMS is a software that facilities the processes of defining, constructing, manipulating, and sharing databases. Example: MySQL server, MS ACESS, Microsoft SQL server.

Fundamental of Database Systems module | PDF page 13 | lines 18-27

3.6 The Relational Database Model The relational model represents the database as a collection of relations. A table is represented with columns and rows. Each table is an entity in the ER diagram. Each row is known as a tuple. Each table of the column has a name or attribute of the entity. 3.7 Relational Model Concepts in DBMS Attribute: Each column in a Table. Attributes are the properties which define a relation Tables - In the Relational model, relations are saved in the table format. It is stored along with its entities. A table has two properties rows and columns. Rows represent records and columns represent attributes. Tuple - It is a single row of a table, which contains a single record.

Question sources

Database Fundamentals practice questions · Question 6

Question 138 | Q01388B

In ER diagram Diamond/Ellipses represent

A. Relationship sets/Attributes

B. Entity sets/Attributes

C. Attributes/Relationships sets

D. Relationship sets/Entity sets

Hint

Review entity, attribute and relationship notation before interpreting the model.

Answer A: Diamonds represent relationship sets; ellipses represent attributes.

FDB06 maps rectangles to entity types, diamonds to relationships and ellipses to attributes in Chen notation. The question asks for the diamond/ellipse pair in that order. A preserves that order and meaning; the other choices either substitute entity sets or reverse the symbol meanings. A diagram-specific legend would override the generic convention.

Why each choice is right or wrong

A - Correct: The two shapes map to relationships and attributes respectively in Chen notation.

B - Incorrect: Entity types use rectangles, so a diamond does not represent the first item listed.

C - Incorrect: This reverses the requested meanings: diamonds indicate relationships, while ellipses indicate attributes.

D - Incorrect: The first meaning fits, but ellipses represent attributes rather than entity sets.

Primary note proof

Study-note section FDB06

> An entity is a distinguishable real or conceptual thing, such as one student or one course. An entity type describes common properties; its current collection of entities is an entity set. A relationship associates entities. In Chen notation rectangles represent entity types, diamonds relationships and ellipses attributes; double ellipses denote multivalued attributes and dashed ellipses derived attributes. Always inspect the diagram legend.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 10 | lines 3-13

> An entity may be an object with a physical existence (for example, a particular person, car, house, or employee) or it may be an object with a conceptual existence (for instance, a company, a job, or a university course). In ER diagrams, an entity is placed in a rectangle. Each entity has attributes, the particular properties that describe it. Entities that do not have key attributes of their own are called weak entity. The regular entity types that have a key attribute are called strong entity types. Weak entities are identified by being related to specific strong entities in combination with one of their attribute values. A weak entity type has a partial key, which is the attribute that can uniquely identify weak entities that are related to the same owner entity. In ER diagrams, both a weak entity type and its identifying relationship are distinguished by surrounding their boxes and diamonds with double lines. The partial key attribute is underlined with a dashed or dotted line.

Fundamental of Database Systems module | PDF page 11 | lines 13-15

> A relationship type represents the association between entity types. For example, _Enrolled in‘ is a relationship type that exists between entity Student and Course. In ER diagram, relationship is represented by a diamond and connecting the entities with lines.

Question sources

Database Fundamentals practice questions · Question 63

Question 139 | Q01388C

A relation is in 2NF if:

A. All the values of non-key attributes are dependent fully on the candidate key.

B. Any non-key attribute that are dependent on only part of the candidate key should be moved to another relation where the partial key is the actual full key.

C. It must be already in the 1NF.

D. All of the above.

Hint

Check atomicity, candidate keys and partial dependencies in that order.

Answer D: All of the above.

Second normal form requires 1NF and full dependence of each non-prime attribute on candidate keys; partial dependencies must be moved to another relation. A states the criterion, B the repair, and C the prerequisite; D collects all three. A alone is not a complete definition without C.

Why each choice is right or wrong

A - Incorrect: Full dependency is a required 2NF property. (PDF pp. 17.)

B - Incorrect: Moving a partially dependent attribute to the relation where its determinant is the whole key is the stated repair. (PDF pp. 17.)

C - Incorrect: 1NF is expressly required. (PDF pp. 17.)

D - Correct: All three agree with the module's definition and repair rule. (PDF pp. 17.)

Primary note proof

Study-note section FDB20

> 2NF requires 1NF and no nonprime attribute partially dependent on any candidate key. For Enrollment(SID,CID,SName,CTitle,Grade), assume key (SID,CID), SID→SName and CID→CTitle. Split into Student(SID,SName), Course(CID,CTitle) and Enrollment(SID,CID,Grade). Grade still depends on the whole pair. A relation whose every candidate key is single-attribute has no nonprime partial-key dependency. Higher forms inherit 2NF, so no partial dependencies establishes the minimum guaranteed stage only when 1NF is also assumed.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 17 | lines 10-15

> Second normal form (2NF) Second normal form (2NF) is based on the concept of full functional dependency. A relation schema R is in 2NF if it is in 1NF and every non-prime attribute A in R is fully functionally dependent on the primary key (i.e. the non-prime attributes are not partially dependent on key attributes). Remove any partially dependent attributes and place them in another relation. A partial dependency is when the attribute(s) is/are dependent on a part of a key.

Question 140 | SM0017

Which one of the following is NOT a single level ordered index?

A. Secondary index

B. Primary index

C. Clustering index

D. Multilevel index

Hint

Compare index organization with its access benefits and maintenance costs.

Answer D: Multilevel index

In this single-level ordered-index classification, the listed types are primary, clustering and secondary indexes. A multilevel index is the exception to that listed single-level classification.

Why each choice is right or wrong

A - Incorrect: Secondary is listed as single level. (PDF pp. 21.)

B - Incorrect: Primary is listed as single level. (PDF pp. 21.)

C - Incorrect: Clustering is listed as single level. (PDF pp. 21.)

D - Correct: Multilevel is outside the specified single-level group. (PDF pp. 21.)

Primary note proof

Study-note section FDB25

> In ordered-file indexing terminology, a primary ordered index is on the file's ordering key and can have one entry per page, hence sparse. A clustering index is on a nonunique ordering field, often with an entry per distinct value. Secondary indexes provide other access paths and must represent all searchable values with record pointers or pointer lists. A dense index represents each search value; sparse indexes rely on ordered data between entries. Multilevel indexes index lower index levels. B/B+ trees support ordered and range search; hashing targets equality; bitmap indexes suit some analytic workloads. No one type is universally best.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 21 | lines 19-24

> Single Level Ordered Indexes Here it is assumed that a file already exists with some primary organization like unordered, ordered, or hashed organizations. For a file with a given record structure consisting of several fields, an index access structure is usually defined on a single field of a file, called an indexing field (or indexing attribute). Types of Single Level Ordered Indexes are Primary, Clustering and Secondary.

Question 141 | SM0023

Among the following, which one best describes a Database Management System (DBMS)?

A. It is responsible for creating and maintaining a database

B. It can help users to manage computer's activity

C. It can assist process images

D. It can assist you to process document

Hint

Review the database approach and match each claimed benefit or cost to its mechanism.

Answer A: It is responsible for creating and maintaining a database

A DBMS is software facilitating definition, construction, manipulation and sharing of databases. This directly matches creating and maintaining a database.

Why each choice is right or wrong

A - Correct: Matches the module's DBMS definition. (PDF pp. 5.)

B - Incorrect: Managing general computer activity describes a broader different role. (PDF pp. 5.)

C - Incorrect: Image processing is not the database-management role. (PDF pp. 5.)

D - Incorrect: Document processing is not the database-management definition. (PDF pp. 5.)

Primary note proof

Study-note section FDB01

> A database is a coherent collection of related facts with meaning for an application. A DBMS is software that defines, stores, retrieves, updates, protects and shares that data. The database is the content; the DBMS manages it. A database system also includes applications, people and infrastructure.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 5 | lines 14-16

> Database Management System (DBMS) is then a tool for creating and managing databases. DBMS is a software that facilities the processes of defining, constructing, manipulating, and sharing databases. Example: MySQL server, MS ACESS, Microsoft SQL server.

Question 142 | SM0034

Given the schemas: BOOK (Book_id, Title, Publisher_name), BOOK_AUTHOR (Book_id, Author_name), PUBLISHER (Name, Address, Phone). Which one of the following SQL is correct to delete the
publisher named 'XWZ' from the PUBLISHER table?

A. DELETE FROM BOOK_AUTHOR WHERE Address = 'XWZ'

B. DELETE FROM PUBLISHER WHERE Name = 'XWZ'

C. DELETE FROM PUBLISHER WHERE Address = 'XWZ'

D. DELETE FROM BOOK WHERE Name = 'XWZ'

Hint

Track which rows each data-changing command affects.

Answer B: DELETE FROM PUBLISHER WHERE Name = 'XWZ'

The module illustrates DELETE FROM HumanResources.JobCandidate WHERE JobCandidateID = 13 (PDF p.77). Substitute the requested relation PUBLISHER and its identifying Name predicate: DELETE FROM PUBLISHER WHERE Name = 'XWZ'. The stem's schemas distinguish Name from Address and omit both from BOOK_AUTHOR. This identifies the requested statement; successful execution may additionally depend on existing referencing rows and the deletion policy (PDF pp.48-49).

Why each choice is right or wrong

A - Incorrect: BOOK_AUTHOR is the wrong target and has no Address column in the supplied schema (compare the target/predicate form on PDF p.77).

B - Correct: PUBLISHER is the target and Name is the requested name filter, matching the module's DELETE FROM ... WHERE example (PDF p.77).

C - Incorrect: Filtering Address does not select by publisher name, despite a valid target table (PDF p.77's predicate pattern).

D - Incorrect: BOOK is the wrong target and has no Name column in the supplied schema (PDF p.77's target/predicate pattern).

Primary note proof

Study-note section FDB29

> INSERT INTO Hotel(HotelID,HotelName,SubCity) VALUES (1,'Hilton','Yeka'); pairs each named column with a compatible value. Counts and types must match; keys and other constraints still apply. Without a column list, values must follow the table's declared column order.

Study-note section FDB29

DELETE FROM Publisher WHERE Name = 'XWZ'; deletes matching publisher rows, subject to reference policies.

Study-note section FDB29

Both clear relation entries and delete rows describe that effect.

Question 143 | SM0048

What does program data independence in the database approach entail?

A. The application may be affected when data changes

B. Data and applications are defined separately

C. Programs can create redundant data independently

D. Both program and data are defined together

Hint

Trace which schema levels a proposed change affects.

Answer B: Data and applications are defined separately

Program/data insulation separates application definitions from data definitions, allowing schema changes without corresponding higher-level changes under the relevant independence conditions.

Why each choice is right or wrong

A - Incorrect: Says changes necessarily affect applications, contrary to insulation. (PDF pp. 5, 6, 8.)

B - Correct: Separate definitions express program/data insulation. (PDF pp. 5, 6, 8.)

C - Incorrect: Creating redundant data independently is not the defined independence. (PDF pp. 5, 6, 8.)

D - Incorrect: Defining both together contradicts insulation. (PDF pp. 5, 6, 8.)

Primary note proof

Study-note section FDB04

> Physical data independence permits changing internal storage without changing the conceptual schema, for example adding an index. Logical data independence permits conceptual changes while preserving affected external views and application interfaces, for example splitting a table while maintaining a compatible view. It is harder because applications depend on logical meaning. Data abstraction hides irrelevant details; program-data insulation separates data definitions from application code.

> 1.3 Characteristics of the Database Approach The main characteristics of the database approach are Self-describing nature, Data abstraction and Insulation between programs and data, Support of multiple views of the data, sharing of data and multiuser transaction processing.

Fundamental of Database Systems module | PDF page 6 | lines 2-4

Data abstraction and Insulation between programs and data- Data Abstraction is a process of hiding unwanted or irrelevant details from the end user. It provides a different view and helps in achieving data independence which is used to enhance the security of data.

Fundamental of Database Systems module | PDF page 8 | lines 8-15

2.4 Data Independence The three-schema architecture can be used to further explain the concept of data independence, which can be defined as the capacity to change the schema at one level of a database system without having to change the schema at the next higher level. The two types of data independence: 1. Logical data independence is the capacity to change the conceptual schema without having to change external schemas or application programs. 2. Physical data independence is the capacity to change the internal schema without having to change the conceptual schema. Hence, the external schemas do not need be changed as well.

Question 144 | SM0071

Which statements are NOT correct descriptions of a fan trap or its general remedy in an ER diagram? Select all that apply. Treat B as a warning pattern, not a sufficient condition.

A. It occurs when there is no pathway between related entities

B. Highly likely when more than two one-to-many relationships fan out from an entity

C. When there is ambiguous pathway between some entity occurrences in related entity types

D. It can be resolved by readjusting the model so that no one-to-many relationships fan out from an entity

Hint

Trace the actual relationship paths and check whether the requested association follows.

Answer A, D: A. It occurs when there is no pathway between related entities; D. It can be resolved by readjusting the model so that no one-to-many relationships fan out from an entity

A fan trap concerns an ambiguous association inferred through branches from a common entity. A missing or broken path is instead a chasm-type issue. Also, legitimate one-to-many branches need not all be eliminated: the model should record the actual missing association. Multiple branches can warn of a fan trap, and ambiguity is its defining issue, so B and C are not false.

Why each choice is right or wrong

A - Correct: This is false about fan traps: a missing or broken path describes a chasm-type problem.

B - Incorrect: Several 1:N branches from a common entity can create the ambiguous association characteristic of fan traps.

C - Incorrect: Ambiguity about associations between entity occurrences is the defining fan-trap problem.

D - Correct: This is false as a general remedy: valid 1:N fans may remain after explicitly modeling the required association.

Primary note proof

Study-note section FDB14

> A fan trap occurs when two 1:N relationships fan from a common entity and a path suggests an association it cannot determine. Department→Employee and Department→Project do not reveal which employee works on which project; joining through Department pairs every employee with every project in that department. Record WorksOn explicitly when that is the fact needed.

Study-note section FDB14

> A missing path describes a chasm, not the defining ambiguity of a fan.

Study-note section FDB14

> Multiple 1:N relationships are legitimate; eliminating all fans is not a universal repair.

Module passages - related reading

Fundamental of Database Systems module | PDF page 9 | lines 27-31

> 3.3 ERD (Entity Relationship Diagram) ERD a graphical technique for representing a database schema. It is a modeling tool used to depict graphically a DB design before it is actually implemented. It shows the various entities being modeled and the important relationships among them. ERD has three basic components Entity, Relationship and Attribute.

Fundamental of Database Systems module | PDF page 11 | lines 24-31

> Cardinality The number of times an entity of an entity set participates in a relationship set is known as cardinality. Cardinality can be of different types: One to one (1-1) - When each entity in each entity set can take part only once in the relationship, the cardinality is one to one. One to many(1-M)- When entities in one entity set can take part only once in the relationship set and entities in other entity set can take part more than once in the relationship set, cardinality is many to one.

Question 145 | SM0086

In which situation does using a DBMS become costly and not recommended?

A. In embedded systems having too small storage space

B. In situation where more than one user should access the database

C. To deny access to unauthorized users

D. To control redundancy

Hint

Review the database approach and match each claimed benefit or cost to its mechanism.

Answer A: Severely storage-constrained embedded systems can make a DBMS too costly.

FDB01 says storage, administration and complexity may outweigh DBMS benefits in a tiny fixed application, while also recognizing lightweight embedded DBMSs. A is therefore the listed situation where resource constraints can make a DBMS inappropriate. The other scenarios are central reasons for using a DBMS: sharing, authorization and redundancy control. Embedded use alone does not forbid a DBMS.

Why each choice is right or wrong

A - Correct: Severely limited storage can make DBMS overhead unjustified, though lightweight embedded DBMSs may still fit.

B - Incorrect: Controlled multiuser access is a benefit supplied by database management rather than a reason to avoid it.

C - Incorrect: Authorization helps deny unauthorized access and is a reason to use DBMS protection.

D - Incorrect: Controlling redundancy is a benefit of shared database management rather than a contraindication.

Primary note proof

Study-note section FDB01

> A database is a coherent collection of related facts with meaning for an application. A DBMS is software that defines, stores, retrieves, updates, protects and shares that data. The database is the content; the DBMS manages it. A database system also includes applications, people and infrastructure.

Study-note section FDB01

Complexity, administration, storage and licensing can outweigh benefits for a tiny fixed application; lightweight embedded DBMSs also exist.

Study-note section FDB01

It controls redundancy rather than guaranteeing zero duplication.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 5 | lines 14-25

Database Management System (DBMS) is then a tool for creating and managing databases. DBMS is a software that facilities the processes of defining, constructing, manipulating, and sharing databases. Example: MySQL server, MS ACESS, Microsoft SQL server. 1.2 Database System versus File System The traditional file processing system is file-directory structure supported by a conventional operating system. A file system organization of data lucks a number of major features of a database system, such as Data redundancy and inconsistency, Difficulty in accessing data, Data isolation, Integrity problems, Atomicity problems, Concurrent access anomalies. 1.3 Characteristics of the Database Approach The main characteristics of the database approach are Self-describing nature, Data abstraction and Insulation between programs and data, Support of multiple views of the data, sharing of data and multiuser transaction processing.

Fundamental of Database Systems module | PDF page 19 | lines 4-10

5.1 Introduction To translate the logical description of data into technical specifications for storing and retrieving data, a physical database design is needed. The goal is to create a design for storing and retrieving data that will provide adequate performance and insure database integrity, security, and availability. Some decisions need to be made on the physical database design. They are Attribute data types, data/file storages, File organizations and Indexes.

Question 146 | SM0208

Indexes in database tables speed up the _____ operations.

A. Read operations

B. Delete operations

C. Update operations

D. Write operations

Hint

Compare index organization with its access benefits and maintenance costs.

Answer A: Read operations

Indexes are auxiliary access structures explicitly used to speed record retrieval for search conditions. This is a read-performance purpose; it does not claim that maintaining indexes makes every change operation faster.

Why each choice is right or wrong

A - Correct: Read retrieval is the stated purpose. (PDF pp. 21.)

B - Incorrect: Deletion may require maintenance; it is not the stated general benefit. (PDF pp. 21.)

C - Incorrect: Updating data is not the stated general purpose. (PDF pp. 21.)

D - Incorrect: Writing is not the stated retrieval purpose. (PDF pp. 21.)

Primary note proof

Study-note section FDB25

> An index stores search keys with pointers or row identifiers. It often speeds selective retrieval but consumes space and must be maintained on writes. A full scan can win for a tiny table or a query returning most rows. Indexes do not themselves establish referential integrity.

Study-note section FDB25

> Secondary indexes provide other access paths and must represent all searchable values with record pointers or pointer lists.

Study-note section FDB25

> A dense index represents each search value; sparse indexes rely on ordered data between entries.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 21 | lines 5-9

> 5.5 Index Indexes are additional auxiliary access structures which are used to speed up the retrieval of records in response to certain search conditions. Index structures are additional files, which provide alternative ways to access the records without affecting the physical placement of records on disk.

Computer Science Exit Exam · Sene 2016 · Question 3-1

Computer Science Exit Exam practice collection · Question 56

Question 147 | SM0226

An e-commerce database already has a suitable normalized schema. Customer-order queries repeatedly select a small fraction of rows by a search key. Which technique directly adds a maintained search path for those lookups?

A. Normalization

B. Denormalization

C. Partitioning

D. Indexing

Hint

Compare design techniques by the specific problem each solves.

Answer D: D. Indexing

Indexing stores search keys and pointers that support selective retrieval without scanning every row. That directly meets the requested search-path improvement. Normalization addresses dependency anomalies, denormalization stores redundant or precomputed facts, and partitioning divides a dataset. Those techniques can be useful elsewhere, but the specified task is to add an access path to the existing normalized schema.

Why each choice is right or wrong

A - Incorrect: Normalization organizes dependencies; it does not add the requested search path.

B - Incorrect: Denormalization repeats or precomputes facts rather than directly adding an index path.

C - Incorrect: Partitioning divides the dataset rather than adding the requested maintained search-key structure.

D - Correct: Indexing directly supplies the selective lookup search path.

Primary note proof

Study-note section FDB38

> Normalization reduces dependency-driven anomalies. Indexing supplies search paths. Denormalization deliberately repeats or precomputes facts to reduce selected read costs, increasing maintenance work. Partitioning divides rows or columns; replication creates copies to improve locality or availability while complicating updates. These techniques can coexist. An e-commerce or gaming label alone does not select one.

Study-note section FDB25

> An index stores search keys with pointers or row identifiers.

Study-note section FDB25

> It often speeds selective retrieval but consumes space and must be maintained on writes.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 16 | lines 17-27

> 4.4 Normalization Normalization is a process of organizing the data in database to avoid data redundancy, insertion anomaly, update anomaly & deletion anomaly. It is a technique of organizing the data in the database. It is a systematic approach of decomposing tables to eliminate data redundancy (repetition) and undesirable characteristics like Insertion, Update and Deletion Anomalies. It is a multi-step process that puts data into tabular form, removing duplicated data from the relation tables. Normal forms Redundancy in a relation may causes insertion, deletion, and update anomalies. Normalization is database design technique that minimizes redundancy from a relation or a set of relations. Normalization rules divides larger tables into smaller tables and links them using relationship.

Fundamental of Database Systems module | PDF page 21 | lines 5-9

> 5.5 Index Indexes are additional auxiliary access structures which are used to speed up the retrieval of records in response to certain search conditions. Index structures are additional files, which provide alternative ways to access the records without affecting the physical placement of records on disk.

Fundamental of Database Systems module | PDF page 117 | lines 18-29

> I. Data Replication • The system maintain several identical copies of the relation & store each copy at a different site • In general it enhance the performance of read operation and increase the availability of data to read only transaction. However, update transactions incur greater overhead II. Data Fragmentation - Split a relation into logically related and correct parts. - The main reasons for fragmenting a relation are • Efficiency- data that is not needed by the local applications is not stored • Parallelism - a transaction can be divided into several subqueries that operate on fragments which will increase the degree of concurrency

Computer Science Exit Exam practice collection · Question 68

Question 148 | SM0251

Which SQL command is used to modify existing data in a table?

A. ALTER

B. UPDATE

C. MODIFY

D. CHANGE

Hint

Track which rows each data-changing command affects.

Answer B: UPDATE

UPDATE changes existing row values using a target table, SET assignments and an optional WHERE predicate. ALTER instead changes an object's definition. The bare words MODIFY and CHANGE do not form the UPDATE statement required for changing stored row values in the stated SQL forms. They should not be treated as synonyms for the command merely because they describe the task in everyday language. B names the actual row-update command.

Why each choice is right or wrong

A - Incorrect: Incorrect: ALTER changes schema definitions rather than stored row values.

B - Correct: Correct: UPDATE changes existing rows using SET and, when needed, WHERE.

C - Incorrect: Incorrect: MODIFY is not the UPDATE command required for the stated row-value operation.

D - Incorrect: Incorrect: CHANGE is not the UPDATE command required for the stated row-value operation.

Primary note proof

Study-note section FDB29

> UPDATE Book SET Price = 600 WHERE ID = 'B001'; changes matching rows. UPDATE without WHERE targets every row.

Study-note section FDB26

> DDL changes structure: CREATE, ALTER, DROP, commonly RENAME and TRUNCATE in textbook classifications. DML retrieves or changes data: SELECT, INSERT, UPDATE, DELETE.

Module passages - related reading

Computer Science Exit Exam · Sene 2016 · Question 16-4

Computer Science Exit Exam practice collection · Question 54

Question 149 | SM0252

Which is the first normal form in the usual normalization sequence that requires atomic values and no repeating groups?

A. Second Normal Form (2NF)

B. Third Normal Form (3NF)

C. Boyce-Codd Normal Form (BCNF)

D. First Normal Form (1NF)

Hint

Check atomicity, candidate keys and partial dependencies in that order.

Answer D: First Normal Form (1NF)

First normal form is the first stage requiring atomic values and no repeating groups in cells. It does not by itself remove partial or transitive functional dependencies. Second normal form adds the full-dependency condition, third normal form adds the determinant/prime-attribute rule, and BCNF requires every nontrivial determinant to be a superkey. These stronger forms inherit atomicity, but the question asks for the first stage defining it.

Why each choice is right or wrong

A - Incorrect: Incorrect: 2NF inherits atomicity and additionally excludes nonprime partial dependencies; it is a later stage.

B - Incorrect: Incorrect: 3NF inherits the earlier atomicity condition and adds a stronger dependency test.

C - Incorrect: Incorrect: BCNF adds the superkey-determinant rule and is not the first stage requiring atomicity.

D - Correct: Correct: 1NF is the first stage defining atomic values and no repeating groups.

Primary note proof

Study-note section FDB20

> 1NF requires atomic values in the chosen relational domains and no repeating groups in cells.

Study-note section FDB20

> 2NF requires 1NF and no nonprime attribute partially dependent on any candidate key.

Study-note section FDB21

> For every nontrivial FD X→A, 3NF permits it when X is a superkey or A is prime. BCNF requires X to be a superkey. The mnemonic whole key and nothing but the key describes the common single-key case; it cannot replace the full tests when keys overlap. Remove dependencies of nonprime facts on nonkey determinants.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 17 | lines 2-15

> First normal form (1NF) A relation (table) R is in 1NF if and only if (iff) all underlying domains of attributes contain only atomic (simple or indivisible) values. i.e. The value of any attribute in a tuple (row) must be a single value from the domain of their attribute. It is defined to disallow multivalued attributes, composite attributes, and their combinations. In other words, 1NF disallows relations within relations or relations as attribute values within tuples. It must be remove repeating groups (values) in a single field. The primary key with repeating group attributes are moved into a new table. When a relation contains no repeating groups (values), it is in first normal form (1NF). Second normal form (2NF) Second normal form (2NF) is based on the concept of full functional dependency. A relation schema R is in 2NF if it is in 1NF and every non-prime attribute A in R is fully functionally dependent on the primary key (i.e. the non-prime attributes are not partially dependent on key attributes). Remove any partially dependent attributes and place them in another relation. A partial dependency is when the attribute(s) is/are dependent on a part of a key.

Fundamental of Database Systems module | PDF page 18 | lines 5-8

> Third Normal Form (3NF) A relation schema R is in third normal form (3NF) if it is in 2NF and every non-prime attribute of _R‘ are fully functionally dependent on every key of R and non-transitively dependent on every key of R.

Question sources

Computer Science Exit Exam · Sene 2016 · Question 17-1

Question 150 | SM0254

What is the purpose of normalization in database design?

A. To increase data redundancy

B. To decrease data integrity

C. To eliminate data duplication

D. To simplify data retrieval

Hint

Distinguish dependency-based design problems from the contents of one sample table.

Answer C: To eliminate data duplication

Normalization systematically decomposes relations to eliminate or reduce duplication and insertion/update/deletion anomalies. Eliminate is understood as the design goal, not a claim that every possible repeated value or necessary key reference disappears.

Why each choice is right or wrong

A - Incorrect: Increasing redundancy reverses the goal. (PDF pp. 16.)

B - Incorrect: Decreasing integrity reverses the anomaly-prevention goal. (PDF pp. 16.)

C - Correct: Eliminating duplicated data is directly stated. (PDF pp. 16.)

D - Incorrect: Simplifying retrieval is not the stated normalization purpose and does not follow automatically from decomposition. (PDF pp. 16.)

Primary note proof

Study-note section FDB19

> Suppose Enrollment repeats StudentName for every course. An update anomaly requires changing every copy of the student's name; missed copies disagree. An insertion anomaly prevents recording a new student until some enrollment exists. A deletion anomaly loses the only record of a student's details when their last enrollment is deleted. Revoke anomaly is not a normalization anomaly.

Study-note section FDB19

> Adding a generated row ID may make insertion technically possible, but does not remove repeated facts or fix the dependency design.

Study-note section FDB19

> Reduced redundancy can improve integrity and storage use, but extra keys and joins mean neither storage savings nor faster retrieval is guaranteed.

Related reading (context, not primary note proof)

> 4.4 Normalization Normalization is a process of organizing the data in database to avoid data redundancy, insertion anomaly, update anomaly & deletion anomaly. It is a technique of organizing the data in the database. It is a systematic approach of decomposing tables to eliminate data redundancy (repetition) and undesirable characteristics like Insertion, Update and Deletion Anomalies. It is a multi-step process that puts data into tabular form, removing duplicated data from the relation tables. Normal forms Redundancy in a relation may causes insertion, deletion, and update anomalies. Normalization is database design technique that minimizes redundancy from a relation or a set of relations. Normalization rules divides larger tables into smaller tables and links them using relationship. Normal Forms are maintenance rules that are used to eliminate or reduce the redundancy in database relations. These normal forms are 1NF (First Normal Form), 2NF (Second Normal Form)

Variant 1 | Alternative version 1

What is the purpose of normalization in database design?

A. To reduce redundancy and improve data integrity

B. To speed up query performance

C. To create complex relationships between tables

D. To encrypt sensitive data

Answer A: To reduce redundancy and improve data integrity

Normalization systematically decomposes relations to eliminate or reduce duplication and insertion/update/deletion anomalies. Eliminate is understood as the design goal, not a claim that every possible repeated value or necessary key reference disappears.

Why each choice is right or wrong

A - Correct: Reducing redundancy and preventing anomalies is the normalization goal (PDF p.16).

B - Incorrect: Query performance is not the stated normalization purpose; decomposition can require additional joins.

C - Incorrect: Relationships support decomposition but creating complexity is not its goal.

D - Incorrect: Encryption is a security mechanism, not normalization.

Primary note proof

Study-note section FDB19

> Suppose Enrollment repeats StudentName for every course. An update anomaly requires changing every copy of the student's name; missed copies disagree. An insertion anomaly prevents recording a new student until some enrollment exists. A deletion anomaly loses the only record of a student's details when their last enrollment is deleted. Revoke anomaly is not a normalization anomaly.

Study-note section FDB19

> Reduced redundancy can improve integrity and storage use, but extra keys and joins mean neither storage savings nor faster retrieval is guaranteed.

Study-note section FDB19

> Adding a generated row ID may make insertion technically possible, but does not remove repeated facts or fix the dependency design.

Question 151 | SM0262

Which of the following IS NOT a type of database management system (DBMS)?

A. PostgreSQL

B. MongoDB

C. Java

D. MySQL

Hint

Compare the data models by how they organize records and relationships.

Answer C: Java is a programming language, not a DBMS.

The question uses type loosely to list named systems. FDB02 identifies PostgreSQL and MySQL as relational DBMS products and MongoDB as a document DBMS. Java is explicitly a programming language. Its ability to connect to databases does not make it a database management system, so C alone fits the negative question.

Why each choice is right or wrong

A - Incorrect: PostgreSQL is a relational DBMS product, so it does not satisfy the negative question.

B - Incorrect: MongoDB is a document DBMS, even though it is not a relational system.

C - Correct: Java is a programming language rather than a database management system.

D - Incorrect: MySQL is a relational DBMS product and therefore is not the requested exception.

Primary note proof

Study-note section FDB02

> PostgreSQL, MySQL, Oracle Database, Microsoft SQL Server and IBM Db2 are relational DBMS products. MongoDB is a document DBMS. Java is a programming language. IBM alone names a vendor, not a database product. Distinguish a vendor such as IBM from a specific database product.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 5 | lines 14-16

> Database Management System (DBMS) is then a tool for creating and managing databases. DBMS is a software that facilities the processes of defining, constructing, manipulating, and sharing databases. Example: MySQL server, MS ACESS, Microsoft SQL server.

Question 152 | SM0273

The E-R data model is based on a perception of the real world that consists of a set of basic objects called _____.

A. Objects

B. Classes

C. Entities

D. Attributes

Hint

Review entity, attribute and relationship notation before interpreting the model.

Answer C: Entities

The ER model uses entities, attributes and relationships; the actual physical/conceptual objects are entities. Objects is a generic word, while entities is the model-specific category requested.

Why each choice is right or wrong

A - Incorrect: Objects is the generic description, not the requested ER term. (PDF pp. 9, 10.)

B - Incorrect: Classes are not the basic-object term in this ER definition. (PDF pp. 9, 10.)

C - Correct: Entities is the named category for those real-world objects. (PDF pp. 9, 10.)

D - Incorrect: Attributes are properties of entities rather than the objects themselves. (PDF pp. 9, 10.)

Primary note proof

Study-note section FDB06

> An entity is a distinguishable real or conceptual thing, such as one student or one course. An entity type describes common properties; its current collection of entities is an entity set. A relationship associates entities. In Chen notation rectangles represent entity types, diamonds relationships and ellipses attributes; double ellipses denote multivalued attributes and dashed ellipses derived attributes. Always inspect the diagram legend.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 9 | lines 3-6

> 3.1 Database Modeling High-level conceptual data models provide concepts for presenting data in ways that are close to the way people perceive data. A typical example is the entity relationship model, which uses main concepts like entities, attributes and relationships.

Fundamental of Database Systems module | PDF page 10 | lines 3-8

> An entity may be an object with a physical existence (for example, a particular person, car, house, or employee) or it may be an object with a conceptual existence (for instance, a company, a job, or a university course). In ER diagrams, an entity is placed in a rectangle. Each entity has

attributes, the particular properties that describe it. Entities that do not have key attributes of their own are called weak entity. The regular entity types that have a key attribute are called strong entity types. Weak entities are identified by being related to specific strong entities

Computer Science Exit Exam · Sene 2016 · Question 24-1

Computer Science Exit Exam practice collection · Question 52

Question 153 | SM0275

What is the primary key in a relational database?

A. A unique identifier for each row in a table

B. A foreign key from another table

C. A key used for encryption

D. An index on a non-unique column

Hint

Test uniqueness and minimality separately when classifying keys.

Answer A: A unique identifier for each row in a table

A primary key is the selected candidate key used to identify tuples uniquely; its values must be unique and non-null. The key may consist of more than one attribute.

Why each choice is right or wrong

A - Correct: Uniquely identifies each row, consistent with the key definition. (PDF pp. 11, 14.)

B - Incorrect: A foreign key serves a reference role and need not be this table's primary key. (PDF pp. 11, 14.)

C - Incorrect: Encryption keys have a different security role. (PDF pp. 11, 14.)

D - Incorrect: A non-unique index does not meet key uniqueness. (PDF pp. 11, 14.)

Primary note proof

Study-note section FDB07

A superkey uniquely identifies a tuple. A candidate key is a minimal superkey: removing any component loses uniqueness. Minimal means no unnecessary attribute, not necessarily the fewest columns among all keys. A primary key is one selected candidate key; remaining candidates are alternate keys. A composite key contains multiple attributes and need not be the chosen primary key.

Study-note section FDB07

A table can have several candidates and foreign keys but at most one declared primary-key constraint, possibly containing several columns.

Study-note section FDB07

> If ID is unique, both {ID} and {ID,City} are superkeys, but only {ID} is minimal.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 11 | lines 7-11

> Super Key − A set of attributes (one or more) that collectively identifies an entity in an entity set. Candidate Key − A minimal super key is called a candidate key. An entity set may have more than one candidate key. Primary Key − A primary key is one of the candidate keys chosen by the database designer to uniquely identify the entity set.

Fundamental of Database Systems module | PDF page 14 | lines 17-20

> Key Constraints- These are called uniqueness constraints since it ensures that every tuple in the relation should be unique. An attribute that can uniquely identify a tuple in a relation is called the key or primary key of the table. The value of the attribute for different tuples in the relation has to be unique. Primary keys must be unique and cannot be null.

Question 154 | SM0280

What is the role of a database administrator (DBA)?

A. Designing user interfaces for database applications

B. Developing front-end applications

C. Writing complex SQL queries

D. Managing and maintaining databases

Hint

Review the database approach and match each claimed benefit or cost to its mechanism.

Answer D: Managing and maintaining databases

The DBA administers the database and DBMS, authorizes access, coordinates/monitors use and acquires resources. Those responsibilities fit management and maintenance.

Why each choice is right or wrong

A - Incorrect: User-interface design is not the defining DBA responsibility described. (PDF pp. 6.)

B - Incorrect: Front-end development is not the defining responsibility. (PDF pp. 6.)

C - Incorrect: Writing a difficult query may occur, but is not the administration role defined. (PDF pp. 6.)

D - Correct: Management and maintenance match the listed administration duties. (PDF pp. 6.)

Primary note proof

Study-note section FDB01

> The DBA manages access authorization, backup/recovery, availability, monitoring, tuning and routine maintenance, coordinating database use; designers define the schema and application developers build user-facing programs.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 6 | lines 10-16

> 1.4 Actors on the scene The people whose jobs involve the day-to-day use of a large database are called actors on the scene. In a database environment, the primary resource is the database itself, and the secondary resource is the DBMS and related software. Administering these resources is the responsibility of the database administrator (DBA). The DBA is responsible for authorizing access to the database, coordinating and monitoring its use, and acquiring software and hardware resources as needed.

Which of the following IS NOT a type of database model?

A. Linear

B. Object-Oriented

C. Hierarchical

D. Relational

Hint

Compare the data models by how they organize records and relationships.

Answer A: Linear

The model taxonomy names object-oriented, hierarchical/network, and relational concepts. Linear is not among the stated database-model categories; this is a taxonomy question within that stated list, not a universal claim about every possible model name.

Why each choice is right or wrong

A - Correct: Linear is outside the supplied taxonomy. (PDF pp. 7, 13.)

B - Incorrect: Object-Oriented is explicitly a conceptual-model example. (PDF pp. 7, 13.)

C - Incorrect: Hierarchical is named in the model discussion. (PDF pp. 7, 13.)

D - Incorrect: Relational is explicitly defined as a database model. (PDF pp. 7, 13.)

Primary note proof

Study-note section FDB02

A data model supplies concepts for structure, relationships, constraints and operations. Conceptual ER models describe entities and relationships. Relational models use tables; hierarchical models organize records in a parent-child tree; classic network models connect records through pointer-based owner/member links, allowing multiple parents. Object models represent objects with identity, state and behavior. A physical model specifies record layouts and access paths. These are different representation choices, not stages of one query.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 7 | lines 8-19

Types of Data Models 1. High-level or conceptual data models provide concepts that are close to the way many users perceive data. Entity - Relationship (E/R) model and Object-Oriented Model are examples of conceptual/high level data model. 2. Low-level or physical data models provide concepts that describe the details of how data is stored on the computer storage media. Concepts provided by physical data models are generally meant for computer specialists, not for end users. 3. representational (or implementation) data model provides concepts that may be easily understood by end users but that are not too far from the way data is organized in computer storage. Representational data models hide many details of data storage on disk but can be implemented on a computer system directly. The widely used relational data models are the network and hierarchical.

Fundamental of Database Systems module | PDF page 13 | lines 18-20

3.6 The Relational Database Model The relational model represents the database as a collection of relations. A table is represented with columns and rows. Each table is an entity in the ER diagram. Each row is known as a tuple.

Question sources

Computer Science Exit Exam · Sene 2016 · Question 34-1

Computer Science Exit Exam practice collection · Question 58

Question 156 | SS133

A relation has atomic values with no repeating groups, and no nonprime attribute partially depends on any candidate key. What is the strongest normal form guaranteed by these facts alone?

A. 4NF

B. 2NF

C. 1NF

D. 3NF

Hint

Check atomicity, candidate keys and partial dependencies in that order.

Answer B: B. 2NF

Atomic values without repeating groups establish 1NF. Adding the absence of nonprime partial dependencies establishes 2NF. Higher normal forms have additional requirements involving nonkey determinants or multivalued dependencies, and none of those requirements follows from the stated facts. Thus 2NF is the strongest guaranteed level, even though the relation could also happen to satisfy higher forms.

Why each choice is right or wrong

A - Incorrect: No restriction on nontrivial multivalued dependencies has been established.

B - Correct: 1NF plus the absence of nonprime partial dependencies guarantees 2NF.

C - Incorrect: 1NF holds, but 2NF is the stronger guarantee.

D - Incorrect: 3NF requires additional determinant/prime-attribute conditions.

Primary note proof

Study-note section FDB20

> 1NF requires atomic values in the chosen relational domains and no repeating groups in cells. It does not mean merely declaring a primary key. A mapped ER design that correctly splits composite and multivalued structures gives ordinary 1NF tables; ER drawing alone guarantees no higher form.

Study-note section FDB20

> 2NF requires 1NF and no nonprime attribute partially dependent on any candidate key.

Study-note section FDB20

> Higher forms inherit 2NF, so no partial dependencies establishes the minimum guaranteed stage only when 1NF is also assumed.

Related reading (context, not primary note proof)

Study-note section FDB21

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 17 | lines 2-15

> First normal form (1NF) A relation (table) R is in 1NF if and only if (iff) all underlying domains of attributes contain only atomic (simple or indivisible) values. i.e. The value of any attribute in a tuple (row) must be a single value from the domain of their attribute. It is defined to disallow multivalued attributes, composite attributes, and their combinations. In other words, 1NF disallows relations within relations or relations as attribute values within tuples. It must be remove repeating groups (values) in a single field. The primary key with repeating group attributes are moved into a new table. When a relation contains no repeating groups (values), it is in first normal form (1NF). Second normal form (2NF) Second normal form (2NF) is based on the concept of full functional dependency. A relation schema R is in 2NF if it is in 1NF and every non-prime attribute A in R is fully functionally dependent on the primary key (i.e. the non-prime attributes are not partially dependent on key attributes). Remove any partially dependent attributes and place them in another relation. A partial dependency is when the attribute(s) is/are dependent on a part of a key.

Fundamental of Database Systems module | PDF page 18 | lines 5-8

> Third Normal Form (3NF) A relation schema R is in third normal form (3NF) if it is in 2NF and every non-prime attribute of _R‘ are fully functionally dependent on every key of R and non-transitively dependent on every key of R.

Computer Science model exam collection · Question 40

Question 157 | SS142

Which one of the following is not among the characterizing features of database approach?

A. Sharing of data

B. @-tTM Application-data dependency

C. j Oc. Self-describing

D. Data abstraction

Hint

Review the database approach and match each claimed benefit or cost to its mechanism.

Answer B: @-tTM Application-data dependency

Database systems support sharing, self-description and abstraction/insulation. Application-data dependency is the opposite of insulation and independence.

Why each choice is right or wrong

A - Incorrect: Sharing is expressly a characteristic. (PDF pp. 5, 6.)

B - Correct: Application-data dependency contradicts the stated insulation characteristic. (PDF pp. 5, 6.)

C - Incorrect: Self-description is expressly a characteristic. (PDF pp. 5, 6.)

D - Incorrect: Abstraction is expressly a characteristic. (PDF pp. 5, 6.)

Primary note proof

Study-note section FDB01

> A database is a coherent collection of related facts with meaning for an application. A DBMS is software that defines, stores, retrieves, updates, protects and shares that data. The database is the content; the DBMS manages it. A database system also includes applications, people and infrastructure.

Study-note section FDB04

> Data abstraction hides irrelevant details; program-data insulation separates data definitions from application code.

Study-note section FDB04

> Logical data independence permits conceptual changes while preserving affected external views and application interfaces, for example splitting a table while maintaining a compatible view.

Related reading (context, not primary note proof)

Fundamental of Database Systems module | PDF page 5 | lines 22-29

> 1.3 Characteristics of the Database Approach The main characteristics of the database approach are Self-describing nature, Data abstraction and Insulation between programs and data, Support of multiple views of the data, sharing of data and multiuser transaction processing.
> Self-describing nature - A fundamental characteristic of the database approach is that the database system contains not only the database itself (data) but also a complete definition or description of the database structure and constraints. This information is called meta-data, and it describes the structure of the database.

Fundamental of Database Systems module | PDF page 6 | lines 2-9

> Data abstraction and Insulation between programs and data- Data Abstraction is a process of hiding unwanted or irrelevant details from the end user. It provides a different view and helps in achieving data independence which is used to enhance the security of data. Support of multiple views of the data - A view may be a subset of the database or it may contain virtual data that is derived from the database files but is not explicitly stored. Sharing of data and multiuser transaction processing - A multiuser DBMS must allow multiple users to access the database at the same time. This is essential if data for multiple applications is to be integrated and maintained in a single database.

Question sources

Computer Science model exam collection · Question 49

Question 158 | SS146

"Database is a logically coherent collection of data with some inherent meaning" describes that

A. the entity should be physical object

B. number of attributes should be limited

C. there should be one primary key attribute

D. all attributes of the entity should be related

Hint

Review the database approach and match each claimed benefit or cost to its mechanism.

Answer D: all attributes of the entity should be related

A database is a collection of related data with implicit meaning. D is the closest reading of coherence in the question: attributes should describe related subject matter, not arbitrary unrelated data. It does not mean every attribute functionally determines every other.

Why each choice is right or wrong

A - Incorrect: Entities may have conceptual existence too. (PDF pp. 5, 10, 11.)

B - Incorrect: No bound on the number of attributes is implied. (PDF pp. 5, 10, 11.)

C - Incorrect: A primary key may have multiple attributes; coherence does not require a single attribute. (PDF pp. 5, 10, 11.)

D - Correct: Related attributes are the offered interpretation consistent with meaningful related data. (PDF pp. 5, 10, 11.)

Primary note proof

Study-note section FDB01

> A database is a coherent collection of related facts with meaning for an application. A DBMS is software that defines, stores, retrieves, updates, protects and shares that data. The database is the content; the DBMS manages it. A database system also includes applications, people and infrastructure.

Study-note section FDB07

> A composite key contains multiple attributes and need not be the chosen primary key.

Study-note section FDB06

> An entity type describes common properties; its current collection of entities is an entity set.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 5 | lines 5-9

> Data is known facts that can be recorded and that have implicit meaning. Database is a collection of related data. For example, consider the names, telephone numbers, and addresses of the people you know. Nowadays, this data is typically stored in mobile phones, which have their own simple database software. This collection of related data with an implicit meaning is a database. A database can be defined as a self-describing collection of integrated records.

Fundamental of Database Systems module | PDF page 10 | lines 3-5

> An entity may be an object with a physical existence (for example, a particular person, car, house, or employee) or it may be an object with a conceptual existence (for instance, a company, a job, or a university course). In ER diagrams, an entity is placed in a rectangle.

Fundamental of Database Systems module | PDF page 11 | lines 7-11

> Super Key − A set of attributes (one or more) that collectively identifies an entity in an entity set. Candidate Key − A minimal super key is called a candidate key. An entity set may have more than one candidate key. Primary Key − A primary key is one of the candidate keys chosen by the database designer to uniquely identify the entity set.

Question sources

Computer Science model exam collection · Question 53

Question 159 | SS157

For HOTEL(Hotel_id INTEGER PRIMARY KEY, Hotel_Name STRING, Sub_city STRING), which statement correctly inserts one row? Assume Hotel_id = 1 is unused and no other constraints prevent the insert.

A. INSERT INTO HOTEL(Hotel_id,Hotel_Name,Sub_city) Values('Hilton', Yeka')

B. INSERT INTO HOTEL(Hotel_id,Hotel_Name,Sub_city) Values (1,'Hilton','Yeka')

C. INSERT INTO HOTEL(1,'Hilton','Yeka')

D. INSERT Values INTO HOTEL(Hotel_id,Hotel_Name,Sub_city) Values(1,'Hilton','Yeka')

Hint

Track which rows each data-changing command affects.

Answer B: INSERT INTO HOTEL(Hotel_id,Hotel_Name,Sub_city) Values (1,'Hilton','Yeka')

An INSERT must match each named column with a compatible value and follow INSERT INTO ... VALUES syntax. B supplies the integer identifier and the two text values in the named order; the stated unused-key assumption removes a possible primary-key conflict. A supplies too few values and has damaged string quoting. C puts values where column names belong and omits VALUES, while D places an extra Values token before INTO. These are incorrect statements, not unresolved alternatives.

Why each choice is right or wrong

A - Incorrect: Incorrect: three named columns require three compatible values; this text supplies only two and also has malformed quoting.

B - Correct: Correct: it supplies an unused integer key and two strings in the named column order with the required INSERT syntax.

C - Incorrect: Incorrect: literal values occupy the column-list position and the VALUES clause is absent.

D - Incorrect: Incorrect: INSERT Values INTO has an extra token before INTO and breaks the required INSERT structure.

Primary note proof

Study-note section FDB29

> INSERT INTO Hotel(HotelID,HotelName,SubCity) VALUES (1,'Hilton','Yeka'); pairs each named column with a compatible value. Counts and types must match; keys and other constraints still apply. Without a column list, values must follow the table's declared column order.

Study-note section FDB15

> Domain integrity restricts type and allowed values. Key integrity enforces uniqueness. Entity integrity requires every primary-key component to be non-NULL. Referential integrity requires a non-NULL foreign-key value to match an eligible referenced unique/candidate key; self-references are allowed. A parent need not have a child.

Related reading (context, not primary note proof)

Study-note section FDB07

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 77 | lines 19-24

> Example 2: Rollback Transaction CREATE TABLE ValueTable (id int); BEGIN TRANSACTION; INSERT INTO ValueTable VALUES(1); INSERT INTO ValueTable VALUES(2); ROLLBACK;

Fundamental of Database Systems module | PDF page 14 | lines 14-20

> Domain Constraints - Every domain (cell in the table or attribute value) must contain atomic values (smallest indivisible units). We perform data type check here, which means we need to assign a data type to a column and limit the values that it can contain. Key Constraints- These are called uniqueness constraints since it ensures that every tuple in the relation should be unique. An attribute that can uniquely identify a tuple in a relation is called the key or primary key of the table. The value of the attribute for different tuples in the relation has to be unique. Primary keys must be unique and cannot be null.

Fundamental of Database Systems module | PDF page 19 | lines 11-19

5.2 Choosing Attribute Data Types CHAR - fixed-length character VARCHAR() - variable-length characters DATE - actual date BLOB - binary large object (good for graphics images, audio, sound clips, etc.) NUMERIC - positive/negative numbers Exact • SMALLINT → 16 bit • INT → 32 bit

Question sources

Computer Science model exam collection · Question 64

Question 160 | SS172

DORM(DormID, FloorNumber) has primary key DormID. STUDENT(IdNo, Name, Department, DormID) has primary key IdNo. Which table-constraint fragment correctly declares STUDENT.DormID as a reference to DORM? Capacity six is enforced separately; the surrounding CREATE TABLE syntax is supplied.

A. FOREIGN KEY (DormID) REFERENCED BY DORM(DormID)

B. DORM table is a referencing relation

C. FOREIGN KEY (DormID) REFERENCES DORM(DormID)

D. STUDENT table is a referenced relation

Hint

Trace keys and cardinalities through the integrated schema.

Answer C: C. FOREIGN KEY (DormID) REFERENCES DORM(DormID)

The student row stores the dorm identifier, making STUDENT the referencing child and DORM the referenced parent. The required clause names the child column and uses REFERENCES to identify Dorm's key. C has this syntax after the naming repair. The foreign key validates a dorm reference; it does not by itself enforce the six-student capacity rule, which the question handles separately.

Why each choice is right or wrong

A - Incorrect: REFERENCED BY is not the required child-to-parent clause.

B - Incorrect: DORM is the referenced parent, not the referencing child.

C - Correct: REFERENCES DORM(DormID) correctly targets the parent key.

D - Incorrect: STUDENT is the referencing child.

Primary note proof

Study-note section FDB39

Use Department(DeptID,Name), Student(SID,Name,DeptID,DormID), Course(CID,Title), Enrollment(SID,CID,Grade) and Dorm(DormID,FloorNumber). Declare all entity IDs primary keys; Student.DeptID and Student.DormID reference their parents; Enrollment has composite key (SID,CID) and both references. Make DormID nullable until assignment. Separate StudentPhone(SID,Phone) for multiple contacts. Normalize repeated department/course facts into their owning tables. A simple foreign key does not enforce the six-student capacity; use a

concurrency-safe trigger, allocation transaction or explicit slot design with six unique slots per dorm.

Study-note section FDB39

STUDENT is the referencing child; DORM is referenced.

Study-note section FDB39

Consistent names and an added Student.DormID column are required before execution.

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 12 | lines 18-21

4. For each binary 1:N relationship type R, identify the relation S that represent the participating entity type at the N-side of the relationship type. Include the primary key of the relation T as foreign key in S that represents the other entity type participating in R. Include any attributes of the 1:N relation type as attributes of S.

Fundamental of Database Systems module | PDF page 48 | lines 13-17

iv. Referential Integrity • A —foreign key‖ links each occurrence in a relation representing a child entity to the occurrence of the parent entity containing the matching candidate (usually primary) key • Referential Integrity means that if the foreign key contains a value, that value must refer to an existing occurrence in the parent entity

Fundamental of Database Systems module | PDF page 49 | lines 23-28

Referential Integrity • Ensures that dependent relationships in the data are maintained. In Oracle, for example: • CREATE TABLE table-name (attr1 attr-type PRIMARY KEY, attr2 attr-type NOT NULL, ..., attrM attr-type REFERENCES owner.tablename(attrname) ON DELETE CASCADE, ...

Question sources

Computer Science model exam collection · Question 79

Question 161 | SS189

Which one of the following is an appropriate sequence of database design processes?

A. Logical database design, Enterprise data modeling, Physical database design, Database implementation

B. Enterprise data modeling, Logical database design, Database implementation, Physical database design

C. Logical database design, Enterprise data modeling, Physical database design, Database implementation

D. Enterprise data modeling, Logical database design, Physical database design, Database implementation

Hint

Identify the design phase from its inputs and intended deliverable.

Answer D: Enterprise modeling → logical design → physical design → implementation.

FDB05 starts with business requirements and conceptual ER modeling, then maps to relations and constraints in logical design, chooses storage and indexes in physical design, and creates/loads actual objects in implementation. D preserves that order. The other choices either begin logical design before enterprise modeling or place implementation before the storage decisions it must implement.

Why each choice is right or wrong

A - Incorrect: Logical design should use the conceptual enterprise model rather than precede its creation.

B - Incorrect: Physical storage decisions precede implementation, not follow it in the stated design sequence.

C - Incorrect: This duplicates A and again places logical design before enterprise modeling.

D - Correct: It follows conceptual enterprise modeling, relational mapping, storage design and actual implementation.

Primary note proof

Study-note section FDB05

> First collect business facts, required transactions, reports, volumes, privacy rules and quality targets. Conceptual design turns them into an ER/EER model. Logical design maps the conceptual model to relations, keys and constraints and checks normalization. Physical design chooses file organization, indexes and storage. Implementation creates and loads the actual objects; testing checks requirements.

Fundamental of Database Systems module | PDF page 9 | lines 7-26

> 3.2 Phases of database design The phases of database development life cycle (DDLC) in the Database Management System (DBMS) are explained below. Requirement Analysis The most important step in implementing a database system is to find out what is needed i.e what type of a database is required for the business organization, daily volume of data, how much data needs to be stored in the master files etc. In order to collect all this information, a database analyst spends a lot of time within the business organization talking to people, end users and getting acquainted with the day-to-day process. Conceptual Database Design In this phase the database designers will make a decision on the database model that perfectly suits the organization‘s requirement. The database designers will study the documents prepared by the analysis in the requirement analysis stage and then start development of a system model that fulfils the needs. Logical database design (Data model mapping) The conceptual design is translated into internal model which includes mapping of all objects i.e design of tables, indexes, views, transaction, access privileges etc. Physical Design Physical design or Database implementation needs the

formation of special storage related constructs. These constructs consist of storage groups, table spaces, data files, tables etc.

Question sources

Computer Science model exam collection · Question 96

Question 162 | AM0132

Which of the following is a primary key in a relational database?

A. A unique identifier for a row in a table

B. A foreign key from another table

C. A non-unique attribute in a table

D. A combination of attributes in a table

Hint

Test uniqueness and minimality separately when classifying keys.

Answer A: A unique identifier for a row in a table

A primary key is selected from candidate keys to uniquely identify a row and must be unique/non-null. Multiple attributes alone do not make a set a primary key unless those requirements and selection hold.

Why each choice is right or wrong

A - Correct: Gives the essential identifying property. (PDF pp. 11, 14.)

B - Incorrect: A foreign key is a reference and is not necessarily the selected primary identifier. (PDF pp. 11, 14.)

C - Incorrect: Non-unique attributes cannot uniquely identify rows. (PDF pp. 11, 14.)

D - Incorrect: A combination can be a composite primary key, but an arbitrary combination is not sufficient. (PDF pp. 11, 14.)

Primary note proof

Study-note section FDB07

A superkey uniquely identifies a tuple. A candidate key is a minimal superkey: removing any component loses uniqueness. Minimal means no unnecessary attribute, not necessarily the fewest columns among all keys. A primary key is one selected candidate key; remaining candidates are alternate keys. A composite key contains multiple attributes and need not be the chosen primary key.

Study-note section FDB07

A table can have several candidates and foreign keys but at most one declared primary-key constraint, possibly containing several columns.

Study-note section FDB16

PRIMARY KEY implies uniqueness and non-NULL.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 11 | lines 7-11

Super Key − A set of attributes (one or more) that collectively identifies an entity in an entity set. Candidate Key − A minimal super key is called a candidate key. An entity set may have more than one candidate key. Primary Key − A primary key is one of the candidate keys chosen by the database designer to uniquely identify the entity set.

Fundamental of Database Systems module | PDF page 14 | lines 17-20

Key Constraints- These are called uniqueness constraints since it ensures that every tuple in the relation should be unique. An attribute that can uniquely identify a tuple in a relation is called the key or primary key of the table. The value of the attribute for different tuples in the relation has to be unique. Primary keys must be unique and cannot be null.

Question sources

Computer Science MCQ practice collection · Question 132

Question 163 | AM0133

What is the purpose of foreign keys in a relational database?

A. To establish relationships between tables

B. To store encrypted data

C. To enforce data types in columns

D. To improve query performance

Hint

Match the validity requirement to the appropriate constraint definition.

Answer A: To establish relationships between tables

Foreign keys link child records to matching parent keys and preserve consistency between related tables.

Why each choice is right or wrong

A - Correct: Establishes the described reference relationship. (PDF pp. 48, 14.)

B - Incorrect: Encryption is a security mechanism, not the FK purpose. (PDF pp. 48, 14.)

C - Incorrect: Data types are controlled by domain constraints. (PDF pp. 48, 14.)

D - Incorrect: Performance improvement is not the stated FK purpose. (PDF pp. 48, 14.)

Primary note proof

Study-note section FDB15

> Domain integrity restricts type and allowed values. Key integrity enforces uniqueness. Entity integrity requires every primary-key component to be non-NULL. Referential integrity requires a non-NULL foreign-key value to match an eligible referenced unique/candidate key; self-references are allowed. A parent need not have a child.

Study-note section FDB07

> A primary key is one selected candidate key; remaining candidates are alternate keys.

Study-note section FDB07

> Minimal means no unnecessary attribute, not necessarily the fewest columns among all keys.

> iv. Referential Integrity • A —foreign key‖ links each occurrence in a relation representing a child entity to the occurrence of the parent entity containing the matching candidate (usually primary) key • Referential Integrity means that if the foreign key contains a value, that value must refer to an existing occurrence in the parent entity

Fundamental of Database Systems module | PDF page 14 | lines 21-26

> Referential Integrity Constraints - The Referential integrity constraints is specified between two relations or tables and used to maintain the consistency among the tuples in two relations. Referential Integrity constraints in DBMS are based on the concept of Foreign Keys. A foreign key is an important attribute of a relation which should be referred to in other relationships. Referential integrity constraint state happens where relation refers to a key attribute of a different or same relation. However, that key element must exist in the table.

Question sources

Computer Science MCQ practice collection · Question 133

Question 164 | AM0134

In the usual normalization sequence, which is the first normal form requiring every nonprime attribute to depend fully on every candidate key, rather than on a proper subset?

A. First normal form (1NF)

B. Second normal form (2NF)

C. Third normal form (3NF)

D. Boyce-Codd normal form (BCNF)

Hint

Check atomicity, candidate keys and partial dependencies in that order.

Answer B: Second normal form (2NF)

Second normal form is the first stage requiring atomic relations to have no nonprime attribute partially dependent on any candidate key. First normal form addresses atomic values, so it does not impose that dependency rule. Third normal form and BCNF are stronger stages that inherit the absence of partial dependencies, but they are not the first stage introducing it. BCNF specifically requires every nontrivial functional-dependency determinant to be a superkey.

Why each choice is right or wrong

A - Incorrect: Incorrect: 1NF requires atomic values but does not exclude partial dependencies.

B - Correct: Correct: 2NF is the first stage excluding nonprime partial dependencies on candidate keys.

C - Incorrect: Incorrect: 3NF inherits 2NF and imposes its additional determinant/prime-attribute condition; it is not the first stage.

D - Incorrect: Incorrect: BCNF requires every nontrivial determinant to be a superkey; it is stronger than the first stage imposing the partial-dependency rule.

Primary note proof

Study-note section FDB20

> 1NF requires atomic values in the chosen relational domains and no repeating groups in cells.

Study-note section FDB20

> 2NF requires 1NF and no nonprime attribute partially dependent on any candidate key.

Study-note section FDB21

> For every nontrivial FD X→A, 3NF permits it when X is a superkey or A is prime. BCNF requires X to be a superkey. The mnemonic whole key and nothing but the key describes the common single-key case; it cannot replace the full tests when keys overlap. Remove dependencies of nonprime facts on nonkey determinants.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 17 | lines 10-15

> Second normal form (2NF) Second normal form (2NF) is based on the concept of full functional dependency. A relation schema R is in 2NF if it is in 1NF and every non-prime attribute A in R is fully functionally dependent on the primary key (i.e. the non-prime attributes are not partially dependent on key attributes). Remove any partially dependent attributes and place them in another relation. A partial dependency is when the attribute(s) is/are dependent on a part of a key.

Fundamental of Database Systems module | PDF page 18 | lines 5-8

> Third Normal Form (3NF) A relation schema R is in third normal form (3NF) if it is in 2NF and every non-prime attribute of _R‘ are fully functionally dependent on every key of R and non-transitively dependent on every key of R.

Question sources

Computer Science MCQ practice collection · Question 134

Question 165 | AM0135

What defines a composite key in database design?

A. A key made up of two or more attributes

B. A foreign key that references multiple tables

C. A unique identifier for a column in a table

D. A key used for data encryption

Hint

Test uniqueness and minimality separately when classifying keys.

Answer A: A. A key made up of two or more attributes

Composite describes the number of attributes in a key: it contains two or more attributes. It does not mean the key has necessarily been selected as the primary key, nor does it refer to the number of tables reached by a reference. A column name alone is not a multicolumn identification key. Encryption uses a different meaning of key.

Why each choice is right or wrong

A - Correct: Two or more key attributes are the defining feature.

B - Incorrect: The number of referenced tables does not define composition.

C - Incorrect: A column identifier does not describe a multicolumn key.

D - Incorrect: An encryption key is a different concept.

Primary note proof

Study-note section FDB07

> A superkey uniquely identifies a tuple. A candidate key is a minimal superkey: removing any component loses uniqueness. Minimal means no unnecessary attribute, not necessarily the fewest columns among all keys. A primary key is one selected candidate key; remaining candidates are alternate keys. A composite key contains multiple attributes and need not be the chosen primary key.

Study-note section FDB07

> A composite-key example must include multiple columns; a single-column key is not composite.

Study-note section FDB07

A table can have several candidates and foreign keys but at most one declared primary-key constraint, possibly containing several columns.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 15 | lines 11-17

Partial Dependency - If an attribute which is not a member of the key is dependent on some part of the key (if we have composite/candidate key) then that attribute is partially functionally dependent on the key. Let {A, B} is the key set and C is no key attribute, then if {A, B} → C and [B → C or A → C] holds. We say C is partially functionally dependent on {A, B}. Partial dependency occurs when a non-prime attribute is functionally dependent on part of a candidate/composite key.

Fundamental of Database Systems module | PDF page 11 | lines 7-11

Super Key − A set of attributes (one or more) that collectively identifies an entity in an entity set. Candidate Key − A minimal super key is called a candidate key. An entity set may have more than one candidate key. Primary Key − A primary key is one of the candidate keys chosen by the database designer to uniquely identify the entity set.

Computer Science MCQ practice collection · Question 135

Question 166 | AM0136

What is the purpose of an index in a database?

A. To store large binary objects

B. To enforce referential integrity

C. To improve data retrieval performance

D. To encrypt sensitive data

Hint

Compare index organization with its access benefits and maintenance costs.

Answer C: To improve data retrieval performance

Indexes are auxiliary structures used to speed retrieval for search conditions, rather than stored binary values or security mechanisms.

Why each choice is right or wrong

A - Incorrect: BLOB is the named large-binary-object type. (PDF pp. 21, 19.)

B - Incorrect: Foreign keys handle referential links; indexes are defined for retrieval. (PDF pp. 21, 19.)

C - Correct: Exactly the stated retrieval-performance purpose. (PDF pp. 21, 19.)

D - Incorrect: Encryption is a separate security mechanism. (PDF pp. 21, 19.)

Primary note proof

Study-note section FDB25

> An index stores search keys with pointers or row identifiers. It often speeds selective retrieval but consumes space and must be maintained on writes. A full scan can win for a tiny table or a query returning most rows. Indexes do not themselves establish referential integrity.

Study-note section FDB23

> DATE represents a date and BLOB binary content such as images.

Study-note section FDB15

> Domain integrity restricts type and allowed values.

> 5.5 Index Indexes are additional auxiliary access structures which are used to speed up the retrieval of records in response to certain search conditions. Index structures are additional files, which provide alternative ways to access the records without affecting the physical placement of records on disk.

Fundamental of Database Systems module | PDF page 19 | lines 11-15

> 5.2 Choosing Attribute Data Types CHAR - fixed-length character VARCHAR() - variable-length characters DATE - actual date BLOB - binary large object (good for graphics images, audio, sound clips, etc.)

Question sources

Computer Science MCQ practice collection · Question 136

Question 167 | AM0137

What is a data dictionary in database design?

A. A database table that stores user information

B. A collection of tables in a database

C. A file system used to store database files

D. A repository of metadata about the database structure

Hint

Distinguish a relation's structure from its current contents and its descriptive metadata.

Answer D: A repository of database metadata.

A data dictionary describes the database rather than serving as ordinary application data storage. FDB03 says it records definitions, types, constraints and often privileges and optimizer statistics. User information may appear in an application table, but that is not the dictionary definition. Nor is a dictionary simply all tables or the physical file system.

Why each choice is right or wrong

A - Incorrect: Ordinary user records are application data, not the defining purpose of a metadata repository.

B - Incorrect: A collection of tables is not specifically the repository describing those tables and constraints.

C - Incorrect: The physical file system stores files; a dictionary records descriptive database metadata.

D - Correct: The dictionary is the repository describing database structure, data types and constraints.

Primary note proof

Study-note section FDB03

> A schema describes names, structures and constraints; an instance, state or snapshot is the data at a particular time. Inserting a student changes the state, while adding a column changes the schema. Metadata is data describing data. The catalog or data dictionary records table definitions, types, constraints and often access privileges and optimizer statistics. A schema diagram draws tables and key references; labels such as database diagram can overlap.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 5 | lines 26-29

> Self-describing nature - A fundamental characteristic of the database approach is that the database system contains not only the database itself (data) but also a complete definition or description of the database structure and constraints. This information is called meta-data, and it describes the structure of the database.

Question sources

Computer Science MCQ practice collection · Question 137

Question 168 | AM0138

Which of the following is an example of a database constraint?

A. UNIQUE

B. SELECT

C. INSERT

D. DELETE

Hint

Read each SQL constraint's scope and enforcement rule.

Answer A: UNIQUE

Uniqueness constrains distinct tuple identifiers, whereas SELECT, INSERT and DELETE are language operations in the DML list. UNIQUE is the offered constraint name matching that property.

Why each choice is right or wrong

A - Correct: Uniqueness is explicitly an integrity condition. (PDF pp. 14, 26.)

B - Incorrect: SELECT is a retrieval command. (PDF pp. 14, 26.)

C - Incorrect: INSERT is a manipulation command. (PDF pp. 14, 26.)

D - Incorrect: DELETE is a manipulation command. (PDF pp. 14, 26.)

Primary note proof

Study-note section FDB16

> Example: CREATE TABLE Enrollment (StudentID INTEGER NOT NULL REFERENCES Student(StudentID), CourseID INTEGER NOT NULL REFERENCES Course(CourseID), Grade INTEGER CHECK (Grade BETWEEN 0 AND 100), PRIMARY KEY (StudentID,CourseID)); Each column declaration gives its name then type, with commas between declarations. CHECK is a constraint clause, not a standalone GRANT-like statement. POSITIVE is not a general SQL constraint keyword; CHECK (Amount > 0) expresses positivity.

Study-note section FDB26

> DML retrieves or changes data: SELECT, INSERT, UPDATE, DELETE.

Study-note section FDB26

> Some texts separate SELECT as DQL.

> Key Constraints- These are called uniqueness constraints since it ensures that every tuple in the relation should be unique. An attribute that can uniquely identify a tuple in a relation is called

> the key or primary key of the table. The value of the attribute for different tuples in the relation has to be unique. Primary keys must be unique and cannot be null.

Fundamental of Database Systems module | PDF page 26 | lines 10-11

> 7.1.2 DML (data manipulation language) Basic DDL commands are: SELECT, PROJECT, JOIN, INSERT, DELETE, and UPDATE

Question sources

Computer Science MCQ practice collection · Question 138

Question 169 | AM0139

What is the purpose of referential integrity in a database?

A. To prevent unauthorized access to data

B. To ensure data consistency and integrity across related tables

C. To improve query performance

D. To encrypt sensitive data

Hint

Match the validity requirement to the appropriate constraint definition.

Answer B: To ensure data consistency and integrity across related tables

Referential integrity maintains consistency between related tuples by requiring non-null child references to resolve to existing parent keys. It controls valid relationships rather than authorization, performance, or encoding.

Why each choice is right or wrong

A - Incorrect: Unauthorized access is a security issue. (PDF pp. 14, 48.)

B - Correct: Matches the module's consistency-between-relations definition. (PDF pp. 14, 48.)

C - Incorrect: Query performance is not the referential validity rule. (PDF pp. 14, 48.)

D - Incorrect: Encryption is a separate security mechanism. (PDF pp. 14, 48.)

Primary note proof

Study-note section FDB15

> Domain integrity restricts type and allowed values. Key integrity enforces uniqueness. Entity integrity requires every primary-key component to be non-NULL. Referential integrity requires a non-NULL foreign-key value to match an eligible referenced unique/candidate key; self-references are allowed. A parent need not have a child.

Study-note section FDB38

> Both encryption and access control can protect patient data.

Study-note section FDB38

> Authentication verifies identity; role-based authorization limits allowed records/actions; encryption protects data at rest or in transit; auditing records activity.

Related reading (context, not primary note proof)

Fundamental of Database Systems module | PDF page 14 | lines 21-26

> Referential Integrity Constraints - The Referential integrity constraints is specified between two relations or tables and used to maintain the consistency among the tuples in two relations. Referential Integrity constraints in DBMS are based on the concept of Foreign Keys. A foreign key is an important attribute of a relation which should be referred to in other relationships. Referential integrity constraint state happens where relation refers to a key attribute of a different or same relation. However, that key element must exist in the table.

Fundamental of Database Systems module | PDF page 48 | lines 13-17

> iv. Referential Integrity • A —foreign key‖ links each occurrence in a relation representing a child entity to the occurrence of the parent entity containing the matching candidate (usually primary) key • Referential Integrity means that if the foreign key contains a value, that value must refer to an existing occurrence in the parent entity

Variant 1 | Alternative version 1

What is the purpose of referential integrity in a database?

A. To prevent unauthorized access to data

B. To ensure data consistency and integrity

C. To improve query performance

D. To encrypt sensitive data

Answer B: To ensure data consistency and integrity

Referential integrity maintains consistency between related tuples by requiring non-null child references to resolve to existing parent keys. It controls valid relationships rather than authorization, performance, or encoding.

Why each choice is right or wrong

A - Incorrect: Authorization controls access; referential integrity checks reference validity (PDF pp.47-48).

B - Correct: Consistent valid references between related records match the integrity definition (PDF pp.14,48).

C - Incorrect: Retrieval speed is not the foreign-key consistency condition.

D - Incorrect: Encoding sensitive data is a separate security mechanism.

Primary note proof

Study-note section FDB15

> Domain integrity restricts type and allowed values. Key integrity enforces uniqueness. Entity integrity requires every primary-key component to be non-NULL. Referential integrity requires a non-NULL foreign-key value to match an eligible referenced unique/candidate key; self-references are allowed. A parent need not have a child.

Study-note section FDB38

> Scalability, availability, fast retrieval, redundancy control and security are all reasonable design considerations.

Study-note section FDB38

> Authentication verifies identity; role-based authorization limits allowed records/actions; encryption protects data at rest or in transit; auditing records activity.

Computer Science MCQ practice collection · Question 139

Computer Science MCQ practice collection · Question 154

Question 170 | AM0140

What is denormalization in database design?

A. The process of breaking down a complex table into smaller tables

B. The process of adding redundancy to improve data retrieval performance

C. The process of eliminating duplicate values from a table

D. The process of converting data into a different format for storage

Hint

Compare design techniques by the specific problem each solves.

Answer B: Deliberately adding redundancy to improve selected retrieval workloads.

FDB38 defines denormalization as deliberately repeating or precomputing facts to reduce selected read costs, with extra maintenance work. It is a workload-driven trade-off rather than elimination of all duplication. Breaking tables apart typically describes normalization; changing storage format is a different concern. Thus B captures both the mechanism and its intended retrieval benefit.

Why each choice is right or wrong

A - Incorrect: Splitting tables according to dependencies is normalization, rather than the redundancy introduced by denormalization.

B - Correct: Denormalization deliberately repeats or precomputes information to improve selected retrieval workloads.

C - Incorrect: Eliminating duplication describes a different direction from deliberately introducing useful redundant facts.

D - Incorrect: Changing storage format does not define the dependency and redundancy trade-off of denormalization.

Primary note proof

Study-note section FDB38

> Normalization reduces dependency-driven anomalies. Indexing supplies search paths. Denormalization deliberately repeats or precomputes facts to reduce selected read costs, increasing maintenance work. Partitioning divides rows or columns; replication creates copies to improve locality or availability while complicating updates. These techniques can coexist. An e-commerce or gaming label alone does not select one.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 16 | lines 17-27

> 4.4 Normalization Normalization is a process of organizing the data in database to avoid data redundancy, insertion anomaly, update anomaly & deletion anomaly. It is a technique of organizing the data in the database. It is a systematic approach of decomposing tables to eliminate data redundancy (repetition) and undesirable characteristics like Insertion, Update and Deletion Anomalies. It is a multi-step process that puts data into tabular form, removing duplicated data from the relation tables. Normal forms Redundancy in a relation may causes insertion, deletion, and update anomalies. Normalization is database design technique that minimizes redundancy from a relation or a set of relations. Normalization rules divides larger tables into smaller tables and links them using relationship.

Question sources

Computer Science MCQ practice collection · Question 140

Question 171 | AM0141

What is the purpose of a view in a database?

A. To define the structure of a table

B. To store complex queries for reuse

C. To encrypt sensitive data

D. To enforce data types in columns

Hint

Distinguish a stored query definition from stored data and trace subquery scope.

Answer B: Store a query definition for reuse as a virtual table.

FDB33 says CREATE VIEW stores a query definition and presents a virtual table. B describes reusing that query, although a view need not be complex. Ordinary views do not inherently store result rows. Table definitions and column types belong to schema DDL, and views do not encrypt sensitive content merely by hiding columns or rows.

Why each choice is right or wrong

A - Incorrect: A view defines a virtual query result rather than the base table's storage structure.

B - Correct: A view saves a query definition that can be reused as a virtual table.

C - Incorrect: Restricting exposed data through a view does not encrypt that data.

D - Incorrect: Column data types are enforced by schema definitions and constraints rather than the view's primary purpose.

Primary note proof

Study-note section FDB33

> A subquery is a SELECT nested inside another statement. It may appear in WHERE, HAVING or FROM, not only the first two. IN tests membership; EXISTS tests whether at least one qualifying row exists. Correlated subqueries refer to the outer row. A scalar subquery must produce an appropriate single value. Beware NOT IN when its subquery can return NULL; NOT EXISTS often expresses the intended absence more safely.

Study-note section FDB33

> CREATE VIEW CSStudent AS SELECT StudentID,Name FROM Student WHERE Major = 'CS'; stores a query definition and presents a virtual table.

Study-note section FDB33

> An ordinary view does not necessarily store its result; a materialized view does.

> Support of multiple views of the data - A view may be a subset of the database or it may contain virtual data that is derived from the database files but is not explicitly stored.

Fundamental of Database Systems module | PDF page 56 | lines 7-12

> Views ● A subset of the database presented to some set of users ◦ SQL: CREATE VIEW viewname AS SELECT field1, field2, field3,..., FROM table1, table2 WHERE <where clause>; ◦ Note: —queries‖ in Access function as views

Fundamental of Database Systems module | PDF page 57 | lines 14-21

> ● Views, along with privileges, allow for customised access ● Views provide _derived‘ tables ◦ A view is the result of a SELECT statement which is treated like a table ◦ You can SELECT from (and

sometimes UPDATE etc) views just like tables Creating Views CREATE VIEW <name> AS <select stmt> ● <name> is the name of the new view

Question sources

Computer Science MCQ practice collection · Question 141

Question 172 | AM0142

Which database model represents data as a collection of objects?

A. Hierarchical model

B. Relational model

C. Object-oriented model

D. Network model

Hint

Compare the data models by how they organize records and relationships.

Answer C: Object-oriented model.

FDB02 says object models represent objects with identity, state and behavior. That matches a collection of objects directly. Hierarchical models use a parent-child tree, relational models use tables, and classic network models link records through owner/member pointers. Those representations should not be conflated merely because programming languages can wrap their data in objects.

Why each choice is right or wrong

A - Incorrect: The hierarchical model organizes records in a parent-child tree rather than primarily as objects.

B - Incorrect: The relational model represents data in tables with tuples and attributes.

C - Correct: The object model represents objects with identity, state and behavior.

D - Incorrect: The network model represents linked records through owner/member connections rather than object behavior.

Primary note proof

Study-note section FDB02

A data model supplies concepts for structure, relationships, constraints and operations. Conceptual ER models describe entities and relationships. Relational models use tables; hierarchical models organize records in a parent-child tree; classic network models connect records through pointer-based owner/member links, allowing multiple parents. Object models represent objects with identity, state and behavior. A physical model specifies record layouts and access paths. These are different representation choices, not stages of one query.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 7 | lines 8-19

> Types of Data Models 1. High-level or conceptual data models provide concepts that are close to the way many users perceive data. Entity - Relationship (E/R) model and Object-Oriented Model are examples of conceptual/high level data model. 2. Low-level or physical data models provide concepts that describe the details of how data is stored on the computer storage media. Concepts provided by physical data models are generally meant for computer specialists, not for end users. 3. representational (or implementation) data model provides concepts that may be easily understood by end users but that are not too far from the way data is organized in computer storage. Representational data models hide many details of data storage on disk but can be implemented on a computer system directly. The widely used relational data models are the network and hierarchical.

Fundamental of Database Systems module | PDF page 13 | lines 18-27

> 3.6 The Relational Database Model The relational model represents the database as a collection of relations. A table is represented with columns and rows. Each table is an entity in the ER diagram. Each row is known as a tuple. Each table of the column has a name or attribute of the entity. 3.7 Relational Model Concepts in DBMS Attribute: Each column in a Table. Attributes are the properties which define a relation Tables - In the Relational model, relations are saved in the table format. It is stored along with its entities. A table has two properties rows and columns. Rows represent records and columns represent attributes. Tuple - It is a single row of a table, which contains a single record.

Question sources

Computer Science MCQ practice collection · Question 142

Question 173 | AM0143

What is the purpose of data normalization in database design?

A. To improve data storage efficiency

B. To simplify the database structure

C. To eliminate data redundancy

D. To optimize query performance

Hint

Distinguish dependency-based design problems from the contents of one sample table.

Answer C: To eliminate data redundancy

Normalization organizes/decomposes tables to avoid redundancy and anomalies. Storage may benefit, but the explicit defining purpose among these choices is reducing/eliminating repeated data.

Why each choice is right or wrong

A - Incorrect: Storage efficiency can be a consequence, but the cited definition does not guarantee a storage result. (PDF pp. 16.)

B - Incorrect: Decomposition does not necessarily simplify the whole schema. (PDF pp. 16.)

C - Correct: Eliminating redundancy is explicitly stated. (PDF pp. 16.)

D - Incorrect: Query speed is not the stated normalization goal. (PDF pp. 16.)

Primary note proof

Study-note section FDB19

> Suppose Enrollment repeats StudentName for every course. An update anomaly requires changing every copy of the student's name; missed copies disagree. An insertion anomaly prevents recording a new student until some enrollment exists. A deletion anomaly loses the only record of a student's details when their last enrollment is deleted. Revoke anomaly is not a normalization anomaly.

Study-note section FDB19

> Adding a generated row ID may make insertion technically possible, but does not remove repeated facts or fix the dependency design.

Study-note section FDB19

> Normalization separates facts according to their determinants, reducing avoidable repetition and associated anomalies.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 16 | lines 17-29

> 4.4 Normalization Normalization is a process of organizing the data in database to avoid data redundancy, insertion anomaly, update anomaly & deletion anomaly. It is a technique of organizing the data in the database. It is a systematic approach of decomposing tables to eliminate data redundancy (repetition) and undesirable characteristics like Insertion, Update and Deletion Anomalies. It is a multi-step process that puts data into tabular form, removing duplicated data from the relation tables. Normal forms Redundancy in a relation may causes insertion, deletion, and update anomalies. Normalization is database design technique that minimizes redundancy from a relation or a set of relations. Normalization rules divides larger tables into smaller tables and links them using relationship. Normal Forms are maintenance rules that are used to eliminate or reduce the redundancy in database relations. These normal forms are 1NF (First Normal Form), 2NF (Second Normal Form)

Question sources

Computer Science MCQ practice collection · Question 143

Question 174 | AM0143_2

In the customary single-key teaching case, which is the first normalization stage summarized as dependence on the key, the whole key, and nothing but the key?

A. First normal form (1NF)

B. Second normal form (2NF)

C. Third normal form (3NF)

D. Boyce-Codd normal form (BCNF)

Hint

Check atomicity, candidate keys and partial dependencies in that order.

Answer C: Third normal form (3NF)

In the stated single-key teaching case, 2NF excludes partial dependencies but can still allow a nonprime fact to depend on the key through a nonkey determinant. The next defining stage is 3NF, summarized by the whole-key-and-nothing-but-the-key mnemonic. BCNF strengthens the determinant rule, and 4NF addresses multivalued dependencies. Stronger forms inherit earlier conditions, so the explicit first-stage scope makes 3NF the unique selection rather than treating inherited properties as rival answers.

Why each choice is right or wrong

A - Incorrect: Incorrect: 1NF concerns atomic values and does not eliminate the specified transitive dependencies.

B - Incorrect: Incorrect: 2NF excludes partial dependencies but can retain a nonprime transitive dependency through a nonkey determinant.

C - Correct: Correct: 3NF is the first stage imposing the specified nonprime transitive-dependency restriction in this teaching case.

D - Incorrect: Incorrect: BCNF strengthens 3NF by requiring every nontrivial determinant to be a superkey; it is not the first stage described.

Primary note proof

Study-note section FDB20

> 1NF requires atomic values in the chosen relational domains and no repeating groups in cells.

Study-note section FDB20

> 2NF requires 1NF and no nonprime attribute partially dependent on any candidate key.

Study-note section FDB21

> For every nontrivial FD X→A, 3NF permits it when X is a superkey or A is prime. BCNF requires X to be a superkey. The mnemonic whole key and nothing but the key describes the common single-key case; it cannot replace the full tests when keys overlap. Remove dependencies of nonprime facts on nonkey determinants.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 17 | lines 10-15

> Second normal form (2NF) Second normal form (2NF) is based on the concept of full functional dependency. A relation schema R is in 2NF if it is in 1NF and every non-prime attribute A in R is fully functionally dependent on the primary key (i.e. the non-prime attributes are not partially dependent on key attributes). Remove any partially dependent attributes and place them in another relation. A partial dependency is when the attribute(s) is/are dependent on a part of a key.

Fundamental of Database Systems module | PDF page 18 | lines 5-8

> Third Normal Form (3NF) A relation schema R is in third normal form (3NF) if it is in 2NF and every non-prime attribute of _R‘ are fully functionally dependent on every key of R and non-transitively dependent on every key of R.

Question sources

Computer Science MCQ practice collection · Question 143

Question 175 | AM0144

Which database model represents data as a collection of records linked through pointers?

A. Hierarchical model

B. Relational model

C. Object-oriented model

D. Network model

Hint

Compare the data models by how they organize records and relationships.

Answer D: Network model.

FDB02 specifically describes the classic network model as records connected by pointer-based owner/member links, allowing multiple parents. That is the representation in the stem. Hierarchical data is restricted to a parent-child tree; relational data uses tables; object-oriented data emphasizes identity, state and behavior. Pointer-linked records therefore identify the network model in this comparison.

Why each choice is right or wrong

A - Incorrect: A hierarchical model restricts record organization to a parent-child tree rather than general network links.

B - Incorrect: A relational model uses tables and logical keys rather than the classic pointer-based network representation.

C - Incorrect: Object modeling is defined by identity, state and behavior, not this classic linked-record formulation.

D - Correct: Classic network databases connect records through pointer-based owner/member links.

Primary note proof

Study-note section FDB02

A data model supplies concepts for structure, relationships, constraints and operations. Conceptual ER models describe entities and relationships. Relational models use tables; hierarchical models organize records in a parent-child tree; classic network models connect records through pointer-based owner/member links, allowing multiple parents. Object models represent objects with identity, state and behavior. A physical model specifies record layouts and access paths. These are different representation choices, not stages of one query.

Question 176 | AM0145

What is the purpose of database indexing?

A. To encrypt sensitive data

B. To enforce data integrity constraints

C. To improve data retrieval performance

D. To ensure data consistency

Hint

Compare index organization with its access benefits and maintenance costs.

Answer C: To improve data retrieval performance

Indexes provide additional access paths and explicitly speed retrieval in response to search conditions; the purpose is performance of reads.

Why each choice is right or wrong

A - Incorrect: Encoding data is not the defined indexing purpose. (PDF pp. 21.)

B - Incorrect: The cited purpose is access speed, not integrity enforcement. (PDF pp. 21.)

C - Correct: Directly matches the retrieval definition. (PDF pp. 21.)

D - Incorrect: Consistency is a constraint/transaction concern rather than the indexing purpose defined. (PDF pp. 21.)

Primary note proof

Study-note section FDB25

> An index stores search keys with pointers or row identifiers. It often speeds selective retrieval but consumes space and must be maintained on writes. A full scan can win for a tiny table or a query returning most rows. Indexes do not themselves establish referential integrity.

Study-note section FDB25

> Secondary indexes provide other access paths and must represent all searchable values with record pointers or pointer lists.

Study-note section FDB38

> Indexing supplies search paths.

Question 177 | AM0146

Which database model represents data as a collection of tables with rows and columns?

A. Hierarchical model

B. Relational model

C. Object-oriented model

D. Network model

Hint

Compare the data models by how they organize records and relationships.

Answer B: Relational model

The relational model represents data using relations, conventionally shown as tables of tuples and attributes. The other choices have different defining structures: a hierarchical model uses a parent-child tree, a classic network model uses pointer-based owner/member links, and an object model uses objects with identity, state and behavior. Products may combine features, but the question asks for the model defined by rows and columns, which is relational.

Why each choice is right or wrong

A - Incorrect: Incorrect: the hierarchical model organizes records in a parent-child tree.

B - Correct: Correct: the relational model uses relations represented as tables of rows and columns.

C - Incorrect: Incorrect: the object model represents objects with identity, state and behavior.

D - Incorrect: Incorrect: the classic network model uses pointer-based owner/member links, allowing multiple parents.

Primary note proof

Study-note section FDB02

A data model supplies concepts for structure, relationships, constraints and operations. Conceptual ER models describe entities and relationships. Relational models use tables; hierarchical models organize records in a parent-child tree; classic network models connect records through pointer-based owner/member links, allowing multiple parents. Computer Science MCQ practice collection · Question 146

Question 178 | AM0147

What is the purpose of a database schema?

A. To enforce data types in columns

B. To store database files

C. To define the structure and organization of a database

D. To ensure data integrity

Hint

Distinguish a relation's structure from its current contents and its descriptive metadata.

Answer C: To define the structure and organization of a database

A schema is the database description specified during design. It expresses structure, types, relationships and constraints; enforcing a particular constraint is narrower than the description's overall purpose.

Why each choice is right or wrong

A - Incorrect: Types are included, but enforcement alone is narrower than the schema description. (PDF pp. 7, 7.)

B - Incorrect: Files hold data physically; the schema describes the database. (PDF pp. 7, 7.)

C - Correct: Structure and organization match the schema definition. (PDF pp. 7, 7.)

D - Incorrect: Integrity conditions can be specified in a schema, but integrity alone is not its overall descriptive purpose. (PDF pp. 7, 7.)

Primary note proof

Study-note section FDB03

A schema describes names, structures and constraints; an instance, state or snapshot is the data at a particular time. Inserting a student changes the state, while adding a column changes the schema. Metadata is data describing data. The catalog or data dictionary records table definitions, types, constraints and often access privileges and optimizer statistics. A schema diagram draws tables and key references; labels such as database diagram can overlap.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 7 | lines 4-7

A data model a collection of concepts that can be used to describe the structure of a database and provides the necessary means to achieve data abstraction. By structure of a database we mean the data types, relationships, and constraints that apply to the data. Most data models also include a set of basic operations for specifying retrievals and updates on the database.

Fundamental of Database Systems module | PDF page 7 | lines 20-24

2.2 Schemas and Instances The description of a database is called the database schema, which is specified during database design and is not expected to change frequently. The data in the database at a particular moment of time is called a database state or snapshot. It is also called the current set of occurrences or instances in the database.

Question 179 | AM0148

What is the role of a database administrator (DBA) in database management?

A. To design and implement the database schema

B. To write complex SQL queries

C. To manage and maintain the database system

D. To develop database applications

Hint

Review the database approach and match each claimed benefit or cost to its mechanism.

Answer C: To manage and maintain the database system

The DBA administers database and DBMS resources, authorizes access and coordinates/monitors use. Management and maintenance summarize those system responsibilities.

Why each choice is right or wrong

A - Incorrect: Schema design may be a duty in practice but is not the defining administrator role stated. (PDF pp. 6.)

B - Incorrect: Complex query writing is not the defining administrative responsibility. (PDF pp. 6.)

C - Correct: Matches resource administration and monitoring. (PDF pp. 6.)

D - Incorrect: Developing applications is a different role from the stated administration duties. (PDF pp. 6.)

Primary note proof

Study-note section FDB01

> The DBA manages access authorization, backup/recovery, availability, monitoring, tuning and routine maintenance, coordinating database use; designers define the schema and application developers build user-facing programs.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 6 | lines 10-16

> 1.4 Actors on the scene The people whose jobs involve the day-to-day use of a large database are called actors on the scene. In a database environment, the primary resource is the database itself, and the secondary resource is the DBMS and related software. Administering these resources is the responsibility of the database administrator (DBA). The DBA is responsible for authorizing access to the database, coordinating and monitoring its use, and acquiring software and hardware resources as needed.

Computer Science MCQ practice collection · Question 169

Question 180 | AM0149

Which database model represents data as a hierarchical structure with parent-child relationships?

A. Hierarchical model

B. Relational model

C. Object-oriented model

D. Network model

Hint

Compare the data models by how they organize records and relationships.

Answer A: Hierarchical model.

The defining phrase is a hierarchical parent-child structure. FDB02 assigns that tree organization to the hierarchical model. The relational model uses tables; the object model represents identity, state and behavior; the network model permits more general links including multiple parents. A parent-child tree therefore selects A directly.

Why each choice is right or wrong

A - Correct: The hierarchical model organizes records into a parent-child tree.

B - Incorrect: The relational model represents data as tables rather than a prescribed parent-child tree.

C - Incorrect: The object model represents object identity, state and behavior rather than requiring a tree.

D - Incorrect: The network model permits more general connections and multiple parents rather than the restricted tree structure.

Primary note proof

Study-note section FDB02

> A data model supplies concepts for structure, relationships, constraints and operations. Conceptual ER models describe entities and relationships. Relational models use tables; hierarchical models organize records in a parent-child tree; classic network models connect records through pointer-based owner/member links, allowing multiple parents. Object models represent objects with identity, state and behavior. A physical model specifies record layouts and access paths. These are different representation choices, not stages of one query.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 7 | lines 8-19

> Types of Data Models 1. High-level or conceptual data models provide concepts that are close to the way many users perceive data. Entity - Relationship (E/R) model and Object-Oriented Model are examples of conceptual/high level data model. 2. Low-level or physical data models provide concepts that describe the details of how data is stored on the computer storage media. Concepts provided by physical data models are generally meant for computer specialists, not for end users. 3. representational (or implementation) data model provides concepts that may be easily understood by end users but that are not too far from the way data is organized in computer storage. Representational data models hide many details of data storage on disk but can be implemented on a computer system directly. The widely used relational data models are the network and hierarchical.

Fundamental of Database Systems module | PDF page 13 | lines 5-8

> Subclasses and super classes can be thought as useful ways to describe similarities in the entities represented. Because subclasses inherit their attributes and relationships from the superclass, the database designer can represent complex, hierarchical interdependencies (inheritance) within the system being described.

Question sources

Computer Science MCQ practice collection · Question 149

Question 181 | AM0150

What is the first step in the database design process?

A. Defining relationships between tables

B. Determining the database schema

C. Analyzing the information requirements

D. Creating database queries

Hint

Identify the design phase from its inputs and intended deliverable.

Answer C: Analyzing the information requirements

The initial design step is to understand the organization's information needs, required transactions, reports and constraints. Those requirements guide conceptual modeling, which is then mapped into a logical schema. Defining table relationships and determining the schema therefore depend on the earlier analysis. Queries express required operations against a model rather than replacing the initial work of identifying what information and behavior are needed. C is the first step in that sequence.

Why each choice is right or wrong

A - Incorrect: Incorrect: table relationships are designed to satisfy requirements already identified.

B - Incorrect: Incorrect: schema choices follow the analysis of required information and operations.

C - Correct: Correct: analyze information requirements before choosing the model and schema.

D - Incorrect: Incorrect: query construction depends on understanding the required information and intended database structure.

Primary note proof

Study-note section FDB05

> First collect business facts, required transactions, reports, volumes, privacy rules and quality targets. Conceptual design turns them into an ER/EER model. Logical design maps the conceptual model to relations, keys and constraints and checks normalization. Physical design chooses file organization, indexes and storage. Implementation creates and loads the actual objects; testing checks requirements.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 9 | lines 7-20

3.2 Phases of database design The phases of database development life cycle (DDLC) in the Database Management System (DBMS) are explained below. Requirement Analysis The most important step in implementing a database system is to find out what is needed i.e what type of a database is required for the business organization, daily volume of data, how much data needs to be stored in the master files etc. In order to collect all this information, a database analyst spends a lot of time within the business organization talking to people, end users and getting acquainted with the day-to-day process. Conceptual Database Design In this phase the database designers will make a decision on the database model that perfectly suits the organization‘s requirement. The database designers will study the documents prepared by the analysis in the requirement analysis stage and then start development of a system model that fulfils the needs.

Question sources

Computer Science MCQ practice collection · Question 150

Question 182 | AM0151

Read pairs left→right. Student↔Course and Product↔Supplier permit many occurrences in both directions. Each employee belongs to one department with many employees. Each order belongs to one customer, who may place many orders. Which pair is one-to-many?

A. Student and Course

B. Employee and Department

C. Customer and Order

D. Product and Supplier

Hint

Read the relationship in both directions and check participation constraints.

Answer C: C. Customer and Order

Customer→Order is one-to-many because one customer can place several orders and each order belongs to one customer. Employee→Department runs in the opposite direction: many employees share one department, making it many-to-one. The student/course and product/supplier pairs explicitly permit many partners in both directions and are many-to-many. Cardinality follows these rules and the direction of the pair.

Why each choice is right or wrong

A - Incorrect: Student→Course is M:N under the stated enrollment rule.

B - Incorrect: Employee→Department is N:1.

C - Correct: Customer→Order is 1:N under the ownership rule.

D - Incorrect: Product→Supplier is M:N under the stated supply rule.

Primary note proof

Study-note section FDB09

> Cardinality specifies maximum associated occurrences: 1:1, 1:N or M:N. Minimum cardinality specifies optional/partial participation (zero permitted) or mandatory/total participation (at least one). A maximum of one does not mean participation is compulsory. Relationship degree counts participating entity roles: unary recursive, binary or ternary.

Study-note section FDB09

> If each employee belongs to one department and each department has many employees, Employee→Department is N:1; Department→Employee is 1:N.

Study-note section FDB09

> Read business rules in both directions.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 11 | lines 24-31

> Cardinality The number of times an entity of an entity set participates in a relationship set is known as cardinality. Cardinality can be of different types: One to one (1-1) - When each entity in each entity set can take part only once in the relationship, the cardinality is one to one. One to many(1-M)- When entities in one entity set can take part only once in the relationship set and entities in other entity set can take part more than once in the relationship set, cardinality is many to one.

Fundamental of Database Systems module | PDF page 12 | lines 2-3

> Many to many (M-M) - When entities in all entity sets can take part more than once in the relationship cardinality is many to many.

Question sources

Computer Science MCQ practice collection · Question 151

Question 183 | AM0153

Which of the following is a benefit of using database indexes?

A. Increased data redundancy

B. Decreased data integrity

C. Improved data retrieval performance

D. Simplified data modeling

Hint

Compare index organization with its access benefits and maintenance costs.

Answer C: Improved data retrieval performance

The auxiliary index provides alternative access paths to speed retrieval under search conditions. This is the directly supported benefit.

Why each choice is right or wrong

A - Incorrect: Redundancy is not the benefit identified by the index definition. (PDF pp. 21.)

B - Incorrect: Reduced integrity is not a stated benefit. (PDF pp. 21.)

C - Correct: Retrieval improvement is explicitly stated. (PDF pp. 21.)

D - Incorrect: Simplification of the logical model is not the index's stated function. (PDF pp. 21.)

Primary note proof

Study-note section FDB25

> An index stores search keys with pointers or row identifiers. It often speeds selective retrieval but consumes space and must be maintained on writes. A full scan can win for a tiny table or a query returning most rows. Indexes do not themselves establish referential integrity.

Study-note section FDB25

> Secondary indexes provide other access paths and must represent all searchable values with record pointers or pointer lists.

Study-note section FDB25

> A dense index represents each search value; sparse indexes rely on ordered data between entries.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 21 | lines 5-9

> 5.5 Index Indexes are additional auxiliary access structures which are used to speed up the retrieval of records in response to certain search conditions. Index structures are additional files, which provide alternative ways to access the records without affecting the physical placement of records on disk.

Question sources

Computer Science MCQ practice collection · Question 153

Question 184 | AM0155

Employee has required, unique SSN and Employee ID values. Names and salaries may repeat. Which listed individual attributes are candidate keys? Select all that apply.

A. Social Security Number (SSN)

B. Employee Name

C. Employee ID

D. Employee Salary

Hint

Test uniqueness and minimality separately when classifying keys.

Answer A, C: A. Social Security Number (SSN); C. Employee ID

A candidate key is a minimal attribute set guaranteed to identify a tuple. Each required unique single-attribute identifier is already minimal, so SSN and Employee ID both qualify. Names and salaries may repeat and therefore cannot guarantee identification. The question asks for candidate keys rather than the one candidate later selected as the primary key, allowing both identifiers.

Why each choice is right or wrong

A - Correct: Required unique SSN identifies each employee and is minimal.

B - Incorrect: Repeated names are permitted, so Name is not a candidate key.

C - Correct: Required unique Employee ID independently identifies each employee.

D - Incorrect: Repeated salaries are permitted, so Salary is not a candidate key.

Primary note proof

Study-note section FDB07

> A superkey uniquely identifies a tuple. A candidate key is a minimal superkey: removing any component loses uniqueness. Minimal means no unnecessary attribute, not necessarily the fewest columns among all keys. A primary key is one selected candidate key; remaining candidates are alternate keys. A composite key contains multiple attributes and need not be the chosen primary key.

Study-note section FDB07

> If ID is unique, both {ID} and {ID,City} are superkeys, but only {ID} is minimal.

Study-note section FDB07

> Prefer stable, compact identifiers when practical, but Email, SSN or EmployeeID is a candidate only if business rules guarantee uniqueness.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 11 | lines 7-11

Super Key − A set of attributes (one or more) that collectively identifies an entity in an entity set. Candidate Key − A minimal super key is called a candidate key. An entity set may have more than one candidate key. Primary Key − A primary key is one of the candidate keys chosen by the database designer to uniquely identify the entity set.

Question sources

Computer Science MCQ practice collection · Question 155

Question 185 | AM0156

What is the purpose of a foreign key in database design?

A. To enforce data types in columns

B. To define primary key constraints

C. To establish relationships between tables

D. To optimize query performance

Hint

Match the validity requirement to the appropriate constraint definition.

Answer C: To establish relationships between tables

A foreign key links a child occurrence to the matching parent candidate/primary key. Its defining purpose is the intertable relationship.

Why each choice is right or wrong

A - Incorrect: Domain constraints specify legal types. (PDF pp. 48.)

B - Incorrect: The parent key is an identifying constraint, while the child FK expresses the reference. (PDF pp. 48.)

C - Correct: Matches the stated linking purpose. (PDF pp. 48.)

D - Incorrect: Performance is not the defining reference function. (PDF pp. 48.)

Primary note proof

Study-note section FDB15

Domain integrity restricts type and allowed values. Key integrity enforces uniqueness. Entity integrity requires every primary-key component to be non-NULL. Referential integrity requires a non-NULL foreign-key value to match an eligible referenced unique/candidate key; self-references are allowed. A parent need not have a child.

Study-note section FDB07

A primary key is one selected candidate key; remaining candidates are alternate keys.

Study-note section FDB07

A composite key contains multiple attributes and need not be the chosen primary key.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 48 | lines 13-17

> iv. Referential Integrity ● A —foreign key‖ links each occurrence in a relation representing a child entity to the occurrence of the parent entity containing the matching candidate (usually primary) key ● Referential Integrity means that if the foreign key contains a value, that value must refer to an existing occurrence in the parent entity

Question sources

Computer Science MCQ practice collection · Question 156

Question 186 | AM0157

Which of the following database design principles promotes data independence?

A. Entity-Relationship (ER) modeling

B. Normalization

C. Database indexing

D. Data abstraction

Hint

Trace which schema levels a proposed change affects.

Answer D: Data abstraction

Abstraction hides irrelevant details and helps achieve data independence. Three-schema separation then permits changes at one level without forcing higher-level schema changes.

Why each choice is right or wrong

A - Incorrect: ER modeling describes conceptual structure but is not the explicit independence principle here. (PDF pp. 6, 8.)

B - Incorrect: Normalization addresses redundancy/anomalies. (PDF pp. 6, 8.)

C - Incorrect: Indexes address retrieval paths and performance. (PDF pp. 6, 8.)

D - Correct: Abstraction is explicitly connected to independence. (PDF pp. 6, 8.)

Primary note proof

Study-note section FDB04

> Physical data independence permits changing internal storage without changing the conceptual schema, for example adding an index. Logical data independence permits conceptual changes while preserving affected external views and application interfaces, for example splitting a table while maintaining a compatible view. It is harder because applications depend on logical meaning. Data abstraction hides irrelevant details; program-data insulation separates data definitions from application code.

Study-note section FDB05

> Conceptual design turns them into an ER/EER model.

Study-note section FDB05

> Logical design maps the conceptual model to relations, keys and constraints and checks normalization.

Related reading (context, not primary note proof)

Study-note section FDB19

Study-note section FDB25

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 6 | lines 2-4

> Data abstraction and Insulation between programs and data- Data Abstraction is a process of hiding unwanted or irrelevant details from the end user. It provides a different view and helps in achieving data independence which is used to enhance the security of data.

Fundamental of Database Systems module | PDF page 8 | lines 8-15

> 2.4 Data Independence The three-schema architecture can be used to further explain the concept of data independence, which can be defined as the capacity to change the schema at one level of a database system without having to change the schema at the next higher level. The two types of data independence: 1. Logical data independence is the capacity to change the conceptual schema without having to change external schemas or application programs. 2. Physical data independence is the capacity to change the internal schema without having to change the conceptual schema. Hence, the external schemas do not need be changed as well.

Question sources

Computer Science MCQ practice collection · Question 157

Question 187 | AM0158

Which type of database relationship is represented by a join table?

A. One-to-one relationship

B. One-to-many relationship

C. Many-to-many relationship

D. Hierarchical relationship

Hint

Identify relationship degree and cardinality before choosing a relational mapping.

Answer C: Many-to-many relationship.

A join table stores pairs of references to the two participating entity tables, optionally with relationship attributes. FDB12 uses Enrollment(StudentID,CourseID,Grade) for the many-to-many Student-Course relationship. One-to-one and one-to-many relationships normally use a foreign key in an entity table instead. A hierarchy is a structural pattern, not the relationship cardinality represented by this usual association mapping.

Why each choice is right or wrong

A - Incorrect: A 1:1 relationship normally uses a UNIQUE foreign key rather than requiring a join table.

B - Incorrect: A 1:N relationship normally stores the one-side key in the many-side entity table.

C - Correct: A join or association table stores the pairs making up a many-to-many relationship.

D - Incorrect: Hierarchical organization is not the standard cardinality category represented by this association-table mapping.

Primary note proof

Study-note section FDB12

> A binary M:N relationship needs an association table in addition to the two entity tables. Enrollment(StudentID,CourseID,Grade) references Student and Course; (StudentID,CourseID) is a key if one enrollment per pair is allowed. Repeated attempts require Term or AttemptNo in the key. This ordinarily produces three tables.

Study-note section FDB11

> For 1:N, place the one-side key as a foreign key in the many-side table; store relationship attributes there.

Study-note section FDB11

> For 1:1, one side may hold the other key with a UNIQUE constraint.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 12 | lines 2-3

> Many to many (M-M) - When entities in all entity sets can take part more than once in the relationship cardinality is many to many.

Fundamental of Database Systems module | PDF page 12 | lines 8-24

> 3.4 Mapping ER-models to relational tables 1. For each strong entity type E, create a relation R that includes all the attributes of E. 2. Choose one of the key attributes of E as the primary key for R. For each weak entity type W with owner entity type E (which is a strong entity), create a relation R & include all attributes of ‗W‘ as attributes of R. Also, include the primary key attribute of the relation that correspond to the owner entity type as foreign key attributes of R . 3. For each binary 1:1 relationship type R in the ER schema, identify the relations S and T that correspond to the entity types participating in R. Foreign Key approach: Choose one of the relations-say S-and

include a foreign key in S the primary key of T. It is better to choose an entity type with total participation in R in the role of S. 4. For each binary 1:N relationship type R, identify the relation S that represent the participating entity type at the N-side of the relationship type. Include the primary key of the relation T as foreign key in S that represents the other entity type participating in R. Include any attributes of the 1:N relation type as attributes of S. 5. For each n-ary relationship type R, where n>2, create a new relationship S to represent R. Include the primary keys of the relations that represent the participating entity types as foreign key attributes in S. Also include any attributes of the n-ary relationship type as attributes of S.

Question sources

Computer Science MCQ practice collection · Question 158

Question 188 | AM0159

Employee ID uniquely identifies an employee and their name, salary and department. Names may repeat; the same salary may occur in different departments, and a department may contain different salaries. Which listed functional dependency is guaranteed?

A. Employee ID -> Employee Name

B. Employee Name -> Employee ID

C. Employee Salary -> Employee Department

D. Employee Department -> Employee Salary

Hint

Compute closures using the declared dependencies and test minimality.

Answer A: A. Employee ID -> Employee Name

A functional dependency is guaranteed by business rules for every legal state. Unique Employee ID determines all employee attributes, including Name, so A follows. Repeated names can correspond to different IDs, equal salaries can occur in different departments, and one department may contain different salaries. Those permissions prevent the other proposed directions from being guaranteed dependencies.

Why each choice is right or wrong

A - Correct: The unique employee identifier determines the employee's name.

B - Incorrect: Repeated names can belong to different IDs.

C - Incorrect: The same salary may occur in different departments.

D - Incorrect: One department may contain employees with different salaries.

Primary note proof

Study-note section FDB17

X→Y means every legal pair of tuples agreeing on X also agrees on Y. It is a business constraint, not a correlation observed in one sample. Full dependency requires all determinant attributes;

partial dependency holds through a proper subset. A prime attribute belongs to some candidate key; a nonprime attribute belongs to none.

Study-note section FDB17

Remove attributes and recompute to test minimality.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 15 | lines 5-9

A functional dependency is a constraint between two attributes or sets of attributes of entities in a database. A functional dependency is denoted by X → Y, between two sets of attributes X and Y that are subsets of relation R. The constraint is that, the values of Y component of a tuple in r depend on, or are determined by the values of X component. Alternatively, the values of X component of a tuple uniquely (or functionally) determine the values of Y component.

Fundamental of Database Systems module | PDF page 11 | lines 7-11

Super Key − A set of attributes (one or more) that collectively identifies an entity in an entity set. Candidate Key − A minimal super key is called a candidate key. An entity set may have more than one candidate key. Primary Key − A primary key is one of the candidate keys chosen by the database designer to uniquely identify the entity set.

Question sources

Computer Science MCQ practice collection · Question 159

Question 189 | AM0160

What is the purpose of a data dictionary in database design?

A. To store user credentials

B. To manage database backups

C. To define the structure and attributes of data elements

D. To enforce referential integrity constraints

Hint

Distinguish a relation's structure from its current contents and its descriptive metadata.

Answer C: To describe the structure and attributes of data elements.

The dictionary contains metadata explaining table definitions, attribute types and constraints. FDB03 therefore supports C as its purpose. It may record privileges, but storing user credentials is not its defining function. Backup management is an administrative operation, and enforcing a reference requires DBMS constraint machinery rather than merely the repository that describes the constraint.

Why each choice is right or wrong

A - Incorrect: Credential storage is not the defining purpose of the database structure metadata repository.

B - Incorrect: Backup management is an administrative activity rather than the dictionary's structural-description purpose.

C - Correct: The dictionary records definitions, attributes, data types and constraints describing database elements.

D - Incorrect: It describes constraints; the DBMS enforcement machinery actually checks referential integrity during operations.

Primary note proof

Study-note section FDB03

> A schema describes names, structures and constraints; an instance, state or snapshot is the data at a particular time. Inserting a student changes the state, while adding a column changes the schema. Metadata is data describing data. The catalog or data dictionary records table definitions, types, constraints and often access privileges and optimizer statistics. A schema diagram draws tables and key references; labels such as database diagram can overlap.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 5 | lines 26-29

> Self-describing nature - A fundamental characteristic of the database approach is that the database system contains not only the database itself (data) but also a complete definition or description of the database structure and constraints. This information is called meta-data, and it describes the structure of the database.

Fundamental of Database Systems module | PDF page 7 | lines 4-7

> A data model a collection of concepts that can be used to describe the structure of a database and provides the necessary means to achieve data abstraction. By structure of a database we mean the data types, relationships, and constraints that apply to the data. Most data models also include a set of basic operations for specifying retrievals and updates on the database.

Question sources

Computer Science MCQ practice collection · Question 160

Computer Science MCQ practice collection · Question 184

Question 190 | AM0161

Compared with scanning all pages of a large heap file, which advantage can an RDBMS with a suitable index provide for a query selecting a small fraction of rows? Assume index lookup costs less than the scan.

A. Easy integration with external systems

B. Lower storage requirements

C. No need for data normalization

D. Faster data retrieval

Hint

Compare design techniques by the specific problem each solves.

Answer D: D. Faster data retrieval

The suitable index provides a search path for the selective query, reducing the work compared with scanning the large heap under the stated cost assumption. This supports faster retrieval for this workload. It does not remove normalization concerns, guarantee smaller storage or establish external-system compatibility. Index space and maintenance costs remain separate trade-offs from the query's retrieval advantage.

Why each choice is right or wrong

A - Incorrect: External integration is outside the stated lookup comparison.

B - Incorrect: Indexes consume additional storage rather than guaranteeing a reduction.

C - Incorrect: An index does not remove the need for dependency-aware design.

D - Correct: The stated cheaper indexed lookup supports faster retrieval for this query.

Primary note proof

Study-note section FDB38

> Normalization reduces dependency-driven anomalies. Indexing supplies search paths. Denormalization deliberately repeats or precomputes facts to reduce selected read costs, increasing maintenance work. Partitioning divides rows or columns; replication creates copies to improve locality or availability while complicating updates. These techniques can coexist. An e-commerce or gaming label alone does not select one.

Study-note section FDB25

> It often speeds selective retrieval but consumes space and must be maintained on writes.

Study-note section FDB25

> A full scan can win for a tiny table or a query returning most rows.

> Database Management System (DBMS) is then a tool for creating and managing databases. DBMS is a software that facilities the processes of defining, constructing, manipulating, and sharing databases. Example: MySQL server, MS ACESS, Microsoft SQL server. 1.2 Database System versus File System The traditional file processing system is file-directory structure supported by a conventional operating system. A file system organization of data lucks a number of major features of a database system, such as Data redundancy and inconsistency, Difficulty in accessing data, Data isolation, Integrity problems, Atomicity problems, Concurrent access anomalies.

Fundamental of Database Systems module | PDF page 21 | lines 5-9

> 5.5 Index Indexes are additional auxiliary access structures which are used to speed up the retrieval of records in response to certain search conditions. Index structures are additional files, which provide alternative ways to access the records without affecting the physical placement of records on disk.

Question sources

Computer Science MCQ practice collection · Question 161

Question 191 | AM0163

OrderLine has one row per line number within an order. OrderID and LineNo together uniquely identify a row; neither alone does. Which listed attribute set is a composite key?

A. Employee ID

B. Product SKU

C. Customer Name

D. (OrderID, LineNo)

Hint

Test uniqueness and minimality separately when classifying keys.

Answer D: D. (OrderID, LineNo)

A composite key contains more than one attribute. OrderID identifies an order and LineNo identifies a line within it; the stated rules make their pair unique while neither component alone is sufficient. That establishes a minimal composite key. The other options each name only one attribute and therefore do not illustrate a composite key, regardless of any separate uniqueness policy.

Why each choice is right or wrong

A - Incorrect: Employee ID is a single attribute.

B - Incorrect: Product SKU is a single attribute.

C - Incorrect: Customer Name is a single listed attribute.

D - Correct: The pair is unique and requires both stated attributes.

Primary note proof

Study-note section FDB07

> A superkey uniquely identifies a tuple. A candidate key is a minimal superkey: removing any component loses uniqueness. Minimal means no unnecessary attribute, not necessarily the fewest columns among all keys. A primary key is one selected candidate key; remaining candidates are alternate keys. A composite key contains multiple attributes and need not be the chosen primary key.

Study-note section FDB07

> If ID is unique, both {ID} and {ID,City} are superkeys, but only {ID} is minimal.

Study-note section FDB07

> A composite-key example must include multiple columns; a single-column key is not composite.

> Super Key − A set of attributes (one or more) that collectively identifies an entity in an entity set. Candidate Key − A minimal super key is called a candidate key. An entity set may have more than one candidate key. Primary Key − A primary key is one of the candidate keys chosen by the database designer to uniquely identify the entity set.

Fundamental of Database Systems module | PDF page 15 | lines 11-17

> Partial Dependency - If an attribute which is not a member of the key is dependent on some part of the key (if we have composite/candidate key) then that attribute is partially functionally dependent on the key. Let {A, B} is the key set and C is no key attribute, then if {A, B} → C and [B → C or A → C] holds. We say C is partially functionally dependent on {A, B}. Partial dependency occurs when a non-prime attribute is functionally dependent on part of a candidate/composite key.

Question sources

Computer Science MCQ practice collection · Question 163

Question 192 | AM0164

What is the purpose of data validation in database design?

A. To enforce referential integrity constraints

B. To improve query performance

C. To eliminate data redundancy

D. To ensure data integrity and quality

Hint

Match the validity requirement to the appropriate constraint definition.

Answer D: To ensure data integrity and quality

Validation checks that input values meet legal domains/criteria, protecting integrity and consistency. D is the broad purpose; referential validation is one narrower kind rather than the whole definition.

Why each choice is right or wrong

A - Incorrect: Referential checks are one specific constraint, not the overall purpose of validation. (PDF pp. 47, 48, 49.)

B - Incorrect: Performance is not the legal-input goal. (PDF pp. 47, 48, 49.)

C - Incorrect: Redundancy reduction belongs to normalization. (PDF pp. 47, 48, 49.)

D - Correct: Integrity and input quality match domain validation and CHECK criteria. (PDF pp. 47, 48, 49.)

Primary note proof

Study-note section FDB15

> Domain integrity restricts type and allowed values. Key integrity enforces uniqueness. Entity integrity requires every primary-key component to be non-NULL. Referential integrity requires a non-NULL foreign-key value to match an eligible referenced unique/candidate key; self-references are allowed. A parent need not have a child.

Study-note section FDB19

> Reduced redundancy can improve integrity and storage use, but extra keys and joins mean neither storage savings nor faster retrieval is guaranteed.

Study-note section FDB25

> Indexes do not themselves establish referential integrity.

Module passages - related reading

Fundamental of Database Systems module | PDF page 47 | lines 4-19

> ● Security vs Integrity ◦ Database security makes sure that the user is authorised to access information ◦ Database integrity makes sure that (authorised) users use that information correctly ● Integrity constraints ◦ Domain constraints apply to data types ◦ Attribute constraints apply to columns ◦ Relation constraints apply to rows in a single table ◦ Database constraints apply between tables ● Intrarecord integrity (enforcing constraints on contents of fields, etc.) ● Referential Integrity (enforcing the validity of references between records in the database) ● Concurrency control (ensuring the validity of database updates in a shared multiuser

environment) ● The constraints we wish to impose in order to protect the database from becoming inconsistent.

Fundamental of Database Systems module | PDF page 48 | lines 4-8

ii. Attribute domain constraints ● Every attribute has a domain, that is a set of values that are legal for it to use ● For example: ◦ The domain of sex in the employee relation is —M‖ or —F‖ ● Domain ranges can be used to validate input to the database

Fundamental of Database Systems module | PDF page 49 | lines 19-22

● CREATE TABLE table-name (attr2 attr-type NOT NULL, forbids NULL values attrN attr-type CHECK (attrN = UPPER(attrN) verifies that the data meets certain criteria attrO attr-type DEFAULT default_value); Supplies default values

Question sources

Computer Science MCQ practice collection · Question 164

Question 193 | AM0165

Which normal forms have defining restrictions on functional dependencies? Select all that apply. Treat 1NF as the atomic-value/no-repeating-groups requirement.

A. First Normal Form (1NF)

B. Second Normal Form (2NF)

C. Third Normal Form (3NF)

D. Boyce-Codd Normal Form (BCNF)

Hint

Test determinants and prime attributes against the stated normal-form rules.

Answer B, C, D: B. Second Normal Form (2NF); C. Third Normal Form (3NF); D. Boyce-Codd Normal Form (BCNF)

Second normal form excludes nonprime partial functional dependencies on candidate keys. Third normal form checks each nontrivial dependency using the determinant's superkey status or the dependent's prime status. BCNF strengthens that test by requiring a superkey determinant. These three therefore use functional-dependency restrictions. First normal form instead establishes the atomic-value foundation and absence of repeating groups.

Why each choice is right or wrong

A - Incorrect: 1NF addresses atomic values and repeating groups rather than the stated dependency-based tests.

B - Correct: 2NF is defined through absence of nonprime partial functional dependencies on candidate keys.

C - Correct: 3NF tests nontrivial FDs using determinant superkeys and prime dependent attributes.

D - Correct: BCNF requires every nontrivial FD determinant to be a superkey.

Primary note proof

Study-note section FDB21

For every nontrivial FD X→A, 3NF permits it when X is a superkey or A is prime. BCNF requires X to be a superkey. The mnemonic whole key and nothing but the key describes the common single-key case; it cannot replace the full tests when keys overlap. Remove dependencies of nonprime facts on nonkey determinants.

Study-note section FDB20

A relation whose every candidate key is single-attribute has no nonprime partial-key dependency.

Study-note section FDB20

2NF requires 1NF and no nonprime attribute partially dependent on any candidate key.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 17 | lines 2-15

First normal form (1NF) A relation (table) R is in 1NF if and only if (iff) all underlying domains of attributes contain only atomic (simple or indivisible) values. i.e. The value of any attribute in a tuple (row) must be a single value from the domain of their attribute. It is defined to disallow multivalued attributes, composite attributes, and their combinations. In other words, 1NF disallows relations within relations or relations as attribute values within tuples. It must be remove repeating groups (values) in a single field. The primary key with repeating group attributes are moved into a new table. When a relation contains no repeating groups (values), it is in first normal form (1NF). Second normal form (2NF) Second normal form (2NF) is based on the concept of full functional dependency. A relation schema R is in 2NF if it is in 1NF and every non-prime attribute A in R is fully functionally dependent on the primary key (i.e. the non-prime attributes are not partially dependent on key attributes). Remove any partially dependent attributes and place them in another relation. A partial dependency is when the attribute(s) is/are dependent on a part of a key.

Fundamental of Database Systems module | PDF page 18 | lines 5-8

Third Normal Form (3NF) A relation schema R is in third normal form (3NF) if it is in 2NF and every non-prime attribute of _R‘ are fully functionally dependent on every key of R and non-transitively dependent on every key of R.

Question sources

Computer Science MCQ practice collection · Question 165

Question 194 | AM0166

Which are direct representational purposes of conceptual/logical data modeling, rather than DBMS enforcement or physical query tuning? Select all that apply.

A. To enforce data constraints

B. To optimize query performance

C. To define the structure and organization of a database

D. To represent real-world entities and their relationships

Hint

Identify the design phase from its inputs and intended deliverable.

Answer C, D: C. To define the structure and organization of a database; D. To represent real-world entities and their relationships

Conceptual modeling represents domain entities and their relationships, while logical modeling defines database structures, keys and constraints. Both are direct representational purposes, so C and D qualify. Modeling can describe constraints, but the DBMS and application implementation enforce them during operations. Query performance can inform physical design, yet it is not the direct representational task specified in this question.

Why each choice is right or wrong

A - Incorrect: A model describes constraints, while implementation and DBMS machinery enforce them on actual operations.

B - Incorrect: Query performance can inform physical design, but it is not the general representational purpose asked here.

C - Correct: Modeling specifies the database's structure and organization.

D - Correct: Conceptual modeling represents real-world entities and their relationships.

Primary note proof

Study-note section FDB05

> First collect business facts, required transactions, reports, volumes, privacy rules and quality targets. Conceptual design turns them into an ER/EER model. Logical design maps the conceptual model to relations, keys and constraints and checks normalization. Physical design chooses file organization, indexes and storage. Implementation creates and loads the actual objects; testing checks requirements.

Study-note section FDB02

> A data model supplies concepts for structure, relationships, constraints and operations.

Study-note section FDB02

> Conceptual ER models describe entities and relationships.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 7 | lines 4-7

> A data model a collection of concepts that can be used to describe the structure of a database and provides the necessary means to achieve data abstraction. By structure of a database we mean the data types, relationships, and constraints that apply to the data. Most data models also include a set of basic operations for specifying retrievals and updates on the database.

Fundamental of Database Systems module | PDF page 9 | lines 3-6

> 3.1 Database Modeling High-level conceptual data models provide concepts for presenting data in ways that are close to the way people perceive data. A typical example is the entity relationship model, which uses main concepts like entities, attributes and relationships.

Fundamental of Database Systems module | PDF page 9 | lines 27-31

> 3.3 ERD (Entity Relationship Diagram) ERD a graphical technique for representing a database schema. It is a modeling tool used to depict graphically a DB design before it is actually implemented. It shows the various entities being modeled and the important relationships among them. ERD has three basic components Entity, Relationship and Attribute.

Question sources

Computer Science MCQ practice collection · Question 166

Question 195 | AM0167

Which option states a measurable nonfunctional quality requirement for a database system?

A. The database service must achieve at least 99.9% uptime.

B. User authentication

C. Entity-Relationship (ER) diagram

D. Data normalization

Hint

Compare design techniques by the specific problem each solves.

Answer A: A. The database service must achieve at least 99.9% uptime.

A nonfunctional requirement states a quality target such as availability or response time. The uptime threshold specifies a measurable availability requirement and fits that category. User authentication names system behavior, while an ER diagram is a modeling artifact and normalization is a design technique. These may support requirements, but they do not themselves state the quantified quality requested here.

Why each choice is right or wrong

A - Correct: The 99.9% uptime threshold is a measurable availability target.

B - Incorrect: Authentication names behavior rather than a quantified quality target.

C - Incorrect: An ER diagram is a design artifact.

D - Incorrect: Normalization is a design technique.

Primary note proof

Study-note section FDB38

Privacy requires a threat model. Authentication verifies identity; role-based authorization limits allowed records/actions; encryption protects data at rest or in transit; auditing records activity. Both encryption and access control can protect patient data. Scalability, availability, fast retrieval, redundancy control and security are all reasonable design considerations. Functional requirements describe behavior; nonfunctional requirements quantify qualities such as 99.9% uptime or response time. Authentication and encryption mechanisms alone do not uniquely establish that distinction.

Study-note section FDB19

Adding a generated row ID may make insertion technically possible, but does not remove repeated facts or fix the dependency design.

Study-note section FDB05

Conceptual design turns them into an ER/EER model.

2.2 Database Security • Views or restricted subschemas • Authorization rules to identify users and the actions they can perform • User-defined procedures (and rule systems) to define additional constraints or limitations in using the database • Encryption to encode sensitive data

Fundamental of Database Systems module | PDF page 53 | lines 2-13

• Authentication schemes to positively identify a person attempting to gain access to the database • Database security is about controlling access to information • Some information should be available freely • Other information should only be available to certain people or groups • Many aspects to consider for security • Legal issues • Physical security • OS/Network security • Security policies and protocols • Encryption and passwords • DBMS security

Question sources

Computer Science MCQ practice collection · Question 167

Question 196 | AM0168

What is the purpose of data manipulation in database management?

A. To define the database schema

B. To create database backups

C. To insert, update, and delete data

D. To manage concurrent access to data

Hint

Classify each SQL command by the kind of change it performs.

Answer C: To insert, update, and delete data

The DML subsection includes INSERT, UPDATE and DELETE. SQL examples show insertion/deletion and an UPDATE privilege permits changing values, grounding the data-manipulation purpose. DML also includes retrieval, so C describes its modification part rather than all of DML.

Why each choice is right or wrong

A - Incorrect: Schema definition is DDL. (PDF pp. 26, 55, 77.)

B - Incorrect: Backup is not the DML purpose identified. (PDF pp. 26, 55, 77.)

C - Correct: Insertion, updating and deletion are explicitly DML operations. (PDF pp. 26, 55, 77.)

D - Incorrect: Concurrency control is a separate transaction-management responsibility. (PDF pp. 26, 55, 77.)

Primary note proof

Study-note section FDB26

> DDL changes structure: CREATE, ALTER, DROP, commonly RENAME and TRUNCATE in textbook classifications. DML retrieves or changes data: SELECT, INSERT, UPDATE, DELETE. Some texts separate SELECT as DQL. DCL manages privileges through GRANT and REVOKE. TCL includes COMMIT, ROLLBACK and SAVEPOINT. Classify a statement by its effect, not its length.

Module passages - related reading

Fundamental of Database Systems module | PDF page 26 | lines 4-11

> SQL represents Structured Query Language. SQL is a comprehensive database language: It has statements for data definitions, and updates. Hence, it is both a DDL (Data Definition language) and a DML (Data Manipulation Language). 7.1.1 DDL (data definition language) Basic DDL commands we usually use are: CREATE, DROP, ALTER, TRUNCATE and RENAME 7.1.2 DML (data manipulation language) Basic DDL commands are: SELECT, PROJECT, JOIN, INSERT, DELETE, and UPDATE

Fundamental of Database Systems module | PDF page 55 | lines 2-5

> UPDATE(Salary) ON Employee TO Finance The user _Finance‘ can view the entire Employee table, and can change Salary values, but cannot change other values or pass on their privilege

Fundamental of Database Systems module | PDF page 77 | lines 14-24

> Example 1: Commit Transaction BEGIN TRANSACTION; DELETE FROM HumanResources.JobCandidate WHERE JobCandidateID = 13; COMMIT; Example 2: Rollback Transaction CREATE TABLE ValueTable (id int); BEGIN TRANSACTION; INSERT INTO ValueTable VALUES(1); INSERT INTO ValueTable VALUES(2); ROLLBACK;

Question sources

Computer Science MCQ practice collection · Question 168

Question 197 | AM0170

During conceptual database design, which listed goal directly concerns representing the business domain before choosing storage layouts and access paths?

A. Efficient storage of data

B. Secure data transmission

C. Optimal query performance

D. Effective representation of real-world entities

Hint

Identify the design phase from its inputs and intended deliverable.

Answer D: D. Effective representation of real-world entities

Conceptual design turns business facts into an ER/EER representation of entities and relationships. Effective representation of the domain is therefore the direct goal in this phase. Storage efficiency and query access paths are later physical design concerns. Secure transmission can be an important requirement, but it is not the conceptual representational task singled out by the revised question.

Why each choice is right or wrong

A - Incorrect: Storage layout efficiency belongs to physical decisions.

B - Incorrect: Transmission security is a requirement or mechanism, not the specified conceptual representation goal.

C - Incorrect: Query performance is addressed through later physical design and tuning.

D - Correct: Representing real-world entities directly matches conceptual design.

Primary note proof

Study-note section FDB05

First collect business facts, required transactions, reports, volumes, privacy rules and quality targets. Conceptual design turns them into an ER/EER model. Logical design maps the conceptual model to relations, keys and constraints and checks normalization. Physical design chooses file organization, indexes and storage. Implementation creates and loads the actual objects; testing checks requirements.

Study-note section FDB38

Indexing supplies search paths.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 9 | lines 16-26

Conceptual Database Design In this phase the database designers will make a decision on the database model that perfectly suits the organization‘s requirement. The database designers will study the documents prepared by the analysis in the requirement analysis stage and then start development of a system model that fulfils the needs. Logical database design (Data model mapping) The conceptual design is translated into internal model which includes mapping of all objects i.e design of tables, indexes, views, transaction, access privileges etc. Physical Design Physical design or Database implementation needs the formation of special storage related constructs. These constructs consist of storage groups, table spaces, data files, tables etc.

Fundamental of Database Systems module | PDF page 19 | lines 4-10

5.1 Introduction To translate the logical description of data into technical specifications for storing and retrieving data, a physical database design is needed. The goal is to create a design for storing and retrieving data that will provide adequate performance and insure database integrity, security, and availability. Some decisions need to be made on the physical database design. They are Attribute data types, data/file storages, File organizations and Indexes.

Question sources

Computer Science MCQ practice collection · Question 170

Question 198 | AM0171

Which are legitimate considerations when designing a database for a large e-commerce site? Select all that apply. Minimal redundancy means controlling avoidable duplication while permitting deliberate replicas.

A. High availability and scalability

B. Minimal data redundancy

C. Fast data retrieval

D. Secure user authentication

Hint

Compare design techniques by the specific problem each solves.

Answer A, B, C, D: A. High availability and scalability; B. Minimal data redundancy; C. Fast data retrieval; D. Secure user authentication

Large e-commerce databases need several complementary qualities. Availability and scalability support continued service and growth; retrieval speed supports interactive use; security protects accounts and records. Controlling avoidable redundancy reduces consistency and maintenance problems even where intentional replicas are useful. All listed considerations therefore belong in the design discussion, with their relative priority determined by the site's actual requirements.

Why each choice is right or wrong

A - Correct: High availability and scalability support growth and continued service for a large site.

B - Correct: Controlling unnecessary redundancy improves consistency and maintenance even when deliberate copies are retained.

C - Correct: Fast retrieval is a legitimate quality target for browsing, orders and customer-facing operations.

D - Correct: Secure authentication is a legitimate security consideration for customer and administrative access.

Primary note proof

Study-note section FDB38

> Privacy requires a threat model. Authentication verifies identity; role-based authorization limits allowed records/actions; encryption protects data at rest or in transit; auditing records activity. Both encryption and access control can protect patient data. Scalability, availability, fast retrieval, redundancy control and security are all reasonable design considerations. Functional requirements describe behavior; nonfunctional requirements quantify qualities such as 99.9% uptime or response time. Authentication and encryption mechanisms alone do not uniquely establish that distinction.

Study-note section FDB38

> In a CMS, tags/categories describe meaning, while foreign keys preserve valid references between content and tags.

> iv. Increased reliability and availability: • Reliability refers to system live time, that is, system is running efficiently most of the time. Availability is the probability that the system is continuously available (usable or accessible) during a time interval. • A distributed database system has multiple nodes (computers) and if one fails then others are available to do the job. v. Improved performance: • A distributed DBMS fragments the database to keep data closer to where it is needed most. • This reduces data management (access and modification) time significantly.

Fundamental of Database Systems module | PDF page 117 | lines 2-4

> vi. Easier expansion (scalability): • Allows new nodes (computers) to be added anytime without changing the entire configuration.

Question sources

Computer Science MCQ practice collection · Question 171

Question 199 | AM0172

Which listed mechanisms directly protect patient confidentiality, covering both protected stored/transmitted content and restrictions on authorized user actions? Select all that apply.

A. Database normalization

B. Data encryption

C. Role-based access control

D. Database indexing

Hint

Compare design techniques by the specific problem each solves.

Answer B, C: B. Data encryption; C. Role-based access control

Encryption protects patient content at rest or in transit against the disclosure threats it covers. Role-based access control restricts which users can read or change patient records. These are complementary privacy protections and both qualify. Normalization reduces dependency anomalies, while indexing supplies retrieval paths; neither mechanism by itself decides who may see patient information or protects encoded content.

Why each choice is right or wrong

A - Incorrect: Normalization reduces dependency anomalies but does not itself restrict unauthorized disclosure.

B - Correct: Encryption protects patient content at rest or in transit against appropriate disclosure threats.

C - Correct: Role-based access control limits which users may access patient records or perform actions.

D - Incorrect: Indexes provide search paths and do not by themselves enforce patient confidentiality.

Primary note proof

Study-note section FDB38

> Privacy requires a threat model. Authentication verifies identity; role-based authorization limits allowed records/actions; encryption protects data at rest or in transit; auditing records activity. Both encryption and access control can protect patient data. Scalability, availability, fast retrieval, redundancy control and security are all reasonable design considerations. Functional requirements describe behavior; nonfunctional requirements quantify qualities such as 99.9% uptime or response time. Authentication and encryption mechanisms alone do not uniquely establish that distinction.

Study-note section FDB25

> Secondary indexes provide other access paths and must represent all searchable values with record pointers or pointer lists.

Study-note section FDB19

> Adding a generated row ID may make insertion technically possible, but does not remove repeated facts or fix the dependency design.

Question sources

Computer Science MCQ practice collection · Question 172

Question 200 | AM0173

Which techniques can improve query performance for some suitable workloads, without implying that they always help? Select all that apply.

A. Indexing

B. Data replication

C. Denormalization

D. Partitioning

Hint

Compare design techniques by the specific problem each solves.

Answer A, B, C, D: A. Indexing; B. Data replication; C. Denormalization; D. Partitioning

Indexes add search paths for selective queries. Replicas can improve read locality, denormalization can reduce selected joins or computations, and partitioning can reduce relevant data access when aligned with queries. Each technique can therefore help some workloads. Their benefits are conditional and can involve extra storage or update costs, so selecting all four does not mean every database should use all of them.

Why each choice is right or wrong

A - Correct: Indexes can reduce reads for selective predicates when maintenance and lookup costs are justified.

B - Correct: Replication can place read copies near users or spread suitable read workloads.

C - Correct: Denormalization can avoid selected joins or repeated computation by storing redundant/precomputed facts.

D - Correct: Partitioning can limit relevant data or improve locality when partitioning matches query predicates.

Primary note proof

Study-note section FDB38

Normalization reduces dependency-driven anomalies. Indexing supplies search paths. Denormalization deliberately repeats or precomputes facts to reduce selected read costs, increasing maintenance work. Partitioning divides rows or columns; replication creates copies to improve locality or availability while complicating updates. These techniques can coexist. An e-commerce or gaming label alone does not select one.

Study-note section FDB25

B/B+ trees support ordered and range search; hashing targets equality; bitmap indexes suit some analytic workloads.

Study-note section FDB24

Choose organization from actual reads, writes and predicates.

5.5 Index Indexes are additional auxiliary access structures which are used to speed up the retrieval of records in response to certain search conditions. Index structures are additional files, which provide alternative ways to access the records without affecting the physical placement of records on disk.

Fundamental of Database Systems module | PDF page 116 | lines 25-28

v. Improved performance: • A distributed DBMS fragments the database to keep data closer to where it is needed most. • This reduces data management (access and modification) time significantly.

Fundamental of Database Systems module | PDF page 117 | lines 18-29

I. Data Replication • The system maintain several identical copies of the relation & store each copy at a different site • In general it enhance the performance of read operation and increase the availability of data to read only transaction. However, update transactions incur greater overhead II. Data Fragmentation - Split a relation into logically related and correct parts. - The main reasons for fragmenting a relation are • Efficiency- data that is not needed by the local applications is not stored • Parallelism - a transaction can be divided into several subqueries that operate on fragments which will increase the degree of concurrency

Question sources

Computer Science MCQ practice collection · Question 173

Question 201 | AM0174

Users may follow many other users, and each user may be followed by many users. Which option describes the cardinality of this recursive user relationship, rather than a key constraint or procedural enforcement mechanism?

A. Primary key constraints

B. Foreign key constraints

C. Many-to-many relationships

D. Triggers and stored procedures

Hint

Identify relationship degree and cardinality before choosing a relational mapping.

Answer C: C. Many-to-many relationships

The follow rules permit multiple related users in both directions, which is many-to-many cardinality. A recursive association table can store two user references to represent those links. Primary and foreign keys support identification and referential integrity, but they are constraint mechanisms rather than the requested multiplicity classification. Triggers and stored procedures are also not a cardinality category.

Why each choice is right or wrong

A - Incorrect: Primary keys identify rows rather than name relationship multiplicity.

B - Incorrect: Foreign keys validate references rather than describe the many-to-many cardinality.

C - Correct: Both endpoints permit many partners, establishing M:N.

D - Incorrect: Procedures are implementation mechanisms rather than a cardinality type.

Primary note proof

Study-note section FDB12

> A recursive M:N friendship uses UserLink(UserID,OtherUserID), two foreign keys to User; decide whether links are directed and whether self-links are allowed. A recursive 1:N supervision uses a nullable SupervisorID reference in Employee. For a ternary Supply(SupplierID,PartID,ProjectID,Quantity), preserve all participating references; binary replacements can lose which triple occurred. Choose the association key from actual cardinalities rather than automatically assuming every reference is necessary.

Study-note section FDB07

> A composite key contains multiple attributes and need not be the chosen primary key.

Study-note section FDB15

> Referential integrity requires a non-NULL foreign-key value to match an eligible referenced unique/candidate key; self-references are allowed.

Fundamental of Database Systems module | PDF page 11 | lines 7-15

> Super Key − A set of attributes (one or more) that collectively identifies an entity in an entity set. Candidate Key − A minimal super key is called a candidate key. An entity set may have more than one candidate key. Primary Key − A primary key is one of the candidate keys chosen by the database designer to uniquely identify the entity set. Relationship A relationship type represents the association between entity types. For example, ‗Enrolled in' is a relationship type that exists between entity Student and Course. In ER diagram, relationship is represented by a diamond and connecting the entities with lines.

Fundamental of Database Systems module | PDF page 12 | lines 2-3

> Many to many (M-M) - When entities in all entity sets can take part more than once in the relationship cardinality is many to many.

Fundamental of Database Systems module | PDF page 48 | lines 13-17

> iv. Referential Integrity • A ―foreign key‖ links each occurrence in a relation representing a child entity to the occurrence of the parent entity containing the matching candidate (usually primary) key • Referential Integrity means that if the foreign key contains a value, that value must refer to an existing occurrence in the parent entity

Question sources

Computer Science MCQ practice collection · Question 174

Question 202 | AM0175

In the usual normalization sequence, which is the first normal form excluding transitive dependence of nonprime attributes on a key through a nonkey determinant?

A. First Normal Form (1NF)

B. Second Normal Form (2NF)

C. Third Normal Form (3NF)

D. Boyce-Codd Normal Form (BCNF)

Hint

Check atomicity, candidate keys and partial dependencies in that order.

Answer C: Third Normal Form (3NF)

In the stated single-key teaching case, 2NF excludes partial dependencies but can still allow a nonprime fact to depend on the key through a nonkey determinant. The next defining stage is 3NF, summarized by the whole-key-and-nothing-but-the-key mnemonic. BCNF strengthens the determinant rule, and 4NF addresses multivalued dependencies. Stronger forms inherit earlier conditions, so the explicit first-stage scope makes 3NF the unique selection rather than treating inherited properties as rival answers.

Why each choice is right or wrong

A - Incorrect: Incorrect: 1NF concerns atomic values and does not eliminate the specified transitive dependencies.

B - Incorrect: Incorrect: 2NF excludes partial dependencies but can retain a nonprime transitive dependency through a nonkey determinant.

C - Correct: Correct: 3NF is the first stage imposing the specified nonprime transitive-dependency restriction in this teaching case.

D - Incorrect: Incorrect: BCNF strengthens 3NF by requiring every nontrivial determinant to be a superkey; it is not the first stage described.

Primary note proof

Study-note section FDB20

> 1NF requires atomic values in the chosen relational domains and no repeating groups in cells.

Study-note section FDB20

> 2NF requires 1NF and no nonprime attribute partially dependent on any candidate key.

Study-note section FDB21

> For every nontrivial FD X→A, 3NF permits it when X is a superkey or A is prime. BCNF requires X to be a superkey. The mnemonic whole key and nothing but the key describes the common single-key case; it cannot replace the full tests when keys overlap. Remove dependencies of nonprime facts on nonkey determinants.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 17 | lines 10-15

> Second normal form (2NF) Second normal form (2NF) is based on the concept of full functional dependency. A relation schema R is in 2NF if it is in 1NF and every non-prime attribute A in R is fully functionally dependent on the primary key (i.e. the non-prime attributes are not partially dependent on key attributes). Remove any partially dependent attributes and place them in another relation. A partial dependency is when the attribute(s) is/are dependent on a part of a key.

Fundamental of Database Systems module | PDF page 18 | lines 5-8

Third Normal Form (3NF) A relation schema R is in third normal form (3NF) if it is in 2NF and every non-prime attribute of _R‘ are fully functionally dependent on every key of R and non-transitively dependent on every key of R.

Question sources

Computer Science MCQ practice collection · Question 175

Question 203 | AM0176

What is the purpose of denormalization in database design for real-world scenarios?

A. To eliminate data redundancy

B. To optimize query performance

C. To enforce referential integrity

D. To simplify the database schema

Hint

Compare design techniques by the specific problem each solves.

Answer B: To improve selected query performance.

Denormalization repeats or precomputes facts so that selected queries can perform less work, such as fewer joins. FDB38 also states the cost: more maintenance when underlying facts change. It does not aim to eliminate redundancy or enforce foreign-key references. A simpler query path may result, but a simpler schema is not the essential purpose.

Why each choice is right or wrong

A - Incorrect: Denormalization introduces controlled redundancy instead of eliminating it.

B - Correct: Its goal is to reduce costs of selected read queries using repeated or precomputed information.

C - Incorrect: Foreign-key constraints enforce references; denormalization itself does not establish referential integrity.

D - Incorrect: It may simplify selected reads, but schema simplicity is not the defining or guaranteed goal.

Primary note proof

Study-note section FDB38

Normalization reduces dependency-driven anomalies. Indexing supplies search paths. Denormalization deliberately repeats or precomputes facts to reduce selected read costs, increasing maintenance work. Partitioning divides rows or columns; replication creates copies to improve locality or availability while complicating updates. These techniques can coexist. An e-commerce or gaming label alone does not select one.

Study-note section FDB15

Referential integrity requires a non-NULL foreign-key value to match an eligible referenced unique/candidate key; self-references are allowed.

Study-note section FDB15

Key integrity enforces uniqueness.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 16 | lines 17-27

4.4 Normalization Normalization is a process of organizing the data in database to avoid data redundancy, insertion anomaly, update anomaly & deletion anomaly. It is a technique of organizing the data in the database. It is a systematic approach of decomposing tables to eliminate data redundancy (repetition) and undesirable characteristics like Insertion, Update and Deletion Anomalies. It is a multi-step process that puts data into tabular form, removing duplicated data from the relation tables. Normal forms Redundancy in a relation may causes insertion, deletion, and update anomalies. Normalization is database design technique that minimizes redundancy from a relation or a set of relations. Normalization rules divides larger tables into smaller tables and links them using relationship.

Question sources

Computer Science MCQ practice collection · Question 176

Question 204 | AM0178

Which listed modeling technique directly includes superclass/subclass inheritance? Interpret ER modeling in A as basic ER without the EER extension, relational modeling as ordinary tables/keys, and XML modeling as document structure.

A. Entity-Relationship (ER) modeling

B. Object-oriented data modeling

C. Relational data modeling

D. XML data modeling

Hint

Review inheritance, specialization and category constraints.

Answer B: B. Object-oriented data modeling

Object-oriented data modeling directly represents superclass/subclass inheritance. Enhanced ER also supports inheritance, but A is explicitly limited to basic ER in this question. Ordinary relational tables can encode subtype data through references without making inheritance a direct modeling construct, and document structure is not the object inheritance mechanism being tested. The scope distinction makes the selected technique definite.

Why each choice is right or wrong

A - Incorrect: Basic ER excludes the EER inheritance extension under the stated scope.

B - Correct: Object models directly support superclass/subclass inheritance.

C - Incorrect: Ordinary relational tables encode facts and references rather than directly declaring this inheritance construct.

D - Incorrect: Document structure is not the direct object inheritance model asked for.

Primary note proof

Study-note section FDB13

> EER extends ER with superclass/subclass structure. A subclass inherits the superclass attributes and relationships. Specialization divides Student into Undergraduate and Graduate; generalization combines common properties into Student. Disjoint subclasses cannot overlap; overlapping subclasses can. Total specialization requires every superclass member in some subclass; partial specialization does not.

Study-note section FDB13

> Object models also support inheritance; distinguish basic ER notation from EER when comparing models.

Study-note section FDB13

> Structural EER inheritance alone does not define executable object methods.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 7 | lines 8-11

> Types of Data Models 1. High-level or conceptual data models provide concepts that are close to the way many users perceive data. Entity - Relationship (E/R) model and Object-Oriented Model are examples of conceptual/high level data model.

Fundamental of Database Systems module | PDF page 12 | lines 25-31

> 3.5 Enhanced Entity Relationship (EER) Model The complexityof the data is increasing so it becomes more and more difficult to use the traditional ER model for database modeling. To reduce this complexity of modeling we have to make improvements or enhancements to the existing ER model to make it able to handle the complex application in a better way. Enhanced ER (EER) model is a database model that incorporates the concepts of class/subclass relationships and type inheritance into the ER model. The EER model includes all the modeling

Fundamental of Database Systems module | PDF page 13 | lines 2-8

> concepts of the ER model. In addition, it includes the concepts of subclass and superclass, categories (UNION types), attribute and relationship inheritance. EER is created to design more accurate database schemas. Subclasses and super classes can be thought as useful ways to describe similarities in the entities represented. Because subclasses inherit their attributes and

relationships from the superclass, the database designer can represent complex, hierarchical interdependencies (inheritance) within the system being described.

Question sources

Computer Science MCQ practice collection · Question 178

Question 205 | AM0179

Which CMS features directly support either semantic grouping of content or valid stored references between content and tags? Select all that apply.

A. Referential integrity constraints

B. Full-text search capabilities

C. Content categorization and tagging

D. Distributed database architecture

Hint

Compare design techniques by the specific problem each solves.

Answer A, C: A. Referential integrity constraints; C. Content categorization and tagging

Categories and tags describe semantic associations among content items. Referential integrity constraints keep the stored links between content and tags valid. These two features address meaning and reference validity respectively, so both fit. Full-text search supports finding text, while a distributed architecture concerns data placement and coordination. Neither is the requested direct representation or validation of content-to-tag relationships.

Why each choice is right or wrong

A - Correct: Referential constraints preserve valid links between content and related rows, such as tags.

B - Incorrect: Full-text search finds textual content rather than primarily defining or validating item relationships.

C - Correct: Categories and tags describe semantic groupings and associations among content items.

D - Incorrect: Distribution determines placement and coordination rather than directly representing the stated content relationships.

Primary note proof

Study-note section FDB38

In a CMS, tags/categories describe meaning, while foreign keys preserve valid references between content and tags. A ContentTag(ContentID,TagID) association models multiple tags per item; these functions complement each other.

Study-note section FDB15

Referential integrity requires a non-NULL foreign-key value to match an eligible referenced unique/candidate key; self-references are allowed.

Study-note section FDB15

Key integrity enforces uniqueness.

Fundamental of Database Systems module | PDF page 9 | lines 27-31

3.3 ERD (Entity Relationship Diagram) ERD a graphical technique for representing a database schema. It is a modeling tool used to depict graphically a DB design before it is actually implemented. It shows the various entities being modeled and the important relationships among them. ERD has three basic components Entity, Relationship and Attribute.

Fundamental of Database Systems module | PDF page 48 | lines 13-17

iv. Referential Integrity ● A —foreign key‖ links each occurrence in a relation representing a child entity to the occurrence of the parent entity containing the matching candidate (usually primary) key ● Referential Integrity means that if the foreign key contains a value, that value must refer to an existing occurrence in the parent entity

Fundamental of Database Systems module | PDF page 116 | lines 25-28

v. Improved performance: • A distributed DBMS fragments the database to keep data closer to where it is needed most. • This reduces data management (access and modification) time significantly.

Question sources

Computer Science MCQ practice collection · Question 179

Question 206 | AM0180

Which database design technique is used to represent a hierarchical structure of data elements?

A. Relational data modeling

B. Network data modeling

C. Hierarchical data modeling

D. Object-relational data modeling

Hint

Compare the data models by how they organize records and relationships.

Answer C: Hierarchical data modeling.

A hierarchical structure organizes elements into parent-child levels. FDB02 assigns this representation to the hierarchical model, so C directly matches the requested design concept. Relational modeling instead uses tables, network modeling permits more general record links, and richer object-relational types do not by themselves require a hierarchical organization.

Why each choice is right or wrong

A - Incorrect: Relational modeling represents facts in tables rather than requiring a hierarchical tree.

B - Incorrect: Network modeling permits linked records with multiple parents rather than a restricted hierarchy.

C - Correct: Hierarchical modeling explicitly represents the parent-child structure asked for in the stem.

D - Incorrect: An object-relational approach adds richer types to relational storage rather than defining this tree organization.

Primary note proof

Study-note section FDB02

> A data model supplies concepts for structure, relationships, constraints and operations. Conceptual ER models describe entities and relationships. Relational models use tables; hierarchical models organize records in a parent-child tree; classic network models connect records through pointer-based owner/member links, allowing multiple parents. Object models represent objects with identity, state and behavior. A physical model specifies record layouts and access paths. These are different representation choices, not stages of one query.

Study-note section FDB-S02

> Richer relational types do not by themselves require all data to form a parent-child tree; that representation is the defining concern of hierarchical modeling.

Study-note section FDB-S02

> An object-relational DBMS retains relational data management while supporting richer extensions such as user-defined data types, functions and operators.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 7 | lines 8-19

> Types of Data Models 1. High-level or conceptual data models provide concepts that are close to the way many users perceive data. Entity - Relationship (E/R) model and Object-Oriented Model are examples of conceptual/high level data model. 2. Low-level or physical data models provide concepts that describe the details of how data is stored on the computer storage media. Concepts provided by physical data models are generally meant for computer specialists, not for end users. 3. representational (or implementation) data model provides concepts that may be easily understood by end users but that are not too far from the way data is organized in computer

> storage. Representational data models hide many details of data storage on disk but can be implemented on a computer system directly. The widely used relational data models are the network and hierarchical.

Fundamental of Database Systems module | PDF page 13 | lines 5-8

> Subclasses and super classes can be thought as useful ways to describe similarities in the entities represented. Because subclasses inherit their attributes and relationships from the superclass, the database designer can represent complex, hierarchical interdependencies (inheritance) within the system being described.

Question sources

Computer Science MCQ practice collection · Question 180

Question 207 | AM0181

Which benefit directly follows from reducing dependency-driven insertion, deletion and update anomalies through normalization, without assuming reduced storage or simpler queries?

A. Simplified data retrieval

B. Increased data redundancy

C. Enhanced data integrity

D. Reduced storage requirements

Hint

Distinguish dependency-based design problems from the contents of one sample table.

Answer C: C. Enhanced data integrity

Normalization separates facts according to their determinants, reducing repeated facts and the insertion, deletion and update anomalies they cause. That directly supports enhanced data integrity. Storage savings and simpler retrieval are not guaranteed because decomposition can introduce additional keys and joins. Increased redundancy is opposite to the intended reduction of avoidable repetition, so it is not the benefit identified by this question.

Why each choice is right or wrong

A - Incorrect: Normalized retrieval may require more joins, so simplification does not follow.

B - Incorrect: Normalization aims to reduce avoidable repetition.

C - Correct: Reducing inconsistent updates and related anomalies improves integrity.

D - Incorrect: Storage savings can be offset by extra keys and relation overhead.

Primary note proof

Study-note section FDB19

> Suppose Enrollment repeats StudentName for every course. An update anomaly requires changing every copy of the student's name; missed copies disagree. An insertion anomaly

prevents recording a new student until some enrollment exists. A deletion anomaly loses the only record of a student's details when their last enrollment is deleted. Revoke anomaly is not a normalization anomaly.

Study-note section FDB19

Normalization separates facts according to their determinants, reducing avoidable repetition and associated anomalies.

Study-note section FDB19

Reduced redundancy can improve integrity and storage use, but extra keys and joins mean neither storage savings nor faster retrieval is guaranteed.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 16 | lines 5-29

4.3 Database Anomalies Database Anomalies are the flaws in databases which occurs because of poor database design and storing everything in a single flat database. They are problems that are caused usually by redundant data. Types of database anomalies are Insertion anomaly, Deletion anomaly, and Update anomaly. Insertion Anomaly - occurs when the entire primary key is not known and the database cannot insert a new record properly. This would violate entity integrity. It can be avoided by using a sequence number for the primary key. Deletion Anomaly - happens when a record is deleted that results in the loss of other related data. It can be avoided by normalizing tables in a database to minimize their dependency. Update Anomaly - occurs when a change to one attribute value causes the database to either contain inconsistent data or causes multiple records to need changing. It may be prevented by making sure tables are in third normal form. 4.4 Normalization Normalization is a process of organizing the data in database to avoid data redundancy, insertion anomaly, update anomaly & deletion anomaly. It is a technique of organizing the data in the database. It is a systematic approach of decomposing tables to eliminate data redundancy (repetition) and undesirable characteristics like Insertion, Update and Deletion Anomalies. It is a multi-step process that puts data into tabular form, removing duplicated data from the relation tables. Normal forms Redundancy in a relation may causes insertion, deletion, and update anomalies. Normalization is database design technique that minimizes redundancy from a relation or a set of relations. Normalization rules divides larger tables into smaller tables and links them using relationship. Normal Forms are maintenance rules that are used to eliminate or reduce the redundancy in database relations. These normal forms are 1NF (First Normal Form), 2NF (Second Normal Form)

Question sources

Computer Science MCQ practice collection · Question 181

Question 208 | AM0182

Which database design concept allows the division of a large database into smaller, manageable units?

A. Data partitioning

B. Database replication

C. Data migration

D. Data archiving

Hint

Distinguish logical records, disk pages and physical file organization.

Answer A: Data partitioning.

FDB24 explicitly contrasts partitioning, replication, migration and archiving. Partitioning divides the dataset into smaller portions, matching the question. Replication makes additional copies, migration moves data, and archiving takes older data out of active service. Those operations can accompany partitioning, but none of them defines division into manageable units.

Why each choice is right or wrong

A - Correct: Partitioning divides a large dataset into smaller portions or manageable units.

B - Incorrect: Replication creates copies rather than dividing the original dataset into distinct units.

C - Incorrect: Migration moves data to another location or system rather than defining a split.

D - Incorrect: Archiving removes older data from active service rather than generally dividing the database.

Primary note proof

Study-note section FDB24

> A page/block is a unit of database I/O and holds several records. For fixed unspanned records of size r in usable page space B, the blocking factor is floor(B/r), and n records occupy ceil(n/blocking factor) pages. Page headers and slots reduce usable space.

Study-note section FDB24

> Partitioning splits a large dataset; replication copies it; migration moves it; archiving removes older data from active service.

Study-note section FDB24

> A heap has no search-key order and supports simple inserts, but searches may scan all pages.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 117 | lines 15-30

6.2 Data Replication and Fragmentation: Distributed data storage • There are two approaches to store the relation in the distributed database : Replication and Fragmentation I. Data Replication • The system maintain several identical copies of the relation & store each copy at a different site • In general it enhance the performance of read operation and increase the availability of data to read only transaction. However, update transactions incur greater overhead II. Data Fragmentation - Split a relation into logically related and correct parts. - The main reasons for fragmenting a relation are • Efficiency- data that is not needed by the local applications is not stored • Parallelism - a transaction can be divided into several subqueries that operate on fragments which will increase the degree of concurrency - but reconstruction of the whole relation will require accessing data from all sites

Fundamental of Database Systems module | PDF page 118 | lines 2-18

• A relation can be fragmented in two ways: • Horizontal fragmentation • It is a horizontal subset of a relation which contain those of rows which satisfy selection conditions. • Consider the Employee relation with selection condition (DNO = 5). All rows satisfy this condition will create a subset which will be a horizontal fragment of Employee relation. • A selection condition may be composed of several conditions connected by AND or OR. • Vertical fragmentation • It is a subset of a relation which is created by a subset of columns. Thus a vertical fragment of a relation will contain values of selected columns. - Consider the Employee relation. A vertical fragment of can be created by keeping the values of Name, Bdate, Sex, and Address. - Because there is no condition for creating a vertical fragment, each fragment must include the primary key attribute of the parent relation Employee. In this way all vertical fragments of a relation are connected.

Computer Science MCQ practice collection · Question 182

Question 209 | AM0183

Which database design technique is used to capture the relationships between entities in a graphical representation?

A. Relational data modeling

B. Entity-Relationship (ER) modeling

C. Object-oriented data modeling

D. Document data modeling

Hint

Review entity, attribute and relationship notation before interpreting the model.

Answer B: Entity-Relationship (ER) modeling

ERD is explicitly a graphical database-schema technique showing modeled entities and their important relationships. This directly establishes ER modeling for the graphical representation asked about.

Why each choice is right or wrong

A - Incorrect: Relational modeling describes tables; ERD is the named graphical technique. (PDF pp. 9.)

B - Correct: ER modeling is the explicit graphical entities/relationships technique. (PDF pp. 9.)

C - Incorrect: Object-oriented is named but not the described ERD technique. (PDF pp. 9.)

D - Incorrect: Document modeling is not the technique defined in the module. (PDF pp. 9.)

Primary note proof

Study-note section FDB06

> An entity is a distinguishable real or conceptual thing, such as one student or one course. An entity type describes common properties; its current collection of entities is an entity set. A relationship associates entities. In Chen notation rectangles represent entity types, diamonds relationships and ellipses attributes; double ellipses denote multivalued attributes and dashed ellipses derived attributes. Always inspect the diagram legend.

Study-note section FDB02

> Conceptual ER models describe entities and relationships.

Study-note section FDB02

> Relational models use tables; hierarchical models organize records in a parent-child tree; classic network models connect records through pointer-based owner/member links, allowing multiple parents.

> 3.3 ERD (Entity Relationship Diagram) ERD a graphical technique for representing a database schema. It is a modeling tool used to depict graphically a DB design before it is actually implemented. It shows the various entities being modeled and the important relationships among them. ERD has three basic components Entity, Relationship and Attribute.

Question sources

Computer Science MCQ practice collection · Question 183

Question 210 | CS0049

In contrary to the traditional file-based approach, in the database approach:

A. Programs define and access their own data

B. Store data items in multiple copies

C. Don't care about the definition of programs and data

D. Data and programs are defined independently

Hint

Trace which schema levels a proposed change affects.

Answer D: Data and programs are defined independently

The database approach insulates programs from data definitions and supports data independence. This is the relevant distinction from programs managing their own files.

Why each choice is right or wrong

A - Incorrect: Own program-specific definitions do not express the database approach's insulation. (PDF pp. 5, 6, 8.)

B - Incorrect: Multiple uncontrolled copies are not the defining benefit and can cause inconsistency. (PDF pp. 5, 6, 8.)

C - Incorrect: The approach explicitly maintains metadata and definitions, not indifference to them. (PDF pp. 5, 6, 8.)

D - Correct: Independent definitions match program/data insulation and independence. (PDF pp. 5, 6, 8.)

Primary note proof

Study-note section FDB04

> Physical data independence permits changing internal storage without changing the conceptual schema, for example adding an index. Logical data independence permits conceptual changes while preserving affected external views and application interfaces, for example splitting a table while maintaining a compatible view. It is harder because applications depend on logical meaning. Data abstraction hides irrelevant details; program-data insulation separates data definitions from application code.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 5 | lines 17-25

> 1.2 Database System versus File System The traditional file processing system is file-directory structure supported by a conventional operating system. A file system organization of data lucks a number of major features of a database system, such as Data redundancy and inconsistency, Difficulty in accessing data, Data isolation, Integrity problems, Atomicity problems, Concurrent access anomalies. 1.3 Characteristics of the Database Approach The main characteristics of the database approach are Self-describing nature, Data abstraction and Insulation between programs and data, Support of multiple views of the data, sharing of data and multiuser transaction processing.

Fundamental of Database Systems module | PDF page 6 | lines 2-4

> Data abstraction and Insulation between programs and data- Data Abstraction is a process of hiding unwanted or irrelevant details from the end user. It provides a different view and helps in achieving data independence which is used to enhance the security of data.

Fundamental of Database Systems module | PDF page 8 | lines 8-15

2.4 Data Independence The three-schema architecture can be used to further explain the concept of data independence, which can be defined as the capacity to change the schema at one level of a database system without having to change the schema at the next higher level. The two types of data independence: 1. Logical data independence is the capacity to change the conceptual schema without having to change external schemas or application programs. 2. Physical data independence is the capacity to change the internal schema without having to change the conceptual schema. Hence, the external schemas do not need be changed as well.

Question sources

Computer Science Exit Exam practice collection · Question 49

Question 211 | CS0050

Assume you are a database designer and you are given a task to specify entities, relationships, constraints on relations and data types for the data to be stored. At which level of the three-schema architecture
would this be addressed?

A. View level

B. Internal level

C. External level

D. Conceptual level

Hint

Trace which schema levels a proposed change affects.

Answer D: Conceptual level

The conceptual level describes the whole database and explicitly concentrates on entities, data types, relationships, operations and constraints while hiding physical storage. The stem repeats those conceptual responsibilities.

Why each choice is right or wrong

A - Incorrect: View level shows a user-group subset. (PDF pp. 7, 8.)

B - Incorrect: Internal level describes physical storage and access paths. (PDF pp. 7, 8.)

C - Incorrect: External is another name for user view, not the global description. (PDF pp. 7, 8.)

D - Correct: Conceptual is the level explicitly listing the requested structural components. (PDF pp. 7, 8.)

Primary note proof

Study-note section FDB04

The external level gives each user group a selected view. The conceptual level describes the whole logical database: entity types, relationships, data types and constraints. The

internal/physical level describes files, record placement and access paths. These are abstraction levels, distinct from client/server deployment tiers.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 7 | lines 25-30

2.3 Three-schema Architecture and Data Independence The goal of the three-schema architecture is to separate the user applications from the physical database. In this architecture, schemas can be defined at the following three levels: 1. The internal level has an internal schema, which describes the physical storage structure of the database. The internal schema uses a physical data model and describes the complete details of data storage and access paths for the database.

Fundamental of Database Systems module | PDF page 8 | lines 2-7

2. The conceptual level has a conceptual schema, which describes the structure of the whole database for users. The conceptual schema hides the details of physical storage structures and concentrates on describing entities, data types, relationships, user operations, and constraints. 3. The external or view level includes a number of external schemas or user views. Each external schema describes the part of the database that a particular user group is interested in and hides the rest of the database from that user group.

Question sources

Computer Science Exit Exam practice collection · Question 50

Question 212 | NS0217

What is the purpose of normalization in database design?

A. To reduce redundancy and improve data integrity

B. To speed up query performance

C. To create complex relationships between tables

D. To encrypt sensitive data

Hint

Distinguish dependency-based design problems from the contents of one sample table.

Answer A: Reduce avoidable redundancy and associated integrity anomalies.

FDB19 defines normalization as separating facts according to their determinants, reducing avoidable repetition and insertion, deletion and update anomalies. That supports both parts of A. It does not promise universally faster queries, deliberately create complexity for its own sake or encrypt content. Performance and security need their own workload and threat-model choices.

Why each choice is right or wrong

A - Correct: Normalization reduces repeated facts and the anomalies that threaten data consistency.

B - Incorrect: More joins may be needed, so faster query execution is not a universal normalization purpose.

C - Incorrect: Relationships follow fact dependencies; creating complexity is not the goal.

D - Incorrect: Normalization restructures facts and does not encrypt sensitive values.

Primary note proof

Study-note section FDB19

> Suppose Enrollment repeats StudentName for every course. An update anomaly requires changing every copy of the student's name; missed copies disagree. An insertion anomaly prevents recording a new student until some enrollment exists. A deletion anomaly loses the only record of a student's details when their last enrollment is deleted. Revoke anomaly is not a normalization anomaly.

Study-note section FDB19

> Normalization separates facts according to their determinants, reducing avoidable repetition and associated anomalies.

Study-note section FDB19

> Adding a generated row ID may make insertion technically possible, but does not remove repeated facts or fix the dependency design.

Question sources

Computer Science Exit Exam practice collection · Question 53

Question 213 | NS0295

A weak entity uses its partial key together with the key of an independently keyed owner. Which terms describe that associated entity set? Select all that apply.

A. Identifying set

B. Strong entity set

C. Neighbor set

D. Owner set

Hint

Check how a dependent entity obtains its complete identity.

Answer B, D: B. Strong entity set; D. Owner set

The weak entity lacks a complete independent identifier. Its owner's key combines with the partial key to identify it. Because the owner is independently keyed in this question, strong entity set and owner set both describe the associated set. Identifying describes the relationship connecting the sets, while neighbor does not state the necessary ownership and identification dependency.

Why each choice is right or wrong

A - Incorrect: Identifying is normally the relationship role rather than the defined name of the owner entity set.

B - Correct: The owner that supplies an independent identifying key is normally a strong entity set.

C - Incorrect: Neighbor does not express the necessary ownership and identification dependency.

D - Correct: Owner set is the associated entity set whose key identifies the weak entity together with its partial key.

Primary note proof

Study-note section FDB08

> A weak entity lacks a complete independent key. Its owner is normally a strong entity, so owner entity set and strong entity set may both describe the associated set. Its partial key, also called discriminator, distinguishes weak entities of the same owner. Identification combines the owner key and partial key.

Study-note section FDB08

> The weak entity participates totally in its identifying relationship.

Study-note section FDB08

> Chen notation uses a double rectangle, double identifying diamond and dashed underline for a partial key.

Question sources

Computer Science Exit Exam · 2018 · Question 12

Question 214 | NS0297

A language that allows the DBA or user to describe and name the entities, attributes, and relationships required for the application is_____

A. Transaction control language (TCL)

B. Data control language (DCL)

C. Data Manipulation Language (DML)

D. Data Definition Language (DDL)

Hint

Classify each SQL command by the kind of change it performs.

Answer D: Data Definition Language.

Describing and naming application entities, attributes and relationships defines schema structure. FDB26 assigns structural changes to DDL through CREATE, ALTER and DROP. TCL manages transaction boundaries, DCL controls privileges and DML retrieves or changes data. These categories have different effects, so DDL uniquely matches the schema-description role in the stem.

Why each choice is right or wrong

A - Incorrect: TCL manages commit, rollback and savepoints rather than defining schema elements.

B - Incorrect: DCL manages privileges through GRANT and REVOKE rather than describing entities and attributes.

C - Incorrect: DML retrieves or changes instance data rather than defining the application schema.

D - Correct: DDL defines and changes schema structure, including tables, attributes and constraints.

Primary note proof

Study-note section FDB26

> DDL changes structure: CREATE, ALTER, DROP, commonly RENAME and TRUNCATE in textbook classifications. DML retrieves or changes data: SELECT, INSERT, UPDATE, DELETE. Some texts separate SELECT as DQL. DCL manages privileges through GRANT and REVOKE. TCL includes COMMIT, ROLLBACK and SAVEPOINT. Classify a statement by its effect, not its length.

Question sources

Computer Science Exit Exam · 2018 · Question 14

Question 215 | NS0302

In relational-table terminology, which terms describe a unit of related field values treated together by an application? Select all that apply.

A. Rows

B. Field

C. Record

D. Database

Hint

Distinguish a relation's structure from its current contents and its descriptive metadata.

Answer A, C: A. Rows; C. Record

A tuple holds a set of related attribute values as one table unit. Row and record are synonymous names for that unit, so both alternatives qualify. A field is only an individual property, and a database is the larger coherent collection of related data. Grammatical number in Rows does not create a different relational concept from Record.

Why each choice is right or wrong

A - Correct: Rows contain related field values and are the relational counterpart of records.

B - Incorrect: A field is an individual property rather than a collection of related fields.

C - Correct: Record is the stated unit that groups related fields for application use.

D - Incorrect: A database contains a larger coherent collection of data rather than just one record.

Primary note proof

Study-note section FDB03

> A relation is a set of tuples, represented as a table. A tuple/row/record contains related attribute values; an attribute/column/field describes a property. Degree counts columns; cardinality counts rows. Classical relations have distinct tuples, atomic cells and domains for attributes; row order has no meaning. Column order has no logical meaning when attributes are identified by name. SQL tables can contain duplicate rows unless constrained.

Question sources

Computer Science Exit Exam · 2018 · Question 20

Question 216 | NS0315

Which template creates a table with one column? Treat table_name, column_name and column_type as placeholders for valid identifiers and a data type.

A. CREATE table_name (column_name, column type);

B. CREATE table_name (column_type, column name);

C. CREATE TABLE table_name (column_name column_type);

D. CREATE TABLE table_name (column_type, column name);

Hint

Distinguish table definition changes from changes to stored rows.

Answer C: C. CREATE TABLE table_name (column_name column_type);

CREATE TABLE introduces a new table definition. Within its parentheses, each column declaration places the column name before its data type, without a comma between those two parts. Commas separate whole declarations. Option C matches this pattern. A and B omit TABLE, while D reverses and separates the intended name/type pair and therefore fails the requested template.

Why each choice is right or wrong

A - Incorrect: TABLE is absent and the column declaration is split incorrectly.

B - Incorrect: TABLE is absent and the name/type order is reversed.

C - Correct: The name/type pair forms one complete column declaration.

D - Incorrect: The type/name order and comma do not form the intended declaration.

Primary note proof

Study-note section FDB30

> CREATE TABLE Employee (EmpID INTEGER PRIMARY KEY, Name VARCHAR(80)); declares two columns. The name and its type stay together; the comma separates whole column declarations. To add a primary key later: ALTER TABLE Employee ADD PRIMARY KEY (EmpID); existing data must be unique and non-NULL. A table cannot gain a second primary key without replacing the existing constraint.

Question sources

Computer Science Exit Exam · 2018 · Question 40

Question 217 | NS0320

From the following alternatives which one is FALSE about database system?

A. It is very difficult to protect a file under the system

B. In database system the user is not required to write the procedures

C. In database system, DBMS provides a good protection mechanism.

D. It contains a wide variety of sophisticated techniques to store and retrieve the data.

Hint

Review the database approach and match each claimed benefit or cost to its mechanism.

Answer A: The claim that protection is very difficult under a database system is false.

FDB01 contrasts unmanaged file difficulties with DBMS authorization, shared integrity, transactions and recovery. A therefore reverses a stated database benefit. B is understood in the data-access sense: declarative requests need not prescribe retrieval procedures, as FDB36 explains; it does not mean applications never contain code. Protection and sophisticated storage/access facilities in C and D are consistent with the note.

Why each choice is right or wrong

A - Correct: This reverses the note's benefit: a DBMS provides coordinated protection rather than inherently making protection very difficult.

B - Incorrect: Declarative data requests need not prescribe retrieval procedures; this does not exclude ordinary application code.

C - Incorrect: Authorization and controlled data access are explicit DBMS protection mechanisms.

D - Incorrect: DBMS storage and access facilities include indexes, buffers, query processing and other sophisticated mechanisms.

Primary note proof

Study-note section FDB01

> A database is a coherent collection of related facts with meaning for an application. A DBMS is software that defines, stores, retrieves, updates, protects and shares that data. The database is the content; the DBMS manages it. A database system also includes applications, people and infrastructure.

Study-note section FDB01

> Traditional file applications define their own formats and access procedures.

Study-note section FDB01

> A DBMS centralizes metadata and supports multiple views, authorization, transactions, backup and recovery.

Question sources

Computer Science Exit Exam · 2018 · Question 45

Question 218 | NS0329

Consider a directed line(->) from the relationship set advisor to both entity sets instructor and student. This indicates _____ cardinality

A. Many to one

B. Many to many

C. One to one

D. One to many

Hint

Read the relationship in both directions and check participation constraints.

Answer C: One-to-one under the common ER arrow convention.

FDB09 explicitly discusses arrows from advisor to both Instructor and Student. Under its common convention, each arrow imposes a maximum of one on the corresponding end. Both ends are therefore maximum-one, producing 1:1. This does not imply total participation, and another diagram notation would require a legend, but the complete note supplies the convention for this example.

Why each choice is right or wrong

A - Incorrect: Many-to-one permits many at one end, contrary to maximum-one arrows at both ends.

B - Incorrect: Many-to-many imposes neither of the maximum-one constraints stated by the arrows.

C - Correct: Maximum one at both ends produces a one-to-one relationship.

D - Incorrect: One-to-many permits multiple associations at one end rather than maximum one at both.

Primary note proof

Study-note section FDB09

> Read business rules in both directions. If each employee belongs to one department and each department has many employees, Employee→Department is N:1; Department→Employee is 1:N. Building→Location could also be N:1, so names alone cannot select a unique example. Under the common arrow convention, arrows from advisor to both Instructor and Student impose maximum-one at both ends, giving 1:1. Without a notation convention, arrows are unsafe evidence.

Question sources

Computer Science Exit Exam · 2018 · Question 56

Question 219 | NS0339

What is the basic goal of Normalization?

A. To decrease data integrity

B. To reduce redundancy

C. To maximize transitive dependency

D. To increase dependency

Hint

Distinguish dependency-based design problems from the contents of one sample table.

Answer B: Reduce avoidable redundancy.

Normalization separates facts by their determinants to reduce repeated storage and the anomalies that repetition can cause. FDB19 therefore supports reducing redundancy as the basic listed goal. Decreasing integrity is the opposite intended effect, and maximizing transitive or unspecified dependencies is not a normalization objective. Proper dependencies are analyzed rather than increased indiscriminately.

Why each choice is right or wrong

A - Incorrect: Normalization aims to improve integrity by reducing anomalies, not decrease it.

B - Correct: Reducing avoidable repeated facts is a basic normalization goal.

C - Incorrect: Problematic nonkey transitive dependencies are removed or separated rather than maximized.

D - Incorrect: Dependencies are analyzed to place facts correctly; increasing them indiscriminately is not the objective.

Primary note proof

Study-note section FDB19

> Suppose Enrollment repeats StudentName for every course. An update anomaly requires changing every copy of the student's name; missed copies disagree. An insertion anomaly prevents recording a new student until some enrollment exists. A deletion anomaly loses the only record of a student's details when their last enrollment is deleted. Revoke anomaly is not a normalization anomaly.

Study-note section FDB19

> Normalization separates facts according to their determinants, reducing avoidable repetition and associated anomalies.

Study-note section FDB21

> Remove dependencies of nonprime facts on nonkey determinants.

Question sources

Computer Science Exit Exam · 2018 · Question 70

Question 220 | NS0344

For a relation with ID, CITY and NAME, ID is guaranteed unique and non-NULL while CITY and NAME may repeat. Which listed sets are superkeys? Select all that apply.

A. NAME

B. ID

C. CITY

D. CITY, ID

Hint

Test uniqueness and minimality separately when classifying keys.

Answer B, D: B. ID; D. CITY, ID

A superkey is any set of attributes guaranteed to identify a tuple. ID has that guarantee, and the larger set containing CITY and ID keeps it. Both sets therefore qualify, even though the larger one is not minimal. CITY and NAME may repeat and cannot independently identify all tuples. Minimality would distinguish candidate keys, but it is not required for superkeys.

Why each choice is right or wrong

A - Incorrect: Repeated names are permitted, so NAME is not guaranteed unique.

B - Correct: ID uniquely identifies every tuple.

C - Incorrect: Repeated cities are permitted, so CITY is not guaranteed unique.

D - Correct: Including unique ID preserves identification even with the extra CITY attribute.

Primary note proof

Study-note section FDB07

> A superkey uniquely identifies a tuple. A candidate key is a minimal superkey: removing any component loses uniqueness. Minimal means no unnecessary attribute, not necessarily the fewest columns among all keys. A primary key is one selected candidate key; remaining candidates are alternate keys. A composite key contains multiple attributes and need not be the chosen primary key.

Study-note section FDB07

> If ID is unique, both {ID} and {ID,City} are superkeys, but only {ID} is minimal.

Study-note section FDB07

> A table can have several candidates and foreign keys but at most one declared primary-key constraint, possibly containing several columns.

Question sources

Computer Science Exit Exam · 2018 · Question 77

Question 221 | NS0357

_____is one of the candidate keys chosen by the database designer to uniquely identify the entity set.

A. Super key

B. Candidate key

C. Social security key

D. Primary key

Hint

Test uniqueness and minimality separately when classifying keys.

Answer D: Primary key.

FDB07 defines a primary key as the selected candidate key, with the remaining candidates called alternate keys. The stem asks specifically for the designer's selection rather than every unique attribute set. Superkey is broader and candidate key denotes eligibility before selection. A social-security identifier could be chosen, but is not the generic name of that role.

Why each choice is right or wrong

A - Incorrect: A superkey is any unique identifier set and may include unnecessary attributes.

B - Incorrect: Candidate keys are eligible minimal identifiers, not specifically the one selected for the primary role.

C - Incorrect: A social-security identifier is a possible attribute choice, not the generic selected-key category.

D - Correct: The selected candidate key is the primary key.

Primary note proof

Study-note section FDB07

> A superkey uniquely identifies a tuple. A candidate key is a minimal superkey: removing any component loses uniqueness. Minimal means no unnecessary attribute, not necessarily the fewest columns among all keys. A primary key is one selected candidate key; remaining candidates are alternate keys. A composite key contains multiple attributes and need not be the chosen primary key.

Question sources

Computer Science Exit Exam · 2018 · Question 95

Question 222 | NS0627

What is the difference between a primary key and a foreign key?

Hint

Test uniqueness and minimality separately when classifying keys.

Answer: A primary key is the selected unique non-NULL identifier; a foreign key references an eligible key.

FDB07 defines the primary key as a selected candidate key. FDB15 requires non-NULL foreign-key values to match an eligible referenced unique/candidate key; foreign keys need not be unique and may permit NULL.

Primary note proof

Study-note section FDB07

> A superkey uniquely identifies a tuple. A candidate key is a minimal superkey: removing any component loses uniqueness. Minimal means no unnecessary attribute, not necessarily the fewest columns among all keys. A primary key is one selected candidate key; remaining candidates are alternate keys. A composite key contains multiple attributes and need not be the chosen primary key.

Study-note section FDB15

> Referential integrity requires a non-NULL foreign-key value to match an eligible referenced unique/candidate key; self-references are allowed.

Study-note section FDB15

> Entity integrity requires every primary-key component to be non-NULL.

Related reading (context, not primary note proof)

Study-note section FDB16

Question sources

Database Fundamentals review questions · Question 1

Question 223 | NS0628

Why is database normalization important? What problems does it solve?

Hint

Distinguish dependency-based design problems from the contents of one sample table.

Answer: Normalization reduces repeated facts and insertion, deletion and update anomalies.

Repeating a student name across enrollments risks inconsistent updates, prevents storing some facts without unrelated rows and can lose a fact when its last repeated row is deleted. Normalization separates facts by their determinants to reduce these anomalies.

Primary note proof

Study-note section FDB19

> Suppose Enrollment repeats StudentName for every course. An update anomaly requires changing every copy of the student's name; missed copies disagree. An insertion anomaly prevents recording a new student until some enrollment exists. A deletion anomaly loses the only record of a student's details when their last enrollment is deleted. Revoke anomaly is not a normalization anomaly.

Study-note section FDB19

> Normalization separates facts according to their determinants, reducing avoidable repetition and associated anomalies.

Study-note section FDB19

> Adding a generated row ID may make insertion technically possible, but does not remove repeated facts or fix the dependency design.

Question sources

Database Fundamentals review questions · Question 2

Question 224 | NS0629

What happens if you UPDATE a row but forget to include a WHERE clause?

Hint

Track which rows each data-changing command affects.

Answer: UPDATE without WHERE targets every row, subject to constraints and transaction outcome.

FDB29 states that an UPDATE without WHERE targets every row. The SET expressions are therefore applied to all rows rather than one intended row; constraints or errors can still prevent completion.

Primary note proof

Study-note section FDB29

> INSERT INTO Hotel(HotelID,HotelName,SubCity) VALUES (1,'Hilton','Yeka'); pairs each named column with a compatible value. Counts and types must match; keys and other constraints still apply. Without a column list, values must follow the table's declared column order.

Study-note section FDB29

> UPDATE without WHERE targets every row.

Study-note section FDB29

> UPDATE Book SET Price = 600 WHERE ID = 'B001'; changes matching rows.

Related reading (context, not primary note proof)

Study-note section FDB16

Question sources

Database Fundamentals review questions · Question 3

Question 225 | NS0630

Why would you use a ROLLBACK command in a transaction?

Hint

Match each transaction guarantee to its precise failure or interference scenario.

Answer: ROLLBACK undoes uncommitted transaction work, for example after a failure or unwanted change.

FDB37 contrasts COMMIT, which completes transaction work, with ROLLBACK, which undoes uncommitted work. Rollback restores the prior transactional state after errors or a decision not to keep the changes; it does not erase other users' committed transactions.

Primary note proof

Study-note section FDB37

> For a transfer, subtracting 100 from one balance and adding 100 to another must commit together; losing either half violates atomicity and may violate the total-balance invariant. BEGIN starts work, COMMIT completes it, ROLLBACK undoes uncommitted work and SAVEPOINT marks an intermediate rollback point. A failed transaction may roll back while other users' committed transactions remain. SQL transaction syntax and error-handling constructs differ by DBMS; @@ERROR/IF is SQL Server-specific.

Question sources

Database Fundamentals review questions · Question 4

Question 226 | NS0631

What is the difference between DELETE and DROP?

Hint

Classify each SQL command by the kind of change it performs.

Answer: DELETE removes rows and retains the table; DROP TABLE removes the table object.

FDB26 distinguishes data deletion from structural removal. DELETE may target selected rows with WHERE, or all rows without it, while leaving the table defined. DROP TABLE removes that relation object.

Primary note proof

Study-note section FDB26

> DELETE removes rows and keeps the table; DROP TABLE removes the table object; ALTER changes its definition. TRUNCATE empties a table using implementation-specific mechanisms. PostgreSQL allows transactional rollback of TRUNCATE, so no rollback information is retained is not a universal SQL property. SQL Server permits DROP DATABASE Sales, suppliers; that comma-list syntax is vendor-specific. SQLite's .databases lists attached names/files in its command-line shell; .database is not the documented command.

Study-note section FDB29

> UPDATE without WHERE targets every row.

Study-note section FDB29

> DELETE FROM r; removes every row but leaves r defined.

Questions & Worked Answers

239 questions + 4 source variants

Question 1 | Q00005

_____ is the process of selecting appropriate query execution strategy?

A. Query graph

B. Query optimization

C. Query tree

D. Query processing

Hint

Separate query representation, strategy selection and execution.

Answer B: Query optimization

Selecting an efficient execution strategy is optimization. A tree or graph represents the query; processing is the broader transformation and execution activity.

Why each choice is right or wrong

A - Incorrect: A graph corresponds to relational calculus, not strategy selection. (PDF pp. 27, 34.)

B - Correct: The module explicitly defines optimization as choosing an efficient strategy. (PDF pp. 27, 34.)

C - Incorrect: A query tree represents relational algebra and operations. (PDF pp. 27, 34.)

D - Incorrect: Processing includes decomposition and execution as well as optimization. (PDF pp. 27, 34.)

Primary note proof

Study-note section ADB17

> Parsing checks SQL grammar; semantic analysis resolves names, types and access permissions. Translation constructs a logical representation, typically relational algebra or a logical query tree. Optimization chooses equivalent operations, join order and physical access methods. Evaluation executes that plan and returns results. Not every implementation exposes exactly the same phase boundaries.

Study-note section ADB17

> Query processing is the whole activity; selecting a suitable efficient strategy is optimization.

Study-note section ADB-S01

A query graph represents the predicate relationships of a relational-calculus expression without itself prescribing an operator execution order.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 27 | lines 7-13

What is Query Optimization?
✓ The activity of choosing a single —efficient‖ execution strategy (from hundreds) as determined by database catalog statistics.
✓ The aim is to answer which relational algebra expression, equivalent to the given query, will lead to the most efficient solution plan?
✓ For each algebraic operator, what algorithm (of several available) do we use to compute that operator?

Fundamental of Database Systems module | PDF page 34 | lines 5-7

2. Apply heuristics rules to optimize the internal representation.
3. A query execution plan is generated to execute groups of operations based on the access paths available on the files involved in the query.

Fundamental of Database Systems module | PDF page 34 | lines 17-27

• Query tree:
1. A tree data structure that corresponds to a relational algebra expression. It represents the input relations of the query as leaf nodes of the tree, and represents the relational algebra operations as internal nodes.
• An execution of the query tree consists of executing an internal node operation whenever its operands are available and then replacing that internal node by the relation that results from executing the operation.
• Query graph:
1. A graph data structure that corresponds to a relational calculus expression. It does not indicate an order on which operations to perform first. There is only a single graph corresponding to each query.

Question sources

MOE Computer Science Exit Exam · 2016 · Question 5

Question 2 | Q00022

Which update-timing policy permits a transaction's changes to reach the persistent database before the transaction commits?

A. In-Place Update

B. Immediate update

C. Shadow update

D. Deferred update

Hint

Separate update timing from update location and follow the commit boundary.

Answer B: Immediate update

Immediate update permits a transaction's changes to be written to the persistent database before commit. If that transaction later aborts, recovery may need to undo those changes. Deferred update keeps uncommitted changes outside the persistent database. In-place update describes overwriting an existing location, while shadow update describes writing a separate version. Those location strategies do not, by their names alone, specify the timing policy requested here. Immediate update need not flush every cache write immediately.

Why each choice is right or wrong

A - Incorrect: Describes overwriting the existing location, not the commit-timing policy.

B - Correct: Correct: immediate update permits persistent database changes before commit and may require undo.

C - Incorrect: Describes writing a separate version while preserving the committed one, not the requested timing policy.

D - Incorrect: Deferred update excludes uncommitted changes from the persistent database.

Primary note proof

Study-note section ADB29

> Deferred update keeps uncommitted changes outside the persistent database; in the usual no-force setting it is NO-UNDO/REDO. Redo-only and NO-UNDO/REDO mean the same thing, so those cannot be separate unique answers. Immediate update allows persistent changes before commit and therefore may require undo; it need not flush every write_item immediately.

Study-note section ADB29

> Shadow/copy-on-write update writes a new location while preserving the committed version.

Study-note section ADB29

> In-place update overwrites the original location.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 110 | lines 14-30

> ◦ Deferred Update:
> • All transaction updates are recorded in the local workspace (cache)
> • All modified data items in the cache is then written after a transaction ends its execution or after a fixed number of transactions have completed their execution.
> • During commit the updates are first recorded on the log and then on the database
> • If a transaction fails before reaching its commit point undo is not needed

because it didn‘t change the database yet
• If a transaction fails after commit (writing on the log) but before finishing saving to the data base redoing is needed from the log
◦ Immediate Update:
• As soon as a data item is modified in cache, the disk copy is updated.
• These update are first recorded on the log and on the disk by force writing, before the database is updated
• If a transaction fails after recording some change to the database but before reaching its commit point , this will be rolled back

Fundamental of Database Systems module | PDF page 111 | lines 2-11

◦ Shadow update:
• The modified version of a data item does not overwrite its disk copy but is written at a separate disk location.
• Multiple version of the same data item can be maintained
• Thus the old value (before image BFIM) and the new value (AFIM) are kept in the disk
• No need of Log for recovery
◦ In-place update: The disk version of the data item is overwritten by the cache version.
• Information for ARIES to accomplish recovery procedures includes:

Question sources

MOE Computer Science Exit Exam · 2016 · Question 22

Question 3 | Q00026

Which query-optimization approach applies relational-algebra properties and equivalences to rewrite a query and reduce intermediate work?

A. Database storage without query rewriting

B. Heuristic approach

C. Deterministic execution without query rewriting

D. Physical-plan cost estimation

Hint

Consider which equivalent transformation changes intermediate work and what assumptions preserve meaning.

Answer B: Heuristic approach

Heuristic optimization uses algebraic rules to reduce intermediate work, for example applying selective filters earlier, replacing a product plus join predicate with a join and projecting away unneeded columns. Storage and execution without rewriting do not perform those transformations. Cost estimation predicts resources for candidate plans rather than naming the algebraic rewrite approach itself. A practical optimizer can combine rewriting and costing, but the question isolates the rule-based transformation role.

Why each choice is right or wrong

A - Incorrect: Incorrect: storage without rewriting does not transform the algebraic query representation.

B - Correct: Correct: heuristic rewriting uses operator properties and equivalences to reduce intermediate work.

C - Incorrect: Incorrect: repeatable execution without rewriting does not apply the requested query transformations.

D - Incorrect: Incorrect: cost estimation predicts candidate-plan resource use rather than identifying the algebraic rewrite approach.

Primary note proof

Study-note section ADB18

> Heuristics reduce intermediate work: push selective row filters toward base tables; replace product followed by a join predicate with a join; project unneeded columns away while retaining join/filter columns; reorder inner joins when equivalence permits; reuse common expressions when worthwhile. Split conjunctive selections when each predicate can be applied earlier to its own input.

Study-note section ADB19

> A cost model estimates resources for a candidate plan: page I/O, CPU, memory, temporary storage and network traffic.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 31 | lines 19-23

> • Heuristics Approach uses the knowledge of the characteristics of the relational algebra operations and the relationship between the operators to optimize the query.
> • Thus the heuristic approach of optimization will make use of:
> ◦ Properties of individual operators
> ◦ Association between operators

MOE Computer Science Exit Exam · 2016 · Question 26

Question 4 | Q00046

In which phase of the two phase locking protocol can a transaction obtain locks?

A. Release phase

B. Roll back phase

C. Shrinking phase

D. Growing phase

Hint

Track the first lock release and the transaction-completion boundary.

Answer D: Growing phase

Two-phase locking acquires locks in the growing phase, then releases them in the shrinking phase without acquiring new ones.

Why each choice is right or wrong

A - Incorrect: Release is the unlocking portion, not acquisition. (PDF pp. 86.)

B - Incorrect: Rollback is not one of the two acquisition/release phases. (PDF pp. 86.)

C - Incorrect: Shrinking forbids new locks. (PDF pp. 86.)

D - Correct: Growing allows acquisition and forbids release. (PDF pp. 86.)

Primary note proof

Study-note section ADB12

> Basic 2PL has a growing phase that acquires/upgrades locks and a shrinking phase that releases/downgrades them. Once any lock is released, no new lock may be acquired. The lock point is the instant the final lock is obtained. 2PL guarantees conflict serializability for well-formed transactions, but can deadlock and basic 2PL alone need not prevent cascading aborts.

Study-note section ADB12

> Two-phase locking orders access to data; two-phase commit coordinates a distributed commit decision.

Study-note section ADB12

> Strict 2PL retains exclusive locks until commit/abort.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 86 | lines 16-24

> ◦ Locking (Growing) Phase:
> • A transaction applies locks (read or write) on desired data items one at a time.

• acquires all locks but cannot release any locks.
◦ Unlocking (Shrinking) Phase:
• A transaction unlocks its locked data items one at a time.
• Releases locks but cannot acquire any new locks.
● Requirement:
◦ For a transaction these two phases must be mutually exclusively, that is, during

Computer Science Exit Exam practice questions · Question 38

Question 5 | Q00053

Which one of the following is not problem if concurrency is not controlled properly?

A. Lost update problem

B. Consistent database

C. Incorrect summary

D. Dirty read

Hint

Trace which transaction wrote each value and whether an overwrite or mixed-version read occurs.

Answer B: Consistent database

Lost update, temporary update/dirty read, and incorrect summary are concurrency problems. A consistent database is the desired outcome of concurrency control.

Why each choice is right or wrong

A - Incorrect: Lost update is explicitly a concurrency anomaly. (PDF pp. 68, 70, 79.)

B - Correct: Consistency is a desired state, so this is the exception. (PDF pp. 68, 70, 79.)

C - Incorrect: Incorrect summary mixes values from different update stages. (PDF pp. 68, 70, 79.)

D - Incorrect: Dirty read exposes an update before its transaction has safely committed. (PDF pp. 68, 70, 79.)

Primary note proof

Study-note section ADB08

Lost update: T1 and T2 both read 500; T2 adds 200 and writes 700; T1 adds 100 to its stale value and writes 600. Correct serial execution yields 800. Dirty read: T2 reads a value written by uncommitted T1; if T1 aborts, dependent work must be reconsidered. Reading one's own changes is not a dirty read.

Study-note section ADB06

Atomicity means all effects or none; consistency means correct work preserves integrity rules; isolation controls concurrent interference; durability preserves committed effects despite failure.

Study-note section ADB06

A transaction is a logical unit of database work, including read-only work.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 68 | lines 4-7

i. The Lost Update Problem
◦ This occurs when two transactions that access the same database items have their operations interleaved in a way that makes the value of some database item incorrect.

Fundamental of Database Systems module | PDF page 70 | lines 2-12

ii. The Temporary Update (or Dirty Read) Problem
◦ This occurs when one transaction updates a database item and then the transaction fails for some reason .
◦ The updated item is accessed by another transaction before it is changed back to its original value. Based on the above scenario:
iii. The Incorrect Summary Problem
◦ If one transaction is calculating an aggregate summary function on a number of records while other transactions are updating some of these records, the aggregate function may calculate some values before they are updated and others after they are updated.
Example: T1 would like to add the values of A=10, B=20 and C=30. after the values are read by

Fundamental of Database Systems module | PDF page 79 | lines 4-15

● Transaction Processor is divided into:
◦ A concurrency-control manager, or scheduler, responsible for assuring isolation of transactions
◦ A logging and recovery manager, responsible for the durability of transactions.
● The scheduler (concurrency-control manager) must assure that the individual actions of multiple transactions are executed in such an order that the net effect is the same as if the transactions had in fact executed one-at-a-time.
1. Purpose of Concurrency Control
◦ To enforce Isolation (through mutual exclusion) among conflicting transactions.
◦ To preserve database consistency through consistency preserving execution of transactions.
◦ To resolve read-write and write-write conflicts.

Question sources

MOE Computer Science Exit Exam · 2016 · Question 53

Question 6 | Q00078

Which one of the following is not a condition for two operations in a schedule to be said to conflict?

A. If they access the same item X

B. If they belong to the same transactions

C. If Write_item (X) is at least one of the operations

D. If they belong to different transactions

Hint

Distinguish transaction ordering, conflict conditions and full execution equivalence.

Answer B: If they belong to the same transactions

Conflict requires different transactions, the same item, and at least one write. Membership in the same transaction is therefore the exception.

Why each choice is right or wrong

A - Incorrect: Accessing the same item is required. (PDF pp. 70, 71.)

B - Correct: Same-transaction operations fail the different-transaction requirement. (PDF pp. 70, 71.)

C - Incorrect: At least one write is required. (PDF pp. 70, 71.)

D - Incorrect: Different transactions is required, so D is not the exception. (PDF pp. 70, 71.)

Primary note proof

Study-note section ADB09

> A serial schedule executes each transaction's operations consecutively. A serializable schedule is equivalent to some serial order; it may interleave transactions. Equality of one final value is insufficient evidence because different executions can accidentally coincide. Two operations conflict when they belong to different transactions, access the same item and at least one writes. Read/read pairs do not conflict.

Fundamental of Database Systems module | PDF page 70 | lines 2-12

> ii. The Temporary Update (or Dirty Read) Problem
> ◦ This occurs when one transaction updates a database item and then the transaction fails for some reason .
> ◦ The updated item is accessed by another transaction before it is changed back to its original value. Based on the above scenario:
> iii. The Incorrect Summary Problem
> ◦ If one transaction is calculating an aggregate summary function on a number of

records while other transactions are updating some of these records, the aggregate function may calculate some values before they are updated and others after they are updated.
Example: T1 would like to add the values of A=10, B=20 and C=30. after the values are read by

Fundamental of Database Systems module | PDF page 71 | lines 15-26

- Recoverable schedule:
  - One where no committed transaction needs to be rolled back.
  - A schedule S is recoverable if no transaction Tj in S commits until all transactions Ti that have written an item that Tj reads have committed. Examples,
- Sc: r1(X); w1(X); r2(X); r1(Y);w2(x);c2;a1; not recoverable
- Sd: r1(X); w1(X); r2(X); r1(Y); w2(X);w1(Y); c1; c2;
- Se: r1(X); w1(X); r2(X); r1(Y); w2(x) ; w1(Y); a1; a2;
- Cascadeless schedule:
  - One where every transaction reads only the items that are written by committed transactions. Eg.
- Sf: r1(X); w1(X); r1(Y); c1; r2(X); w2(X);w1(Y); c2;
- Strict Schedules:

Question sources

MOE Computer Science Exit Exam · 2016 · Question 78

Question 7 | Q00079

During restart recovery after a crash, which operation removes the database effects of a transaction that had not committed?

A. View

B. Commit

C. Rollback

D. Redo

Hint

Identify what failed, what durable resources survive and which restoration action is required.

Answer C: Rollback

Atomicity requires removing the effects of an incomplete transaction after a crash. Rollback performs that undo work, restoring before-images as needed. Commit instead accepts successful transaction effects, and a view is a query representation rather than a recovery action. Redo installs logged after-images to recover missing work; it does not name the removal of uncommitted effects requested here. These actions occur during restart recovery after the system is operating again.

Why each choice is right or wrong

A - Incorrect: Incorrect: a view is not an operation that reverses transaction effects.

B - Incorrect: Incorrect: commit accepts transaction effects rather than undoing the incomplete work.

C - Correct: Correct: rollback undoes the effects of the uncommitted transaction.

D - Incorrect: Incorrect: redo installs logged after-images; the requested removal requires undo/rollback.

Primary note proof

Study-note section ADB26

> Restart recovery restores a valid database after a crash while preserving durable commits and removing incomplete effects. Rollback handles failed/uncommitted work; redo preserves committed work missing from pages; checkpoints reduce log-search work; backups provide another stored copy.

Study-note section ADB27

> Undo restores before-images of incomplete effects, usually traversing that transaction's updates backward. Redo installs logged after-images when necessary, usually forward.

Study-note section ADB25

> A view is a stored query definition, not encryption.

Fundamental of Database Systems module | PDF page 103 | lines 6-23

> • Recovery from catastrophic
> • If there is extensive damage to the wide portion of the database
> • This method restore a past copy of the database from the backup storage and reconstructs operation of a committed transaction from the back up log up to the time of failure
> • Recovery from non-catastrophic failure
> • When the database is not physically damaged but has be come in consistent
> • The strategy uses undoing and redoing some operations in order to restore to a consistent state : example
> • For instance,
> • If failure occurs between commit and database buffers being flushed to secondary storage then, to ensure durability, recovery manager has to redo (roll forward) transaction‘s updates.
> • If transaction had not committed at failure time, recovery manager has to undo

(rollback) any effects of that transaction for atomicity. Example,
Transaction Log
◦ For recovery from any type of failure data values prior to modification (BFIM -

Fundamental of Database Systems module | PDF page 107 | lines 16-28

• Undo: Restore all BFIMs on to disk (Remove all AFIMs).
• Redo: Restore all AFIMs on to disk.
• Database recovery is achieved either by performing only Undos or only Redos or by a combination of the two. These operations are recorded in the log as they happen.
Data Update and Recovery Scheme : Three types
i. Deferred Update (No Undo/Redo)
◦ The data update goes as follows:
• A set of transactions records their updates in the log.
• At commit point under WAL scheme these updates are saved on database disk.
• No undo is required because no AFIM is flushed to the disk before a transaction commits.

Question sources

MOE Computer Science Exit Exam · 2016 · Question 79

Question 8 | Q00081

A system is in a _____ state if there exists a set of transactions such that every transaction in the set is waiting for another transaction in the set.

A. Idle

B. Waiting

C. Deadlock

D. Ready

Hint

Distinguish a waiting cycle, a long wait and indefinite unfair postponement.

Answer C: Deadlock

Mutual waiting among transactions for locks held by one another is a deadlock condition.

Why each choice is right or wrong

A - Incorrect: Idle does not express mutual lock waiting. (PDF pp. 87.)

B - Incorrect: Waiting alone need not involve a cycle. (PDF pp. 87.)

C - Correct: Deadlock is mutual waiting that prevents progress. (PDF pp. 87.)

D - Incorrect: Ready does not describe transactions blocked on one another. (PDF pp. 87.)

Primary note proof

Study-note section ADB13

> Deadlock requires a waiting cycle: T1 holds X and wants Y; T2 holds Y and wants X. In a wait-for graph, an edge Ti→Tj means Ti waits for a lock held by Tj. A cycle indicates deadlock under the ordinary lock-wait model. Abort a suitable victim, undo its effects and release its locks; repeat if other cycles remain. Aborting every deadlocked transaction also breaks cycles but wastes more work.

Study-note section ADB13

> Fair queues, sensible victim selection and retaining original transaction timestamps on retry reduce starvation; deadlock freedom alone does not prove fairness.

Study-note section ADB13

> A timeout aborts long waits but may mistake slow progress for deadlock.

Question sources

MOE Computer Science Exit Exam · 2016 · Question 81

Question 9 | Q00113

Users may request permitted aggregates but must not infer protected individual values by subtracting overlapping aggregate answers. Which security measure specifically addresses this indirect-disclosure threat?

A. Inference control

B. Access control

C. Integrity control

D. Encryption

E. None of the above

Hint

Identify whether the scenario concerns identity, permission, disclosure or valid values.

Answer A: A. Inference control

Inference control targets learning protected individual facts from aggregate answers. For example, subtracting a sum excluding one person from a sum including that person can reveal their value even when their row is hidden. Ordinary access control grants or denies actions, integrity validates data and encryption protects encoded content. The specified indirect-disclosure threat identifies inference control specifically.

Why each choice is right or wrong

A - Correct: This directly prevents disclosure of individual facts inferred from allowed aggregates.

B - Incorrect: Authorization alone does not prevent inference from otherwise allowed answers.

C - Incorrect: Integrity constrains valid data rather than indirect disclosure.

D - Incorrect: Encryption does not stop an authorized user combining decrypted aggregate answers.

E - Incorrect: Inference control directly matches the threat.

Primary note proof

Study-note section ADB24

> Authentication establishes identity; authorization/access control determines permitted actions. Encryption protects stored or transmitted content; integrity constraints restrict valid data; auditing records actions. A user who can view but cannot change a record has restricted access privileges. A view can restrict visible rows/columns, but its privilege and execution rules must support that restriction.

Study-note section ADB24

> Inference control concerns learning protected individual facts indirectly from allowed aggregate answers.

Study-note section ADB24

> Releasing SUM for a group and SUM for the same group excluding one known person may disclose that person's value by subtraction.

Question sources

Addis Ababa University mock exam · Question 15

Question 10 | Q00114

Which approach rewrites a query's internal representation using relational-algebra equivalences, without relying on integrity-constraint deductions or comparison of estimated plan costs?

A. Systematic plan-cost estimation

B. Semantic query optimization

C. Cost Estimation

D. Heuristic rules

E. Both A and C

Hint

Consider which equivalent transformation changes intermediate work and what assumptions preserve meaning.

Answer D: Heuristic rules

Heuristic rules rewrite algebraic representations using equivalences, such as applying suitable selections early or replacing a product followed by a join condition with a join. Semantic optimization additionally reasons from trusted constraints. Cost estimation predicts resources for candidate plans, and doing that systematically remains a costing activity. The stem isolates equivalence-based rewriting without those other bases, so D is correct and combining the two cost-estimation descriptions does not change the answer.

Why each choice is right or wrong

A - Incorrect: Incorrect: systematic cost estimation predicts plan costs rather than performing the specified equivalence-based rewriting.

B - Incorrect: Incorrect: semantic optimization additionally uses trusted constraints, which the stem excludes.

C - Incorrect: Incorrect: cost estimation compares resource predictions for candidate plans.

D - Correct: Correct: heuristic rules apply the stated relational-algebra equivalences.

E - Incorrect: Incorrect: A and C both describe costing, not the isolated algebraic-rewrite approach.

Primary note proof

Study-note section ADB18

> Heuristics reduce intermediate work: push selective row filters toward base tables; replace product followed by a join predicate with a join; project unneeded columns away while retaining join/filter columns; reorder inner joins when equivalence permits; reuse common expressions when worthwhile. Split conjunctive selections when each predicate can be applied earlier to its own input.

Study-note section ADB18

> Semantic optimization additionally uses trusted constraints, such as a key proving a join cannot multiply matching rows. Cost-based optimization estimates candidate plans instead of relying on rules alone.

Study-note section ADB19

> A cost model estimates resources for a candidate plan: page I/O, CPU, memory, temporary storage and network traffic.

> 2. Apply heuristics rules to optimize the internal representation.
> 3. A query execution plan is generated to execute groups of operations based on the access paths available on the files involved in the query.

Fundamental of Database Systems module | PDF page 42 | lines 19-22

> ◦ Estimate and compare the costs of executing a query using different execution strategies and choose the strategy with the lowest cost estimate. (Compare to heuristic query optimization)
> • Issues

Question sources

Addis Ababa University mock exam · Question 16

Question 11 | Q00115

Which of the following is not true about locks?

A. Locks with large granularity are easier for the DBMS to administer.

B. Locks with small granularity cause more conflicts.

C. Locks with large granularity produce fewer details for the DBMS to track.

D. Locks may have a table-level granularity.

E. Locks may have a database-level granularity.

Hint

Consider conflicts, private work and validation costs, or lock-management overhead.

Answer B: Locks with small granularity cause more conflicts.

Fine granularity raises concurrency, whereas coarse granularity locks more data with fewer lock entries. Thus the claim that smaller units cause more conflicts reverses the tradeoff.

Why each choice is right or wrong

A - Incorrect: A single coarse lock can replace many fine locks and reduce management work. (PDF pp. 83, 95.)

B - Correct: Fine units allow more independent access, so this is the false claim. (PDF pp. 83, 95.)

C - Incorrect: Coarse locks reduce the number of entries tracked. (PDF pp. 83, 95.)

D - Incorrect: The file/relation granularity in the hierarchy permits table-level locking. (PDF pp. 83, 95.)

E - Incorrect: Entire-database locking is expressly listed. (PDF pp. 83, 95.)

Primary note proof

Study-note section ADB16

> Fine-grained row locks permit more independent operations but require tracking many locks. Coarse table/database locks simplify management but block unrelated rows and reduce concurrency. Intention locks advertise planned descendant locks in a hierarchy; escalation replaces many small locks with a coarser one. Small granularity does not inherently cause more logical conflicts. Choose granularity from contention and management overhead, not a universal rule.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 83 | lines 2-8

> • Lock Manager:
> • Managing locks on data
> items.
> • Lock table:
> • Lock manager uses it to store the identify of transaction locking a data
> item, the data item, lock mode and pointer to the next data item locked.
> One simple way to implement a lock table is through linked list.

Fundamental of Database Systems module | PDF page 95 | lines 14-28

> • A lockable unit of data defines its granularity
> • Granularity can be coarse (entire database) or it can be fine (an attribute of a relation).
> • Example of data item granularity:
> • A field of a database record
> • A database record
> • A disk block/ page

• An entire file
• The entire database
• Data item granularity significantly affects concurrency control performance.
• Thus, the degree of concurrency is low for coarse granularity and high for fine granularity.
• Example:
• A transaction that expects to access most of the pages in a file should probably set a lock on the entire file , rather than locking individual pages or records
• If a transaction that requires to access relatively few pages of the file , it is better

Question sources

Addis Ababa University mock exam · Question 17

Question 12 | Q00116

For every transaction T participating in the schedule, if all the operations of T are executed consecutively in the schedule. The schedule is

A. Cascaded schedule

B. Serial schedule

C. Cascadeless schedule

D. Recoverable schedule

E. None

Hint

Distinguish transaction ordering, conflict conditions and full execution equivalence.

Answer B: Serial schedule

Consecutive execution of every transaction's operations is the definition of a serial schedule. Recoverability and cascadelessness instead constrain dependencies on commits.

Why each choice is right or wrong

A - Incorrect: Cascading concerns dependent rollbacks, not contiguous execution. (PDF pp. 72, 71.)

B - Correct: Serial exactly matches the consecutive-operations definition. (PDF pp. 72, 71.)

C - Incorrect: Cascadeless means reading only committed writes. (PDF pp. 72, 71.)

D - Incorrect: Recoverable constrains commit order after a read dependency. (PDF pp. 72, 71.)

E - Incorrect: A listed definition does match, so None is wrong. (PDF pp. 72, 71.)

Primary note proof

Study-note section ADB09

A serial schedule executes each transaction's operations consecutively. A serializable schedule is equivalent to some serial order; it may interleave transactions. Equality of one final value is insufficient evidence because different executions can accidentally coincide. Two operations conflict when they belong to different transactions, access the same item and at least one writes. Read/read pairs do not conflict.

Study-note section ADB10

Recoverable means if Tj reads Ti's value, Tj cannot commit before Ti commits.

Study-note section ADB10

Cascadeless means a transaction reads only values written by committed transactions, avoiding cascading aborts.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 72 | lines 6-18

- Serial schedule:
  - A schedule S is serial if, for every transaction Ti participating in the schedule, all the operations of Ti are executed consecutively in the schedule. Otherwise, the schedule is called nonserial schedule.
  - For example, in the banking example suppose there are two transaction where one transaction calculate the interest on the account and another deposit some money into the account. hence the order of execution is important for the final result.
- Serializable schedule:
  - a schedule whose effect on any consistent database instance is identical to that of some complete serial schedule over the set of committed transactions in S.
  - A nonserial schedule S is serializable , is equivalent to say that it is correct to the result of one of the serial schedule .Example,

Fundamental of Database Systems module | PDF page 71 | lines 15-26

- Recoverable schedule:
  - One where no committed transaction needs to be rolled back.
  - A schedule S is recoverable if no transaction Tj in S commits until all transactions Ti that have written an item that Tj reads have committed. Examples,
- Sc: r1(X); w1(X); r2(X); r1(Y);w2(x);c2;a1; not recoverable
- Sd: r1(X); w1(X); r2(X); r1(Y); w2(X);w1(Y); c1; c2;
- Se: r1(X); w1(X); r2(X); r1(Y); w2(x) ; w1(Y); a1; a2;
- Cascadeless schedule:
  - One where every transaction reads only the items that are written by committed transactions. Eg.
- Sf: r1(X); w1(X); r1(Y); c1; r2(X); w2(X);w1(Y); c2;
- Strict Schedules:

Question sources

Addis Ababa University mock exam · Question 18

Question 13 | Q00117

A transaction property state about changes applied to the database by a committed transaction must persist in the database?

A. Isolation

B. Durability or permanency

C. Atomicity

D. Consistency preservation

E. None

Hint

Track the transaction's guarantee or lifecycle boundary described by the scenario.

Answer B: Durability or permanency

Persisting committed modifications despite subsequent failure is durability or permanency.

Why each choice is right or wrong

A - Incorrect: Isolation regulates visibility between transactions. (PDF pp. 66.)

B - Correct: Durability protects committed changes against loss. (PDF pp. 66.)

C - Incorrect: Atomicity is all-or-nothing execution. (PDF pp. 66.)

D - Incorrect: Consistency preserves valid states rather than persistence. (PDF pp. 66.)

E - Incorrect: Durability is a listed matching property. (PDF pp. 66.)

Primary note proof

Study-note section ADB06

> A transaction is a logical unit of database work, including read-only work. Atomicity means all effects or none; consistency means correct work preserves integrity rules; isolation controls concurrent interference; durability preserves committed effects despite failure. A DBMS cannot automatically make incorrect business logic consistent.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 66 | lines 4-13

> • Atomicity: A transaction is an atomic unit of processing; it is either performed in its entirety or not performed at all.
> • Consistency preservation: A correct execution of the transaction must take the database from one consistent state to another.
> • Isolation: A transaction should not make its updates visible to other transactions until it is committed; this property, when enforced strictly, solves the temporary update problem and makes cascading rollbacks of transactions unnecessary

- Durability or permanency: Once a transaction changes the database and the changes are committed, these changes must never be lost because of subsequent failure.

Example

Question sources

Addis Ababa University mock exam · Question 19

Question 14 | Q00118

Which update-timing policy keeps a transaction's uncommitted changes outside the persistent database until commit?

A. Undo

B. In-place modification

C. Immediate-modification

D. Deferred-modification

Hint

Separate update timing from update location and follow the commit boundary.

Answer D: Deferred-modification

Deferred modification keeps uncommitted updates outside the persistent database. If the transaction fails before commit, those database pages do not require undo for its changes; redo can still be needed after commit in a no-force system. Immediate modification permits precommit persistent changes. In-place modification describes overwriting the original location without specifying the commit timing, while undo is an action that reverses applied effects. D therefore names the requested timing policy.

Why each choice is right or wrong

A - Incorrect: Incorrect: undo reverses effects already applied rather than naming a policy postponing them.

B - Incorrect: Incorrect: in-place modification specifies overwriting location, not postponement until commit.

C - Incorrect: Incorrect: immediate modification permits persistent changes before commit.

D - Correct: Correct: deferred modification keeps uncommitted changes outside the persistent database.

Primary note proof

Study-note section ADB29

Deferred update keeps uncommitted changes outside the persistent database; in the usual no-force setting it is NO-UNDO/REDO. Redo-only and NO-UNDO/REDO mean the same thing, so

those cannot be separate unique answers. Immediate update allows persistent changes before commit and therefore may require undo; it need not flush every write_item immediately.

Study-note section ADB29

In-place update overwrites the original location.

Related reading (context, not primary note proof)

Study-note section ADB27

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 107 | lines 16-28

• Undo: Restore all BFIMs on to disk (Remove all AFIMs).
• Redo: Restore all AFIMs on to disk.
• Database recovery is achieved either by performing only Undos or only Redos or by a combination of the two. These operations are recorded in the log as they happen.
Data Update and Recovery Scheme : Three types
i. Deferred Update (No Undo/Redo)
◦ The data update goes as follows:
• A set of transactions records their updates in the log.
• At commit point under WAL scheme these updates are saved on database disk.
• No undo is required because no AFIM is flushed to the disk before a transaction commits.

Fundamental of Database Systems module | PDF page 110 | lines 14-30

◦ Deferred Update:
• All transaction updates are recorded in the local workspace (cache)
• All modified data items in the cache is then written after a transaction ends its execution or after a fixed number of transactions have completed their execution.
• During commit the updates are first recorded on the log and then on the database
• If a transaction fails before reaching its commit point undo is not needed because it didn‘t change the database yet
• If a transaction fails after commit (writing on the log) but before finishing saving to the data base redoing is needed from the log
◦ Immediate Update:
• As soon as a data item is modified in cache, the disk copy is updated.
• These update are first recorded on the log and on the disk by force writing, before the database is updated
• If a transaction fails after recording some change to the database but before reaching its commit point , this will be rolled back

Question sources

Addis Ababa University mock exam · Question 20

Question 15 | Q00119

Which one of the following is false?

A. In object-oriented database, data are stored as collections of rows and tables

B. In relational database, data are perceived by users as tables

C. Object oriented database allows object identification and communication

D. Object oriented database allows reusability of objects

E. None of the above

Hint

Distinguish an object instance from its class, attribute values and persistent identity.

Answer A: The rows-and-tables claim is false for the object-oriented model.

An OODBMS primarily models persistent objects with identity, state and behavior, rather than relational rows and tables. Objects communicate through methods and object references, and inheritance supports reuse. Relational presentation as tables is the contrasting model. Therefore A is the false statement.

Why each choice is right or wrong

A - Correct: This is false: an OODBMS primarily models persistent objects rather than relational rows and tables.

B - Incorrect: Presenting relations as tables describes the relational contrast correctly.

C - Incorrect: Object identity and method-based collaboration are supported object-model concepts.

D - Incorrect: Inheritance and reusable object behavior support reuse, so this is not the false statement.

E - Incorrect: A is false, so none of the above cannot answer this negative question.

Primary note proof

Study-note section ADB01

> An object combines identity, state and behavior. A class specifies the attributes and operations of its instances; an object is one instance. The object identifier (OID) distinguishes objects independently of their attribute values and remains stable over that object's lifetime. Two objects can have equal values and different identities; changing a name does not create a new identity.

Study-note section ADB01

> It does not primarily present objects as rows and tables.

Study-note section ADB01

An object-relational DBMS extends a relational system with richer types; ORM maps programming objects into relational tables.

Related reading (context, not primary note proof)

Fundamental of Database Systems module | PDF page 24 | lines 10-14

Basic operations:
Selection (σ) - Selects a subset of rows from relation.
Projection (π) - Deletes unwanted columns from relation.
Cross-product (x) - Allows us to combine two relations.
Set-difference (-) - Tuples in relation 1, but not in relation 2.

Question sources

Addis Ababa University mock exam · Question 21

Question 16 | Q00296

27.----------is a collection of multiple logically related database distributed over a computer network.

A. Data Fragmentation

B. Distributed Database

C. Data Allocation

D. Data Replication

Hint

Separate coordinated network placement from engine compatibility and semantic integration.

Answer B: Distributed Database

A distributed database is a coordinated collection of logically related data across networked sites. Fragmentation divides a relation into row or column subsets; replication creates copies; allocation chooses the sites storing fragments or copies. These are design decisions within a distributed database rather than alternative names for the whole collection. Distribution does not require every fragment to be replicated, and the question's definition identifies the database as a whole.

Why each choice is right or wrong

A - Incorrect: Incorrect: fragmentation splits relations into subsets rather than naming the entire networked collection.

B - Correct: Correct: a distributed database is the coordinated logically related data collection across networked sites.

C - Incorrect: Incorrect: allocation assigns fragments or copies to sites; it is a placement decision.

D - Incorrect: Incorrect: replication creates copies and is a design choice rather than the definition of the collection.

Primary note proof

Study-note section ADB33

A distributed database contains logically related data across networked sites, managed as a coordinated system.

Study-note section ADB36

Horizontal fragmentation selects row subsets by predicates; their union reconstructs the relation.

Study-note section ADB37

Full replication places the whole database at every relevant site; partial replication copies selected fragments to selected sites; nonredundant allocation stores each fragment once.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 114 | lines 7-13

• A distributed database (DDB) can be defined as :
- A collection of multiple logically related database distributed over a computer network, and a distributed database management system as a software system that manages a distributed database while making the distribution transparent to the user.
- The physical placement of data (files, relations, etc.) which is not known to the user (distribution transparency).

Fundamental of Database Systems module | PDF page 117 | lines 18-31

I. Data Replication
• The system maintain several identical copies of the relation & store each copy at a different site
• In general it enhance the performance of read operation and increase the availability of data to read only transaction. However, update transactions incur greater overhead
II. Data Fragmentation
- Split a relation into logically related and correct parts.
- The main reasons for fragmenting a relation are

• Efficiency- data that is not needed by the local applications is not stored
• Parallelism - a transaction can be divided into several subqueries that operate on fragments which will increase the degree of concurrency
- but reconstruction of the whole relation will require accessing data from all sites containing part of the relation

Computer Science model exam · Question 27

University of Gondar model exam · Question 27

Question 17 | Q00297

..... Means that a transaction must execute exactly once completely or not at all.

A. Consistency

B. Durability

C. Isolation

D. Atomicity

Hint

Track the transaction's guarantee or lifecycle boundary described by the scenario.

Answer D: Atomicity

Atomicity means a transaction is performed in its entirety or not performed at all. 'Exactly once' is interpreted here as all-or-nothing completion, rather than exactly-once delivery semantics.

Why each choice is right or wrong

A - Incorrect: Consistency concerns valid before/after states. (PDF pp. 66.)

B - Incorrect: Durability concerns survival after commit. (PDF pp. 66.)

C - Incorrect: Isolation concerns interaction with other transactions. (PDF pp. 66.)

D - Correct: Atomicity supplies the all-or-nothing rule. (PDF pp. 66.)

Primary note proof

Study-note section ADB06

A transaction is a logical unit of database work, including read-only work. Atomicity means all effects or none; consistency means correct work preserves integrity rules; isolation controls concurrent interference; durability preserves committed effects despite failure. A DBMS cannot automatically make incorrect business logic consistent.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 66 | lines 4-13

- Atomicity: A transaction is an atomic unit of processing; it is either performed in its entirety or not performed at all.
- Consistency preservation: A correct execution of the transaction must take the database from one consistent state to another.
- Isolation: A transaction should not make its updates visible to other transactions until it is committed; this property, when enforced strictly, solves the temporary update problem and makes cascading rollbacks of transactions unnecessary
- Durability or permanency: Once a transaction changes the database and the changes are committed, these changes must never be lost because of subsequent failure.

Example

University of Gondar model exam · Question 28

Question 18 | Q00300

Checkpoints are a part of

A. Recovery measures

B. Concurrency measures

C. Authorization measures

D. Security measures

Hint

Identify which history a recovery boundary can safely exclude and whether active work spans it.

Answer A: Recovery measures

A checkpoint synchronizes database and log so recovery need not search the entire history. Its purpose is recovery work reduction.

Why each choice is right or wrong

A - Correct: Checkpointing is described in database recovery. (PDF pp. 105, 107.)

B - Incorrect: Locking and scheduling are concurrency controls; this checkpoint has a recovery role. (PDF pp. 105, 107.)

C - Incorrect: Privileges authorize access rather than synchronize recovery state. (PDF pp. 105, 107.)

D - Incorrect: Checkpointing does not authenticate users or grant privileges. (PDF pp. 105, 107.)

Primary note proof

Study-note section ADB30

A checkpoint records enough durable recovery state to avoid scanning all old history. In a simple quiescent/checkpoint exercise, specified flushing may make earlier committed work unnecessary to redo. Active transactions can span the checkpoint, so their relevant earlier updates can still need undo. Do not assume every transaction before a checkpoint needs no processing.

Study-note section ADB30

Recovery may start analysis at the checkpoint but redo from an earlier required log position.

Study-note section ADB30

Without checkpoints or another valid truncation boundary, long-running systems may need expensive log scans; deferred update does not avoid that problem.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 105 | lines 25-36

Check pointing
• Log file is used to recover failed DB but we may not know how far back in the log to search. Thus
• Checkpoint is a Point of synchronization between database and log file.
• Time to time (randomly or under some criteria) the database flushes its buffer to database disk to minimize the task of recovery.
• When failure occurs, redo all transactions that committed since the checkpoint and undo all transactions active at time of crash.
• In previous example ,Figure 2, on slide18 , with checkpoint at time tc, changes made by T2 and T3 have been written to secondary storage. Thus: only redo T4 and T5, undo transactions T1 and T6.
• At what interval to take a check pointing may be measured :

Fundamental of Database Systems module | PDF page 107 | lines 16-28

• Undo: Restore all BFIMs on to disk (Remove all AFIMs).
• Redo: Restore all AFIMs on to disk.
• Database recovery is achieved either by performing only Undos or only Redos or by a combination of the two. These operations are recorded in the log as they happen.
Data Update and Recovery Scheme : Three types
i. Deferred Update (No Undo/Redo)
◦ The data update goes as follows:
• A set of transactions records their updates in the log.
• At commit point under WAL scheme these updates are saved on database disk.
• No undo is required because no AFIM is flushed to the disk before a transaction commits.

Question sources

Computer Science model exam · Question 31

University of Gondar model exam · Question 31

Question 19 | Q00304

Which of the following is not a recovery technique?

A. ARIES Algorithm

B. Two-phase commit

C. Immediate update

D. Deferred update

Hint

Distinguish coordinated transaction outcome from concurrent access and local storage.

Answer B: Two-phase commit

Deferred update, immediate update, and ARIES are recovery approaches. Two-phase commit coordinates the distributed commit decision; it is the intended exception among the named recovery algorithms, though commit protocols also support distributed recovery.

Why each choice is right or wrong

A - Incorrect: ARIES is explicitly a recovery algorithm. (PDF pp. 107, 109, 123.)

B - Correct: Two-phase commit is a distributed commit approach, not the listed update-recovery algorithm. (PDF pp. 107, 109, 123.)

C - Incorrect: Immediate update appears under recovery techniques. (PDF pp. 107, 109, 123.)

D - Incorrect: Deferred update is a recovery scheme. (PDF pp. 107, 109, 123.)

Primary note proof

Study-note section ADB39

> Two-phase commit (2PC) first asks participants to prepare and durably promise they can commit. If all vote yes, the coordinator records commit durably and tells participants; otherwise it decides abort. A prepared participant must retain enough state to obey the final decision. Coordinator/communication failure can leave it in doubt and block progress until the decision is learned. Timeout after preparation is not permission to invent a commit or abort.

Study-note section ADB39

> 2PC coordinates atomic outcome; locking/other concurrency protocols provide isolation.

Study-note section ADB29

> Immediate update allows persistent changes before commit and therefore may require undo; it need not flush every write_item immediately.

• No undo is required because no AFIM is flushed to the disk before a transaction commits.

Fundamental of Database Systems module | PDF page 109 | lines 13-22

iii. Shadow Paging
• Maintain two page tables during life of a transaction: current page and shadow page table.
• When transaction starts, two pages are the same.
• Shadow page table is never changed thereafter and is used to restore database in event of failure.
• During transaction, current page table records all updates to database.
• When transaction completes, current page table becomes shadow page table.
X and Y: Shadow copies of data items
X' and Y': Current copies of data items

Fundamental of Database Systems module | PDF page 123 | lines 23-29

i. Primary site technique: A single site is designated as a primary site which serves as a coordinator for transaction management.
• Transaction management:
- Concurrency control and commit are managed by this site.
- In two phase locking, this site manages locking and releasing data items. If all transactions follow two-phase policy at all sites, then serializability is guaranteed.
- Advantages:

Computer Science model exam · Question 35

University of Gondar model exam · Question 35

Question 20 | Q00305

Which of the following is not true about OODBMS (object-oriented database management system).

A. The key concepts is objects

B. The object is persistent

C. The key concept is relation

D. Object Identity is unchangeable

Hint

Distinguish an object instance from its class, attribute values and persistent identity.

Answer C: Relation is not the defining concept of an OODBMS.

The defining unit of an object database is an object with identity, state and behavior. ADB01 explains both persistence beyond program execution and identifier stability throughout an object lifetime. Relation is instead the characteristic abstraction of the relational model. Thus C is the one statement that fails to describe an OODBMS.

Why each choice is right or wrong

A - Incorrect: Objects are the defining units of the object-oriented database model.

B - Incorrect: An OODBMS provides persistence so objects survive the program execution that created them.

C - Correct: This is false for OODBMS: relation is the central abstraction of the relational model.

D - Incorrect: The object identifier remains stable throughout the lifetime of its object.

Primary note proof

Study-note section ADB01

> An object combines identity, state and behavior. A class specifies the attributes and operations of its instances; an object is one instance. The object identifier (OID) distinguishes objects independently of their attribute values and remains stable over that object's lifetime. Two objects can have equal values and different identities; changing a name does not create a new identity.

Study-note section ADB01

> Persistence lets an object survive beyond the program execution that created it.

Study-note section ADB01

> Complex CAD or multimedia structures can suit an object model, but many-to-many relationships alone do not require abandoning relational design.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 119 | lines 11-19

• Heterogeneous
- At least one of the database must be from different vendor : two variants
- Federated: Each site may run different database system but the data access is managed through a single conceptual schema.
• This implies that the degree of local autonomy is minimum. Each site must adhere to a centralized access policy. There may be a global schema.
- Multidatabase: There is no one conceptual global schema. For data access a schema is constructed dynamically as needed by the application software.

Computer Science model exam · Question 36

University of Gondar model exam · Question 36

Question 21 | Q00306

Which optimization approach uses algebraic rules, such as pushing suitable selections before joins, to choose an operation order without exhaustively enumerating plans or comparing estimated costs?

A. Semantic query optimization based on trusted constraints

B. Heuristic- based

C. Cost estimation

D. Exhaustive search

Hint

Consider which equivalent transformation changes intermediate work and what assumptions preserve meaning.

Answer B: Heuristic- based

Heuristic optimization orders or rewrites operations using algebraic rules intended to reduce intermediate work. Applying suitable selections early is a typical example. Semantic optimization additionally uses trusted constraints, cost estimation predicts resource usage for candidate strategies, and exhaustive search enumerates alternatives rather than selecting a small set through rules alone. Although practical optimizers can combine these methods, the stated stem asks specifically for rule-based algebraic ordering, making B unique.

Why each choice is right or wrong

A - Incorrect: Incorrect: this alternative bases deductions on trusted constraints rather than the isolated algebraic ordering rules.

B - Correct: Correct: heuristic optimization orders operations through algebraic rules such as early selection.

C - Incorrect: Incorrect: cost estimation predicts candidate-plan resources instead of the specified rule-only choice.

D - Incorrect: Incorrect: exhaustive search enumerates alternatives, which the stem explicitly excludes.

Primary note proof

Study-note section ADB18

> Heuristics reduce intermediate work: push selective row filters toward base tables; replace product followed by a join predicate with a join; project unneeded columns away while retaining join/filter columns; reorder inner joins when equivalence permits; reuse common expressions when worthwhile. Split conjunctive selections when each predicate can be applied earlier to its own input.

Study-note section ADB18

> Semantic optimization additionally uses trusted constraints, such as a key proving a join cannot multiply matching rows. Cost-based optimization estimates candidate plans instead of relying on rules alone.

Computer Science model exam · Question 37

University of Gondar model exam · Question 37

Question 22 | Q00533

A transaction in which either all of the database actions occur or none of them does is called

A. Atomicity

B. Consistency

C. Isolation

D. Durability

Hint

Track the transaction's guarantee or lifecycle boundary described by the scenario.

Answer A: Atomicity

All database actions occurring or none occurring is atomicity, the first ACID property.

Why each choice is right or wrong

A - Correct: Atomicity is the entire-or-none requirement. (PDF pp. 66.)

B - Incorrect: Consistency is preservation of valid states. (PDF pp. 66.)

C - Incorrect: Isolation separates concurrent effects. (PDF pp. 66.)

D - Incorrect: Durability preserves completed commits. (PDF pp. 66.)

Primary note proof

Study-note section ADB06

> A transaction is a logical unit of database work, including read-only work. Atomicity means all effects or none; consistency means correct work preserves integrity rules; isolation controls concurrent interference; durability preserves committed effects despite failure. A DBMS cannot automatically make incorrect business logic consistent.

Module passages - related reading

Question sources

Computer Science model exam · 2015 · Question 2

Question 23 | Q00540

A transaction is still active when one of its changes is written into the persistent database. Which update-timing policy permits this?

A. Deferred-Update

B. In-place update

C. Immediate-Update

D. Undo

Hint

Separate update timing from update location and follow the commit boundary.

Answer C: Immediate-Update

Immediate update permits persistent database changes while the transaction is still active, before commit. An abort may therefore require undo. Deferred update keeps uncommitted changes outside the persistent database. In-place update describes overwriting a location rather than the commit-timing policy, and undo is the reversal of applied effects. The question concerns which timing policy permits the observed precommit write, not whether all immediate-update systems must flush every cache change immediately.

Why each choice is right or wrong

A - Incorrect: Incorrect: deferred update excludes uncommitted changes from the persistent database.

B - Incorrect: Incorrect: in-place update describes overwriting the existing location rather than the commit-timing policy.

C - Correct: Correct: immediate update permits persistent changes before commit.

D - Incorrect: Incorrect: undo reverses effects; it is not the update-timing policy.

Primary note proof

Study-note section ADB29

> Deferred update keeps uncommitted changes outside the persistent database; in the usual no-force setting it is NO-UNDO/REDO. Redo-only and NO-UNDO/REDO mean the same thing, so those cannot be separate unique answers. Immediate update allows persistent changes before commit and therefore may require undo; it need not flush every write_item immediately.

Study-note section ADB29

> In-place update overwrites the original location.

Related reading (context, not primary note proof)

Study-note section ADB27

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 110 | lines 14-30

◦ Deferred Update:
• All transaction updates are recorded in the local workspace (cache)
• All modified data items in the cache is then written after a transaction ends its execution or after a fixed number of transactions have completed their execution.
• During commit the updates are first recorded on the log and then on the database
• If a transaction fails before reaching its commit point undo is not needed because it didn‘t change the database yet
• If a transaction fails after commit (writing on the log) but before finishing saving to the data base redoing is needed from the log
◦ Immediate Update:
• As soon as a data item is modified in cache, the disk copy is updated.
• These update are first recorded on the log and on the disk by force writing, before the database is updated
• If a transaction fails after recording some change to the database but before reaching its commit point , this will be rolled back

Fundamental of Database Systems module | PDF page 107 | lines 16-28

• Undo: Restore all BFIMs on to disk (Remove all AFIMs).
• Redo: Restore all AFIMs on to disk.
• Database recovery is achieved either by performing only Undos or only Redos or by a combination of the two. These operations are recorded in the log as they happen.
Data Update and Recovery Scheme : Three types
i. Deferred Update (No Undo/Redo)
◦ The data update goes as follows:
• A set of transactions records their updates in the log.
• At commit point under WAL scheme these updates are saved on database disk.
• No undo is required because no AFIM is flushed to the disk before a transaction commits.

Question sources

Computer Science model exam · 2015 · Question 9

Question 24 | Q00556

Which of the following occurs when a transaction cannot proceed for an indefinite period while other transactions in the system continue normally?

A. Starvation

B. Deadlock

C. checkpoint

D. lock point

Hint

Distinguish a waiting cycle, a long wait and indefinite unfair postponement.

Answer A: Starvation

Starvation means indefinite postponement of a transaction while other transactions continue. It can result from repeated waiting or repeated victim selection without any waiting cycle. Deadlock instead involves a cycle of mutually blocked transactions. A checkpoint records recovery state, and the lock point in two-phase locking is the instant a transaction acquires its final lock. Neither is the name of indefinite unfair postponement, so A remains the unique answer.

Why each choice is right or wrong

A - Correct: Correct: indefinite postponement while others proceed is starvation.

B - Incorrect: Incorrect: deadlock requires a waiting cycle, which is not required for starvation.

C - Incorrect: Incorrect: a checkpoint records durable recovery state; it is not an indefinite waiting condition.

D - Incorrect: Incorrect: the lock point is the instant the transaction acquires its final lock in 2PL.

Primary note proof

Study-note section ADB13

> Fixed resource ordering and conservative 2PL prevent cycles. A no-wait policy aborts immediately on an incompatible lock request and needs no age timestamp. A timeout aborts long waits but may mistake slow progress for deadlock. Starvation is indefinite postponement while other work proceeds, without a required cycle. Fair queues, sensible victim selection and retaining original transaction timestamps on retry reduce starvation; deadlock freedom alone does not prove fairness.

Study-note section ADB12

> The lock point is the instant the final lock is obtained.

Study-note section ADB30

> A checkpoint records enough durable recovery state to avoid scanning all old history.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 90 | lines 12-21

◦ Starvation occurs when a particular transaction consistently waits or restarted and never gets a chance to proceed further while other transaction continue normally
◦ This may occur , if the waiting method for item locking:
• Gave priority for some transaction over others
• Problem in Victim selection algorithm- it is possible that the same transaction may consistently be selected as victim and rolled-back .example In Wound-Wait
◦ Solution
• FIFO
• Allow for transaction that wait for a longer time

Question sources

Computer Science model exam · 2015 · Question 25

Question 25 | Q00565

The atom constructor can represent the following basic atomic values except.

A. Integers

B. Real Numbers

C. Strings

D. Array

Hint

Classify the shape of a value separately from an operation that creates an instance.

Answer D: Array is not an atom constructor.

ADB04 lists integer, real, Boolean and string as examples of basic atomic values. An array instead supplies indexed positions and is a collection constructor, even when a programming variable holds it as one value. Consequently integers, reals and strings fit the atom category while an array is the requested exception.

Why each choice is right or wrong

A - Incorrect: An integer is explicitly listed as a basic atomic value.

B - Incorrect: A real number is explicitly included among atomic values.

C - Incorrect: A string is a basic atomic value under the object-model convention used here.

D - Correct: An array contains indexed positions and is a collection constructor rather than an atomic one.

Primary note proof

Study-note section ADB04

> In a common object model, an object is described by (OID,type constructor,state). An atom is one basic value, such as an integer, real, Boolean or string. A tuple constructor groups named component values into one structured record, such as (Street:'A',City:'B'). It is not a collection of records.

Study-note section ADB04

> An array is not an atomic constructor merely because stored as one programming variable.

Study-note section ADB04

> A set is an unordered collection without duplicates; a bag allows duplicates; a list has order; an array provides indexed positions.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 24 | lines 10-14

> Basic operations:
> Selection (σ) - Selects a subset of rows from relation.
> Projection (π) - Deletes unwanted columns from relation.
> Cross-product (x) - Allows us to combine two relations.
> Set-difference (-) - Tuples in relation 1, but not in relation 2.

Question sources

Computer Science model exam · 2015 · Question 34

Question 26 | Q00584

A system crashes again during ARIES recovery. Durable WAL, pageLSNs and compensation log records survive; storage is intact. No checkpoints were taken. Which statement correctly describes the second restart?

A. The same undo and redo list will be used while recovering again

B. The database will become inconsistent

C. Durable compensation records and pageLSNs preserve recovery progress, so already-installed actions can be skipped or safely redone as required.

D. The system cannot any further

Hint

Trace durable recovery metadata and what progress survives a second crash.

Answer C: C. Durable compensation records and pageLSNs preserve recovery progress, so already-installed actions can be skipped or safely redone as required.

ARIES records recovery progress in durable metadata. PageLSNs help determine whether a redo action is already installed, and compensation records preserve undo progress and its continuation. A second restart can therefore recover safely without assuming that the same undo and redo work lists recur. Lack of checkpoints may increase scanning work, but it does not erase this progress or make further recovery impossible.

Why each choice is right or wrong

A - Incorrect: Durable progress can change the required work, so identical lists are not guaranteed.

B - Incorrect: Restartable recovery does not make inconsistency inevitable.

C - Correct: PageLSNs and durable CLRs support safe continuation after repeated crashes.

D - Incorrect: ARIES can restart using surviving durable recovery metadata.

Primary note proof

Study-note section ADB31

> ARIES uses WAL, page log sequence numbers (pageLSN), a transaction table and a dirty-page table. Analysis reconstructs active/loser transactions and dirty-page information. Redo repeats history, starting from the relevant earliest dirty-page update; pageLSNs help skip already-installed actions. Undo reverses loser transactions.

Study-note section ADB31

> This makes recovery restartable: after a second crash, durable undo progress need not be undone again as if no progress occurred.

Study-note section ADB31

> Compensation log records (CLRs) describe undo actions and their continuation information.

Related reading (context, not primary note proof)

Study-note section ADB27

Fundamental of Database Systems module | PDF page 108 | lines 24-29

> • During recovery, all transactions of the commit table are redone and all transactions of active tables are ignored since none of their AFIMs reached the database.
> • It is possible that a commit table transaction may be redone twice but this does not create any inconsistency because of a redone is —idempotent‖,
> • that is, one redone for an AFIM is equivalent to multiple redone for the same AFIM.

Fundamental of Database Systems module | PDF page 110 | lines 14-30

◦ Deferred Update:
• All transaction updates are recorded in the local workspace (cache)
• All modified data items in the cache is then written after a transaction ends its execution or after a fixed number of transactions have completed their execution.
• During commit the updates are first recorded on the log and then on the database
• If a transaction fails before reaching its commit point undo is not needed because it didn‘t change the database yet
• If a transaction fails after commit (writing on the log) but before finishing saving to the data base redoing is needed from the log
◦ Immediate Update:
• As soon as a data item is modified in cache, the disk copy is updated.
• These update are first recorded on the log and on the disk by force writing, before the database is updated
• If a transaction fails after recording some change to the database but before reaching its commit point , this will be rolled back

Question sources

Computer Science model exam · 2015 · Question 53

Question 27 | Q00590

The rigorous two-phase locking protocol permits releasing all locks at the_____

A. Beginning of the transaction

B. During the execution of transaction

C. End of transaction

D. Never in the life-time of transaction

Hint

Track the first lock release and the transaction-completion boundary.

Answer C: At transaction end, on commit or abort.

Rigorous 2PL retains both shared and exclusive locks until commit or abort, unlike basic 2PL, which permits release in its shrinking phase. FDB-style early release would allow interference before completion and would not meet rigorous locking. The locks are eventually released at the transaction boundary, so never is also false.

Why each choice is right or wrong

A - Incorrect: Releasing locks at the beginning would not protect the transaction's later accesses.

B - Incorrect: Rigorous 2PL does not permit early release during ongoing transaction execution.

C - Correct: Both shared and exclusive locks remain held until commit or abort ends the transaction.

D - Incorrect: Locks are released at completion; the protocol does not hold them forever.

Primary note proof

Study-note section ADB12

Strict 2PL retains exclusive locks until commit/abort. Rigorous 2PL retains both shared and exclusive locks until that point. Conservative/static 2PL obtains all needed locks before execution and does not begin while only a subset is available, preventing hold-and-wait deadlock. It requires knowing the lock set and can reduce concurrency. Two-phase locking orders access to data; two-phase commit coordinates a distributed commit decision.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 86 | lines 16-24

◦ Locking (Growing) Phase:
• A transaction applies locks (read or write) on desired data items one at a time.
• acquires all locks but cannot release any locks.
◦ Unlocking (Shrinking) Phase:
• A transaction unlocks its locked data items one at a time.
• Releases locks but cannot acquire any new locks.
● Requirement:
◦ For a transaction these two phases must be mutually exclusively, that is, during

4.2.5 Validation (Optimistic) Concurrency Control Schemes
◦ This technique allow transaction to proceed asynchronously and only at the time of commit, serializability is checked &
◦ transactions are aborted in case of non-serializable schedules.
◦ Good if there is little interference among transaction
◦ It has three phases: Read, Validation , and Write phase
i.. Read phase:
◦ A transaction can read values of committed data items. However, updates are

Question sources

Computer Science model exam · 2015 · Question 59

Question 28 | Q00594

In which of the following state of the transaction executes all its operations successfully and all the effects are now permanently saved on the database system?

A. Active

B. Partial committed

C. Committed

D. Failed

Hint

Track the transaction's guarantee or lifecycle boundary described by the scenario.

Answer C: Committed

The committed state guarantees persistent changes. Partially committed only signals the end of read/write operations and does not yet ensure permanence.

Why each choice is right or wrong

A - Incorrect: Active means execution is in progress. (PDF pp. 65.)

B - Incorrect: Partially committed explicitly does not guarantee permanent modification. (PDF pp. 65.)

C - Correct: Committed ensures persistent changes. (PDF pp. 65.)

D - Incorrect: Failed is an aborted or unsuccessful transaction. (PDF pp. 65.)

Primary note proof

Study-note section ADB06

> Active means operations are executing. Partially committed means the last operation finished but durable commitment is not yet assured. Committed means commitment succeeded. A failure leads to Failed, then Aborted after rollback; a transaction may terminate or be restarted as a new attempt. Concurrency control primarily enforces isolation; recovery supports atomicity and durability. Transaction management is the broader subsystem, so both it and recovery management can be legitimate answers to broad responsibility questions.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 65 | lines 4-7

> ◦ Committed state -ensures that all the changes done on a record by a transition were done persistently
> ◦ Failed state happens when a transaction is aborted during its active state or if one of the rechecking is fails

Question sources

Computer Science model exam · 2015 · Question 63

Question 29 | Q00598

Let transaction T1 has obtained a shared mode lock S on data item Y and transaction T2 has obtained an exclusive lock X on data item Z , according to the above statement which one is correct?

A. T1 can read Y but cannot write Y

B. T2 can read Z but cannot write Z

C. T1 can read Z but cannot write Z

D. T2 can read and write item Y

Hint

Compare access permissions and same-item compatibility before granting a lock request.

Answer A: T1 can read Y but cannot write Y

Shared locks permit reads but not updates. Exclusive locks permit both reading and updating while excluding other transactions' locks on that item.

Why each choice is right or wrong

A - Correct: T1's shared lock authorizes reading Y, not writing it. (PDF pp. 82, 83.)

B - Incorrect: T2's exclusive lock permits both read and update of Z. (PDF pp. 82, 83.)

C - Incorrect: T1 cannot read Z while another transaction holds its exclusive lock. (PDF pp. 82, 83.)

D - Incorrect: T2 cannot obtain an exclusive write lock on Y while T1 holds its shared lock. (PDF pp. 82, 83.)

Primary note proof

Study-note section ADB11

> A shared (S) lock permits reading; multiple S locks on the same item can coexist. An exclusive (X) lock permits its holder to read and write and conflicts with another S or X on that item. Locks on different items do not conflict merely because one is exclusive. These are the basic lock-based rules; multiversion systems can permit additional snapshot-reader behavior.

Study-note section ADB11

> A transaction must own the appropriate lock before access and can release only its own locks.

Study-note section ADB11

> One transaction may request a lock on an already locked item: it is granted if compatible, otherwise waits or aborts under the policy.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 82 | lines 20-26

• Shared mode: shared lock (X)
• More than one transaction can apply share lock on X for reading its value but no write lock can be applied on X by any other transaction.
• Exclusive mode: Write lock (X)
• Only one write lock on X can exist at any time and no shared lock can be applied by any other transaction on X.
• Conflict matrix

Fundamental of Database Systems module | PDF page 83 | lines 2-8

• Lock Manager:
• Managing locks on data items.
• Lock table:
• Lock manager uses it to store the identify of transaction locking a data item, the data item, lock mode and pointer to the next data item locked. One simple way to implement a lock table is through linked list.

Question sources

Computer Science model exam · 2015 · Question 67

Question 30 | Q00615

Which claim about deadlock prevention and starvation is false?

A. In conservative 2PL, starvation may occur

B. Wound-wait guarantees starvation freedom regardless of restart priorities or scheduling fairness

C. Deadlock can be prevented by wait-die

D. Some deadlock-prevention methods may cause starvation

Hint

Identify requester and holder ages before applying the protocol's action.

Answer B: Wound-wait guarantees starvation freedom regardless of restart priorities or scheduling fairness

Deadlock freedom does not itself guarantee that each transaction eventually completes. Wound-wait uses transaction age to decide whether a requester waits or aborts a younger holder, but a starvation-freedom argument also needs appropriate restart priorities, fair scheduling and holders that eventually finish. Its unconditional guarantee in B is therefore false. Conservative 2PL can postpone a transaction indefinitely under unfair admission, and wait-die prevents waiting cycles. Some prevention policies can cause repeated waiting or victimization.

Why each choice is right or wrong

A - Incorrect: True: conservative 2PL prevents cycles but does not by itself guarantee fair admission.

B - Correct: Correct selection: the unconditional starvation-freedom claim omits necessary progress and priority assumptions.

C - Incorrect: True: wait-die is a timestamp-based deadlock-prevention policy.

D - Incorrect: True: preventing deadlock can still leave a transaction repeatedly postponed or aborted.

Primary note proof

Study-note section ADB14

> Retain the original timestamp when restarting an aborted transaction so it gains relative priority as new transactions arrive. Starvation avoidance additionally assumes holders eventually finish and scheduling is fair.

Study-note section ADB13

> Fixed resource ordering and conservative 2PL prevent cycles. A no-wait policy aborts immediately on an incompatible lock request and needs no age timestamp. A timeout aborts long waits but may mistake slow progress for deadlock. Starvation is indefinite postponement while other work proceeds, without a required cycle. Fair queues, sensible victim selection and retaining original transaction timestamps on retry reduce starvation; deadlock freedom alone does not prove fairness.

◦ Starvation occurs when a particular transaction consistently waits or restarted and never gets a chance to proceed further while other transaction continue normally
◦ This may occur , if the waiting method for item locking:
• Gave priority for some transaction over others
• Problem in Victim selection algorithm- it is possible that the same transaction may consistently be selected as victim and rolled-back
.example In Wound-Wait
◦ Solution
• FIFO
• Allow for transaction that wait for a longer time

Question sources

Computer Science model exam · 2015 · Question 84

Question 31 | Q00616

Concurrency control in DBMS is important for which of the following reasons?

A. To ensure data integrity when updates occur to the database in a single user environment

B. To ensure data integrity when reads occur to the database in a single user environment

C. To ensure data integrity when updates occur to the database in a multi user environment

D. To ensure data integrity when reads occur to the database in a multi user environment

Hint

Trace which transaction wrote each value and whether an overwrite or mixed-version read occurs.

Answer C: To ensure data integrity when updates occur to the database in a multi user environment

Concurrency control preserves consistency when multiple users' updates interleave and conflict. Read-only sharing alone does not cause lost updates; the intended scenario is a multiuser system with updates.

Why each choice is right or wrong

A - Incorrect: Single-user updates lack concurrent intertransaction conflicts. (PDF pp. 68, 70, 79.)

B - Incorrect: Single-user reads do not create the cited conflicts. (PDF pp. 68, 70, 79.)

C - Correct: Multiuser updates can create read/write and write/write conflicts requiring scheduling. (PDF pp. 68, 70, 79.)

D - Incorrect: Reads can be involved when others update, but reads alone do not capture the source's motivating condition. (PDF pp. 68, 70, 79.)

Primary note proof

Study-note section ADB08

Lost update: T1 and T2 both read 500; T2 adds 200 and writes 700; T1 adds 100 to its stale value and writes 600. Correct serial execution yields 800. Dirty read: T2 reads a value written by uncommitted T1; if T1 aborts, dependent work must be reconsidered. Reading one's own changes is not a dirty read.

Study-note section ADB06

Atomicity means all effects or none; consistency means correct work preserves integrity rules; isolation controls concurrent interference; durability preserves committed effects despite failure.

Study-note section ADB09

Read/read pairs do not conflict.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 68 | lines 4-7

i. The Lost Update Problem
◦ This occurs when two transactions that access the same database items have their operations interleaved in a way that makes the value of some database item incorrect.

Fundamental of Database Systems module | PDF page 70 | lines 2-12

ii. The Temporary Update (or Dirty Read) Problem
◦ This occurs when one transaction updates a database item and then the transaction fails for some reason .
◦ The updated item is accessed by another transaction before it is changed back to its original value. Based on the above scenario:
iii. The Incorrect Summary Problem
◦ If one transaction is calculating an aggregate summary function on a number of records while other transactions are updating some of these records, the aggregate function may calculate some values before they are updated and others after they are updated.
Example: T1 would like to add the values of A=10, B=20 and C=30. after the values are read by

Fundamental of Database Systems module | PDF page 79 | lines 4-15

- Transaction Processor is divided into:
◦ A concurrency-control manager, or scheduler, responsible for assuring isolation of transactions
◦ A logging and recovery manager, responsible for the durability of transactions.
- The scheduler (concurrency-control manager) must assure that the individual actions of multiple transactions are executed in such an order that the net effect is the same as if the transactions had in fact executed one-at-a-time.

1. Purpose of Concurrency Control

◦ To enforce Isolation (through mutual exclusion) among conflicting transactions.
◦ To preserve database consistency through consistency preserving execution of transactions.
◦ To resolve read-write and write-write conflicts.

Question sources

Computer Science model exam · 2015 · Question 85

Question 32 | Q00624

A lock wait-for graph may contain several independent deadlock cycles. Which termination methods guarantee eliminating all deadlock cycles? Assume each aborted transaction is undone and releases its locks. Select all that apply. 'Half' and 'single' mean arbitrary selections without a repeated cycle check.

A. Abort all deadlocked transaction

B. Abort half of the deadlocked transaction

C. Aborting single deadlocked transactio

D. Aborting one transaction at a time until the deadlock cycle is eliminated

Hint

Distinguish a waiting cycle, a long wait and indefinite unfair postponement.

Answer A, D: A. Abort all deadlocked transaction; D. Aborting one transaction at a time until the deadlock cycle is eliminated

Aborting all deadlocked transactions removes every participating wait, although it wastes work. A more selective complete method aborts a suitable victim, releases its locks and repeats until no cycles remain. An arbitrary half of the participants can leave a cycle intact, and one arbitrary victim may resolve only one of several independent cycles. The guarantee therefore applies to A and D.

Why each choice is right or wrong

A - Correct: Removing all deadlocked participants eliminates all their cycles.

B - Incorrect: An arbitrary half may miss an entire remaining cycle.

C - Incorrect: One victim need not break other independent cycles.

D - Correct: Repeated victim selection and graph checking continues until every cycle is gone.

Primary note proof

Study-note section ADB13

Deadlock requires a waiting cycle: T1 holds X and wants Y; T2 holds Y and wants X. In a wait-for graph, an edge Ti→Tj means Ti waits for a lock held by Tj. A cycle indicates deadlock under the ordinary lock-wait model. Abort a suitable victim, undo its effects and release its locks; repeat if

other cycles remain. Aborting every deadlocked transaction also breaks cycles but wastes more work.

Study-note section ADB13

A no-wait policy aborts immediately on an incompatible lock request and needs no age timestamp.

Study-note section ADB13

Starvation is indefinite postponement while other work proceeds, without a required cycle.

Question sources

Computer Science model exam · 2015 · Question 93

Question 33 | Q00643

Among the components of the DBMS, which one is responsible for keeping the isolation of transactions?

A. Recovery protocol

B. Application programmer

C. Concurrency -control protocol

D. Database administrator

Hint

Track the transaction's guarantee or lifecycle boundary described by the scenario.

Answer C: Concurrency -control protocol

Concurrency control regulates interactions between simultaneous transactions and enforces isolation. Recovery supports atomicity and durability by undoing incomplete effects and preserving committed work. Application programmers must supply correct transaction logic, and the DBA administers the database rather than serving as the executing concurrency-control mechanism. The question asks for that mechanism's primary responsibility, so C is the precise answer even though administration, applications and recovery all contribute to a working database.

Why each choice is right or wrong

A - Incorrect: Incorrect: recovery primarily supports atomicity and durability, rather than scheduling concurrent interactions for isolation.

B - Incorrect: Incorrect: an application programmer supplies transaction logic but is not the executing isolation-control mechanism.

C - Correct: Correct: concurrency control regulates conflicting concurrent operations to enforce isolation.

D - Incorrect: Incorrect: the DBA is an administrative human role, not the DBMS mechanism scheduling transaction interactions.

Primary note proof

Study-note section ADB06

> A transaction is a logical unit of database work, including read-only work. Atomicity means all effects or none; consistency means correct work preserves integrity rules; isolation controls concurrent interference; durability preserves committed effects despite failure. A DBMS cannot automatically make incorrect business logic consistent.

Study-note section ADB06

> Active means operations are executing. Partially committed means the last operation finished but durable commitment is not yet assured. Committed means commitment succeeded. A failure leads to Failed, then Aborted after rollback; a transaction may terminate or be restarted as a new attempt. Concurrency control primarily enforces isolation; recovery supports atomicity and

durability. Transaction management is the broader subsystem, so both it and recovery management can be legitimate answers to broad responsibility questions.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 66 | lines 4-13

- Atomicity: A transaction is an atomic unit of processing; it is either performed in its entirety or not performed at all.
- Consistency preservation: A correct execution of the transaction must take the database from one consistent state to another.
- Isolation: A transaction should not make its updates visible to other transactions until it is committed; this property, when enforced strictly, solves the temporary update problem and makes cascading rollbacks of transactions unnecessary
- Durability or permanency: Once a transaction changes the database and the changes are committed, these changes must never be lost because of subsequent failure.

Example

Fundamental of Database Systems module | PDF page 79 | lines 4-15

- Transaction Processor is divided into:
  - A concurrency-control manager, or scheduler, responsible for assuring isolation of transactions
  - A logging and recovery manager, responsible for the durability of transactions.
- The scheduler (concurrency-control manager) must assure that the individual actions of multiple transactions are executed in such an order that the net effect is the same as if the transactions had in fact executed one-at-a-time.

1. Purpose of Concurrency Control
   - To enforce Isolation (through mutual exclusion) among conflicting transactions.
   - To preserve database consistency through consistency preserving execution of transactions.
   - To resolve read-write and write-write conflicts.

Question sources

Computer Science model exam · 2015 · Question 112

Question 34 | Q00645

_____Occurs when two transactions update the same data item, but both read the same original value before update

A. Dirty read

B. Lost update

C. Incorrect summary

D. Unrepeatable read

Hint

Trace which transaction wrote each value and whether an overwrite or mixed-version read occurs.

Answer B: Lost update

Both transactions reading the original value lets a later write overwrite the earlier transaction's update; that update is lost.

Why each choice is right or wrong

A - Incorrect: Dirty read concerns uncommitted values from another transaction. (PDF pp. 68, 70.)

B - Correct: Lost update matches the stale-original-value overwrite. (PDF pp. 68, 70.)

C - Incorrect: Incorrect summary combines differently timed values in an aggregate. (PDF pp. 68, 70.)

D - Incorrect: Unrepeatable read concerns a later reread seeing a changed value. (PDF pp. 68, 70.)

Primary note proof

Study-note section ADB08

> Lost update: T1 and T2 both read 500; T2 adds 200 and writes 700; T1 adds 100 to its stale value and writes 600. Correct serial execution yields 800. Dirty read: T2 reads a value written by uncommitted T1; if T1 aborts, dependent work must be reconsidered. Reading one's own changes is not a dirty read.

Computer Science model exam · 2015 · Question 114

Question 35 | Q00659

Which of the DBMS component ensures that the concurrent execution of multiple operations on the database results into consistent database state?

A. Log

B. Buffer manager

C. File manager

D. Transaction processing system

Hint

Track the transaction's guarantee or lifecycle boundary described by the scenario.

Answer D: Transaction processing system

The transaction processing system contains the scheduler and recovery managers. Its scheduling ensures concurrent individual actions have a net effect equivalent to one-at-a-time execution.

Why each choice is right or wrong

A - Incorrect: The log records changes but does not itself schedule consistent execution. (PDF pp. 79, 99.)

B - Incorrect: Buffers hold blocks and arrange writes, not the entire consistency protocol. (PDF pp. 79, 99.)

C - Incorrect: File management is not the scheduler responsible for concurrent effects. (PDF pp. 79, 99.)

D - Correct: Transaction processing contains the concurrency-control component implementing this guarantee. (PDF pp. 79, 99.)

Primary note proof

Study-note section ADB06

> A transaction is a logical unit of database work, including read-only work. Atomicity means all effects or none; consistency means correct work preserves integrity rules; isolation controls concurrent interference; durability preserves committed effects despite failure. A DBMS cannot automatically make incorrect business logic consistent.

Study-note section ADB09

> A serial schedule executes each transaction's operations consecutively.

Study-note section ADB09

> A serializable schedule is equivalent to some serial order; it may interleave transactions.

✓ Logging: In order to assure durability, every change in the database is logged separately on disk.
✓ Log manager initially writes the log in buffers and negotiates with the buffer manager to make sure that buffers are written to disk at appropriate times.
✓ Recovery Manager: will be able to examine the log of changes and restore the database to some consistent state.
Recovery techniques and facilities

Question sources

Computer Science model exam · 2015 · Question 128

Question 36 | Q00687

How do you prevent system privileges deletion and updating authority on PRICE and YEAR column of the CATALOGUE table from user Mohammed

A. GRANT DELETE, UPDATE (price,year) ON catalogue From Mohammed

B. ALLOW DELETE, UPDATE (price,year) ON catalogue From Mohammed

C. REVOKE DELETE, UPDATE (price,year) ON catalogue From Mohammed

D. DENY DELETE, UPDATE (price,year) ON catalogue From Mohammed

Hint

Track whether a privilege is being added or withdrawn and whether it applies to rows or columns.

Answer C: REVOKE DELETE, UPDATE (price,year) ON catalogue From Mohammed

To withdraw Mohammed's DELETE and column-specific UPDATE privileges, use REVOKE DELETE, UPDATE(price,year) ON catalogue FROM Mohammed. This concerns object privileges, despite the stem's 'system privileges' wording. Other independent grants may remain.

Why each choice is right or wrong

A - Incorrect: GRANT adds privileges and also uses TO, not FROM. (PDF pp. 54, 55.)

B - Incorrect: ALLOW is not the module's SQL privilege command. (PDF pp. 54, 55.)

C - Correct: REVOKE with ON and FROM matches the module syntax. (PDF pp. 54, 55.)

D - Incorrect: DENY is not the revocation command presented in this module. (PDF pp. 54, 55.)

Primary note proof

Study-note section ADB25

> GRANT SELECT ON Catalogue TO Mohammed; permits reads. REVOKE DELETE, UPDATE (Price,Year) ON Catalogue FROM Mohammed; removes the specified table deletion and column update grants in SQL dialects supporting that form. DELETE applies to rows/table access rather than particular columns; UPDATE can be column-scoped. REVOKE removes permission, whereas GRANT gives it.

Study-note section ADB25

> WITH GRANT OPTION permits a recipient to grant a privilege onward; removing an upstream grant can cascade or be restricted according to the chosen command and DBMS.

Study-note section ADB25

> Removing one direct grant may leave effective access through another role or grant path.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 54 | lines 12-20

> GRANT <privileges>

> [WITH GRANT OPTION]
> • <privileges> is a list of
> SELECT <columns>, INSERT <columns>, DELETE, and UPDATE <columns>, or
> simply ALL
> • <users> is a list of user names or PUBLIC
> • <object> is the name of a table or view

Fundamental of Database Systems module | PDF page 55 | lines 8-12

> REVOKE <privileges>
> ON <object>
> FROM <users>

- If a user has the same privilege from other users then they keep it
- All privileges dependent on the revoked one are also revoked

Question sources

Computer Science model exam 2 · Question 28

Question 37 | Q00890

Inclient-server database architecture, what is the primary role of the server?

A. Provide the GUI for end users

B. Initiate all network connections and poll clients for updates

C. Store and manage shared data, enforce ACID properties, and process client requests

D. Cache all user sessions locally for offline access

Hint

Identify which tier submits, mediates or executes a request.

Answer C: Store and manage shared data, enforce ACID properties, and process client requests

The database server provides database functionality and manages local data, while clients submit requests and combine results. DBMS components enforce transaction properties.

Why each choice is right or wrong

A - Incorrect: The client-facing GUI is not the server's primary data-management role. (PDF pp. 125, 126, 66.)

B - Incorrect: Clients initiate requests; polling clients is not the described workflow. (PDF pp. 125, 126, 66.)

C - Correct: Managing data and processing client requests matches server responsibilities. (PDF pp. 125, 126, 66.)

D - Incorrect: Offline local session caching is not the described database server function. (PDF pp. 125, 126, 66.)

Primary note proof

Study-note section ADB34

In client/server architecture, clients submit requests while servers manage shared data, execute operations and enforce supported integrity/transaction rules. In collaborating-server designs, servers cooperate on subqueries and transactions. Middleware can translate requests, locate data, coordinate operations and combine results across independent servers. These describe communication responsibilities, not fragmentation types.

Study-note section ADB34

State how much schema, transaction and administrative autonomy local sites retain.

Study-note section ADB34

A tightly integrated distributed system can present one global schema and shared control.

Question 38 | Q00892

In two-phase locking (2PL), during which phase may a transaction acquire locks but not release any?

A. Growing phase

B. Commit phase

C. .

Validation phase

D. Shrinking phase

Hint

Track the first lock release and the transaction-completion boundary.

Answer A: Growing phase

The growing phase acquires locks without releasing any. Shrinking starts with release and prohibits new acquisitions.

Why each choice is right or wrong

A - Correct: Growing has the acquisition-without-release rule. (PDF pp. 86.)

B - Incorrect: Commit is not the phase name in basic 2PL. (PDF pp. 86.)

C - Incorrect: Validation belongs to optimistic concurrency control. (PDF pp. 86.)

D - Incorrect: Shrinking permits release, not acquisition. (PDF pp. 86.)

Primary note proof

Study-note section ADB12

> Basic 2PL has a growing phase that acquires/upgrades locks and a shrinking phase that releases/downgrades them. Once any lock is released, no new lock may be acquired. The lock point is the instant the final lock is obtained. 2PL guarantees conflict serializability for well-formed transactions, but can deadlock and basic 2PL alone need not prevent cascading aborts.

Study-note section ADB12

> Two-phase locking orders access to data; two-phase commit coordinates a distributed commit decision.

Study-note section ADB16

> Optimistic/validation control reads and computes privately, validates its read/write sets against overlapping transactions, then publishes if validation succeeds; otherwise it retries.

Fundamental of Database Systems module | PDF page 86 | lines 16-24

◦ Locking (Growing) Phase:
• A transaction applies locks (read or write) on desired data items one at a time.
• acquires all locks but cannot release any locks.
◦ Unlocking (Shrinking) Phase:
• A transaction unlocks its locked data items one at a time.
• Releases locks but cannot acquire any new locks.
● Requirement:
◦ For a transaction these two phases must be mutually exclusively, that is, during

Question sources

Computer Science Exit Exam · 2018 · Question 5

Question 39 | Q00915

Assume durable logs and serializable concurrency control, but no checkpoints or other valid log-truncation boundary. In a high-transaction system using deferred update, which recovery cost can grow after long uptime?

A. Recovery may require scanning a very long accumulated log

B. Increased disk I/O due to frequent page copying

C. Shared locks cannot be used

D. View serializability cannot be ensured

Hint

Identify which history a recovery boundary can safely exclude and whether active work spans it.

Answer A: Recovery may require scanning a very long accumulated log

Checkpoints record recovery state so recovery need not inspect the entire accumulated history. Without a checkpoint or another valid truncation boundary, the log that must be searched can grow throughout a long-running workload. Deferred update does not remove that problem. It specifies when persistent changes occur, not a requirement to copy shadow pages or a prohibition on shared locks. Serializability is enforced by the assumed concurrency-control mechanism, rather than by the existence of checkpoints.

Why each choice is right or wrong

A - Correct: Correct: without a recovery boundary, a long-running system may need to inspect a very large accumulated log.

B - Incorrect: Incorrect: deferred update describes timing and does not require frequent shadow-page copying.

C - Incorrect: Incorrect: deferring persistent writes does not prohibit shared-lock concurrency control.

D - Incorrect: Incorrect: serializability is enforced by the assumed concurrency control; a checkpoint limits recovery work rather than determining schedule equivalence.

Primary note proof

Study-note section ADB30

A fuzzy checkpoint permits ongoing transactions and records active-transaction and dirty-page information without forcing all pages simultaneously. Recovery may start analysis at the checkpoint but redo from an earlier required log position. A checkpoint is neither a full backup nor an automatic commit of active transactions. Without checkpoints or another valid truncation boundary, long-running systems may need expensive log scans; deferred update does not avoid that problem.

Study-note section ADB29

Deferred update keeps uncommitted changes outside the persistent database; in the usual no-force setting it is NO-UNDO/REDO.

Study-note section ADB12

Basic 2PL has a growing phase that acquires/upgrades locks and a shrinking phase that releases/downgrades them. Once any lock is released, no new lock may be acquired. The lock point is the instant the final lock is obtained. 2PL guarantees conflict serializability for well-formed transactions, but can deadlock and basic 2PL alone need not prevent cascading aborts.

Check pointing
• Log file is used to recover failed DB but we may not know how far back in the log to search. Thus
• Checkpoint is a Point of synchronization between database and log file.
• Time to time (randomly or under some criteria) the database flushes its buffer to database disk to minimize the task of recovery.
• When failure occurs, redo all transactions that committed since the checkpoint and undo all transactions active at time of crash.
• In previous example ,Figure 2, on slide18 , with checkpoint at time tc, changes made by T2 and T3 have been written to secondary storage. Thus: only redo T4 and T5, undo transactions T1 and T6.
• At what interval to take a check pointing may be measured :

Fundamental of Database Systems module | PDF page 108 | lines 24-29

• During recovery, all transactions of the commit table are redone and all transactions of active tables are ignored since none of their AFIMs reached the database.
• It is possible that a commit table transaction may be redone twice but this does not create any inconsistency because of a redone is —idempotent‖,
• that is, one redone for an AFIM is equivalent to multiple redone for the same AFIM.

Question sources

Computer Science Exit Exam · 2018 · Question 28

Question 40 | Q00933

Which listed techniques use transaction logs for recovery in the course model? Interpret deferred modification as the conventional logged, no-force deferred-update method. Select all that apply.

A. Recovery in Multi-database Systems

B. ARIES Recovery Algorithm

C. Shadow Paging Technique

D. Deferred Database Modification

Hint

Separate update timing from update location and follow the commit boundary.

Answer B, D: B. ARIES Recovery Algorithm; D. Deferred Database Modification

ARIES uses write-ahead logging and log-driven recovery metadata. Conventional logged deferred modification also uses recorded updates to redo committed effects that have not reached persistent pages. Both are log-based techniques under the stated model. Shadow paging instead preserves committed page mappings and installs a new map at commit. Recovery in multidatabase systems names an environment rather than one particular algorithm.

Why each choice is right or wrong

A - Incorrect: Multidatabase recovery names an environment rather than identifying a particular log-based technique.

B - Correct: ARIES explicitly relies on WAL and logged recovery metadata.

C - Incorrect: Shadow paging preserves page maps as an alternative to conventional log-based recovery.

D - Correct: Deferred modification can use a log to redo committed changes without undo.

Primary note proof

Study-note section ADB29

> Deferred update keeps uncommitted changes outside the persistent database; in the usual no-force setting it is NO-UNDO/REDO. Redo-only and NO-UNDO/REDO mean the same thing, so those cannot be separate unique answers. Immediate update allows persistent changes before commit and therefore may require undo; it need not flush every write_item immediately.

Study-note section ADB31

> ARIES uses WAL, page log sequence numbers (pageLSN), a transaction table and a dirty-page table.

Study-note section ADB29

Shadow paging keeps an unchanged committed page map and a modified map; commit durably installs a new root/map pointer atomically after required pages are durable.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 104 | lines 19-25

• For Undo: Before a data item‘s AFIM is flushed to the database disk (overwriting the BFIM) its BFIM must be written to the log and the log must be saved on a stable store (log disk).
• For Redo: Before a transaction executes its commit operation, all its AFIMs must be written to the log and the log must be saved on a stable store.
• Standard Recovery Terminology

Fundamental of Database Systems module | PDF page 107 | lines 16-28

• Undo: Restore all BFIMs on to disk (Remove all AFIMs).
• Redo: Restore all AFIMs on to disk.
• Database recovery is achieved either by performing only Undos or only Redos or by a combination of the two. These operations are recorded in the log as they happen.
Data Update and Recovery Scheme : Three types
i. Deferred Update (No Undo/Redo)
◦ The data update goes as follows:
• A set of transactions records their updates in the log.
• At commit point under WAL scheme these updates are saved on database disk.
• No undo is required because no AFIM is flushed to the disk before a transaction commits.

Fundamental of Database Systems module | PDF page 109 | lines 13-22

iii. Shadow Paging
• Maintain two page tables during life of a transaction: current page and shadow page table.
• When transaction starts, two pages are the same.
• Shadow page table is never changed thereafter and is used to restore database in event of failure.
• During transaction, current page table records all updates to database.
• When transaction completes, current page table becomes shadow page table.
X and Y: Shadow copies of data items
X' and Y': Current copies of data items

Question sources

Computer Science Exit Exam · 2018 · Question 46

Question 41 | Q00969

Which type of fragmentation in a distributed database divides a relation into subrelations defined by subsets of its columns, normally repeating a key to support reconstruction?

A. Replication

B. Location

C. Horizontal

D. Vertical

Hint

Identify whether rows or columns are split and reverse the split to reconstruct the original relation.

Answer D: Vertical

Vertical fragmentation projects column subsets into separate fragments. Repeating an appropriate key or row identifier allows a join to reconstruct the original rows without spurious combinations. Horizontal fragmentation instead selects subsets of rows, reconstructed by union. Replication creates copies rather than dividing the relation by attributes. Location transparency hides where data resides; it does not name the column-splitting design operation. The corrected category therefore supports the existing vertical-fragmentation answer.

Why each choice is right or wrong

A - Incorrect: Replication creates copies of data rather than splitting a relation into column subsets.

B - Incorrect: Location transparency hides placement details; it is not a fragmentation method.

C - Incorrect: Horizontal fragmentation partitions rows, not columns.

D - Correct: Correct: vertical fragmentation splits columns and normally repeats a reconstruction key.

Primary note proof

Study-note section ADB36

> Horizontal fragmentation selects row subsets by predicates; their union reconstructs the relation. Check completeness so every original row is represented and disjointness if no overlap is intended. Define an explicit fragment for NULL/other values when needed. Vertical fragmentation projects column subsets and repeats a key or row identifier so joining on it reconstructs the original rows without spurious matches.

Study-note section ADB35

> Location transparency hides which site holds a named object.

Study-note section ADB37

> Full replication places the whole database at every relevant site; partial replication copies selected fragments to selected sites; nonredundant allocation stores each fragment once.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 116 | lines 11-28

ii. Replication transparency:
• It allows to store copies of a data at multiple sites as shown in the above diagram.
• This is done to minimize access time to the required data.
iii. Fragmentation transparency:
• Allows to fragment a relation horizontally (create a subset of rows of a relation) or vertically (create a subset of columns of a relation).
iv. Increased reliability and availability:
• Reliability refers to system live time, that is, system is running efficiently most of the time. Availability is the probability that the system is continuously available (usable or accessible) during a time interval.
• A distributed database system has multiple nodes (computers) and if one fails then others are available to do the job.
v. Improved performance:
• A distributed DBMS fragments the database to keep data closer to where it is needed most.
• This reduces data management (access and modification) time significantly.

Fundamental of Database Systems module | PDF page 118 | lines 3-21

• Horizontal fragmentation
• It is a horizontal subset of a relation which contain those of rows which satisfy selection conditions.
• Consider the Employee relation with selection condition (DNO = 5). All rows satisfy this condition will create a subset which will be a horizontal fragment of Employee relation.
• A selection condition may be composed of several conditions connected by AND or OR.
• Vertical fragmentation
• It is a subset of a relation which is created by a subset of columns. Thus a vertical fragment of a relation will contain values of selected columns.
- Consider the Employee relation. A vertical fragment of can be created by keeping the values of Name, Bdate, Sex, and Address.
- Because there is no condition for creating a vertical fragment, each fragment must include the primary key attribute of the parent relation Employee. In this way all vertical fragments of a relation are connected.
• Representation
• There three rules that must be followed during fragmentation
• Completeness - if a relation r is decomposed into fragments r1, r2... rn ,

Computer Science Exit Exam · 2018 · Question 82

Question 42 | Q00993

In two-phase locking, which phase permits releasing existing locks but forbids acquiring new locks?

A. Expanding phase

B. Waiting phase

C. Shrinking phase

D. All of the above

Hint

Track the first lock release and the transaction-completion boundary.

Answer C: Shrinking phase

Two-phase locking divides lock use into a growing phase and a shrinking phase. During growing, a transaction may acquire or upgrade locks; once it releases a lock, it enters shrinking and cannot acquire any new lock. Waiting describes delay on a conflicting request, not a separate 2PL phase defined by releasing locks. Because the growing phase allows acquisition instead of release, the all-of-the-above alternative also fails.

Why each choice is right or wrong

A - Incorrect: Incorrect: the growing/expanding phase acquires locks and does not release them.

B - Incorrect: Incorrect: waiting on a conflicting request is a delay condition, not the formal 2PL release phase.

C - Correct: Correct: shrinking permits release while forbidding new acquisitions.

D - Incorrect: Incorrect: the growing phase does not meet the release/no-new-lock rule.

Primary note proof

Study-note section ADB12

> Basic 2PL has a growing phase that acquires/upgrades locks and a shrinking phase that releases/downgrades them. Once any lock is released, no new lock may be acquired. The lock point is the instant the final lock is obtained. 2PL guarantees conflict serializability for well-formed transactions, but can deadlock and basic 2PL alone need not prevent cascading aborts.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 86 | lines 16-24

> ◦ Locking (Growing) Phase:
> • A transaction applies locks (read or write) on desired data items one at a time.
> • acquires all locks but cannot release any locks.

◦ Unlocking (Shrinking) Phase:
• A transaction unlocks its locked data items one at a time.
• Releases locks but cannot acquire any new locks.
● Requirement:
◦ For a transaction these two phases must be mutually exclusively, that is, during

Question 43 | Q01002

Which one of the SQL keywords is used to provide access?

A. REVOKE

B. DISTINCT

C. GRANT

D. None of the above

Hint

Track whether a privilege is being added or withdrawn and whether it applies to rows or columns.

Answer C: GRANT

GRANT gives specified users privileges on an object. REVOKE removes privileges.

Why each choice is right or wrong

A - Incorrect: REVOKE withdraws access privileges. (PDF pp. 54, 55.)

B - Incorrect: DISTINCT is not the module's access-authorization command. (PDF pp. 54, 55.)

C - Correct: GRANT supplies the privileges on tables or views. (PDF pp. 54, 55.)

D - Incorrect: GRANT is listed, so None is false. (PDF pp. 54, 55.)

Primary note proof

Study-note section ADB25

GRANT SELECT ON Catalogue TO Mohammed; permits reads. REVOKE DELETE, UPDATE (Price,Year) ON Catalogue FROM Mohammed; removes the specified table deletion and column update grants in SQL dialects supporting that form. DELETE applies to rows/table access rather than particular columns; UPDATE can be column-scoped. REVOKE removes permission, whereas GRANT gives it.

Study-note section ADB25

WITH GRANT OPTION permits a recipient to grant a privilege onward; removing an upstream grant can cascade or be restricted according to the chosen command and DBMS.

Study-note section ADB25

Roles group privileges.

Question 44 | Q01156

is a tree data structure that corresponds to a relational algebra expression.

A. a | Query graph x

B. i? Query tree WA

C. '@| Query optimizer x

D. | None of the above x

Hint

Separate query representation, strategy selection and execution.

Answer B: i? Query tree WA

A query tree corresponds to a relational algebra expression, with relations as leaves and operations as internal nodes.

Why each choice is right or wrong

A - Incorrect: Query graph corresponds to relational calculus. (PDF pp. 34.)

B - Correct: Query tree is the exact defined algebraic tree. (PDF pp. 34.)

C - Incorrect: The optimizer chooses an execution strategy; it is not this data structure. (PDF pp. 34.)

D - Incorrect: The matching tree is explicitly listed. (PDF pp. 34.)

Primary note proof

Study-note section ADB17

> Parsing checks SQL grammar; semantic analysis resolves names, types and access permissions. Translation constructs a logical representation, typically relational algebra or a logical query tree. Optimization chooses equivalent operations, join order and physical access methods. Evaluation executes that plan and returns results. Not every implementation exposes exactly the same phase boundaries.

Study-note section ADB-S01

> A query tree corresponds to a relational-algebra expression: base relations appear at leaves and operators at internal nodes.

Study-note section ADB17

> A query tree has base relations at leaves and operators at internal nodes; a query graph emphasizes relations and predicates.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 34 | lines 5-7

> 2. Apply heuristics rules to optimize the internal representation.
> 3. A query execution plan is generated to execute groups of operations based on the access paths available on the files involved in the query.

Question sources

Computer Science Exit Exam practice questions · Question 17

Question 45 | Q01184

Which listed approaches use both undo and redo? Interpret Immediate Update as the conventional steal/no-force logged model and Deferred Update as no-steal/no-force; use the course's ARIES definition. Select all that apply.

A. Immediate Update

B. Deferred Update

C. ARIES Algorithm

D. None

Hint

Determine whether uncommitted changes or unflushed committed changes may exist on persistent pages.

Answer A, C: A. Immediate Update; C. ARIES Algorithm

Steal allows uncommitted changes to reach persistent pages, creating a possible need for undo. No-force allows committed changes to remain buffered, creating a possible need for redo. Immediate update under the specified combined policy therefore needs both. ARIES also performs redo and then undoes losers. The specified deferred no-steal/no-force model needs redo but no undo, so it does not qualify.

Why each choice is right or wrong

A - Correct: The stated steal/no-force policy requires undo and redo.

B - Incorrect: The specified deferred policy prevents persistent uncommitted effects and needs redo only.

C - Correct: ARIES repeats history with redo and reverses losers with undo.

D - Incorrect: Two listed approaches use both actions.

Primary note proof

Study-note section ADB28

> Steal permits a page with uncommitted changes to be written to disk; hence recovery may need undo. No-steal prevents those uncommitted effects reaching the persistent database. Force writes a transaction's updated data pages at commit; no-force permits committed dirty pages to remain buffered, hence recovery may need redo.

Study-note section ADB28

> For the conventional page/log model: steal/no-force needs undo and redo; steal/force needs undo but no redo; no-steal/no-force needs redo but no undo; no-steal/force needs neither data-page undo nor redo after a system crash.

Study-note section ADB29

> Deferred update keeps uncommitted changes outside the persistent database; in the usual no-force setting it is NO-UNDO/REDO.

Related reading (context, not primary note proof)

Study-note section ADB31

Fundamental of Database Systems module | PDF page 105 | lines 25-36

Check pointing
• Log file is used to recover failed DB but we may not know how far back in the log to search. Thus
• Checkpoint is a Point of synchronization between database and log file.
• Time to time (randomly or under some criteria) the database flushes its buffer to database disk to minimize the task of recovery.
• When failure occurs, redo all transactions that committed since the checkpoint and undo all transactions active at time of crash.
• In previous example ,Figure 2, on slide18 , with checkpoint at time tc, changes made by T2 and T3 have been written to secondary storage. Thus: only redo T4 and T5, undo transactions T1 and T6.
• At what interval to take a check pointing may be measured :

Fundamental of Database Systems module | PDF page 109 | lines 13-22

iii. Shadow Paging
• Maintain two page tables during life of a transaction: current page and shadow page table.
• When transaction starts, two pages are the same.
• Shadow page table is never changed thereafter and is used to restore database in event of failure.
• During transaction, current page table records all updates to database.
• When transaction completes, current page table becomes shadow page table.
X and Y: Shadow copies of data items
X' and Y': Current copies of data items

Fundamental of Database Systems module | PDF page 110 | lines 14-30

◦ Deferred Update:
• All transaction updates are recorded in the local workspace (cache)
• All modified data items in the cache is then written after a transaction ends its execution or after a fixed number of transactions have completed their execution.
• During commit the updates are first recorded on the log and then on the database
• If a transaction fails before reaching its commit point undo is not needed because it didn‘t change the database yet
• If a transaction fails after commit (writing on the log) but before finishing saving to the data base redoing is needed from the log
◦ Immediate Update:
• As soon as a data item is modified in cache, the disk copy is updated.
• These update are first recorded on the log and on the disk by force writing,

before the database is updated
• If a transaction fails after recording some change to the database but before reaching its commit point , this will be rolled back

Question sources

Computer Science model exam 2 · Question 5

Question 46 | Q01209

Which recovery mechanism preserves the committed page map while writing modified pages elsewhere, then atomically installs a new map at commit as an alternative to conventional log-based recovery?

A. Disk recovery

B. Shadow paging

C. Deferred update

D. Crash recovery

Hint

Separate update timing from update location and follow the commit boundary.

Answer B: Shadow paging

Shadow paging preserves the committed page map and writes modified pages to separate locations. Once the required pages are durable, commit atomically installs the new map; before that point, recovery can use the old committed map. Deferred update instead describes postponing persistent database changes until commit and does not itself specify this page-map mechanism. Disk recovery and crash recovery name recovery domains or events, not the particular algorithm requested.

Why each choice is right or wrong

A - Incorrect: Incorrect: disk recovery describes a recovery domain, not the specified preserved-page-map mechanism.

B - Correct: Correct: shadow paging preserves the committed map and installs the new map atomically at commit.

C - Incorrect: Incorrect: deferred update specifies commit timing, not this copy-on-write page-map algorithm.

D - Incorrect: Incorrect: crash recovery describes recovery after an event rather than the particular page-map mechanism.

Primary note proof

Study-note section ADB29

In-place update overwrites the original location. Shadow/copy-on-write update writes a new location while preserving the committed version. Shadow paging keeps an unchanged committed page map and a modified map; commit durably installs a new root/map pointer atomically after required pages are durable. Before commit, a crash uses the old map. It is an alternative to conventional log-based recovery, with allocation, fragmentation and concurrency costs; it is not primarily a special action done only during recovery.

Study-note section ADB29

Deferred update keeps uncommitted changes outside the persistent database; in the usual no-force setting it is NO-UNDO/REDO.

Related reading (context, not primary note proof)

Study-note section ADB26

Fundamental of Database Systems module | PDF page 109 | lines 13-22

iii. Shadow Paging
• Maintain two page tables during life of a transaction: current page and shadow page table.
• When transaction starts, two pages are the same.
• Shadow page table is never changed thereafter and is used to restore database in event of failure.
• During transaction, current page table records all updates to database.
• When transaction completes, current page table becomes shadow page table.
X and Y: Shadow copies of data items
X' and Y': Current copies of data items

Question sources

Computer Science model exam 2 · Question 30

Question 47 | Q01225

Which specific DBMS component directly handles undo of incomplete persistent changes after failure to support transaction atomicity? Choose the specialized component rather than its broader parent subsystem.

A. Transaction management component of DBMS

B. Application Programmer

C. Concurrency control component of DBMS

D. Recovery management component of DBMS

Hint

Track the transaction's guarantee or lifecycle boundary described by the scenario.

Answer D: D. Recovery management component of DBMS

Atomicity requires all transaction effects or none. After failure, recovery can undo incomplete persistent changes to enforce that outcome. Transaction management is the broader subsystem containing these responsibilities, but the question asks for the specialized component. Concurrency control primarily addresses isolation, and application code alone cannot provide the DBMS's crash-recovery undo of partially persisted work.

Why each choice is right or wrong

A - Incorrect: This is the parent subsystem, not the specialized failure-undo component requested.

B - Incorrect: Application logic alone does not provide durable crash undo.

C - Incorrect: Concurrency control primarily enforces isolation.

D - Correct: Recovery directly supports atomicity by undoing incomplete effects.

Primary note proof

Study-note section ADB06

> A transaction is a logical unit of database work, including read-only work. Atomicity means all effects or none; consistency means correct work preserves integrity rules; isolation controls concurrent interference; durability preserves committed effects despite failure. A DBMS cannot automatically make incorrect business logic consistent.

Study-note section ADB27

> Undo restores before-images of incomplete effects, usually traversing that transaction's updates backward.

Study-note section ADB27

> Write-ahead logging requires the update log needed for recovery to reach stable storage before the corresponding changed data page reaches disk.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 66 | lines 4-13

- Atomicity: A transaction is an atomic unit of processing; it is either performed in its entirety or not performed at all.
- Consistency preservation: A correct execution of the transaction must take the database from one consistent state to another.
- Isolation: A transaction should not make its updates visible to other transactions until it is committed; this property, when enforced strictly, solves the temporary update problem and makes cascading rollbacks of transactions unnecessary
- Durability or permanency: Once a transaction changes the database and the changes are committed, these changes must never be lost because of subsequent failure.

Example

Fundamental of Database Systems module | PDF page 97 | lines 4-13

i. Purpose of Database Recovery
◦ To bring the database into the last consistent state, which existed prior to the failure.
◦ To preserve transaction properties (Atomicity &and Durability).
• The recovery manager of a DBMS is responsible to ensure
• atomicity by undoing the action of transaction that do not commit
• Durability by making sure that all actions of committed transaction survive system crash
ii. Types of Failure
◦ The database may become unavailable for use due to :

Fundamental of Database Systems module | PDF page 66 | lines 22-31

- Atomicity- either all or none of the above operation will be done - this is materialized by transaction management component of DBMS
- Consistency-the sum of CA2090 and SB2359 be unchanged by the execution of Ti i.e 8500- this is the responsibility of application programmer who codes the transaction
- Isolation- when several transaction are being processed concurrently on a data item they may create many inconsistent problems. So handling such case is the responsibility of Concurrency control component of the DBMS
- Durability - once Ti writes its update this will remain there when the database restarted from failure . This is the responsibility of recovery management components of the DBMS

Question sources

Computer Science model exam 2 · Question 46

Question 48 | Q01238

If a database server is referenced in a distributed transaction, the value of its commit point strength determines which role it plays in the _____.

A. Two-phase commit

B. Transaction locking

C. Two-phase locking

D. Checkpoints

Hint

Distinguish coordinated transaction outcome from concurrent access and local storage.

Answer A: Two-phase commit.

ADB39 explicitly links Oracle COMMIT_POINT_STRENGTH to choosing the commit point site in distributed transactions. This is a role in two-phase commit, which coordinates an atomic outcome among participants. It is not a setting for acquiring or releasing locks, nor for checkpoints that bound recovery work. Higher eligible strength is preferred for the commit point.

Why each choice is right or wrong

A - Correct: Commit-point strength selects an Oracle distributed-commit role within the two-phase commit mechanism.

B - Incorrect: Transaction locking controls concurrent access rather than choosing the distributed commit point site.

C - Incorrect: Two-phase locking governs lock acquisition and release, not the distributed commit decision.

D - Incorrect: Checkpoints record recovery state and do not choose an Oracle commit point site.

Primary note proof

Study-note section ADB39

> Two-phase commit (2PC) first asks participants to prepare and durably promise they can commit. If all vote yes, the coordinator records commit durably and tells participants; otherwise it decides abort. A prepared participant must retain enough state to obey the final decision. Coordinator/communication failure can leave it in doubt and block progress until the decision is learned. Timeout after preparation is not permission to invent a commit or abort.

Study-note section ADB39

> Oracle's COMMIT_POINT_STRENGTH helps choose the commit point site in its distributed transaction mechanism, with higher eligible strength preferred.

Study-note section ADB12

> Two-phase locking orders access to data; two-phase commit coordinates a distributed commit decision.

Related reading (context, not primary note proof)

Study-note section ADB30

Fundamental of Database Systems module | PDF page 123 | lines 15-29

• Distributed commit:
• A transaction may be fragmented and they may be executed by a number of sites. This require a two or three-phase commit approach for transaction commit.
• Distributed deadlock:
• Since transactions are processed at multiple sites, two or more sites may get involved in deadlock. This must be resolved in a distributed manner.
6.5.1 Distributed Concurrency control
i. Primary site technique: A single site is designated as a primary site which serves as a coordinator for transaction management.
• Transaction management:
- Concurrency control and commit are managed by this site.
- In two phase locking, this site manages locking and releasing data items. If all transactions follow two-phase policy at all sites, then serializability is guaranteed.
- Advantages:

Question sources

Computer Science model exam 2 · Question 59

Question 49 | Q01240

What is the distinctive purpose of query optimization within the broader query-processing pipeline? Select the most specific description.

A. Both are used to process SQL statements to return answers.

B. Both filter retrieved rows by a date/time condition.

C. Both improve the performance of the database by efficiently executing a query.

D. Both are important in executing queries to access information from the DB.

Hint

Separate query representation, strategy selection and execution.

Answer C: C. Both improve the performance of the database by efficiently executing a query.

Query optimization selects a suitable efficient execution strategy among equivalent ways of answering a query. C explicitly states that efficiency objective. Returning answers and accessing information are broader descriptions of processing and do not distinguish optimization's particular purpose. Filtering data by a date or time is a query condition rather than the general goal of choosing a plan.

Why each choice is right or wrong

A - Incorrect: Returning answers describes the broad pipeline but omits the distinctive efficiency objective.

B - Incorrect: Temporal filtering is query logic, not the general purpose of optimization.

C - Correct: Efficient execution is the specific objective of selecting a suitable plan.

D - Incorrect: Accessing information describes the broad pipeline rather than optimization's efficiency role.

Primary note proof

Study-note section ADB17

> Parsing checks SQL grammar; semantic analysis resolves names, types and access permissions. Translation constructs a logical representation, typically relational algebra or a logical query tree. Optimization chooses equivalent operations, join order and physical access methods. Evaluation executes that plan and returns results. Not every implementation exposes exactly the same phase boundaries.

Study-note section ADB17

> Query processing is the whole activity; selecting a suitable efficient strategy is optimization.

Study-note section ADB17

> DDL is not a mandatory stage before each SELECT, so authentication→DDL→DML permutations do not describe the processing sequence.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 27 | lines 4-15

> What is Query Processing?
> Steps required to transform high level SQL query into a correct and —efficient‖ strategy for execution and retrieval.
> What is Query Optimization?
> ✓ The activity of choosing a single —efficient‖ execution strategy (from hundreds) as determined by database catalog statistics.
> ✓ The aim is to answer which relational algebra expression, equivalent to the given query, will lead to the most efficient solution plan?
> ✓ For each algebraic operator, what algorithm (of several available) do we use to

compute that operator?
✓ How do operations pass data (main memory buffer, disk buffer,...)?
✓ Will this plan minimize resource usage? (CPU/Response Time/Disk)

Fundamental of Database Systems module | PDF page 30 | lines 17-30

1.8 Query Optimization
• Everyone wants the performance of their database to be optimal. In particular, there is often a requirement for a specific query or object that is query based, to run faster.
• Problem of query optimization is to find the sequence of steps that produces the answer to user request in the most efficient manner, given the database structure.
• The performance of a query is affected by the tables or views that underlies the query and by the complexity of the query.
• Given a request for data manipulation or retrieval, an optimizer will choose an optimal plan for evaluating the request from among the manifold alternative strategies. i.e. there are many ways (access paths) for accessing desired file/record.
• Hence ,DBMS is responsible to pick the best execution strategy based on various considerations(Least amount of I/O and CPU resources.)
• Example: Consider relations r(AB) and s(CD). We require r X s.
• Method 1 :

Question sources

Computer Science model exam 2 · Question 61

Question 50 | Q01245

What is the objective of a Serializable schedule?

A. Find a Non-serial schedule that allows the interleaving of a transaction and produces the same result as a serial schedule.

B. Find a Serial schedule that allows the interleaving of a transaction and produces the same result as a serial schedule.

C. Find a Serial schedule that doesn't allow the interleaving of a transaction and produces the same result as a serial schedule.

D. Find a Non-serial schedule that doesn't allow the interleaving of a transaction and produces the same result as a serial schedule.

Hint

Distinguish transaction ordering, conflict conditions and full execution equivalence.

Answer A: Find a Non-serial schedule that allows the interleaving of a transaction and produces the same result as a serial schedule.

Serial schedules run each transaction consecutively. Serializability permits nonserial interleaving while preserving the effect of a complete serial schedule (p.72). A expresses this concurrency objective.

Why each choice is right or wrong

A - Correct: Interleaving plus serial-equivalent effect meets the objective.

B - Incorrect: A serial schedule cannot interleave transactions as claimed.

C - Incorrect: This describes serial execution, not the benefit of serializable interleaving.

D - Incorrect: Nonserial execution is distinguished by departure from consecutive transaction execution; this denies the intended interleaving.

Primary note proof

Study-note section ADB09

A serial schedule executes each transaction's operations consecutively. A serializable schedule is equivalent to some serial order; it may interleave transactions. Equality of one final value is insufficient evidence because different executions can accidentally coincide. Two operations conflict when they belong to different transactions, access the same item and at least one writes. Read/read pairs do not conflict.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 72 | lines 6-18

- Serial schedule:
  - A schedule S is serial if, for every transaction Ti participating in the schedule, all the operations of Ti are executed consecutively in the schedule. Otherwise, the schedule is called nonserial schedule.
  - For example, in the banking example suppose there are two transaction where one transaction calculate the interest on the account and another deposit some money into the account. hence the order of execution is important for the final result.
- Serializable schedule:
  - a schedule whose effect on any consistent database instance is identical to that of some complete serial schedule over the set of committed transactions in S.
  - A nonserial schedule S is serializable , is equivalent to say that it is correct to the result of one of the serial schedule .Example,

Question sources

Computer Science model exam 2 · Question 66

Question 51 | Q01249

Under the course data-model type-constructor convention, which statements are false? Select all that apply. Interpret type constructor as a data-model term, not an executable Java/C++ object constructor, and consider OID over one object's lifetime.

A. Object Identifier is immutable.

B. Type constructor is used to create a new object.

C. Tuple is a collection of records.

D. The atom constructor is a multi-value constructor.

Hint

Classify the shape of a value separately from an operation that creates an instance.

Answer B, C, D: B. Type constructor is used to create a new object.; C. Tuple is a collection of records.; D. The atom constructor is a multi-value constructor.

An OID remains stable over the object's lifetime, so A is true. A data-model type constructor specifies the shape of a value rather than executing creation of a new object. A tuple groups named components into one structured record, while an atom is one basic value. B, C and D therefore state incorrect properties under the specified convention.

Why each choice is right or wrong

A - Incorrect: OID stability over the object lifetime is true, so it does not answer the negative stem.

B - Correct: This is false under the note's convention: a type constructor specifies shape rather than executing object creation.

C - Correct: A tuple is one structured record of components, not a collection of records.

D - Correct: An atom represents one basic atomic value rather than a multivalued collection.

Primary note proof

Study-note section ADB04

> In a common object model, an object is described by (OID,type constructor,state). An atom is one basic value, such as an integer, real, Boolean or string. A tuple constructor groups named component values into one structured record, such as (Street:'A',City:'B'). It is not a collection of records.

Study-note section ADB04

> A type constructor defines the shape of a value; it is not the same as an executable constructor operation that creates a new object.

Study-note section ADB01

> The object identifier (OID) distinguishes objects independently of their attribute values and remains stable over that object's lifetime.

Question sources

Computer Science model exam 2 · Question 70

Question 52 | Q01264

Assume transaction A holds a shared lock R. If transaction B also requests for a shared lock on R

A. It will result in a deadlock situation

B. It will be granted as soon as it is released by A

C. It will immediately be granted

D. It will immediately be rejected

Hint

Compare access permissions and same-item compatibility before granting a lock request.

Answer C: It will immediately be granted

The shared-mode rule permits more than one transaction to hold a read lock on X, while excluding write locks (p.82). With only A's shared lock specified, B's shared request is compatible.

Why each choice is right or wrong

A - Incorrect: Two compatible shared requests do not produce the stated deadlock.

B - Incorrect: Waiting for A is unnecessary for compatible reads.

C - Correct: The shared request is compatible and may be granted immediately under the stated conditions.

D - Incorrect: The shared rule supplies no rejection condition here.

Primary note proof

Study-note section ADB11

> A shared (S) lock permits reading; multiple S locks on the same item can coexist. An exclusive (X) lock permits its holder to read and write and conflicts with another S or X on that item. Locks on different items do not conflict merely because one is exclusive. These are the basic lock-based rules; multiversion systems can permit additional snapshot-reader behavior.

Study-note section ADB11

> One transaction may request a lock on an already locked item: it is granted if compatible, otherwise waits or aborts under the policy.

Study-note section ADB11

> The lock manager decides requests; the lock table stores granted locks and waiting requests.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 82 | lines 20-26

• Shared mode: shared lock (X)
• More than one transaction can apply share lock on X for reading its value but no write lock can be applied on X by any other transaction.
• Exclusive mode: Write lock (X)
• Only one write lock on X can exist at any time and no shared lock can be applied by any other transaction on X.
• Conflict matrix

Fundamental of Database Systems module | PDF page 83 | lines 23-25

• Reads cannot conflict, so more than one transaction can hold shared locks simultaneously on same item.
• Exclusive lock gives transaction exclusive access to that item.

Question sources

Computer Science model exam 2 · Question 85

Question 53 | Q01266

In the dirty read problem, one transaction reads:

A. an uncommitted value of another transaction

B. the committed value for another transaction

C. another transaction

D. one transaction commits another transaction

Hint

Trace which transaction wrote each value and whether an overwrite or mixed-version read occurs.

Answer A: an uncommitted value of another transaction

The temporary-update/dirty-read definition involves another transaction accessing an updated item before the failed writer's value is restored. The hazard is observing the other transaction's uncommitted value.

Why each choice is right or wrong

A - Correct: This identifies the unsafe value from the other transaction.

B - Incorrect: A committed value lacks the defining uncommitted-update hazard.

C - Incorrect: Transactions read data items; this does not identify the dirty value.

D - Incorrect: One transaction committing another is not the read anomaly described.

Primary note proof

Study-note section ADB08

Lost update: T1 and T2 both read 500; T2 adds 200 and writes 700; T1 adds 100 to its stale value and writes 600. Correct serial execution yields 800. Dirty read: T2 reads a value written by uncommitted T1; if T1 aborts, dependent work must be reconsidered. Reading one's own changes is not a dirty read.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 70 | lines 2-12

ii. The Temporary Update (or Dirty Read) Problem
◦ This occurs when one transaction updates a database item and then the transaction fails for some reason .
◦ The updated item is accessed by another transaction before it is changed back to its original value. Based on the above scenario:
iii. The Incorrect Summary Problem
◦ If one transaction is calculating an aggregate summary function on a number of records while other transactions are updating some of these records, the aggregate function may calculate some values before they are updated and others after they are updated.
Example: T1 would like to add the values of A=10, B=20 and C=30. after the values are read by

Question sources

Computer Science model exam 2 · Question 87

Question 54 | Q01381

Which sequence matches the course's logical query-processing pipeline for a SELECT, from checking the request to returning its result?

A. Parsing and semantic analysis → logical translation → query optimization → evaluation → output

B. DDL->DML->query optimizer-> Authentication->output

C. DML->query optimizer-> Authentication-> DDL-> output

D. All of the mentioned

Hint

Separate query representation, strategy selection and execution.

Answer A: A. Parsing and semantic analysis → logical translation → query optimization → evaluation → output

The request is first checked for grammar and meaning, then translated into a logical representation. Optimization selects equivalent operations and physical access methods; evaluation executes that plan and returns the output. Option A follows those roles in order. The other sequences treat DDL and DML language categories as processing stages and place unrelated checks after optimization, so they do not fit.

Why each choice is right or wrong

A - Correct: This sequence follows checking, representation, strategy selection and execution.

B - Incorrect: DDL/DML categories do not form these phases, and checking is misplaced.

C - Incorrect: DDL is not a mandatory post-optimization phase of SELECT processing.

D - Incorrect: Only option A follows the pipeline, so all sequences are not correct.

Primary note proof

Study-note section ADB17

> Parsing checks SQL grammar; semantic analysis resolves names, types and access permissions. Translation constructs a logical representation, typically relational algebra or a logical query tree. Optimization chooses equivalent operations, join order and physical access methods. Evaluation executes that plan and returns results. Not every implementation exposes exactly the same phase boundaries.

Study-note section ADB17

> DDL is not a mandatory stage before each SELECT, so authentication→DDL→DML permutations do not describe the processing sequence.

Study-note section ADB17

> Query processing is the whole activity; selecting a suitable efficient strategy is optimization.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 29 | lines 9-20

> 1.6 Query Processing Steps
> • Processing can be divided into 4 :Decomposition, Optimization , Execution and Code generation
> 1.7 Query Decomposition
> ● It is the process of transforming a high level query into a relational algebra query, and to check that the query is syntactically and semantically correct. It Consists of parsing and validation
> Typical stages in query decomposition are:
> i. Analysis: lexical and syntactical analysis of the query (correctness) based on attributes, data type.. ,. Query tree will be built for the query containing leaf node for base relations, one or many non-leaf nodes for relations produced by relational algebra operations and root node for the result of the query. Sequence of operation is from the leaves to the

Fundamental of Database Systems module | PDF page 30 | lines 17-30

> 1.8 Query Optimization
> • Everyone wants the performance of their database to be optimal. In particular, there is often a requirement for a specific query or object that is query based, to run faster.
> • Problem of query optimization is to find the sequence of steps that produces the answer to user request in the most efficient manner, given the database structure.

• The performance of a query is affected by the tables or views that underlies the query and by the complexity of the query.
• Given a request for data manipulation or retrieval, an optimizer will choose an optimal plan for evaluating the request from among the manifold alternative strategies. i.e. there are many ways (access paths) for accessing desired file/record.
• Hence ,DBMS is responsible to pick the best execution strategy based on various considerations(Least amount of I/O and CPU resources.)
• Example: Consider relations r(AB) and s(CD). We require r X s.
• Method 1 :

Question sources

Database Fundamentals practice questions · Question 56

Question 55 | Q01501

In object-oriented database, the keyword "inverse" is used in which of the following?

A. Relationship

B. All choices are correct

C. Class

D. Attribute

Hint

Distinguish schema definitions, queries and opposite navigation directions.

Answer A: Relationship.

An inverse declaration connects two navigation directions of the same association, such as Department.employees and Employee.department. ADB05 explains that it maintains their relationship consistency. It does not declare a class, establish inheritance or name an ordinary scalar attribute. Thus Relationship is the applicable category, and the inclusive option is false.

Why each choice is right or wrong

A - Correct: Inverse pairs the two directions of one relationship and expresses their consistency.

B - Incorrect: The other categories are not all valid uses of the inverse declaration.

C - Incorrect: Inverse is not the keyword that declares a class or establishes a class hierarchy.

D - Incorrect: The declaration links relationship directions rather than declaring an ordinary scalar attribute.

Primary note proof

Study-note section ADB05

> An inverse declaration pairs opposite directions of the same relationship. Conceptually, Department.employees is inverse to Employee.department: when an employee belongs to department D, the corresponding employee appears in D's collection. The declaration expresses relationship consistency; it is not an inheritance keyword or an ordinary scalar attribute. An MCQ calling ODL both a DDL and a language for developing logical schemas offers overlapping true descriptions, so its exact wording matters.

Question sources

Mock exam 1 · Question 17

Question 56 | Q01621

Which statements describe ODL? Select all that apply. In A, 'implement' specifically means choosing or carrying out physical storage implementation, rather than expressing a logical definition.

A. A method to implement a logical schema

B. All choices are correct

C. Used to develop logical schemas

D. A data definition language for OODB

Hint

Distinguish schema definitions, queries and opposite navigation directions.

Answer C, D: C. Used to develop logical schemas; D. A data definition language for OODB

ODL is the schema-definition language for object databases and describes classes or interfaces, attributes, operations and relationships. It is therefore both a data definition language and a language used to develop logical schemas. The question defines implementation in A as physical storage work, which is a different task. Because A is false in that sense, All choices are correct is also false.

Why each choice is right or wrong

A - Incorrect: Physical storage implementation is distinct from ODL logical definition.

B - Incorrect: A is false under the specified implementation meaning.

C - Correct: ODL develops logical object schemas.

D - Correct: ODL is a data definition language for object databases.

Primary note proof

Study-note section ADB05

> Object Definition Language (ODL) is the ODMG schema-definition language for object databases; it describes interfaces/classes, attributes, operations and relationships. Object Query Language (OQL) expresses queries. Host-language bindings connect these definitions and operations to languages such as Java or C++. Defining a logical schema is different from implementing its storage.

Question sources

Mock exam 2 · Question 10

Question 57 | Q01622

What are ACID properties of Transactions?

A. Automatically, Concurrency, Isolation, Durability

B. Atomicity, Consistency, Inconsistent, Durability

C. Atomicity, Consistency, Isolation, Database

D. Atomicity, Consistency, Isolation, Durability

Hint

Track the transaction's guarantee or lifecycle boundary described by the scenario.

Answer D: Atomicity, Consistency, Isolation, Durability

Page 66 lists atomicity, consistency preservation, isolation, and durability/permanency. Only D preserves all four terms.

Why each choice is right or wrong

A - Incorrect: Automatically and concurrency replace atomicity and consistency.

B - Incorrect: Inconsistent replaces isolation.

C - Incorrect: Database replaces durability.

D - Correct: All four names match the listed properties.

Primary note proof

Study-note section ADB06

A transaction is a logical unit of database work, including read-only work. Atomicity means all effects or none; consistency means correct work preserves integrity rules; isolation controls concurrent interference; durability preserves committed effects despite failure. A DBMS cannot automatically make incorrect business logic consistent.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 66 | lines 4-13

- Atomicity: A transaction is an atomic unit of processing; it is either performed in its entirety or not performed at all.
- Consistency preservation: A correct execution of the transaction must take the database from one consistent state to another.
- Isolation: A transaction should not make its updates visible to other transactions until it is committed; this property, when enforced strictly, solves the temporary update problem and makes cascading rollbacks of transactions unnecessary
- Durability or permanency: Once a transaction changes the database and the changes are committed, these changes must never be lost because of subsequent failure.

Example

Question sources

Mock exam 2 · Question 11

Question 58 | Q01623

Which of the following commands is used to save any transaction permanently into the database?

A. Rollback

B. None of the choices are correct

C. Savepoint

D. Commit

Hint

Distinguish completing a transaction from marking an intermediate recovery position.

Answer D: Commit

COMMIT successfully completes the transaction and requests a durable committed outcome. ROLLBACK instead cancels uncommitted changes. SAVEPOINT marks an intermediate position to which later work can be rolled back, retaining earlier work within the same transaction; it neither completes that transaction nor makes the retained changes independently durable. Because COMMIT is offered, the none-of-the-choices alternative is false. D therefore identifies the permanent transaction-completion command.

Why each choice is right or wrong

A - Incorrect: Incorrect: ROLLBACK cancels uncommitted work rather than accepting it permanently.

B - Incorrect: Incorrect: COMMIT is offered and is the requested completion command.

C - Incorrect: Incorrect: SAVEPOINT marks an intermediate rollback position inside the still-open transaction; it does not commit.

D - Correct: Correct: COMMIT completes the transaction successfully and requests a durable outcome.

Primary note proof

Study-note section ADB-S02

> In SQL transaction-block notation, BEGIN starts a block, COMMIT completes it successfully, and ROLLBACK cancels its uncommitted changes. Committing requests a durable transaction outcome; it is distinct from merely finishing the last read or write operation.

Study-note section ADB-S02

> SAVEPOINT marks an intermediate position inside the current transaction. ROLLBACK TO discards changes made after that position while retaining earlier work in the transaction. A savepoint is not an independent durable commit, and rolling back to it does not itself commit the retained changes.

Related reading (context, not primary note proof)

Study-note section ADB06

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 65 | lines 4-7

◦ Committed state -ensures that all the changes done on a record by a transition were done persistently
◦ Failed state happens when a transaction is aborted during its active state or if one of the rechecking is fails

● BEGIN TRANSACTION statement and end with the COMMIT or ROLLBACK statement.
● SQL transaction Examples:

Fundamental of Database Systems module | PDF page 65 | lines 17-19

• [commit,T]: Records that transaction T has completed successfully, and affirms that its effect can be committed (recorded permanently) to the database.
• [abort,T]: Records that transaction T has been aborted.

Question sources

Mock exam 2 · Question 12

Question 59 | SM0003

Which one of the following is NOT correct about transaction failure?

A. Transactions fail if logical errors are detected

B. Catastrophes can be a cause of transaction failure

C. Concurrency control enforcement avoids transaction failure

D. Transactions fail if disk blocks lose their data

Hint

Identify what failed, what durable resources survive and which restoration action is required.

Answer C: Concurrency control enforcement avoids transaction failure

The failure list includes logical programming errors, disk blocks losing data, and physical catastrophes. It also explicitly says concurrency enforcement may abort a transaction for serializability or deadlock (p.98). Thus claiming it avoids transaction failure is the incorrect statement.

Why each choice is right or wrong

A - Incorrect: Logical errors are explicitly a cause.

B - Incorrect: Physical problems and catastrophes are explicitly listed.

C - Correct: Concurrency enforcement itself may abort transactions, contradicting the absolute claim.

D - Incorrect: Loss of disk-block data is explicitly listed.

Primary note proof

Study-note section ADB26

Transaction failures include invalid operations, constraint violations and concurrency-control aborts. Enforcing concurrency can deliberately abort work; it does not prevent every transaction failure. A system crash loses volatile memory while disks may survive. Media failure damages persistent storage and normally requires restoring a backup, then replaying available archived logs. Human mistakes may require point-in-time restoration before the bad committed operation.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 98 | lines 4-31

- What causes a Transaction to fail

1. A computer failure (system crash):
A hardware or software error occurs in the computer system during transaction execution. If the hardware crashes, the contents of the computer‘s internal memory may be lost.
2. A transaction or system error:
Some operation in the transaction may cause it to fail, such as integer overflow or division by zero. Transaction failure may also occur because of erroneous parameter values or because of a logical programming error. In addition, the user may interrupt the transaction during its execution.
3. Exception conditions detected by the transaction:
◦ Certain conditions forces cancellation of the transaction.
◦ For example, data for the transaction may not be found. such as insufficient account balance in a banking database, may cause a transaction, such as a fund withdrawal from that account, to be canceled.
4. Concurrency control enforcement:
The concurrency control method may decide to abort the transaction, to be restarted later, because it violates serializability or because several transactions are in a state of deadlock (see Chapter 2).
5. Disk failure:
Some disk blocks may lose their data because of a read or write malfunction or because of a disk read/write head crash. This may happen during a read or a write operation of the transaction.
6. Physical problems and catastrophes:
This refers to an endless list of problems that includes power or air-conditioning failure, fire, theft, overwriting disks or tapes by mistake
Transaction Manager : Accepts transaction commands from an application, which tell the transaction manager when transactions begin and end, as well as information about the

expectations of the application.
The transaction processor performs the following tasks:

Question 60 | SM0004

Which one of the data updates best describes: 'All modified data items in the cache is written either after transaction ends its execution or after a pre-determined number of transactions have concluded their
execution'?

A. Immediate update

B. In-place update

C. Shadow update

D. Deferred update

Hint

Separate update timing from update location and follow the commit boundary.

Answer D: Deferred update

The deferred-update passage on p.110 almost exactly reproduces the stem: modified cache items are written after a transaction ends or a fixed number finish.

Why each choice is right or wrong

A - Incorrect: Immediate update writes as soon as an item changes in cache.

B - Incorrect: In-place describes overwriting the disk version, not the delay policy.

C - Incorrect: Shadow update writes a separate disk location.

D - Correct: Deferred update has precisely the stated timing.

Primary note proof

Study-note section ADB29

Deferred update keeps uncommitted changes outside the persistent database; in the usual no-force setting it is NO-UNDO/REDO. Redo-only and NO-UNDO/REDO mean the same thing, so those cannot be separate unique answers. Immediate update allows persistent changes before commit and therefore may require undo; it need not flush every write_item immediately.

Study-note section ADB29

Shadow/copy-on-write update writes a new location while preserving the committed version.

Study-note section ADB29

In-place update overwrites the original location.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 110 | lines 14-30

◦ Deferred Update:
• All transaction updates are recorded in the local workspace (cache)
• All modified data items in the cache is then written after a transaction ends its execution or after a fixed number of transactions have completed their execution.
• During commit the updates are first recorded on the log and then on the database
• If a transaction fails before reaching its commit point undo is not needed because it didn‘t change the database yet
• If a transaction fails after commit (writing on the log) but before finishing saving to the data base redoing is needed from the log
◦ Immediate Update:
• As soon as a data item is modified in cache, the disk copy is updated.
• These update are first recorded on the log and on the disk by force writing, before the database is updated
• If a transaction fails after recording some change to the database but before reaching its commit point , this will be rolled back

Fundamental of Database Systems module | PDF page 111 | lines 2-9

◦ Shadow update:
• The modified version of a data item does not overwrite its disk copy but is written at a separate disk location.
• Multiple version of the same data item can be maintained
• Thus the old value (before image BFIM) and the new value (AFIM) are kept in the disk
• No need of Log for recovery
◦ In-place update: The disk version of the data item is overwritten by the cache

Question 61 | SM0015

T1 writes X but has not committed. T2 reads that value; T1 then fails and its write is rolled back. Which anomaly did T2 experience?

A. Nonrepeatable-read problem

B. It is dirty read

C. It is an incorrect summary problem

D. It is a lost update problem

Hint

Trace which transaction wrote each value and whether an overwrite or mixed-version read occurs.

Answer B: B. It is dirty read

T2 consumes a value written by another transaction before that transaction commits. The writer's later failure makes this a dirty-read dependency requiring reconsideration of dependent work. A nonrepeatable read involves repeated reads seeing a committed change, while an incorrect summary mixes inconsistent versions in an aggregate. Lost update involves a stale overwrite, which this trace does not describe.

Why each choice is right or wrong

A - Incorrect: No repeated read observing a committed change is described.

B - Correct: T2 reads another transaction's uncommitted write.

C - Incorrect: No aggregate combines inconsistent versions.

D - Incorrect: No stale value is written over another update.

Primary note proof

Study-note section ADB08

> Lost update: T1 and T2 both read 500; T2 adds 200 and writes 700; T1 adds 100 to its stale value and writes 600. Correct serial execution yields 800. Dirty read: T2 reads a value written by uncommitted T1; if T1 aborts, dependent work must be reconsidered. Reading one's own changes is not a dirty read.

Module passages - related reading

Question 62 | SM0045

When two transactions that access the same database items have their operations interleaved in a way that makes the value of some database item incorrect. Which option correctly identifies this?

A. It is a temporary read problem

B. It is a dirty read problem

C. It is an incorrect summary problem

D. It is a lost update problem

Hint

Trace which transaction wrote each value and whether an overwrite or mixed-version read occurs.

Answer D: It is a lost update problem

The lost-update definition on p.68 is the wording in the stem. The other anomalies concern reading a temporary failed update or mixing summary values.

Why each choice is right or wrong

A - Incorrect: Temporary-update/dirty-read requires access to an uncommitted failed update, not merely the interleaving described.

B - Incorrect: Dirty read is the temporary-update anomaly.

C - Incorrect: Incorrect summary concerns aggregate evaluation over mixed versions.

D - Correct: Lost update matches the stated definition.

Primary note proof

Study-note section ADB08

Lost update: T1 and T2 both read 500; T2 adds 200 and writes 700; T1 adds 100 to its stale value and writes 600. Correct serial execution yields 800. Dirty read: T2 reads a value written by uncommitted T1; if T1 aborts, dependent work must be reconsidered. Reading one's own changes is not a dirty read.

Question 63 | SM0046

Which listed policy prevents lock-wait deadlock without comparing transaction-age timestamps? Here 'wait-wait' means allowing every conflicting request to wait with no ordering or cycle restriction.

A. Wait-wait

B. No-wait

C. Wound-wait

D. Wait-die

Hint

Distinguish a waiting cycle, a long wait and indefinite unfair postponement.

Answer B: No-wait

No-wait aborts immediately when a lock request conflicts, so transactions cannot form a lock-wait cycle and no age comparison is needed. Wait-die and wound-wait use relative transaction ages to decide who waits or aborts. Under the explicitly defined wait-wait alternative, every conflicting request may wait without a cycle-prevention restriction, so a transaction can hold one item while waiting for another in a cycle. That alternative therefore fails the deadlock-prevention requirement.

Why each choice is right or wrong

A - Incorrect: Incorrect: unrestricted waiting permits a hold-and-wait cycle, so this defined policy does not prevent deadlock.

B - Correct: Correct: immediate abort on a conflicting request prevents lock waits without comparing ages.

C - Incorrect: Incorrect: wound-wait compares requester and holder ages to choose waiting or aborting a younger holder.

D - Incorrect: Incorrect: wait-die compares ages to choose whether the requester waits or aborts.

Primary note proof

Study-note section ADB13

> Fixed resource ordering and conservative 2PL prevent cycles. A no-wait policy aborts immediately on an incompatible lock request and needs no age timestamp. A timeout aborts long waits but may mistake slow progress for deadlock. Starvation is indefinite postponement while other work proceeds, without a required cycle. Fair queues, sensible victim selection and retaining original transaction timestamps on retry reduce starvation; deadlock freedom alone does not prove fairness.

Study-note section ADB14

> A smaller timestamp means an older transaction. In wait-die, an older requester may wait for a younger holder; a younger requester needing an older holder aborts itself. In wound-wait, an

older requester aborts the younger holder; a younger requester waits for the older holder. Always identify requester versus holder before applying the names.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 88 | lines 6-28

• Transaction Timestamp(TS(T))
− We can prevent deadlocks by giving each transaction a priority and ensuring that lower priority transactions are not allowed to wait for higher priority transactions (or vice versa).
− One way to assign priorities is to give each transaction a timestamp when it starts up.
− it is a unique identifier given to each transaction based on time in which it is started. i.e if T1 starts before T2 , TS(T1)<TS(T2)
− The lower the timestamp, the higher the transaction's priority, that is, the oldest transaction has the highest priority.
− If a transaction Ti requests a lock and transaction Tj holds a conflicting lock, the lock manager can use one of the following two policies: Wait-die & Wound-wait
● Wait-die
◦ If Ti has higher priority, it is allowed to wait; otherwise it is aborted.
◦ An older transaction is allowed to wait on a younger transaction.
◦ A younger transaction requesting an item held by an older transaction is aborted
◦ If TS(Ti) < TS(Tj), then (Ti older than Tj)Ti is allowed to wait.
◦ Otherwise (Ti younger than Tj)Abort Ti (Ti dies) and restart it later with the same timestamp
T1(ts =10): M is locked , K is requested
T2 (ts =20): K is locked, Z is requested
88

Fundamental of Database Systems module | PDF page 89 | lines 4-13

• Wound-wait
- The opposite of wait-die
- If Ti has higher priority, abort Tj; otherwise Ti waits.
- A younger transaction is allowed to wait on an older one
- An older transaction requesting an item held by a younger transaction preempts the younger transaction by aborting it.
- If TS(Ti) < TS(Tj), then (Ti older than Tj),Abort Tj (Ti wounds Tj) and restart Tj later with the same timestamp
- Otherwise (Ti younger than Tj)Ti is allowed to wait
T2 (ts =20)

Question 64 | SM0047

A database management system (DBMS) has _____ to control locks.

A. Lock manager

B. Lock table

C. Query optimizer

D. Query processor

Hint

Compare access permissions and same-item compatibility before granting a lock request.

Answer A: Lock manager

Page 83 distinguishes the manager that manages locks from the table it uses to store lock identities and modes. The controlling component is the lock manager.

Why each choice is right or wrong

A - Correct: This component manages locks.

B - Incorrect: The table stores lock information for the manager.

C - Incorrect: Optimization selects execution strategies, not lock ownership.

D - Incorrect: The named lock-control component is the manager, not query processing.

Primary note proof

Study-note section ADB11

> A transaction must own the appropriate lock before access and can release only its own locks. S→X is an upgrade, possible only after conflicting other holders leave. X→S is a downgrade. The lock manager decides requests; the lock table stores granted locks and waiting requests. One transaction may request a lock on an already locked item: it is granted if compatible, otherwise waits or aborts under the policy. No double-locking is not a prohibition on shared readers.

Study-note section ADB17

> Query processing is the whole activity; selecting a suitable efficient strategy is optimization.

Study-note section ADB17

> A physical execution plan adds scan/index choices and algorithms.

Computer Science Exit Exam practice collection · Question 64

Question 65 | SM0205

In a columnar database, data is stored:

A. Row-wise

B. In a hierarchical structure

C. Column-wise

D. In a network model

Hint

Distinguish operational transactions, analytical workloads and physical storage layout.

Answer C: Column-wise.

ADB41 defines columnar storage as grouping values by column, which avoids reading irrelevant columns and can improve compression for scans. Row-oriented storage instead groups each record's fields. Hierarchical and network models are logical representation alternatives rather than the physical column-oriented layout requested by the stem. Columnar layout alone does not determine the logical data model.

Why each choice is right or wrong

A - Incorrect: Row-wise grouping is row-oriented storage, the contrasting physical layout.

B - Incorrect: A hierarchy describes parent-child organization, not the columnar physical storage arrangement.

C - Correct: Columnar storage groups the values of each column together.

D - Incorrect: A network model concerns linked records rather than this column-oriented physical layout.

Primary note proof

Study-note section ADB41

> OLTP handles frequent operational transactions, such as account updates; OLAP scans and summarizes large datasets for analysis. A warehouse integrates data for historical analysis, often through extraction, transformation and loading. These are workload tendencies: OLTP can retain history and warehouses can be updated.

Study-note section ADB41

> Columnar storage groups values by column, reducing unnecessary column reads and aiding compression in scans; row-oriented storage groups each record's fields.

Study-note section ADB41

> Neither physical layout alone determines whether the logical model is relational.

Related reading (context, not primary note proof)

Question sources

Computer Science Exit Exam · Sene 2016 · Question 2-1

Computer Science Exit Exam practice collection · Question 69

Question 66 | SM0247

An online game wants extra read copies of player reference data near regional users while retaining the same logical data. Which concept specifically creates those additional copies, rather than dividing the only copy into fragments or choosing a model family?

A. Replication

B. NoSQL databases

C. Distributed databases

D. Partitioning

Hint

Separate copy placement, propagation timing and update-maintenance cost.

Answer A: A. Replication

Replication creates additional copies of selected data and can improve read locality by placing them near users. That directly satisfies the specified regional read-copy requirement. Distribution is the broader arrangement across sites, partitioning divides data into fragments, and NoSQL names a family of data models. Neither the broader architecture nor a model label specifically says that extra copies are created.

Why each choice is right or wrong

A - Correct: Replication creates the required regional read copies.

B - Incorrect: NoSQL selects a model family and does not itself create copies.

C - Incorrect: Distribution is broader than the requested copy-creation policy.

D - Incorrect: Partitioning divides data; by itself it creates no spare copy.

Primary note proof

Study-note section ADB37

> Full replication places the whole database at every relevant site; partial replication copies selected fragments to selected sites; nonredundant allocation stores each fragment once. Copies improve read locality and can improve availability but require storage and update propagation. They can also spread mistakes, so replication does not replace independent backups.

Study-note section ADB36

> Partitioning improves locality and parallelism but alone creates no spare copy.

Study-note section ADB42

> Flexible schema does not mean no schema rules, and NoSQL does not imply no transactions.

Related reading (context, not primary note proof)

Study-note section ADB33

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 114 | lines 3-13

> 6.1 Distributed Database Concepts
> • A transaction can be executed by multiple networked computers in a unified manner.
> • A distributed database (DDB) processes Unit of execution (a transaction) in a distributed manner.
> • A distributed database (DDB) can be defined as :
> - A collection of multiple logically related database distributed over a computer network, and a distributed database management system as a software system that manages a distributed database while making the distribution transparent to the user.
> - The physical placement of data (files, relations, etc.) which is not known to the user (distribution transparency).

Fundamental of Database Systems module | PDF page 117 | lines 15-31

> 6.2 Data Replication and Fragmentation: Distributed data storage
> • There are two approaches to store the relation in the distributed database : Replication and Fragmentation
> I. Data Replication
> • The system maintain several identical copies of the relation & store each copy at a

different site
• In general it enhance the performance of read operation and increase the availability of data to read only transaction. However, update transactions incur greater overhead
II. Data Fragmentation
- Split a relation into logically related and correct parts.
- The main reasons for fragmenting a relation are
• Efficiency- data that is not needed by the local applications is not stored
• Parallelism - a transaction can be divided into several subqueries that operate on fragments which will increase the degree of concurrency
- but reconstruction of the whole relation will require accessing data from all sites containing part of the relation

Question sources

Computer Science Exit Exam · Sene 2016 · Question 15-3

Computer Science Exit Exam practice collection · Question 67

Question 67 | SM0298

In a generic DBMS component model applied to a MySQL deployment, which specialized role coordinates restoring valid data from stored backups and logs after data loss? Use generic functional roles, not claims about named MySQL engine internals.

A. Buffer Manager

B. Transaction Manager

C. Query Engine

D. Recovery Manager

Hint

Identify what failed, what durable resources survive and which restoration action is required.

Answer D: D. Recovery Manager

Recovery is the specialized responsibility for restoring valid database state after failure or loss. Backups supply a separate stored copy, and available logs can restore later recoverable changes. The recovery-manager role therefore matches the question's generic component model. Buffer management caches working pages; transaction management is the broader parent responsibility, while the query engine processes requests. This makes no claim about MySQL's internal module names.

Why each choice is right or wrong

A - Incorrect: Buffers cache working data and are not durable backup copies.

B - Incorrect: Transaction management is broader than the specialized restoration role requested.

C - Incorrect: A query engine processes queries rather than coordinating restoration.

D - Correct: The generic recovery role coordinates restoration using durable recovery resources.

Primary note proof

Study-note section ADB26

> Transaction failures include invalid operations, constraint violations and concurrency-control aborts. Enforcing concurrency can deliberately abort work; it does not prevent every transaction failure. A system crash loses volatile memory while disks may survive. Media failure damages persistent storage and normally requires restoring a backup, then replaying available archived logs. Human mistakes may require point-in-time restoration before the bad committed operation.

Study-note section ADB26

> Generic recovery-manager terminology should not be mistaken for an exact MySQL component specification.

Study-note section ADB26

> A full backup copies the database to separate storage; scheduled backups plus archived logs support restoration to a chosen recoverable point.

Fundamental of Database Systems module | PDF page 99 | lines 2-7

> ✓ Logging: In order to assure durability, every change in the database is logged separately on disk.
> ✓ Log manager initially writes the log in buffers and negotiates with the buffer manager to make sure that buffers are written to disk at appropriate times.
> ✓ Recovery Manager: will be able to examine the log of changes and restore the database to some consistent state.

Question sources

Computer Science Exit Exam · Sene 2016 · Question 32-1

Computer Science Exit Exam practice collection · Question 70

Question 68 | SS102

Which listed sources can contain unstructured free text, images or audio? Select all that apply. Here Google search collections include free-text web pages; RDBMS systems may store text/BLOB attachments; the Apple Employee and Registrar student examples contain only fixed-field structured records.

A. Google search engine

B. RDBMS systems

C. Apple Employee database

D. Registrar student database

Hint

Classify the actual content or pattern being analyzed rather than the storage product.

Answer A, B: A. Google search engine; B. RDBMS systems

Unstructured classification depends on the actual content rather than the storage product. Search collections can contain free text and images, and an RDBMS can store text or binary attachments, so A and B qualify under the stated contents. The employee and registrar examples are explicitly restricted to fixed-field structured records, excluding the otherwise possible attachments that would change their classification.

Why each choice is right or wrong

A - Correct: The specified web collection includes unstructured free text.

B - Correct: The specified relational store may contain unstructured text/BLOB attachments.

C - Incorrect: This example is restricted to structured fixed-field records.

D - Incorrect: This example is restricted to structured fixed-field records.

Primary note proof

Study-note section ADB43

> Structured data follows explicit fields, such as a registrar's relational tables. Unstructured data includes free text, images and audio; web/search collections can include these alongside structured content. A DBMS can also store text or BLOBs, so a storage product does not prove all its contents are structured.

Study-note section ADB43

> Clustering groups similar cases without target labels; classification predicts categories and regression predicts numeric outcomes.

Study-note section ADB43

> If 75 of 100 shoe purchases include socks, confidence(shoes⇒socks)=0.75.

Question sources

Computer Science model exam collection · Question 9

Question 69 | SS123

Business people always remodel their business by closely studying their customers' purchasing habits over the course of their purchase history.
Accordingly, a salesperson at Markato shop noticed that people who always buy shoes will also buy socks with probability of 0.75 and hence decided
to put shoes and socks side by side for ease of accessibility. Which big data analytics technique could this salesperson could employ?

A. Association rule

B. Clustering algorithm

C. Predictive modeling

D. Regression modeling

Hint

Classify the actual content or pattern being analyzed rather than the storage product.

Answer A: Association-rule mining: shoes ⇒ socks has confidence 0.75.

The observation is a conditional co-purchase pattern: among shoe purchases, socks also appear with probability 0.75. ADB43 defines this as the confidence of an association rule and explicitly distinguishes co-occurrence mining from clustering, classification and numeric regression. The store-layout decision uses that rule; it does not change the underlying technique or prove causation.

Why each choice is right or wrong

A - Correct: The rule captures shoe/sock co-occurrence with conditional confidence 0.75.

B - Incorrect: Clustering groups similar cases without target labels rather than directly discovering this co-purchase rule.

C - Incorrect: The stated evidence is an association rule, not a separately specified predictive modeling task.

D - Incorrect: Regression predicts numeric outcomes rather than identifying this purchasing co-occurrence rule.

Primary note proof

Study-note section ADB43

> An association rule X⇒Y describes co-occurrence. Support=count(X and Y)/N; confidence=count(X and Y)/count(X)=P(Y|X). If 75 of 100 shoe purchases include socks, confidence(shoes⇒socks)=0.75. This does not prove causation or specify support without total transaction count. Clustering groups similar cases without target labels; classification predicts categories and regression predicts numeric outcomes. Purchasing co-occurrence is association mining even when its result informs store layout.

Question sources

Computer Science model exam collection · Question 30

Question 70 | SS130

Using this convention, Model Testing means measuring a trained model on held-out test data; Model Evaluation means the subsequent release decision using those results and business success criteria. Which sequence applies before deploying this newly trained model?

A. Model Training, Model Evaluation, Model Testing, Model Deployment

B. Model Training, Model Testing, Model Deployment, Model Evaluation

C. Model Training, Model Testing, Model Evaluation, Model Deployment

D. Model Evaluation, Model Training , Model Testing, Model Deployment

Hint

Identify the objective and the stated meanings of the workflow stages.

Answer C: C. Model Training, Model Testing, Model Evaluation, Model Deployment

Under the stated convention, training first produces the model. Testing then measures it on held-out data, and evaluation uses those results to decide whether business criteria justify deployment. C follows that sequence. Evaluation during model selection can use a different ordering, but this question explicitly assigns evaluation to the subsequent release review, so the other sequences misplace that review.

Why each choice is right or wrong

A - Incorrect: It puts the specified post-test release review before testing.

B - Incorrect: It deploys before the required release review.

C - Correct: Training, held-out testing, release evaluation and deployment follow the defined roles.

D - Incorrect: It evaluates the newly trained model before that model has been trained.

Primary note proof

Study-note section ADB44

> CRISP-DM starts with business understanding: define the decision and success criteria. Then understand data, prepare it, model, evaluate and deploy; the process is iterative. Cleaning, integration and feature selection occur during preparation, not before the business problem exists.

Study-note section ADB44

> If an MCQ asks training→testing→evaluation→deployment, state that convention; another valid workflow can evaluate during model selection before final testing.

Study-note section ADB44

> Within modeling, split data appropriately, train on training data, tune using validation and evaluate once on a held-out test set before deployment.

Question sources

Computer Science model exam collection · Question 37

Question 71 | SS188

Identify the one that comes first in data mining process

A. Business understanding

B. Data integration

C. Data cleaning

D. Data selection

Hint

Identify the objective and the stated meanings of the workflow stages.

Answer A: Business understanding.

ADB44 starts the data-mining workflow by defining the business decision and its success criteria. This establishes why data will be collected and modeled. Integration, cleaning and feature selection prepare data after the problem has been understood; they do not replace the initial business-understanding stage. Thus A precedes the other listed activities.

Why each choice is right or wrong

A - Correct: Business understanding first defines the decision to support and the criteria for success.

B - Incorrect: Data integration prepares sources after the business problem has been identified.

C - Incorrect: Cleaning improves data quality during preparation rather than defining the initial business objective.

D - Incorrect: Selecting relevant data depends on an already understood business problem and modeling objective.

Primary note proof

Study-note section ADB44

> CRISP-DM starts with business understanding: define the decision and success criteria. Then understand data, prepare it, model, evaluate and deploy; the process is iterative. Cleaning, integration and feature selection occur during preparation, not before the business problem exists.

Study-note section ADB44

> Deployment includes monitoring and may trigger another preparation/modeling cycle.

Study-note section ADB44

If an MCQ asks training→testing→evaluation→deployment, state that convention; another valid workflow can evaluate during model selection before final testing.

Question sources

Computer Science model exam collection · Question 95

Question 72 | AM0162

What is the defining purpose of a transaction in database management?

A. To secure the database from unauthorized access

B. To optimize query performance

C. To group database operations into one logical unit of work

D. To define the structure and organization of a database

Hint

Track the transaction's guarantee or lifecycle boundary described by the scenario.

Answer C: C. To group database operations into one logical unit of work

A transaction groups database operations into one logical unit of work. The DBMS supports its atomicity, consistency, isolation and durability requirements, including controlled interference with concurrent transactions. Grouping is the defining concept, rather than query tuning, access authorization or schema construction. Read-only work can also form a transaction, so the definition is not limited to operations that change stored data.

Why each choice is right or wrong

A - Incorrect: Authorization governs who may access data rather than defining transaction grouping.

B - Incorrect: Optimization chooses query execution strategies.

C - Correct: A transaction is one logical unit of database work.

D - Incorrect: Schema definition describes data structures rather than a unit of work.

Primary note proof

Study-note section ADB06

A transaction is a logical unit of database work, including read-only work. Atomicity means all effects or none; consistency means correct work preserves integrity rules; isolation controls concurrent interference; durability preserves committed effects despite failure. A DBMS cannot automatically make incorrect business logic consistent.

Study-note section ADB11

A transaction must own the appropriate lock before access and can release only its own locks.

Study-note section ADB11

One transaction may request a lock on an already locked item: it is granted if compatible, otherwise waits or aborts under the policy.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 63 | lines 3-9

3.1 Introduction to Transaction
- A Transaction:
  - Logical unit of database processing that includes one or more access operations (read -retrieval, write - insert or update, delete).
- Examples include ATM transactions, credit card approvals, flight reservations, hotel check-in, phone calls, supermarket scanning, academic registration and billing.
- Transaction boundaries:

Fundamental of Database Systems module | PDF page 66 | lines 4-13

- Atomicity: A transaction is an atomic unit of processing; it is either performed in its entirety or not performed at all.
- Consistency preservation: A correct execution of the transaction must take the database from one consistent state to another.
- Isolation: A transaction should not make its updates visible to other transactions until it is committed; this property, when enforced strictly, solves the temporary update problem and makes cascading rollbacks of transactions unnecessary
- Durability or permanency: Once a transaction changes the database and the changes are committed, these changes must never be lost because of subsequent failure.

Example

Question sources

Computer Science MCQ practice collection · Question 162

Question 73 | AM0177

A correctly implemented financial transaction must preserve a declared total-balance invariant when it completes. Which ACID property names preservation of such integrity rules? Focus on the invariant rather than partial execution, concurrent interference or survival after a crash.

A. Atomicity

B. Consistency

C. Isolation

D. Durability

Hint

Track the transaction's guarantee or lifecycle boundary described by the scenario.

Answer B: B. Consistency

Consistency means that correct transactional work preserves declared integrity rules. Maintaining the total-balance invariant is therefore the consistency requirement. Atomicity addresses whether the effects happen together, isolation controls interference among concurrent transactions and durability preserves committed effects after failure. These properties cooperate, but the revised question identifies invariant preservation as the particular guarantee to name.

Why each choice is right or wrong

A - Incorrect: Atomicity names all-or-none effects rather than invariant preservation itself.

B - Correct: Consistency names preservation of declared integrity rules by correct work.

C - Incorrect: Isolation controls concurrent interference.

D - Incorrect: Durability preserves committed effects after failure.

Primary note proof

Study-note section ADB06

> A transaction is a logical unit of database work, including read-only work. Atomicity means all effects or none; consistency means correct work preserves integrity rules; isolation controls concurrent interference; durability preserves committed effects despite failure. A DBMS cannot automatically make incorrect business logic consistent.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Question sources

Computer Science MCQ practice collection · Question 177

Question 74 | AM0185

In the object-oriented model, an object is defined as:

A. An instance of a class

B. A collection of attributes

C. A primary key in a database

D. A relationship between tables

Hint

Distinguish an object instance from its class, attribute values and persistent identity.

Answer A: An instance of a class.

ADB01 explicitly distinguishes a class specification from each object instantiated from it. A class defines available attributes and operations, while an object is one individual instance with identity, state and behavior. A collection of attributes omits identity and behavior; a key or an intertable relationship belongs to a different relational description.

Why each choice is right or wrong

A - Correct: An object is an individual instance of a class with its own identity and state.

B - Incorrect: Attributes describe state but omit the identity and behavior that also characterize an object.

C - Incorrect: A database primary key is an identifier constraint, not the definition of an object instance.

D - Incorrect: A relationship between tables is a relational association rather than an object instance.

Primary note proof

Study-note section ADB01

> An object combines identity, state and behavior. A class specifies the attributes and operations of its instances; an object is one instance. The object identifier (OID) distinguishes objects independently of their attribute values and remains stable over that object's lifetime. Two objects can have equal values and different identities; changing a name does not create a new identity.

Study-note section ADB01

> Complex CAD or multimedia structures can suit an object model, but many-to-many relationships alone do not require abandoning relational design.

Study-note section ADB01

> An object-relational DBMS extends a relational system with richer types; ORM maps programming objects into relational tables.

Question sources

Computer Science MCQ practice collection · Question 185

Question 75 | AM0186

In the object-oriented model, encapsulation refers to:

A. Combining multiple classes into a single entity

B. Hiding the internal details of an object

C. Establishing relationships between objects

D. Defining the inheritance hierarchy

Hint

Separate the object boundary, the exposed contract and links between objects.

Answer B: Hiding and controlling access to internal object details.

ADB02 describes encapsulation as grouping state with operations and controlling access to implementation details. A withdrawal method can enforce rules while hiding storage. B states the relevant information-hiding aspect. Combining classes, associating objects and defining subtype hierarchies are distinct activities; none describes the encapsulation boundary around an object's state and operations.

Why each choice is right or wrong

A - Incorrect: Encapsulation groups an object's state and operations, not multiple classes into one entity.

B - Correct: Encapsulation controls access to the internal representation behind the object's operations.

C - Incorrect: Links between objects are associations rather than encapsulation itself.

D - Incorrect: Superclass/subclass structure concerns inheritance rather than information-hiding boundaries.

Primary note proof

Study-note section ADB02

> Encapsulation groups state with operations and controls access to implementation details. Account.withdraw(amount) can enforce a balance rule while hiding its storage. Abstraction presents the relevant contract-what withdrawal does-without exposing how it is implemented. These ideas overlap in information hiding, but combining state and methods specifically describes encapsulation.

Study-note section ADB02

> A class defines structure and behavior; an attribute describes state; a method implements an operation.

Study-note section ADB02

It is different from inheritance, which means an is-a relationship between types.

Question sources

Computer Science MCQ practice collection · Question 186

Question 76 | AM0187

In the object-oriented model, inheritance allows:

A. Objects to have multiple parents

B. Objects to inherit attributes and behaviors from a superclass

C. Objects to be created dynamically at runtime

D. Objects to establish relationships with other objects

Hint

Distinguish the subtype relationship from use through a common interface.

Answer B: Inherit applicable attributes and behavior from a superclass.

ADB03 defines inheritance as deriving a subtype from a superclass and reusing its applicable attributes and behavior. B captures that idea. It does not inherently require multiple parents, dynamically create objects, or merely link unrelated objects. Those alternatives concern particular inheritance forms, instantiation or association rather than the general meaning of inheritance.

Why each choice is right or wrong

A - Incorrect: Multiple parents are not a general requirement or guarantee of inheritance.

B - Correct: A subtype inherits applicable superclass attributes and behavior.

C - Incorrect: Dynamic object creation is instantiation, not the capability defined by inheritance.

D - Incorrect: Relationships between separate objects are associations rather than the is-a subtype relationship.

Primary note proof

Study-note section ADB03

Inheritance derives a subtype from a superclass, reusing applicable attributes and behavior. GraduateStudent is a Student; association instead says Student belongs to Department. EER teaches inherited attributes and relationships, while a programming object model also specifies behavior.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 13 | lines 5-9

Subclasses and super classes can be thought as useful ways to describe similarities in the entities represented. Because subclasses inherit their attributes and relationships from the superclass, the
database designer can represent complex, hierarchical interdependencies (inheritance) within the
system being described.
Specialization is the process of dividing a parent-level entity (super-class) into narrower

Question sources

Computer Science MCQ practice collection · Question 187

Question 77 | AM0188

Which concept in the object-oriented model allows different classes to share the same method name but with different implementations?

A. Polymorphism

B. Abstraction

C. Encapsulation

D. Inheritance

Hint

Distinguish the subtype relationship from use through a common interface.

Answer A: Polymorphism.

ADB03 illustrates Shape.area dispatching to Circle.area or Rectangle.area according to the actual object. The common operation name has different compatible implementations, which is polymorphism. Inheritance can provide the subtype structure used by that mechanism, but is not itself the runtime dispatch behavior. Abstraction and encapsulation concern contracts and implementation access instead.

Why each choice is right or wrong

A - Correct: Polymorphism lets the same interface operation invoke different implementations for compatible object types.

B - Incorrect: Abstraction exposes a relevant contract rather than selecting among differing method implementations.

C - Incorrect: Encapsulation controls internal access rather than providing type-dependent method dispatch.

D - Incorrect: Inheritance supplies a structural subtype relation; polymorphism describes the differing implementations through a common interface.

Primary note proof

Study-note section ADB03

> Subtype polymorphism lets a superclass/interface reference denote objects of different compatible subclasses. The same operation can dispatch to different implementations: Shape.area() calls Circle.area() or Rectangle.area() according to the actual object. This is not arbitrary conversion of an object into an unrelated class, nor dynamic class mutation. Inheritance establishes a subtype relationship; polymorphism uses that relationship through a common interface. Distinguish inheritance as a structural relationship from polymorphism as a use of that relationship at runtime.

Question sources

Computer Science MCQ practice collection · Question 188

Question 78 | AM0189

The process of combining data and methods into a single entity is known as:

A. Inheritance

B. Polymorphism

C. Abstraction

D. Encapsulation

Hint

Separate the object boundary, the exposed contract and links between objects.

Answer D: Encapsulation.

The question specifically asks about placing data and methods inside one entity. ADB02 identifies that grouping as encapsulation, along with controlled access to implementation details. Abstraction concerns what the contract exposes; inheritance derives compatible subtypes; polymorphism invokes different implementations through a common interface. None of those replaces the state-and-method grouping named in the stem.

Why each choice is right or wrong

A - Incorrect: Inheritance derives a subtype and reuses superclass features rather than naming state/method grouping.

B - Incorrect: Polymorphism varies implementations behind a compatible common interface rather than grouping data and methods.

C - Incorrect: Abstraction presents a relevant contract; the specific grouping asked for is encapsulation.

D - Correct: Encapsulation packages state and operations together within the object boundary.

Primary note proof

Study-note section ADB02

> Encapsulation groups state with operations and controls access to implementation details. Account.withdraw(amount) can enforce a balance rule while hiding its storage. Abstraction presents the relevant contract-what withdrawal does-without exposing how it is implemented. These ideas overlap in information hiding, but combining state and methods specifically describes encapsulation.

Study-note section ADB02

> It is different from inheritance, which means an is-a relationship between types.

Study-note section ADB02

> A class defines structure and behavior; an attribute describes state; a method implements an operation.

Question sources

Computer Science MCQ practice collection · Question 189

Question 79 | AM0190

The object-oriented model supports the concept of association, which represents:

A. Inheritance relationships between classes

B. Shared attributes among objects

C. The interactions between objects

D. Data duplication in the database

Hint

Separate the object boundary, the exposed contract and links between objects.

Answer C: Links and interactions between objects.

ADB02 defines association as links between objects, commonly implemented with references, and describes methods invoking operations on other objects. C is the closest description of that collaboration. An association is not an is-a inheritance hierarchy, shared attribute definitions or duplication. For example, Student belonging to Department links objects without making either a subtype of the other.

Why each choice is right or wrong

A - Incorrect: Inheritance is an is-a relationship between types, distinct from association links between objects.

B - Incorrect: Having similar attributes does not itself define an association between particular objects.

C - Correct: Associations link objects and support their interactions or collaboration through references.

D - Incorrect: Association represents relationships rather than duplicated copies of the same database facts.

Primary note proof

Study-note section ADB02

> An association links objects, often through references; Department.employees can reference Employee objects. It is different from inheritance, which means an is-a relationship between types. Methods can invoke operations on other objects, supporting collaboration. A class defines structure and behavior; an attribute describes state; a method implements an operation. Do not treat each of these as an interchangeable name for the whole object.

Question sources

Computer Science MCQ practice collection · Question 190

Question 80 | AM0191

Circle and Rectangle already inherit from Shape. A Shape reference can hold either object and dispatch area() to its actual implementation at runtime. Which concept names this common-interface use, rather than the structural subtype relationship?

A. Polymorphism

B. Inheritance

C. Abstraction

D. Encapsulation

Hint

Distinguish the subtype relationship from use through a common interface.

Answer A: A. Polymorphism

Subtype polymorphism allows a common superclass or interface reference to denote different compatible subclass objects. Dispatching area() according to whether the actual object is a Circle or Rectangle is that runtime use. Inheritance establishes the subtype relationship already given in the stem. Abstraction exposes a contract and encapsulation controls representation, but neither names this particular substitutable runtime dispatch.

Why each choice is right or wrong

A - Correct: Using one superclass interface with subclass-specific dispatch is subtype polymorphism.

B - Incorrect: Inheritance is the established structural prerequisite, not the runtime use requested.

C - Incorrect: Abstraction describes a contract rather than the dispatch behavior.

D - Incorrect: Encapsulation controls internal representation and access.

Primary note proof

Study-note section ADB03

> Subtype polymorphism lets a superclass/interface reference denote objects of different compatible subclasses. The same operation can dispatch to different implementations: Shape.area() calls Circle.area() or Rectangle.area() according to the actual object. This is not arbitrary conversion of an object into an unrelated class, nor dynamic class mutation. Inheritance establishes a subtype relationship; polymorphism uses that relationship through a common interface. Distinguish inheritance as a structural relationship from polymorphism as a use of that relationship at runtime.

Study-note section ADB02

> Encapsulation groups state with operations and controls access to implementation details.

Study-note section ADB02

These ideas overlap in information hiding, but combining state and methods specifically describes encapsulation.

Question sources

Computer Science MCQ practice collection · Question 191

Question 81 | AM0192

What is the purpose of abstraction in the object-oriented model?

A. To combine multiple classes into a single entity

B. To hide the internal details of an object

C. To establish relationships between objects

D. To define the attributes and behaviors of a class

Hint

Separate the object boundary, the exposed contract and links between objects.

Answer B: Hide implementation details while exposing a relevant contract.

ADB02 explains abstraction through an operation's relevant contract: what withdrawal does is exposed without showing how storage implements it. B captures hiding those irrelevant internal details. This overlaps encapsulation, but abstraction emphasizes the view or contract. Combining classes, creating associations or listing class members is not its defining purpose.

Why each choice is right or wrong

A - Incorrect: Abstraction does not mean merging several classes into one entity.

B - Correct: Abstraction exposes relevant behavior while hiding implementation details from the client view.

C - Incorrect: Establishing links between objects is association rather than abstraction's defining purpose.

D - Incorrect: A class specifies attributes and behavior; abstraction chooses the relevant contract exposed to users.

Primary note proof

Study-note section ADB02

Encapsulation groups state with operations and controls access to implementation details. Account.withdraw(amount) can enforce a balance rule while hiding its storage. Abstraction presents the relevant contract-what withdrawal does-without exposing how it is implemented. These ideas overlap in information hiding, but combining state and methods specifically describes encapsulation.

Study-note section ADB03

EER teaches inherited attributes and relationships, while a programming object model also specifies behavior.

Study-note section ADB02

An association links objects, often through references; Department.employees can reference Employee objects.

Question sources

Computer Science MCQ practice collection · Question 192

Question 82 | AM0193

The concept of polymorphism allows objects to:

A. Inherit attributes from multiple classes

B. Change their class dynamically at runtime

C. Access private methods of other objects

D. Be treated as objects of different classes

Hint

Distinguish the subtype relationship from use through a common interface.

Answer D: Use an object through a compatible superclass or interface type.

ADB03 allows a superclass or interface reference to denote compatible subclass objects. D is correct in that sense: the same object can be treated through its actual type and a compatible supertype. This does not permit arbitrary conversion to unrelated classes. Multiple inheritance, runtime class mutation and access to another object's private methods are different concepts and are not granted by polymorphism.

Why each choice is right or wrong

A - Incorrect: Inheriting from multiple classes is multiple inheritance, not the operation described by polymorphism.

B - Incorrect: Polymorphism does not change the actual class of an object dynamically.

C - Incorrect: Polymorphism does not bypass private-access restrictions on other objects.

D - Correct: An object can be used through compatible superclass/interface types; this does not mean arbitrary unrelated classes.

Primary note proof

Study-note section ADB03

> Subtype polymorphism lets a superclass/interface reference denote objects of different compatible subclasses. The same operation can dispatch to different implementations: Shape.area() calls Circle.area() or Rectangle.area() according to the actual object. This is not arbitrary conversion of an object into an unrelated class, nor dynamic class mutation. Inheritance establishes a subtype relationship; polymorphism uses that relationship through a common interface. Distinguish inheritance as a structural relationship from polymorphism as a use of that relationship at runtime.

Question sources

Computer Science MCQ practice collection · Question 193

Question 83 | AM0194

Which concept in the object-oriented model defines the structure and behavior of objects?

A. Class

B. Object

C. Attribute

D. Method

Hint

Distinguish an object instance from its class, attribute values and persistent identity.

Answer A: Class.

A class is the specification that defines attributes and operations for its instances, as ADB01 states. An object is an instance conforming to that specification. An attribute accounts for part of state and a method for one operation, but neither individually defines the whole structure and behavior of the object type.

Why each choice is right or wrong

A - Correct: A class specifies the structure and available operations for its object instances.

B - Incorrect: An object is one instance of the specification rather than the specification itself.

C - Incorrect: An attribute represents part of an object's state rather than its whole structure and behavior.

D - Incorrect: A method implements an operation but does not alone define the complete object type.

Primary note proof

Study-note section ADB01

> An object combines identity, state and behavior. A class specifies the attributes and operations of its instances; an object is one instance. The object identifier (OID) distinguishes objects independently of their attribute values and remains stable over that object's lifetime. Two objects can have equal values and different identities; changing a name does not create a new identity.

Study-note section ADB01

> Complex CAD or multimedia structures can suit an object model, but many-to-many relationships alone do not require abandoning relational design.

Study-note section ADB01

> An object-relational DBMS extends a relational system with richer types; ORM maps programming objects into relational tables.

Question sources

Computer Science MCQ practice collection · Question 194

Question 84 | AM0195

Which recovery method aims to restore the database to a previous consistent state by undoing the effects of incomplete or failed transactions?

A. Rollback recovery

B. Redo recovery

C. Checkpoint recovery

D. Restart recovery

Hint

Track durable-write ordering and distinguish reversing incomplete work from installing logged effects.

Answer A: Rollback recovery

Undo restores before images and removes after images; failed transactions that updated the database must roll back (p.107). This directly answers the specific action, although undo may be one phase of broader crash recovery.

Why each choice is right or wrong

A - Correct: Rollback is the direct undo operation.

B - Incorrect: Redo restores after images instead.

C - Incorrect: Checkpoints synchronize database and log; they do not name the undo action.

D - Incorrect: A restart can include undo, but is broader than the requested failed-transaction reversal.

Primary note proof

Study-note section ADB27

> Undo restores before-images of incomplete effects, usually traversing that transaction's updates backward. Redo installs logged after-images when necessary, usually forward. Setting X to its logged after-value is idempotent; blindly replaying X=X+10 twice is not. In a simple undo/redo teaching model, undo losers and redo winners. ARIES has a different redo phase that repeats history before undoing losers.

Study-note section ADB26

> Restart recovery restores a valid database after a crash while preserving durable commits and removing incomplete effects.

Study-note section ADB30

> Recovery may start analysis at the checkpoint but redo from an earlier required log position.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 103 | lines 6-23

• Recovery from catastrophic
• If there is extensive damage to the wide portion of the database
• This method restore a past copy of the database from the backup storage and reconstructs operation of a committed transaction from the back up log up to the time of failure
• Recovery from non-catastrophic failure
• When the database is not physically damaged but has be come in consistent
• The strategy uses undoing and redoing some operations in order to restore to a consistent state : example
• For instance,
• If failure occurs between commit and database buffers being flushed to secondary storage then, to ensure durability, recovery manager has to redo (roll forward) transaction‘s updates.
• If transaction had not committed at failure time, recovery manager has to undo (rollback) any effects of that transaction for atomicity. Example,
Transaction Log
◦ For recovery from any type of failure data values prior to modification (BFIM -

Fundamental of Database Systems module | PDF page 107 | lines 8-23

Transaction Roll-back (Undo) and Roll-Forward (Redo)
• If transaction fails for what so ever reason after updating the data base it must be necessary to roll back
• If a transaction T is roll back , any transaction that has read the value of some data item X written by T must be also be roll back
• Similarly once S is roll back, any transaction R that has read the values of some data item Y written by S must aslo be roll back, and so on..
• To maintain such cases, a transaction‘s operations are redone or undone.
• Undo: Restore all BFIMs on to disk (Remove all AFIMs).
• Redo: Restore all AFIMs on to disk.
• Database recovery is achieved either by performing only Undos or only Redos or by a combination of the two. These operations are recorded in the log as they happen.
Data Update and Recovery Scheme : Three types
i. Deferred Update (No Undo/Redo)
◦ The data update goes as follows:

Question sources

Computer Science MCQ practice collection · Question 195

Question 85 | AM0196

Which recovery method involves reapplying the changes made by committed transactions from a log file to restore the database?

A. Redo recovery

B. Checkpoint recovery

C. Restart recovery

D. Backup recovery

Hint

Track durable-write ordering and distinguish reversing incomplete work from installing logged effects.

Answer A: Redo recovery

If a transaction committed but its buffers did not reach disk, recovery redoes its updates for durability (p.103). Redo restores after images (p.107), whose log records are required before commit (p.104).

Why each choice is right or wrong

A - Correct: Redo is exactly reapplying logged committed updates.

B - Incorrect: A checkpoint reduces the amount of recovery work; it is not the replay operation.

C - Incorrect: Restart recovery can invoke redo but names a larger process.

D - Incorrect: A backup restores a stored database copy, not this specific logged replay.

Primary note proof

Study-note section ADB27

> Undo restores before-images of incomplete effects, usually traversing that transaction's updates backward. Redo installs logged after-images when necessary, usually forward. Setting X to its logged after-value is idempotent; blindly replaying X=X+10 twice is not. In a simple undo/redo teaching model, undo losers and redo winners. ARIES has a different redo phase that repeats history before undoing losers.

Study-note section ADB30

> Recovery may start analysis at the checkpoint but redo from an earlier required log position.

Study-note section ADB30

> A checkpoint is neither a full backup nor an automatic commit of active transactions.

Question sources

Computer Science MCQ practice collection · Question 196

Question 86 | AM0197

Which recovery method involves creating checkpoints at regular intervals to save the current state of the database and transaction logs?

A. Checkpoint recovery

B. Redo recovery

C. Rollback recovery

D. Restart recovery

Hint

Identify which history a recovery boundary can safely exclude and whether active work spans it.

Answer A: Checkpoint recovery

Checkpointing synchronizes database and log (p.105); its listed steps force modified buffers to disk, write a checkpoint record, and save the log (p.107). This is not necessarily a full database backup.

Why each choice is right or wrong

A - Correct: The named synchronization procedure matches.

B - Incorrect: Redo reapplies after images, not periodic synchronization.

C - Incorrect: Rollback restores before images.

D - Incorrect: Restart follows failure, whereas checkpoints are established during operation.

Primary note proof

Study-note section ADB30

> A checkpoint records enough durable recovery state to avoid scanning all old history. In a simple quiescent/checkpoint exercise, specified flushing may make earlier committed work unnecessary to redo. Active transactions can span the checkpoint, so their relevant earlier updates can still need undo. Do not assume every transaction before a checkpoint needs no processing.

Study-note section ADB27

> To acknowledge a durable commit, force the transaction's required log records, including its commit record, to stable storage.

Study-note section ADB27

> Write-ahead logging requires the update log needed for recovery to reach stable storage before the corresponding changed data page reaches disk.

Module passages - related reading

Question sources

Computer Science MCQ practice collection · Question 197

Question 87 | AM0198

Which recovery method involves restarting the system and recovering the database by applying the necessary redo and undo operations?

A. Restart recovery

B. Checkpoint recovery

C. Redo recovery

D. Rollback recovery

Hint

Identify what failed, what durable resources survive and which restoration action is required.

Answer A: Restart recovery

Recovery from a non-catastrophic crash may combine undo and redo (pp.103,107). A is the best descriptive name for restarting and performing that combined recovery, although the module does not define four mutually exclusive method classes under these exact option names.

Why each choice is right or wrong

A - Correct: Restart recovery describes the complete post-crash recovery process stated in the stem.

B - Incorrect: Checkpointing supplies a saved starting boundary rather than the whole restart process.

C - Incorrect: Redo supplies only the forward part of the stated combination.

D - Incorrect: Rollback supplies only the undo part.

Primary note proof

Study-note section ADB26

> Transaction failures include invalid operations, constraint violations and concurrency-control aborts. Enforcing concurrency can deliberately abort work; it does not prevent every transaction failure. A system crash loses volatile memory while disks may survive. Media failure damages persistent storage and normally requires restoring a backup, then replaying available archived logs. Human mistakes may require point-in-time restoration before the bad committed operation.

Study-note section ADB26

> These are cooperating mechanisms, not four mutually exclusive complete alternatives.

Study-note section ADB27

> Redo installs logged after-images when necessary, usually forward.

Question sources

Computer Science MCQ practice collection · Question 198

Question 88 | AM0199

Which recovery method involves restoring the database from a backup copy taken prior to the failure?

A. Backup recovery

B. Rollback recovery

C. Redo recovery

D. Restart recovery

Hint

Identify what failed, what durable resources survive and which restoration action is required.

Answer A: Backup recovery

For catastrophic damage the module restores a past database copy from backup storage and reconstructs committed operations from the backup log (p.103). A names restoration of that backup copy; a backup alone may need subsequent log replay.

Why each choice is right or wrong

A - Correct: Restoration from a stored copy is the stated backup operation.

B - Incorrect: Rollback reverses updates using before images, not a backup copy.

C - Incorrect: Redo replays logged changes, which may supplement backup restoration.

D - Incorrect: Restart names an overall recovery process rather than its backup-copy source.

Primary note proof

Study-note section ADB26

Transaction failures include invalid operations, constraint violations and concurrency-control aborts. Enforcing concurrency can deliberately abort work; it does not prevent every transaction failure. A system crash loses volatile memory while disks may survive. Media failure damages persistent storage and normally requires restoring a backup, then replaying available archived logs. Human mistakes may require point-in-time restoration before the bad committed operation.

Study-note section ADB26

Rollback handles failed/uncommitted work; redo preserves committed work missing from pages; checkpoints reduce log-search work; backups provide another stored copy.

Study-note section ADB27

Redo installs logged after-images when necessary, usually forward.

Computer Science MCQ practice collection · Question 199

Question 89 | AM0200

Which recovery method is used to recover the database after a media failure, such as a disk crash?

A. Backup recovery

B. Redo recovery

C. Checkpoint recovery

D. Rollback recovery

Hint

Identify what failed, what durable resources survive and which restoration action is required.

Answer A: Backup recovery

Disk-head crash is media failure (p.97). Where that destroys database contents, the catastrophic-recovery strategy restores a past backup and then reconstructs committed operations from the backup log (p.103).

Why each choice is right or wrong

A - Correct: A backup supplies contents lost in the media failure.

B - Incorrect: Redo can advance a restored copy but alone assumes data pages available to update.

C - Incorrect: A checkpoint is not a replacement copy of a destroyed database.

D - Incorrect: Undo cannot recreate arbitrary destroyed pages by reversing incomplete transactions alone.

Primary note proof

Study-note section ADB26

> Transaction failures include invalid operations, constraint violations and concurrency-control aborts. Enforcing concurrency can deliberately abort work; it does not prevent every transaction failure. A system crash loses volatile memory while disks may survive. Media failure damages persistent storage and normally requires restoring a backup, then replaying available archived logs. Human mistakes may require point-in-time restoration before the bad committed operation.

Study-note section ADB30

> Recovery may start analysis at the checkpoint but redo from an earlier required log position.

Study-note section ADB26

> Restart recovery restores a valid database after a crash while preserving durable commits and removing incomplete effects.

Question sources

Computer Science MCQ practice collection · Question 200

Question 90 | AM0201

A crash-recovery system has a long log history and wants to reduce the log-search work compared with scanning all history. Which method adds durable recovery-state records for that purpose?

A. Redo recovery

B. Checkpoint recovery

C. Backup recovery

D. Rollback recovery

Hint

Identify which history a recovery boundary can safely exclude and whether active work spans it.

Answer B: B. Checkpoint recovery

Checkpoints record durable recovery state so recovery need not inspect all old history. That is the requested mechanism for reducing log-search work. Redo reinstalls missing changes, rollback removes incomplete effects and backup recovery starts from a separate copy. They may cooperate with checkpoints, but their defining actions do not name the added recovery-state boundary specified in this question.

Why each choice is right or wrong

A - Incorrect: Redo applies logged after-images rather than defining the recovery-state boundary.

B - Correct: Checkpoint information reduces how much old history must be searched.

C - Incorrect: A backup is a separate stored copy rather than the stated history-bounding record.

D - Incorrect: Rollback reverses incomplete effects rather than adding this recovery-state boundary.

Primary note proof

Study-note section ADB30

> A checkpoint records enough durable recovery state to avoid scanning all old history. In a simple quiescent/checkpoint exercise, specified flushing may make earlier committed work unnecessary to redo. Active transactions can span the checkpoint, so their relevant earlier updates can still need undo. Do not assume every transaction before a checkpoint needs no processing.

Study-note section ADB26

> Rollback handles failed/uncommitted work; redo preserves committed work missing from pages; checkpoints reduce log-search work; backups provide another stored copy.

Computer Science MCQ practice collection · Question 201

Computer Science MCQ practice collection · Question 211

Question 91 | AM0202

Which recovery method is focused on ensuring that all committed changes are durable and can survive system failures?

A. Redo recovery

B. Restart recovery

C. Rollback recovery

D. Checkpoint recovery

Hint

Track durable-write ordering and distinguish reversing incomplete work from installing logged effects.

Answer A: Redo recovery

Durability requires committed effects to survive crashes (p.97). The module specifically redoes committed updates lost between commit and buffer flushing (p.103), making redo the direct mechanism asked for.

Why each choice is right or wrong

A - Correct: Redo reapplies the missing committed updates.

B - Incorrect: Restart is a broader process that can invoke redo and undo.

C - Incorrect: Rollback preserves atomicity by removing uncommitted effects.

D - Incorrect: Checkpoints reduce replay work but are not the committed-update replay operation.

Primary note proof

Study-note section ADB27

> Undo restores before-images of incomplete effects, usually traversing that transaction's updates backward. Redo installs logged after-images when necessary, usually forward. Setting X to its logged after-value is idempotent; blindly replaying X=X+10 twice is not. In a simple undo/redo teaching model, undo losers and redo winners. ARIES has a different redo phase that repeats history before undoing losers.

Study-note section ADB26

> Rollback handles failed/uncommitted work; redo preserves committed work missing from pages; checkpoints reduce log-search work; backups provide another stored copy.

Study-note section ADB26

> Restart recovery restores a valid database after a crash while preserving durable commits and removing incomplete effects.

Fundamental of Database Systems module | PDF page 97 | lines 4-13

i. Purpose of Database Recovery
◦ To bring the database into the last consistent state, which existed prior to the failure.
◦ To preserve transaction properties (Atomicity &and Durability).
• The recovery manager of a DBMS is responsible to ensure
• atomicity by undoing the action of transaction that do not commit
• Durability by making sure that all actions of committed transaction survive system crash
ii. Types of Failure
◦ The database may become unavailable for use due to :

Fundamental of Database Systems module | PDF page 103 | lines 6-23

• Recovery from catastrophic
• If there is extensive damage to the wide portion of the database
• This method restore a past copy of the database from the backup storage and reconstructs operation of a committed transaction from the back up log up to the time of failure
• Recovery from non-catastrophic failure
• When the database is not physically damaged but has be come in consistent
• The strategy uses undoing and redoing some operations in order to restore to a consistent state : example
• For instance,
• If failure occurs between commit and database buffers being flushed to secondary storage then, to ensure durability, recovery manager has to redo (roll forward) transaction‘s updates.
• If transaction had not committed at failure time, recovery manager has to undo (rollback) any effects of that transaction for atomicity. Example,
Transaction Log
◦ For recovery from any type of failure data values prior to modification (BFIM -

Computer Science MCQ practice collection · Question 202

Question 92 | AM0203

Which recovery method uses the transaction log to identify the changes made by transactions and undo the effects of incomplete or failed transactions?

A. Rollback recovery

B. Redo recovery

C. Checkpoint recovery

D. Restart recovery

Hint

Track durable-write ordering and distinguish reversing incomplete work from installing logged effects.

Answer A: Rollback recovery

Before images logged under WAL permit undo of failed transaction effects (p.104); rollback restores them (p.107). The stem specifies this particular operation rather than all crash-recovery phases.

Why each choice is right or wrong

A - Correct: Rollback is the direct log-based undo operation.

B - Incorrect: Redo restores new values instead of removing failed updates.

C - Incorrect: Checkpointing records a synchronization boundary.

D - Incorrect: Restart can include rollback, but is broader than the named reversal.

Primary note proof

Study-note section ADB27

> Undo restores before-images of incomplete effects, usually traversing that transaction's updates backward. Redo installs logged after-images when necessary, usually forward. Setting X to its logged after-value is idempotent; blindly replaying X=X+10 twice is not. In a simple undo/redo teaching model, undo losers and redo winners. ARIES has a different redo phase that repeats history before undoing losers.

Question sources

Computer Science MCQ practice collection · Question 203

Question 93 | AM0204

Which recovery method is used to recover the database after a system crash or power failure?

A. Restart recovery

B. Backup recovery

C. Redo recovery

D. Checkpoint recovery

Hint

Identify what failed, what durable resources survive and which restoration action is required.

Answer A: Restart recovery

For a recoverable system crash, recovery uses undo/redo to restore consistency (pp.103,107). A is the broad descriptive answer for restarting the failed system. If power failure also destroys media, backup restoration may additionally be required; the question supplies no such destruction.

Why each choice is right or wrong

A - Correct: Restart recovery denotes the overall post-crash process.

B - Incorrect: Backup is required for damaged/lost storage, which is not specified here.

C - Incorrect: Redo alone may be insufficient when incomplete transactions reached disk.

D - Incorrect: A checkpoint assists recovery but does not itself execute the full crash recovery.

Primary note proof

Study-note section ADB26

> Transaction failures include invalid operations, constraint violations and concurrency-control aborts. Enforcing concurrency can deliberately abort work; it does not prevent every transaction failure. A system crash loses volatile memory while disks may survive. Media failure damages persistent storage and normally requires restoring a backup, then replaying available archived logs. Human mistakes may require point-in-time restoration before the bad committed operation.

Study-note section ADB30

> Recovery may start analysis at the checkpoint but redo from an earlier required log position.

Study-note section ADB26

> Restart recovery restores a valid database after a crash while preserving durable commits and removing incomplete effects.

Fundamental of Database Systems module | PDF page 98 | lines 4-31

- What causes a Transaction to fail

1. A computer failure (system crash):
A hardware or software error occurs in the computer system during transaction execution. If the hardware crashes, the contents of the computer‘s internal memory may be lost.
2. A transaction or system error:
Some operation in the transaction may cause it to fail, such as integer overflow or division by zero. Transaction failure may also occur because of erroneous parameter values or because of a logical programming error. In addition, the user may interrupt the transaction during its execution.
3. Exception conditions detected by the transaction:
◦ Certain conditions forces cancellation of the transaction.
◦ For example, data for the transaction may not be found. such as insufficient account balance in a banking database, may cause a transaction, such as a fund withdrawal from that account, to be canceled.
4. Concurrency control enforcement:
The concurrency control method may decide to abort the transaction, to be restarted later, because it violates serializability or because several transactions are in a state of deadlock (see Chapter 2).
5. Disk failure:
Some disk blocks may lose their data because of a read or write malfunction or because of a disk read/write head crash. This may happen during a read or a write operation of the transaction.
6. Physical problems and catastrophes:
This refers to an endless list of problems that includes power or air-conditioning failure, fire, theft, overwriting disks or tapes by mistake
Transaction Manager : Accepts transaction commands from an application, which tell the transaction manager when transactions begin and end, as well as information about the expectations of the application.
The transaction processor performs the following tasks:

Question sources

Computer Science MCQ practice collection · Question 204

Question 94 | AM0205

What is the primary goal of database recovery after a failure?

A. Restoring the database to a previous state

B. Preventing future failures from occurring

C. Optimizing database performance

D. Enforcing data integrity constraints

Hint

Identify what failed, what durable resources survive and which restoration action is required.

Answer A: Restoring the database to a previous state

The explicit purpose is bringing the database into its last consistent state before failure (p.97). A is correct only with this consistency qualification; restoring an arbitrary earlier corrupt state is not the goal.

Why each choice is right or wrong

A - Correct: Read previous state as the last consistent state, as stated.

B - Incorrect: Recovery handles failures rather than preventing all future ones.

C - Incorrect: Performance is not the stated recovery purpose.

D - Incorrect: Integrity is relevant, but constraint enforcement is not the direct restoration objective stated here.

Primary note proof

Study-note section ADB26

> Transaction failures include invalid operations, constraint violations and concurrency-control aborts. Enforcing concurrency can deliberately abort work; it does not prevent every transaction failure. A system crash loses volatile memory while disks may survive. Media failure damages persistent storage and normally requires restoring a backup, then replaying available archived logs. Human mistakes may require point-in-time restoration before the bad committed operation.

Computer Science MCQ practice collection · Question 205

Question 95 | AM0206

Which recovery method involves periodically making a copy of the entire database onto a separate storage medium?

A. Rollback recovery

B. Checkpoint recovery

C. Restart recovery

D. Backup recovery

Hint

Identify what failed, what durable resources survive and which restoration action is required.

Answer D: Backup recovery

A full backup copies the database to separate storage so it can later be restored, often followed by replay of archived logs. Rollback reverses failed transaction work; restart recovery restores a valid state after a crash. A checkpoint records recovery state to reduce log-search and recovery work and is not a full independent database copy. The question's periodic separate copy is therefore the backup mechanism, represented by backup recovery.

Why each choice is right or wrong

A - Incorrect: Incorrect: rollback reverses transaction effects rather than making an independent database copy.

B - Incorrect: Incorrect: checkpointing records recovery state and limits recovery work; it is not a full backup.

C - Incorrect: Incorrect: restart recovery is the crash-recovery process, not the periodic creation of a separate copy.

D - Correct: Correct: backup recovery relies on a stored independent database copy.

Primary note proof

Study-note section ADB26

> A full backup copies the database to separate storage; scheduled backups plus archived logs support restoration to a chosen recoverable point.

Study-note section ADB26

> Rollback handles failed/uncommitted work; redo preserves committed work missing from pages; checkpoints reduce log-search work; backups provide another stored copy.

Study-note section ADB30

> A checkpoint is neither a full backup nor an automatic commit of active transactions.

Computer Science MCQ practice collection · Question 206

Question 96 | AM0207

Which recovery method involves undoing the effects of incomplete or failed transactions?

A. Rollback recovery

B. Checkpoint recovery

C. Restart recovery

D. Backup recovery

Hint

Track durable-write ordering and distinguish reversing incomplete work from installing logged effects.

Answer A: Rollback recovery

The module calls undoing a failed transaction rollback and specifies restoring before images (p.107). A therefore directly names removal of incomplete effects.

Why each choice is right or wrong

A - Correct: Rollback is the named undo operation.

B - Incorrect: Checkpoint is synchronization, not transaction reversal.

C - Incorrect: Restart can include undo but is the wider process.

D - Incorrect: Backup restores a past copy instead of directly reversing this transaction.

Primary note proof

Study-note section ADB27

> Undo restores before-images of incomplete effects, usually traversing that transaction's updates backward. Redo installs logged after-images when necessary, usually forward. Setting X to its logged after-value is idempotent; blindly replaying X=X+10 twice is not. In a simple undo/redo teaching model, undo losers and redo winners. ARIES has a different redo phase that repeats history before undoing losers.

Question sources

Computer Science MCQ practice collection · Question 207

Question 97 | AM0208

What is the purpose of a checkpoint in the recovery process?

A. To save the current state of the database

B. To recover from a system crash

C. To log all transaction operations

D. To enforce data integrity constraints

Hint

Identify which history a recovery boundary can safely exclude and whether active work spans it.

Answer A: To save the current state of the database

A checkpoint synchronizes database and log by forcing modified buffers and recording the checkpoint (pp.105,107), saving a durable recovery boundary and reducing later work. It is not necessarily a full snapshot copy.

Why each choice is right or wrong

A - Correct: Saving synchronized current state best matches the listed procedure.

B - Incorrect: Crash recovery uses checkpoints, but this is a later use rather than checkpoint creation itself.

C - Incorrect: Logging every operation is the transaction log's role, not checkpoint's distinguishing purpose.

D - Incorrect: Constraint enforcement is not the checkpoint procedure.

Primary note proof

Study-note section ADB30

> A checkpoint records enough durable recovery state to avoid scanning all old history. In a simple quiescent/checkpoint exercise, specified flushing may make earlier committed work unnecessary to redo. Active transactions can span the checkpoint, so their relevant earlier updates can still need undo. Do not assume every transaction before a checkpoint needs no processing.

Study-note section ADB07

> Insert and delete also modify data; sorting is a query-processing operation rather than a primitive item update.

Study-note section ADB07

> Real systems may use physical or logical records, and need not log every read.

Question sources

Computer Science MCQ practice collection · Question 208

Question 98 | AM0209

In a log-based crash restart that uses durable checkpoint state plus relevant transaction logs, which listed labels describe the checkpoint-assisted technique and its overall restoration process? Select all that apply.

A. Rollback recovery

B. Checkpoint recovery

C. Restart recovery

D. Backup recovery

Hint

Identify which history a recovery boundary can safely exclude and whether active work spans it.

Answer B, C: B. Checkpoint recovery; C. Restart recovery

Checkpoint-assisted recovery uses recorded recovery state to limit the necessary log history. Restart recovery is the overall process that restores a valid state after the crash while preserving durable commits and removing incomplete effects. Both labels describe the specified procedure at different levels. Rollback names only undo work, and backup recovery would require starting from a separate stored copy.

Why each choice is right or wrong

A - Incorrect: Rollback specifically undoes incomplete effects rather than naming the checkpoint-plus-log restart procedure.

B - Correct: Checkpoint-assisted recovery uses durable checkpoint information with the relevant log history.

C - Correct: Restart recovery can use checkpoints and transaction logs to reconstruct valid state.

D - Incorrect: Backup recovery starts from a separate database copy, which the description does not mention.

Primary note proof

Study-note section ADB30

> A checkpoint records enough durable recovery state to avoid scanning all old history. In a simple quiescent/checkpoint exercise, specified flushing may make earlier committed work unnecessary to redo. Active transactions can span the checkpoint, so their relevant earlier updates can still need undo. Do not assume every transaction before a checkpoint needs no processing.

Study-note section ADB26

Question sources

Computer Science MCQ practice collection · Question 209

Question 99 | AM0210

Which overall crash-recovery process preserves durable committed work and removes incomplete effects after a system failure, leaving any business-level retry of formerly active transactions to a new controlled attempt?

A. Rollback recovery

B. Checkpoint recovery

C. Restart recovery

D. Backup recovery

Hint

Identify what failed, what durable resources survive and which restoration action is required.

Answer C: C. Restart recovery

Restart recovery restores a valid database state after a crash. It preserves durable committed effects and removes incomplete effects using the required recovery mechanisms. Transactions active at failure are not automatically rerun and committed; a business retry is a separate controlled attempt. Rollback and checkpoint processing can be components, while backup recovery starts from another stored copy when that is needed.

Why each choice is right or wrong

A - Incorrect: Rollback names undo of incomplete work rather than the entire restart process.

B - Incorrect: Checkpoint information guides recovery rather than naming its whole process.

C - Correct: Restart recovery is the overall crash-restoration process described.

D - Incorrect: Backup restoration starts from a separate copy, which this scenario does not require.

Primary note proof

Study-note section ADB26

> Transaction failures include invalid operations, constraint violations and concurrency-control aborts. Enforcing concurrency can deliberately abort work; it does not prevent every transaction failure. A system crash loses volatile memory while disks may survive. Media failure damages persistent storage and normally requires restoring a backup, then replaying available archived logs. Human mistakes may require point-in-time restoration before the bad committed operation.

• During recovery, all transactions of the commit table are redone and all transactions of active tables are ignored since none of their AFIMs reached the database.
• It is possible that a commit table transaction may be redone twice but this does not create any inconsistency because of a redone is —idempotent‖,
• that is, one redone for an AFIM is equivalent to multiple redone for the same AFIM.

Fundamental of Database Systems module | PDF page 110 | lines 14-30

◦ Deferred Update:
• All transaction updates are recorded in the local workspace (cache)
• All modified data items in the cache is then written after a transaction ends its execution or after a fixed number of transactions have completed their execution.
• During commit the updates are first recorded on the log and then on the database
• If a transaction fails before reaching its commit point undo is not needed because it didn‘t change the database yet
• If a transaction fails after commit (writing on the log) but before finishing saving to the data base redoing is needed from the log
◦ Immediate Update:
• As soon as a data item is modified in cache, the disk copy is updated.
• These update are first recorded on the log and on the disk by force writing, before the database is updated
• If a transaction fails after recording some change to the database but before reaching its commit point , this will be rolled back

Fundamental of Database Systems module | PDF page 110 | lines 5-13

◦ Repeating history during redo:
• ARIES will retrace all actions of the database system prior to the crash to reconstruct the database state when the crash occurred.
• Transaction that were un committed at the time of crash are undone
◦ Logging changes during undo:
• It will prevent ARIES from repeating the completed undo operations if a failure occurs during recovery, which causes a restart of the recovery process.
Data Update : Four types

Question sources

Computer Science MCQ practice collection · Question 210

Question 100 | AM0212

After a power failure loses volatile memory but leaves persistent storage intact, which term names the overall process that restores a valid database while preserving durable commits and removing incomplete effects? Choose the umbrella process rather than one component.

A. Rollback recovery

B. Checkpoint recovery

C. Restart recovery

D. Backup recovery

Hint

Identify what failed, what durable resources survive and which restoration action is required.

Answer C: C. Restart recovery

Restart recovery is the overall restoration process following a system crash or power loss when persistent storage survives. It preserves durable commits and removes incomplete effects using the appropriate logged recovery work. Rollback may supply undo and checkpoints can shorten log searches, but these are cooperating mechanisms within the process. Backup restoration addresses a separate stored copy and is not required by this stated failure.

Why each choice is right or wrong

A - Incorrect: Rollback is an undo component rather than the overall process.

B - Incorrect: Checkpoint-assisted work guides restart rather than naming its umbrella process.

C - Correct: Restart recovery names the complete restoration after this system crash.

D - Incorrect: The stated intact persistent storage does not call for restoring a separate backup.

Primary note proof

Study-note section ADB26

> Transaction failures include invalid operations, constraint violations and concurrency-control aborts. Enforcing concurrency can deliberately abort work; it does not prevent every transaction failure. A system crash loses volatile memory while disks may survive. Media failure damages persistent storage and normally requires restoring a backup, then replaying available archived logs. Human mistakes may require point-in-time restoration before the bad committed operation.

Study-note section ADB26

> Restart recovery restores a valid database after a crash while preserving durable commits and removing incomplete effects.

Study-note section ADB30

Recovery may start analysis at the checkpoint but redo from an earlier required log position.

Fundamental of Database Systems module | PDF page 103 | lines 6-23

• Recovery from catastrophic
• If there is extensive damage to the wide portion of the database
• This method restore a past copy of the database from the backup storage and reconstructs operation of a committed transaction from the back up log up to the time of failure
• Recovery from non-catastrophic failure
• When the database is not physically damaged but has be come in consistent
• The strategy uses undoing and redoing some operations in order to restore to a consistent state : example
• For instance,
• If failure occurs between commit and database buffers being flushed to secondary storage then, to ensure durability, recovery manager has to redo (roll forward) transaction‘s updates.
• If transaction had not committed at failure time, recovery manager has to undo (rollback) any effects of that transaction for atomicity. Example,
Transaction Log
◦ For recovery from any type of failure data values prior to modification (BFIM -

Fundamental of Database Systems module | PDF page 107 | lines 8-23

Transaction Roll-back (Undo) and Roll-Forward (Redo)
• If transaction fails for what so ever reason after updating the data base it must be necessary to roll back
• If a transaction T is roll back , any transaction that has read the value of some data item X written by T must be also be roll back
• Similarly once S is roll back, any transaction R that has read the values of some data item Y written by S must aslo be roll back, and so on..
• To maintain such cases, a transaction‘s operations are redone or undone.
• Undo: Restore all BFIMs on to disk (Remove all AFIMs).
• Redo: Restore all AFIMs on to disk.
• Database recovery is achieved either by performing only Undos or only Redos or by a combination of the two. These operations are recorded in the log as they happen.
Data Update and Recovery Scheme : Three types
i. Deferred Update (No Undo/Redo)
◦ The data update goes as follows:

Question sources

Computer Science MCQ practice collection · Question 212

Question 101 | AM0213

In a conventional transaction-log system, which listed mechanisms use logged updates or checkpoint/log state for undo or restart? Select all that apply. Backup recovery in D means restoring only a standalone full backup, without replaying archived logs.

A. Rollback recovery

B. Checkpoint recovery

C. Restart recovery

D. Backup recovery

Hint

Track durable-write ordering and distinguish reversing incomplete work from installing logged effects.

Answer A, B, C: A. Rollback recovery; B. Checkpoint recovery; C. Restart recovery

Logged rollback uses before-images to remove incomplete effects. Checkpoint-assisted recovery combines durable recovery state with relevant log history, and log-based restart uses that history to preserve commits and remove incomplete work. All three fit the specified model. A standalone backup restore instead copies a separately stored database image; the question excludes archived-log replay from D so that this alternative does not overlap.

Why each choice is right or wrong

A - Correct: The logged rollback uses before-images for undo.

B - Correct: Checkpoint-assisted recovery uses recovery-state records and relevant log history.

C - Correct: The specified log-based restart uses durable transaction history.

D - Incorrect: A standalone image restore without log replay does not use the specified logged recovery mechanism.

Primary note proof

Study-note section ADB27

> Write-ahead logging requires the update log needed for recovery to reach stable storage before the corresponding changed data page reaches disk. To acknowledge a durable commit, force the transaction's required log records, including its commit record, to stable storage. A buffer can be changed before that log flush; WAL orders durable writes, not every CPU assignment.

Study-note section ADB27

> Undo restores before-images of incomplete effects, usually traversing that transaction's updates backward.

Study-note section ADB30

Active transactions can span the checkpoint, so their relevant earlier updates can still need undo.

Fundamental of Database Systems module | PDF page 104 | lines 19-25

• For Undo: Before a data item‘s AFIM is flushed to the database disk (overwriting the BFIM) its BFIM must be written to the log and the log must be saved on a stable store (log disk).
• For Redo: Before a transaction executes its commit operation, all its AFIMs must be written to the log and the log must be saved on a stable store.
• Standard Recovery Terminology

Fundamental of Database Systems module | PDF page 105 | lines 25-36

Check pointing
• Log file is used to recover failed DB but we may not know how far back in the log to search. Thus
• Checkpoint is a Point of synchronization between database and log file.
• Time to time (randomly or under some criteria) the database flushes its buffer to database disk to minimize the task of recovery.
• When failure occurs, redo all transactions that committed since the checkpoint

and undo all transactions active at time of crash.
• In previous example ,Figure 2, on slide18 , with checkpoint at time tc, changes made by T2 and T3 have been written to secondary storage. Thus: only redo T4 and T5, undo transactions T1 and T6.
• At what interval to take a check pointing may be measured :

Fundamental of Database Systems module | PDF page 107 | lines 8-23

Transaction Roll-back (Undo) and Roll-Forward (Redo)
• If transaction fails for what so ever reason after updating the data base it must be necessary to roll back
• If a transaction T is roll back , any transaction that has read the value of some data item X written by T must be also be roll back
• Similarly once S is roll back, any transaction R that has read the values of some data item Y written by S must aslo be roll back, and so on..
• To maintain such cases, a transaction‘s operations are redone or undone.
• Undo: Restore all BFIMs on to disk (Remove all AFIMs).
• Redo: Restore all AFIMs on to disk.
• Database recovery is achieved either by performing only Undos or only Redos or by a combination of the two. These operations are recorded in the log as they happen.

Computer Science MCQ practice collection · Question 213

Question 102 | AM0214

Which recovery method is used to recover from media failures, such as disk crashes?

A. Rollback recovery

B. Checkpoint recovery

C. Restart recovery

D. Backup recovery

Hint

Identify what failed, what durable resources survive and which restoration action is required.

Answer D: Backup recovery

For disk media destruction, restore a backup copy and reconstruct committed operations from the backup log (p.103). D supplies the missing database contents.

Why each choice is right or wrong

A - Incorrect: Undo alone does not recreate a destroyed database copy.

B - Incorrect: Checkpoint synchronization alone is not an independent media backup.

C - Incorrect: A restart without restoring lost storage is insufficient.

D - Correct: Backup recovery is the required catastrophic/media restoration approach.

Primary note proof

Study-note section ADB26

> Transaction failures include invalid operations, constraint violations and concurrency-control aborts. Enforcing concurrency can deliberately abort work; it does not prevent every transaction failure. A system crash loses volatile memory while disks may survive. Media failure damages persistent storage and normally requires restoring a backup, then replaying available archived logs. Human mistakes may require point-in-time restoration before the bad committed operation.

Study-note section ADB26

> Rollback handles failed/uncommitted work; redo preserves committed work missing from pages; checkpoints reduce log-search work; backups provide another stored copy.

Study-note section ADB26

> Restart recovery restores a valid database after a crash while preserving durable commits and removing incomplete effects.

Question sources

Computer Science MCQ practice collection · Question 214

Question 103 | AM0215

What is a distributed database system?

A. A database system that is spread across multiple locations

B. A database system that uses multiple database management systems

C. A database system that supports multiple database schemas

D. A database system that is used for storing distributed data

Hint

Separate coordinated network placement from engine compatibility and semantic integration.

Answer A: A database system that is spread across multiple locations

A DDB is multiple logically related databases distributed over a computer network, managed transparently (p.114). A captures the physical distribution; logical relatedness and coordinated management are implicit qualifications.

Why each choice is right or wrong

A - Correct: Multiple locations captures the defining distribution.

B - Incorrect: Different DBMS products are not required; homogeneous DDBs exist.

C - Incorrect: Multiple schemas are not the physical distribution definition.

D - Incorrect: Storing distributed data is circular and omits the network/location criterion.

Primary note proof

Study-note section ADB33

A distributed database contains logically related data across networked sites, managed as a coordinated system. A homogeneous system uses compatible DBMS technology across sites; a heterogeneous system integrates differing DBMSs, data models, schemas or interfaces. Different operating systems are possible but do not define the distinction. Same DBMS does not imply identical local schemas, automatic replication or immediate synchronization.

Study-note section ADB33

Distribution adds communication, coordination and security costs; a site outage can still make needed data unavailable if no usable replica exists.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 114 | lines 3-13

6.1 Distributed Database Concepts
• A transaction can be executed by multiple networked computers in a unified manner.
• A distributed database (DDB) processes Unit of execution (a transaction) in a distributed manner.
• A distributed database (DDB) can be defined as :
- A collection of multiple logically related database distributed over a computer network, and a distributed database management system as a software system that manages a distributed database while making the distribution transparent to the user.
- The physical placement of data (files, relations, etc.) which is not known to the user (distribution transparency).

Variant 1 | Alternative version 1

What is a distributed database system?

A. A system that uses multiple database management systems

B. A system that supports multiple database schemas

C. A system that spans multiple locations or sites

D. A system that replicates data across multiple databases

Answer C: A system that spans multiple locations or sites

Apply the same study-note rule to this alternative source set; the choice contrasts below show the derivation.

Why each choice is right or wrong

A - Incorrect: Multiple DBMS products are not required for distribution.

B - Incorrect: Multiple schemas are not the spatial/network definition.

C - Correct: Spanning sites matches the distributed placement definition on p.114.

D - Incorrect: Replication is optional and narrower than a distributed database.

Primary note proof

Study-note section ADB33

> A distributed database contains logically related data across networked sites, managed as a coordinated system. A homogeneous system uses compatible DBMS technology across sites; a heterogeneous system integrates differing DBMSs, data models, schemas or interfaces. Different operating systems are possible but do not define the distinction. Same DBMS does not imply identical local schemas, automatic replication or immediate synchronization.

Study-note section ADB33

> Distribution adds communication, coordination and security costs; a site outage can still make needed data unavailable if no usable replica exists.

Computer Science MCQ practice collection · Question 225

Question 104 | AM0216

What is the key advantage of a distributed database system?

A. Improved data security

B. Reduced data redundancy

C. Enhanced data availability

D. Simplified data querying

Hint

Separate coordinated network placement from engine compatibility and semantic integration.

Answer C: Enhanced data availability

Multiple nodes allow others to do the job if one fails (p.116), improving availability. The module lists integrity/security difficulty and complexity among disadvantages (p.117).

Why each choice is right or wrong

A - Incorrect: Improved security is not guaranteed; distributed access complicates control.

B - Incorrect: Replication stores multiple copies rather than necessarily reducing redundancy.

C - Correct: Availability is explicitly improved through multiple nodes.

D - Incorrect: Querying across sites adds network and optimization complexity rather than inherently simplifying it.

Primary note proof

Study-note section ADB33

A distributed database contains logically related data across networked sites, managed as a coordinated system. A homogeneous system uses compatible DBMS technology across sites; a heterogeneous system integrates differing DBMSs, data models, schemas or interfaces. Different operating systems are possible but do not define the distinction. Same DBMS does not imply identical local schemas, automatic replication or immediate synchronization.

Study-note section ADB37

Full replication places the whole database at every relevant site; partial replication copies selected fragments to selected sites; nonredundant allocation stores each fragment once.

Study-note section ADB33

Distribution adds communication, coordination and security costs; a site outage can still make needed data unavailable if no usable replica exists.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 116 | lines 2-28

• Advantages of DDB :
i. Distribution and Network transparency:
• Users do not have to worry about operational details of the network.
» There is Location transparency, which refers to freedom of issuing command from any location without affecting its working.
» Then there is Naming transparency, which allows access to any names object (files, relations, etc.) from any location.
ii. Replication transparency:
• It allows to store copies of a data at multiple sites as shown in the above diagram.
• This is done to minimize access time to the required data.
iii. Fragmentation transparency:
• Allows to fragment a relation horizontally (create a subset of rows of a relation) or vertically (create a subset of columns of a relation).
iv. Increased reliability and availability:
• Reliability refers to system live time, that is, system is running efficiently most of the time. Availability is the probability that the system is continuously available (usable or accessible) during a time interval.
• A distributed database system has multiple nodes (computers) and if one fails then others are available to do the job.
v. Improved performance:
• A distributed DBMS fragments the database to keep data closer to where it is needed most.
• This reduces data management (access and modification) time significantly.

Fundamental of Database Systems module | PDF page 117 | lines 15-31

6.2 Data Replication and Fragmentation: Distributed data storage
• There are two approaches to store the relation in the distributed database : Replication and Fragmentation
I. Data Replication
• The system maintain several identical copies of the relation & store each copy at a different site
• In general it enhance the performance of read operation and increase the availability of data to read only transaction. However, update transactions incur greater overhead
II. Data Fragmentation
- Split a relation into logically related and correct parts.
- The main reasons for fragmenting a relation are
• Efficiency- data that is not needed by the local applications is not stored
• Parallelism - a transaction can be divided into several subqueries that operate on fragments which will increase the degree of concurrency
- but reconstruction of the whole relation will require accessing data from all sites containing part of the relation

Question sources

Computer Science MCQ practice collection · Question 216

Question 105 | AM0217

What is a homogenous distributed database system?

A. A system that uses the same database management system across all sites

B. A system that stores the same type of data across all sites

C. A system that uses a single database schema across all sites

D. A system that shares the same network infrastructure across all sites

Hint

Separate coordinated network placement from engine compatibility and semantic integration.

Answer A: A system that uses the same database management system across all sites

A homogeneous distributed database uses the same or compatible DBMS technology at its sites. Sharing data types, a schema or network infrastructure does not by itself establish that DBMS property. In particular, identical DBMS technology does not force all local schemas to be identical, and compatible structures alone do not prove identical DBMSs. The definition concerns the database-management technology, so A identifies the relevant criterion without adding unnecessary sameness requirements.

Why each choice is right or wrong

A - Correct: Correct: the same DBMS technology across sites meets the homogeneous-system criterion.

B - Incorrect: Incorrect: matching data types alone does not establish that the sites use the same DBMS technology.

C - Incorrect: Incorrect: schema agreement alone does not establish DBMS homogeneity, and same DBMS technology need not imply identical local schemas.

D - Incorrect: Incorrect: shared networking does not establish the database-management technology used at the sites.

Primary note proof

Study-note section ADB33

> A distributed database contains logically related data across networked sites, managed as a coordinated system. A homogeneous system uses compatible DBMS technology across sites; a heterogeneous system integrates differing DBMSs, data models, schemas or interfaces. Different operating systems are possible but do not define the distinction. Same DBMS does not imply identical local schemas, automatic replication or immediate synchronization.

Question 106 | AM0218

What is a heterogeneous distributed database system?

A. A system that uses different database management systems across all sites

B. A system that stores different types of data across all sites

C. A system that uses different database schemas across all sites

D. A system that uses different network infrastructures across all sites

Hint

Separate coordinated network placement from engine compatibility and semantic integration.

Answer A: A system that uses different database management systems across all sites

Heterogeneous means at least one database is from a different vendor (p.119), supporting different DBMS software. It does not require every pair of sites to differ; A’s all sites must be read as across the participating sites, not pairwise uniqueness.

Why each choice is right or wrong

A - Correct: Different database-system vendors/software captures the defining distinction with the stated qualification.

B - Incorrect: Different content/types alone do not establish vendor heterogeneity.

C - Incorrect: Federated systems may have one conceptual schema despite heterogeneity.

D - Incorrect: Network differences are not the database-vendor definition.

Primary note proof

Study-note section ADB33

A distributed database contains logically related data across networked sites, managed as a coordinated system. A homogeneous system uses compatible DBMS technology across sites; a heterogeneous system integrates differing DBMSs, data models, schemas or interfaces. Different operating systems are possible but do not define the distinction. Same DBMS does not imply identical local schemas, automatic replication or immediate synchronization.

Study-note section ADB33

Heterogeneous design must reconcile naming, types, units, identifiers, query capabilities and transaction semantics.

Study-note section ADB33

ODBC and JDBC provide connectivity interfaces; they do not automatically solve semantic differences or create one distributed transaction.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 119 | lines 11-20

• Heterogeneous
- At least one of the database must be from different vendor : two variants
- Federated: Each site may run different database system but the data access is managed through a single conceptual schema.
• This implies that the degree of local autonomy is minimum. Each site must adhere to a centralized access policy. There may be a global schema.
- Multidatabase: There is no one conceptual global schema. For data access a schema is constructed dynamically as needed by the application software.

Computer Science MCQ practice collection · Question 227

Question 107 | AM0219

What is data fragmentation in a distributed database system?

A. Storing data in multiple copies at different sites

B. Dividing data into smaller subsets and storing them at different sites

C. Merging data from different sites into a single copy

D. Replicating data across all sites in the system

Hint

Identify whether rows or columns are split and reverse the split to reconstruct the original relation.

Answer B: Dividing data into smaller subsets and storing them at different sites

Fragmentation splits a relation into logically related correct parts (p.117); horizontal fragments select rows and vertical fragments select columns (p.118). B describes storing these subsets across sites.

Why each choice is right or wrong

A - Incorrect: Multiple identical copies describe replication.

B - Correct: Smaller subsets describe fragmentation.

C - Incorrect: Merging is reconstruction/integration, the opposite direction from splitting.

D - Incorrect: Copying data to all sites is replication rather than fragmentation.

Primary note proof

Study-note section ADB36

> Horizontal fragmentation selects row subsets by predicates; their union reconstructs the relation. Check completeness so every original row is represented and disjointness if no overlap is intended. Define an explicit fragment for NULL/other values when needed. Vertical fragmentation projects column subsets and repeats a key or row identifier so joining on it reconstructs the original rows without spurious matches.

Study-note section ADB37

> Full replication places the whole database at every relevant site; partial replication copies selected fragments to selected sites; nonredundant allocation stores each fragment once.

Study-note section ADB24

> Encryption protects stored or transmitted content; integrity constraints restrict valid data; auditing records actions.

Question 108 | AM0220

What is data replication in a distributed database system?

A. Storing data in multiple copies at different sites

B. Dividing data into smaller subsets and storing them at different sites

C. Merging data from different sites into a single copy

D. Deleting data that is no longer needed from the database

Hint

Separate copy placement, propagation timing and update-maintenance cost.

Answer A: Storing data in multiple copies at different sites

Replication maintains several identical copies of a relation at different sites (p.117). This differs from dividing it into fragments.

Why each choice is right or wrong

A - Correct: Multiple copies at different sites exactly matches.

B - Incorrect: Subsets describe fragmentation.

C - Incorrect: Merging into one copy is not maintaining multiple copies.

D - Incorrect: Deletion removes data rather than replicating it.

Primary note proof

Study-note section ADB36

Horizontal fragmentation selects row subsets by predicates; their union reconstructs the relation. Check completeness so every original row is represented and disjointness if no overlap is intended. Define an explicit fragment for NULL/other values when needed. Vertical fragmentation projects column subsets and repeats a key or row identifier so joining on it reconstructs the original rows without spurious matches.

Study-note section ADB37

Full replication places the whole database at every relevant site; partial replication copies selected fragments to selected sites; nonredundant allocation stores each fragment once.

Study-note section ADB24

Encryption protects stored or transmitted content; integrity constraints restrict valid data; auditing records actions.

Fundamental of Database Systems module | PDF page 117 | lines 15-31

6.2 Data Replication and Fragmentation: Distributed data storage
• There are two approaches to store the relation in the distributed database : Replication and Fragmentation
I. Data Replication
• The system maintain several identical copies of the relation & store each copy at a different site
• In general it enhance the performance of read operation and increase the availability of data to read only transaction. However, update transactions incur greater overhead
II. Data Fragmentation
- Split a relation into logically related and correct parts.
- The main reasons for fragmenting a relation are
• Efficiency- data that is not needed by the local applications is not stored
• Parallelism - a transaction can be divided into several subqueries that operate on fragments which will increase the degree of concurrency
- but reconstruction of the whole relation will require accessing data from all sites containing part of the relation

Variant 1 | Alternative version 1

What is data replication in a distributed database system?

A. Storing multiple copies of data at different sites

B. Dividing data into smaller subsets for efficient storage

C. Merging data from different sites into a single database

D. Encrypting data to ensure security during transmission

Answer A: Storing multiple copies of data at different sites

Apply the same study-note rule to this alternative source set; the choice contrasts below show the derivation.

Why each choice is right or wrong

A - Correct: Identical copies at different sites match p.117.

B - Incorrect: Subsets describe fragmentation, not replication.

C - Incorrect: Merging to one database does not retain distributed copies.

D - Incorrect: Encryption does not create replicated copies.

Primary note proof

Study-note section ADB36

> Horizontal fragmentation selects row subsets by predicates; their union reconstructs the relation. Check completeness so every original row is represented and disjointness if no overlap is intended. Define an explicit fragment for NULL/other values when needed. Vertical fragmentation projects column subsets and repeats a key or row identifier so joining on it reconstructs the original rows without spurious matches.

Study-note section ADB37

> Full replication places the whole database at every relevant site; partial replication copies selected fragments to selected sites; nonredundant allocation stores each fragment once.

Study-note section ADB24

> Encryption protects stored or transmitted content; integrity constraints restrict valid data; auditing records actions.

Computer Science MCQ practice collection · Question 229

Question 109 | AM0221

Which transparency hides the physical site storing a named database object, so users can refer to that object without specifying its site?

A. Local-only data access

B. Fragmentation transparency

C. Location transparency

D. Replication transparency

Hint

Identify exactly which detail is hidden from the user.

Answer C: Location transparency

Location transparency hides the physical site holding a named logical object. Fragmentation transparency instead hides the existence and reconstruction of fragments, while replication transparency hides which copy is used and how copies are maintained. Those properties can coexist in a distributed database, so a vague single-logical-database experience would not identify only one. The revised stem isolates hidden site placement. Local-only access restricts what can be accessed rather than making remote placement transparent.

Why each choice is right or wrong

A - Incorrect: Incorrect: restricting access to local data does not hide the placement of a named distributed object.

B - Incorrect: Incorrect: fragmentation transparency hides splitting and reconstruction, not specifically the object's physical site.

C - Correct: Correct: location transparency hides which physical site stores the named object.

D - Incorrect: Incorrect: replication transparency hides copy selection and maintenance, not specifically site placement.

Primary note proof

Study-note section ADB35

> Location transparency hides which site holds a named object. Fragmentation transparency hides the existence and reconstruction of fragments: users query the whole logical relation. Replication transparency hides which copy is used and how copies are maintained. The broad single-logical-database experience may involve all three.

> 6.1 Distributed Database Concepts
> • A transaction can be executed by multiple networked computers in a unified manner.
> • A distributed database (DDB) processes Unit of execution (a transaction) in a distributed manner.
> • A distributed database (DDB) can be defined as :
> - A collection of multiple logically related database distributed over a computer network, and a distributed database management system as a software system that manages a distributed database while making the distribution transparent to the user.
> - The physical placement of data (files, relations, etc.) which is not known to the user (distribution transparency).

Fundamental of Database Systems module | PDF page 116 | lines 2-28

> • Advantages of DDB :
> i. Distribution and Network transparency:
> • Users do not have to worry about operational details of the

network.
» There is Location transparency, which refers to freedom of issuing command from any location without affecting its working.
» Then there is Naming transparency, which allows access to any names object (files, relations, etc.) from any location.
ii. Replication transparency:
• It allows to store copies of a data at multiple sites as shown in the above diagram.
• This is done to minimize access time to the required data.
iii. Fragmentation transparency:
• Allows to fragment a relation horizontally (create a subset of rows of a relation) or vertically (create a subset of columns of a relation).
iv. Increased reliability and availability:
• Reliability refers to system live time, that is, system is running efficiently most of the time. Availability is the probability that the system is continuously available (usable or accessible) during a time interval.
• A distributed database system has multiple nodes (computers) and if one fails then others are available to do the job.
v. Improved performance:
• A distributed DBMS fragments the database to keep data closer to where it is needed most.
• This reduces data management (access and modification) time significantly.

Question sources

Computer Science MCQ practice collection · Question 221

Question 110 | AM0222

A user explicitly names a fragment and can query it without specifying or knowing the physical site that stores it. Which transparency is being provided? The existence of the fragment is visible.

A. Local-only data access

B. Fragmentation transparency

C. Location transparency

D. Replication transparency

Hint

Identify exactly which detail is hidden from the user.

Answer C: Location transparency

Location transparency hides the physical site storing a named object. The user in this scenario still names the fragment, so fragmentation remains visible; fragmentation transparency would hide the split and reconstruction. Replication transparency hides which copy is selected or maintained. Restricting users to local data is an access limitation rather than concealment of a remote fragment's placement. C therefore identifies the particular hidden detail without treating all transparency properties as interchangeable.

Why each choice is right or wrong

A - Incorrect: Incorrect: local-only access restricts accessible data rather than hiding a named remote fragment's physical site.

B - Incorrect: Incorrect: the user explicitly names the fragment, so its existence is not hidden.

C - Correct: Correct: the fragment's physical site is hidden while its logical name remains usable.

D - Incorrect: Incorrect: replica selection and maintenance are different hidden details from the specified site placement.

Primary note proof

Study-note section ADB35

> Location transparency hides which site holds a named object. Fragmentation transparency hides the existence and reconstruction of fragments: users query the whole logical relation. Replication transparency hides which copy is used and how copies are maintained. The broad single-logical-database experience may involve all three.

Study-note section ADB35

> If users explicitly name a fragment but need not specify its site, fragmentation is visible while location can remain transparent. Distinguish whether fragment names, storage sites or both are hidden from the user.

Computer Science MCQ practice collection · Question 222

Question 111 | AM0223

Which data transparency level ensures that users are not aware of the presence of multiple copies of data in different sites?

A. Local data transparency

B. Fragmentation transparency

C. Location transparency

D. Replication transparency

Hint

Identify exactly which detail is hidden from the user.

Answer D: Replication transparency

The module combines transparent distribution (p.114) with replication as storing copies at multiple sites (pp.116-117). Hiding this copying is replication transparency.

Why each choice is right or wrong

A - Incorrect: Local transparency does not identify multiple copies.

B - Incorrect: Fragmentation concerns subsets rather than duplicates.

C - Incorrect: Location hides placement but does not specifically name the copying aspect.

D - Correct: Replication transparency is the copy-specific aspect.

Primary note proof

Study-note section ADB35

> Location transparency hides which site holds a named object. Fragmentation transparency hides the existence and reconstruction of fragments: users query the whole logical relation. Replication transparency hides which copy is used and how copies are maintained. The broad single-logical-database experience may involve all three.

Question sources

Computer Science MCQ practice collection · Question 223

Question 112 | AM0224

What is the role of a distributed query processor in a distributed database system?

A. It ensures the consistency of data across all sites.

B. It manages the distribution and retrieval of data across multiple sites.

C. It controls the access permissions of users in the system.

D. It handles the physical storage of data at each site.

Hint

Compare local processing with the bytes and messages moved between sites.

Answer B: It manages the distribution and retrieval of data across multiple sites.

Distributed query processing compares moving source relations and results among sites, selecting the lower-transfer strategy (pp.120-121). B best captures distributed retrieval, understood as planning transfers for a query rather than deciding the physical database design.

Why each choice is right or wrong

A - Incorrect: Global consistency is assigned to concurrency control/recovery rather than query transfer planning.

B - Correct: Managing query data transfer and retrieval matches the worked example.

C - Incorrect: Access permissions are authorization, not the worked query role.

D - Incorrect: Physical local storage management is not choosing distributed query strategies.

Primary note proof

Study-note section ADB38

Distributed processing decomposes a logical query, localizes referenced relations to fragments/replicas, chooses global placement/order and optimizes local subplans. Include bytes

moved, message latency, bandwidth and local work. Apply filters and projections before shipping when equivalent. A semijoin retains only rows of one input that have a match in the other, returning that input's attributes.

Study-note section ADB24

Authentication establishes identity; authorization/access control determines permitted actions.

Study-note section ADB34

A tightly integrated distributed system can present one global schema and shared control.

6.4 Query Processing in Distributed Databases
• Issues
- Cost of transferring data (files and results) over the network.
• This cost is usually high, so some optimization is necessary.
• Example: suppose there are three sites. Where the relation Employee at site 1, Department at Site 2 and no relation at site 3
- Employee at site 1. 10,000 rows. Row size = 100 bytes. Table size = 106 bytes.
- Department at Site 2. 100 rows. Row size = 35 bytes. Table size = 3,500 bytes.
- And a query is initiated from S3 to retrieve employees [First Name (15 byte long), Last name (15 byte long) and Department name (10 byte long) total of 40 bytes]
• Q: For each employee, retrieve employee Fname, Lname, and department name
• Q: δFname,Lname,Dname (Employee Dno = Dnumber Department)
• Assumption
Site 3

Fundamental of Database Systems module | PDF page 121 | lines 8-24

• Strategies : Minimizing data transfer.
- Transfer Employee and Department to site 3.
• Total transfer bytes = 1,000,000 + 3500 = 1,003,500 bytes.
- Transfer Employee to site 2, execute join at site 2 and send the result to site 3.
• Transferring employees data from site 1 to site 2: 1,000,000 bytes
• Query result size = 40 * 10,000 = 400,000 bytes.
• Total transfer size = 1,000,000 + 400,000 = 1,400,000 bytes.
- Transfer Department relation to site 1, execute the join at site 1, and send the result to site 3.
• Data Transfer from site 2 to site 1: 3500 bytes

• Query result size = 40 * 10,000 = 400,000 bytes
• Total bytes transferred = 3500+ 400,000 = 403,500 bytes.
• Preferred approach: strategy 3.
Example 2 : Consider the query
- Q‟: For each department, retrieve the department name ,Fname and LName of the department manager

Question sources

Computer Science MCQ practice collection · Question 224

Question 113 | AM0230

Which condition specifically makes a distributed database environment homogeneous, rather than merely being useful for distributed operation?

A. Consistency of database schemas across all sites

B. Compatibility of network infrastructures across all sites

C. Standardization of database management systems across all sites

D. Replication of data at each site for fault tolerance

Hint

Separate coordinated network placement from engine compatibility and semantic integration.

Answer C: Standardization of database management systems across all sites

Homogeneity is defined by using the same or compatible DBMS technology across sites. Schema compatibility, functioning network connections and replication can be useful design concerns, but none alone establishes that common DBMS technology. A homogeneous system may have different local schemas, and replication is not required merely because data is distributed. Narrowing the question to the defining condition preserves C while acknowledging that the other design concerns can matter in practice.

Why each choice is right or wrong

A - Incorrect: Incorrect: schema compatibility can be useful but does not establish common DBMS technology.

B - Incorrect: Incorrect: compatible networking supports communication but does not establish DBMS homogeneity.

C - Correct: Correct: DBMS standardization supplies the defining common technology across sites.

D - Incorrect: Incorrect: replication can improve availability but is optional and does not define homogeneity.

Primary note proof

Study-note section ADB33

A distributed database contains logically related data across networked sites, managed as a coordinated system. A homogeneous system uses compatible DBMS technology across sites; a heterogeneous system integrates differing DBMSs, data models, schemas or interfaces. Different operating systems are possible but do not define the distinction. Same DBMS does not imply identical local schemas, automatic replication or immediate synchronization.

Study-note section ADB37

Full replication places the whole database at every relevant site; partial replication copies selected fragments to selected sites; nonredundant allocation stores each fragment once.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 118 | lines 27-32

6.3 Types of Distributed Database Systems
• Homogeneous
- All sites of the database system have identical setup, i.e., same database system software.
- The system may have little or no local autonomy
- The underlying operating systems can be a mixture of Linux, Window, Unix, etc.

Question sources

Computer Science MCQ practice collection · Question 230

Question 114 | AM0231

A heterogeneous distributed database retains different local DBMSs and schemas and must integrate them without requiring full replication. Which integration requirements apply? Select all that apply. D means coherent schema semantics through mappings, not identical schemas.

A. Replication of data at each site for fault tolerance

B. Standardization of database management systems across all sites

C. Compatibility of network infrastructures across all sites

D. Consistency of database schemas across all sites

Hint

Separate coordinated network placement from engine compatibility and semantic integration.

Answer C, D: C. Compatibility of network infrastructures across all sites; D. Consistency of database schemas across all sites

Integration requires interoperable communication so requests and results can move between sites. It also requires coherent mappings for names, types, identifiers and other schema meanings. These support C and D. Replacing every DBMS with one product would remove the retained heterogeneity, and full replication is an optional placement decision rather than a requirement for integrating different local systems.

Why each choice is right or wrong

A - Incorrect: Copying all data everywhere is not required for the stated integration.

B - Incorrect: The scenario retains differing DBMSs rather than replacing all with one standard.

C - Correct: Interoperable communication is needed to exchange requests and results.

D - Correct: Mappings must reconcile schema meanings without requiring identical local schemas.

Primary note proof

Study-note section ADB33

> A distributed database contains logically related data across networked sites, managed as a coordinated system. A homogeneous system uses compatible DBMS technology across sites; a heterogeneous system integrates differing DBMSs, data models, schemas or interfaces. Different operating systems are possible but do not define the distinction. Same DBMS does not imply identical local schemas, automatic replication or immediate synchronization.

Study-note section ADB33

> Heterogeneous design must reconcile naming, types, units, identifiers, query capabilities and transaction semantics.

Study-note section ADB37

> Full replication does not inherently mean every copy is updated simultaneously; its synchronization rule must be stated.

Related reading (context, not primary note proof)

Computer Science MCQ practice collection · Question 231

Question 115 | AM0232

Which approach is commonly used for query processing in a distributed database system?

A. Centralized query processing

B. Distributed query processing

C. Parallel query processing

D. Sequential query processing

Hint

Compare local processing with the bytes and messages moved between sites.

Answer B: Distributed query processing

The module's distributed-query section compares execution and data-transfer locations among multiple sites (pp.120-121). B names the overall approach. A chosen plan may execute a particular join at one site; that does not make the whole system centralized.

Why each choice is right or wrong

A - Incorrect: A local execution site can be part of a distributed plan, but centralized processing does not name the chapter's overall approach.

B - Correct: Distributed query processing matches the section and cross-site strategies.

C - Incorrect: Parallelism may be used, but simultaneous execution is not required by these examples.

D - Incorrect: A plan may contain sequential operations; this does not identify cross-site processing.

Primary note proof

Study-note section ADB38

Distributed processing decomposes a logical query, localizes referenced relations to fragments/replicas, chooses global placement/order and optimizes local subplans. Include bytes moved, message latency, bandwidth and local work. Apply filters and projections before shipping when equivalent. A semijoin retains only rows of one input that have a match in the other, returning that input's attributes.

Study-note section ADB38

If nearly all S matches, key shipping may not help.

Study-note section ADB22

Plan caching reuses an execution strategy, not the rows returned.

Question sources

Computer Science MCQ practice collection · Question 232

Question 116 | AM0233

What is the role of a distributed transaction coordinator in a distributed database system?

A. It ensures the consistency of data across all sites.

B. It manages the distribution and retrieval of data across multiple sites.

C. It controls the access permissions of users in the system.

D. It handles the physical storage of data at each site.

Hint

Distinguish coordinated transaction outcome from concurrent access and local storage.

Answer A: It ensures the consistency of data across all sites.

Global consistency is required of concurrency/recovery (p.122). Under the primary-site technique a coordinator manages transaction concurrency and commit (p.123). A is supported in that transaction-coordination sense, rather than as an unconditional guarantee against every error.

Why each choice is right or wrong

A - Correct: Coordination of concurrency and commit maintains transaction consistency across sites.

B - Incorrect: Query transfer/retrieval is a separate distributed-query task.

C - Incorrect: User permissions are authorization, not commit coordination.

D - Incorrect: Local physical storage is not the primary coordinator’s stated function.

Primary note proof

Study-note section ADB39

Two-phase commit (2PC) first asks participants to prepare and durably promise they can commit. If all vote yes, the coordinator records commit durably and tells participants; otherwise it decides abort. A prepared participant must retain enough state to obey the final decision. Coordinator/communication failure can leave it in doubt and block progress until the decision is learned. Timeout after preparation is not permission to invent a commit or abort.

Study-note section ADB39

The transaction coordinator coordinates decisions rather than physically storing every site's rows.

Study-note section ADB38

Distributed processing decomposes a logical query, localizes referenced relations to fragments/replicas, chooses global placement/order and optimizes local subplans.

6.5 Concurrency Control and Recovery
• Distributed Databases encounter a number of concurrency control and recovery problems which are not present in centralized databases. Some of them are listed below.
• Dealing with multiple copies of data items:
• The concurrency control must maintain global consistency. Likewise the recovery mechanism must recover all copies and maintain consistency after recovery.
• Failure of individual sites:

Fundamental of Database Systems module | PDF page 123 | lines 15-29

• Distributed commit:
• A transaction may be fragmented and they may be executed by a number of sites. This require a two or three-phase commit approach for transaction commit.
• Distributed deadlock:
• Since transactions are processed at multiple sites, two or more sites may get involved in deadlock. This must be resolved in a distributed manner.
6.5.1 Distributed Concurrency control
i. Primary site technique: A single site is designated as a primary site which serves as a coordinator for transaction management.
• Transaction management:
- Concurrency control and commit are managed by this site.
- In two phase locking, this site manages locking and releasing data items. If all

transactions follow two-phase policy at all sites, then serializability is guaranteed.
- Advantages:

Question sources

Computer Science MCQ practice collection · Question 233

Question 117 | AM0234

Which listed approaches are replication policies or transfer methods in distributed databases, allowing dimensions to coexist? Select all that apply.

A. Eager replication

B. Lazy replication

C. Snapshot replication

D. Incremental replication

Hint

Separate copy placement, propagation timing and update-maintenance cost.

Answer A, B, C, D: A. Eager replication; B. Lazy replication; C. Snapshot replication; D. Incremental replication

Eager and lazy replication differ in when propagation occurs relative to the acknowledgment or commit point. Snapshot and incremental replication differ in whether a copy or changes are transferred. These are legitimate replication dimensions and can coexist, so all four qualify. The question asks for recognized approaches rather than claiming that one policy is most prevalent or universally preferable.

Why each choice is right or wrong

A - Correct: Eager replication coordinates propagation before the specified acknowledgment or commit point.

B - Correct: Lazy replication propagates changes later and can expose stale reads or require conflict handling.

C - Correct: Snapshot replication distributes a copy at intervals rather than necessarily sending each individual update.

D - Correct: Incremental replication transfers changes and can coexist with a propagation-timing policy.

Primary note proof

Study-note section ADB37

Full replication places the whole database at every relevant site; partial replication copies selected fragments to selected sites; nonredundant allocation stores each fragment once. Copies

improve read locality and can improve availability but require storage and update propagation. They can also spread mistakes, so replication does not replace independent backups.

Study-note section ADB37

Eager/synchronous replication coordinates propagation before the specified commit/acknowledgment point, increasing update latency.

Study-note section ADB37

Snapshot replication transfers a copy at intervals; incremental replication transfers changes.

6.2 Data Replication and Fragmentation: Distributed data storage
• There are two approaches to store the relation in the distributed database : Replication and Fragmentation
I. Data Replication
• The system maintain several identical copies of the relation & store each copy at a different site
• In general it enhance the performance of read operation and increase the availability of data to read only transaction. However, update transactions incur greater overhead
II. Data Fragmentation
- Split a relation into logically related and correct parts.
- The main reasons for fragmenting a relation are
• Efficiency- data that is not needed by the local applications is not stored
• Parallelism - a transaction can be divided into several subqueries that operate on fragments which will increase the degree of concurrency
- but reconstruction of the whole relation will require accessing data from all sites containing part of the relation

Question sources

Computer Science MCQ practice collection · Question 234

Question 118 | AM0235

When comparing distributed query strategies, which factors can affect estimated execution cost or replica placement decisions? Select all that apply.

A. Cost of query execution

B. Size of the database

C. Network bandwidth

D. Data replication

Hint

Identify the resource objective, counts and unit costs before comparing execution strategies.

Answer A, B, C, D: A. Cost of query execution; B. Size of the database; C. Network bandwidth; D. Data replication

Execution cost summarizes the resources consumed by a candidate plan. Relation sizes affect scans and intermediate work, network bandwidth affects data-transfer time, and replica placement changes which copies are available near the computation. All these inputs can alter a distributed strategy's cost. They are complementary considerations rather than competing names for one exclusively important factor.

Why each choice is right or wrong

A - Correct: Estimated execution cost is the explicit basis for comparing candidate strategies.

B - Correct: Database and relation sizes affect scan work, intermediate sizes and algorithm feasibility.

C - Correct: Bandwidth affects transfer time when data or results move between sites.

D - Correct: Replica locations affect which copy can serve a query and its communication cost.

Primary note proof

Study-note section ADB19

> A cost model estimates resources for a candidate plan: page I/O, CPU, memory, temporary storage and network traffic. Catalog statistics include row/page counts, distinct values and distributions. Selection with fraction s predicts s×N rows. For non-NULL equijoin keys, a common estimate is |R|×|S|/max(V(R,k),V(S,k)), assuming uniform values and containment of the smaller distinct-value domain within the larger. Adjust counts for NULLs; if either non-NULL input is empty, the result is zero. Skew, correlations or incomplete domain overlap can invalidate this estimate; known disjoint domains give zero matches.

Study-note section ADB38

> Distributed processing decomposes a logical query, localizes referenced relations to fragments/replicas, chooses global placement/order and optimizes local subplans.

Study-note section ADB38

> Include bytes moved, message latency, bandwidth and local work.

6.4 Query Processing in Distributed Databases
• Issues
- Cost of transferring data (files and results) over the network.
• This cost is usually high, so some optimization is necessary.
• Example: suppose there are three sites. Where the relation Employee at site 1, Department at Site 2 and no relation at site 3
- Employee at site 1. 10,000 rows. Row size = 100 bytes. Table size = 106 bytes.
- Department at Site 2. 100 rows. Row size = 35 bytes. Table size = 3,500 bytes.
- And a query is initiated from S3 to retrieve employees [First Name (15 byte long), Last name (15 byte long) and Department name (10 byte long) total of 40 bytes]
• Q: For each employee, retrieve employee Fname, Lname, and department name
• Q: δFname,Lname,Dname (Employee Dno = Dnumber Department)
• Assumption
Site 3

Fundamental of Database Systems module | PDF page 42 | lines 15-17

- Many estimates are based on cardinality of the relation, so need to be able to estimate this.

Using Selectivity and Cost Estimates in Query Optimization

Question sources

Computer Science MCQ practice collection · Question 235

Question 119 | AM0236

What is the purpose of query optimization in a database system?

A. To ensure data consistency

B. To minimize query execution time

C. To maximize data replication

D. To manage database security

Hint

Separate query representation, strategy selection and execution.

Answer B: To minimize query execution time

Query optimization chooses an efficient execution strategy and minimizes resource usage including response time (p.27). Page 30 explicitly seeks faster queries and the most efficient sequence of steps.

Why each choice is right or wrong

A - Incorrect: Consistency is a transaction correctness concern, not the stated optimization objective.

B - Correct: Minimizing execution/response time captures the efficiency objective.

C - Incorrect: Maximizing replication is not the execution-plan goal.

D - Incorrect: Authorization/security is not query optimization's stated purpose.

Primary note proof

Study-note section ADB17

> Parsing checks SQL grammar; semantic analysis resolves names, types and access permissions. Translation constructs a logical representation, typically relational algebra or a logical query tree. Optimization chooses equivalent operations, join order and physical access methods. Evaluation executes that plan and returns results. Not every implementation exposes exactly the same phase boundaries.

Study-note section ADB17

> Query processing is the whole activity; selecting a suitable efficient strategy is optimization.

Study-note section ADB06

> A transaction is a logical unit of database work, including read-only work.

What is Query Processing?
Steps required to transform high level SQL query into a correct and —efficient‖ strategy for execution and retrieval.
What is Query Optimization?
✓ The activity of choosing a single —efficient‖ execution strategy (from hundreds) as determined by database catalog statistics.
✓ The aim is to answer which relational algebra expression, equivalent to the given query, will lead to the most efficient solution plan?
✓ For each algebraic operator, what algorithm (of several available) do we use to compute that operator?
✓ How do operations pass data (main memory buffer, disk buffer,...)?
✓ Will this plan minimize resource usage? (CPU/Response Time/Disk)

Fundamental of Database Systems module | PDF page 30 | lines 17-30

1.8 Query Optimization
• Everyone wants the performance of their database to be optimal. In particular, there is often a requirement for a specific query or object that is query based, to run faster.
• Problem of query optimization is to find the sequence of steps that produces the answer to user request in the most efficient manner, given the database structure.
• The performance of a query is affected by the tables or views that underlies the query and by the complexity of the query.
• Given a request for data manipulation or retrieval, an optimizer will choose an optimal plan for evaluating the request from among the manifold alternative strategies. i.e. there are many ways (access paths) for accessing desired file/record.
• Hence ,DBMS is responsible to pick the best execution strategy based on various considerations(Least amount of I/O and CPU resources.)
• Example: Consider relations r(AB) and s(CD). We require r X s.
• Method 1 :

Computer Science MCQ practice collection · Question 236

Question 120 | AM0237

What is a query plan in a database system?

A. A set of database schemas

B. A representation of the query result

C. A sequence of operations to execute a query

D. A collection of database indices

Hint

Separate query representation, strategy selection and execution.

Answer C: A sequence of operations to execute a query

An execution plan includes a relational-algebra query tree, access methods and operator implementations (p.44). Its operations run from leaves toward the root (p.29), so C captures the execution procedure, which can have a tree structure rather than a single linear list.

Why each choice is right or wrong

A - Incorrect: Schemas describe data structure rather than the executable operations.

B - Incorrect: The result is the output, whereas the plan specifies how to obtain it.

C - Correct: An operation sequence/tree with access methods is the stated plan concept.

D - Incorrect: Indices may be access methods within a plan but do not alone constitute it.

Primary note proof

Study-note section ADB17

> Parsing checks SQL grammar; semantic analysis resolves names, types and access permissions. Translation constructs a logical representation, typically relational algebra or a logical query tree. Optimization chooses equivalent operations, join order and physical access methods. Evaluation executes that plan and returns results. Not every implementation exposes exactly the same phase boundaries.

Study-note section ADB17

> DDL is not a mandatory stage before each SELECT, so authentication→DDL→DML permutations do not describe the processing sequence.

Study-note section ADB-S01

> A query tree corresponds to a relational-algebra expression: base relations appear at leaves and operators at internal nodes.

> 1.6 Query Processing Steps
> • Processing can be divided into 4 :Decomposition, Optimization , Execution and Code generation
> 1.7 Query Decomposition
> • It is the process of transforming a high level query into a relational algebra query, and to check that the query is syntactically and semantically correct. It Consists of parsing and validation

Typical stages in query decomposition are:
i. Analysis: lexical and syntactical analysis of the query (correctness) based on attributes, data type.. ,. Query tree will be built for the query containing leaf node for base relations, one or many non-leaf nodes for relations produced by relational algebra operations and root node for the result of the query. Sequence of operation is from the leaves to the

Fundamental of Database Systems module | PDF page 44 | lines 6-13

3. Query Execution Plans
◦ An execution plan for a relational algebra query consists of :
◦ Relational algebra query tree
◦ Information about the access methods to be used for each relation
◦ The methods to be used in computing the relational operators stored in the tree.
1.9 Pipelining
● Pipelined evaluation: evaluate several operations simultaneously, passing the results of one operation on to the next.

Question sources

Computer Science MCQ practice collection · Question 237

Question 121 | AM0238

What is a cost model in query optimization?

A. A statistical model of query execution times

B. A model for estimating the cost of query plans

C. A model for analyzing database schemas

D. A statistical model for data distribution

Hint

Identify the resource objective, counts and unit costs before comparing execution strategies.

Answer B: A model for estimating the cost of query plans

The cost function combines I/O, CPU, communication and storage (p.41); optimization estimates and compares alternative strategy costs (p.42). A cost model therefore estimates costs of query plans.

Why each choice is right or wrong

A - Incorrect: Execution time can contribute, but this is narrower than the listed resource-cost model.

B - Correct: Estimating plan costs is the defining function.

C - Incorrect: Schema analysis is not evaluation of competing execution strategies.

D - Incorrect: Data distribution statistics are possible inputs, not the whole cost model.

Primary note proof

Study-note section ADB19

A cost model estimates resources for a candidate plan: page I/O, CPU, memory, temporary storage and network traffic. Catalog statistics include row/page counts, distinct values and distributions. Selection with fraction s predicts s×N rows. For non-NULL equijoin keys, a common estimate is |R|×|S|/max(V(R,k),V(S,k)), assuming uniform values and containment of the smaller distinct-value domain within the larger. Adjust counts for NULLs; if either non-NULL input is empty, the result is zero. Skew, correlations or incomplete domain overlap can invalidate this estimate; known disjoint domains give zero matches.

Study-note section ADB19

State the assumed cost objective before ranking strategies.

Study-note section ADB19

Disk I/O often dominates textbook local-disk examples; CPU can dominate in-memory work and network can dominate distributed plans.

Question sources

Computer Science MCQ practice collection · Question 238

Question 122 | AM0239

What is a join operation in query processing?

A. Combining tuples from multiple tables based on a common attribute

B. Sorting the query result in ascending order

C. Grouping the query result based on a specific attribute

D. Filtering the query result based on a condition

Hint

Separate the query's representation from the operations used to calculate its result.

Answer A: Combining tuples from multiple tables based on a common attribute

The query joins Staff and Branch by matching branchNo (p.27). The heuristic combines a Cartesian product and selection on the join condition into a join (p.41); the distributed example similarly matches Employee.Dno and Department.Dnumber (p.120). A expresses this equijoin case; joins in general need not always use equality or identical attribute names.

Why each choice is right or wrong

A - Correct: Combining tuples that satisfy the matching attribute condition describes these joins.

B - Incorrect: Sorting changes order rather than combining source tuples.

C - Incorrect: Grouping builds groups/aggregates, not cross-relation matching.

D - Incorrect: Filtering alone selects rows rather than combining related tuples from tables.

Primary note proof

Study-note section ADB-S01

> A relation is represented by a table of tuples. Selection filters its rows by a predicate; projection retains chosen columns. A Cartesian product constructs every pair of input tuples. A matching join combines tuples satisfying its predicate, and can be represented as a selection over a product. Sorting orders results, while grouping collects rows sharing grouping values; these are different operations.

Study-note section ADB18

> Heuristics reduce intermediate work: push selective row filters toward base tables; replace product followed by a join predicate with a join; project unneeded columns away while retaining join/filter columns; reorder inner joins when equivalence permits; reuse common expressions when worthwhile.

Study-note section ADB18

> Cost-based optimization estimates candidate plans instead of relying on rules alone.

Computer Science MCQ practice collection · Question 239

Question 123 | AM0240

Which listed index or clustered-storage approaches can speed a suitable query workload, without a claim that any always wins? Select all that apply.

A. B-tree index

B. Hash index

C. Bitmap index

D. Clustered index

Hint

Match the predicate and workload to the access structure or reasons to choose a plan again.

Answer A, B, C, D: A. B-tree index; B. Hash index; C. Bitmap index; D. Clustered index

B-tree indexes support ordered and range access, hash indexes target equality, and bitmap indexes can support analytic selections. Clustered storage places related rows close together and can reduce access work for suitable queries. Each approach can therefore help an appropriate workload. Space, maintenance and selectivity still matter, so accepting all four does not claim that every query benefits or that one design is universally best.

Why each choice is right or wrong

A - Correct: B-tree indexes support selective ordered and range access for suitable queries.

B - Correct: Hash indexes can accelerate equality lookups on the indexed key.

C - Correct: Bitmap indexes can accelerate suitable analytic selection workloads.

D - Correct: Clustered storage keeps related rows close and can reduce reads for appropriate access patterns.

Primary note proof

Study-note section ADB23

B/B+ tree indexes support ordered and range predicates; hash indexes target equality; bitmap indexes can help some analytic selections. Clustered storage keeps related rows close. An index may reduce reads but adds space and update work; scanning can be faster when most rows qualify. Commonly useful is not a unique property of one index type.

Study-note section ADB23

Avoid universal rules that joins always beat subqueries, functions can never use indexes or more indexes always improve performance.

Study-note section ADB23

Updating statistics does not itself execute the query.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 21 | lines 5-11

5.5 Index
Indexes are additional auxiliary access structures which are used to speed up the retrieval of records in response to certain search conditions. Index structures are additional files, which provide alternative ways to access the records without affecting the physical placement of records on disk.
Types of Indexes
Dense Index

Fundamental of Database Systems module | PDF page 22 | lines 11-20

Clustering Indexes
Here files are assumed as ordered with a Non-key field. If file records are physically ordered on a non-key field which doesn‘t have a distinct value for each record that field is called clustering field and the data file is called a clustered file.
We can create a different type of index, called a clustering index, to speedup retrieval of all records that have the same value for the clustering field. If the ordering field is not a key field i.e; if numerous records in the file can have the same value for the ordering field clustering index can be used.
A clustering index is also an ordered file with two fields. The first field is of the same type as the clustering field of the data file, and the second field is a disk block/cluster pointer.

Computer Science MCQ practice collection · Question 240

Question 124 | AM0241

What is query re-optimization in a database system?

A. Re-executing the query with different parameters

B. Re-evaluating the query cost based on updated statistics

C. Re-writing the query in a different query language

D. Re-organizing the database schema to improve performance

Hint

Match the predicate and workload to the access structure or reasons to choose a plan again.

Answer B: Reconsider the plan using updated cost information or statistics.

ADB23 defines re-optimization as choosing a plan again when statistics, parameters or observed cardinalities suggest that the existing plan is unsuitable. B is the listed description of this cost reconsideration. Merely executing again with other values does not necessarily re-optimize, and changing the query language or redesigning the schema is not the definition.

Why each choice is right or wrong

A - Incorrect: Re-execution with new parameters can reuse the same plan and is not inherently re-optimization.

B - Correct: Updated statistics can change cost estimates and lead to choosing a new execution plan.

C - Incorrect: Changing query language is not required to reconsider an execution strategy.

D - Incorrect: Schema reorganization is a design change rather than the definition of query re-optimization.

Primary note proof

Study-note section ADB23

> B/B+ tree indexes support ordered and range predicates; hash indexes target equality; bitmap indexes can help some analytic selections. Clustered storage keeps related rows close. An index may reduce reads but adds space and update work; scanning can be faster when most rows qualify. Commonly useful is not a unique property of one index type.

Study-note section ADB23

> Re-optimization chooses a plan again when statistics, parameters or observed cardinalities suggest the old plan is unsuitable.

Study-note section ADB23

> Updating statistics does not itself execute the query.

Computer Science MCQ practice collection · Question 241

Question 125 | AM0242

What is query pipelining in query processing?

A. Dividing a query into subqueries and executing them in parallel

B. Dividing a query into stages and executing them sequentially

C. Dividing a query into multiple queries and executing them in parallel

D. Dividing a query into multiple stages and executing them concurrently

Hint

Distinguish overlapping dependent operators, independent workers and reused cached objects.

Answer D: Dividing a query into multiple stages and executing them concurrently

Pipelined evaluation evaluates several operations simultaneously and passes results directly from one to the next (p.44). D means overlapping producer/consumer stages, not necessarily executing independent whole queries.

Why each choice is right or wrong

A - Incorrect: Parallel independent subqueries are not the defining inter-operator tuple stream.

B - Incorrect: Pure sequential completion of each whole stage loses the stated simultaneous overlap.

C - Incorrect: Multiple independent queries are not the defining pipeline within an expression tree.

D - Correct: Concurrent overlapping stages passing tuples match the explicit definition.

Primary note proof

Study-note section ADB22

> Materialization stores an intermediate result before the next operator consumes it. Pipelining passes tuples as they become available, overlapping producer and consumer work and reducing temporary I/O. A sort is normally blocking; a hash join must build its hash table before probing can output, though later probe/output can stream. Pipelining does not require separate CPUs.

Study-note section ADB22

> Parallel execution uses multiple workers, for example partitioned scans/joins, independent subplans or operator pipelines.

Study-note section ADB22

> Specify the kind of query caching being discussed.

Fundamental of Database Systems module | PDF page 44 | lines 12-20

> • Pipelined evaluation: evaluate several operations simultaneously, passing the results of one operation on to the next.
> • E.g., in expression tree, don‘t store result of
> ◦ Instead, pass tuples directly to the join.. Similarly, don‘t store result of join, pass tuples directly to projection.
> • Much cheaper than materialization: no need to store a temporary relation to disk.
> • Pipelining may not always be possible - e.g., sort, hash-join.
> • For pipelining to be effective, use evaluation algorithms that generate output tuples even as tuples are received for inputs to the operation.

Question sources

Computer Science MCQ practice collection · Question 242

Question 126 | AM0243

What is query result caching, specifically caching returned answers rather than execution plans or intermediate rows?

A. Storing query results for future reuse

B. Storing intermediate results during query execution

C. Storing database metadata for query optimization

D. Storing query plans for efficient execution

Hint

Distinguish overlapping dependent operators, independent workers and reused cached objects.

Answer A: A. Storing query results for future reuse

Result caching stores a query's returned rows or answer for future reuse. It needs suitable invalidation when underlying data changes. Plan caching instead stores the execution strategy without its returned rows. Intermediate rows retained during one execution are materialization, while database metadata supports optimization. Naming the cached object makes result caching distinct from these other useful storage mechanisms.

Why each choice is right or wrong

A - Correct: This stores final query answers for future reuse.

B - Incorrect: Intermediate-row storage is materialization rather than final-answer caching.

C - Incorrect: Metadata supports optimization but is not the query's returned answer.

D - Incorrect: Plan caching stores strategy rather than returned rows.

Primary note proof

Study-note section ADB22

> Parallel execution uses multiple workers, for example partitioned scans/joins, independent subplans or operator pipelines. Interleaving on one CPU is concurrency; simultaneous cores provide parallelism. Result caching reuses answers and needs invalidation when underlying data changes. Plan caching reuses an execution strategy, not the rows returned. Buffer caching keeps data pages; materialization retains intermediate rows. Specify the kind of query caching being discussed.

Study-note section ADB22

> Materialization stores an intermediate result before the next operator consumes it.

Study-note section ADB19

> Catalog statistics include row/page counts, distinct values and distributions.

Question 127 | AM0244

What is query parallelization in query processing?

A. Dividing a query into subqueries and executing them in parallel

B. Dividing a query into stages and executing them sequentially

C. Dividing a query into multiple queries and executing them in parallel

D. Dividing a query into multiple stages and executing them concurrently

Hint

Distinguish overlapping dependent operators, independent workers and reused cached objects.

Answer A: Dividing a query into subqueries and executing them in parallel

The fragmentation discussion says a transaction can be divided into several subqueries operating on fragments, increasing concurrency (p.117). A matches this parallel decomposition; it is distinct from pipelining a dependent stream of stages.

Why each choice is right or wrong

A - Correct: Independent fragment subqueries can run in parallel as described.

B - Incorrect: Sequential stages do not supply parallelism.

C - Incorrect: Replacing one query with multiple separate whole queries is not the stated subquery decomposition.

D - Incorrect: Concurrent stages describe pipelining when results flow between dependent operators, not the specific fragment-subquery approach.

Primary note proof

Study-note section ADB22

> Materialization stores an intermediate result before the next operator consumes it. Pipelining passes tuples as they become available, overlapping producer and consumer work and reducing temporary I/O. A sort is normally blocking; a hash join must build its hash table before probing can output, though later probe/output can stream. Pipelining does not require separate CPUs.

Study-note section ADB17

> Query processing is the whole activity; selecting a suitable efficient strategy is optimization.

Study-note section ADB22

> Parallel execution uses multiple workers, for example partitioned scans/joins, independent subplans or operator pipelines.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 117 | lines 15-31

6.2 Data Replication and Fragmentation: Distributed data storage
• There are two approaches to store the relation in the distributed database : Replication and Fragmentation
I. Data Replication
• The system maintain several identical copies of the relation & store each copy at a different site
• In general it enhance the performance of read operation and increase the availability of data to read only transaction. However, update transactions incur greater overhead
II. Data Fragmentation
- Split a relation into logically related and correct parts.
- The main reasons for fragmenting a relation are
• Efficiency- data that is not needed by the local applications is not stored
• Parallelism - a transaction can be divided into several subqueries that operate on fragments which will increase the degree of concurrency
- but reconstruction of the whole relation will require accessing data from all sites containing part of the relation

Question sources

Computer Science MCQ practice collection · Question 244

Question 128 | CS0066

If power went off while processing a transaction, what should the DBMS do to reverse any changes made to the database?

A. Read_transaction

B. Fail transaction

C. Commit transaction

D. Rollback

Hint

Track durable-write ordering and distinguish reversing incomplete work from installing logged effects.

Answer D: Rollback

To reverse changes of an incomplete failed transaction, recovery undoes its effects (p.103) by restoring before images (p.107). This is rollback. A committed transaction instead requires durability, so the answer assumes the interrupted transaction had not committed, as implied by reverse any changes.

Why each choice is right or wrong

A - Incorrect: Reading a transaction is not an undo operation.

B - Incorrect: Marking failure does not itself restore old values.

C - Incorrect: Committing would preserve rather than reverse the changes.

D - Correct: Rollback/undo is the direct reversal mechanism.

Primary note proof

Study-note section ADB27

> Write-ahead logging requires the update log needed for recovery to reach stable storage before the corresponding changed data page reaches disk. To acknowledge a durable commit, force the transaction's required log records, including its commit record, to stable storage. A buffer can be changed before that log flush; WAL orders durable writes, not every CPU assignment.

Study-note section ADB27

> Undo restores before-images of incomplete effects, usually traversing that transaction's updates backward.

Study-note section ADB06

> Atomicity means all effects or none; consistency means correct work preserves integrity rules; isolation controls concurrent interference; durability preserves committed effects despite failure.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Fundamental of Database Systems module | PDF page 97 | lines 4-13

> i. Purpose of Database Recovery
> ◦ To bring the database into the last consistent state, which existed prior to the failure.
> ◦ To preserve transaction properties (Atomicity &and Durability).
> • The recovery manager of a DBMS is responsible to ensure
> • atomicity by undoing the action of transaction that do not commit
> • Durability by making sure that all actions of committed transaction survive system crash
> ii. Types of Failure
> ◦ The database may become unavailable for use due to :

Fundamental of Database Systems module | PDF page 103 | lines 6-23

> • Recovery from catastrophic
> • If there is extensive damage to the wide portion of the database
> • This method restore a past copy of the database from the backup storage and reconstructs operation of a committed transaction from the back up log up to the time of failure
> • Recovery from non-catastrophic failure
> • When the database is not physically damaged but has be come in consistent
> • The strategy uses undoing and redoing some operations in order to restore to a consistent state : example
> • For instance,

• If failure occurs between commit and database buffers being flushed to secondary storage then, to ensure durability, recovery manager has to redo (roll forward) transaction‘s updates.
• If transaction had not committed at failure time, recovery manager has to undo (rollback) any effects of that transaction for atomicity. Example,
Transaction Log
◦ For recovery from any type of failure data values prior to modification (BFIM -

Fundamental of Database Systems module | PDF page 107 | lines 8-23

Transaction Roll-back (Undo) and Roll-Forward (Redo)
• If transaction fails for what so ever reason after updating the data base it must be necessary to roll back
• If a transaction T is roll back , any transaction that has read the value of some data item X written by T must be also be roll back
• Similarly once S is roll back, any transaction R that has read the values of some data item Y written by S must aslo be roll back, and so on..
• To maintain such cases, a transaction‘s operations are redone or undone.
• Undo: Restore all BFIMs on to disk (Remove all AFIMs).
• Redo: Restore all AFIMs on to disk.
• Database recovery is achieved either by performing only Undos or only Redos or by a combination of the two. These operations are recorded in the log as they happen.
Data Update and Recovery Scheme : Three types
i. Deferred Update (No Undo/Redo)
◦ The data update goes as follows:

Question sources

Computer Science Exit Exam practice collection · Question 66

Question 129 | NS0051

What is the main difference between homogeneous and heterogeneous distributed databases?

Hint

Separate coordinated network placement from engine compatibility and semantic integration.

Answer: Homogeneous systems use compatible DBMS technology; heterogeneous systems integrate differing DBMSs, models, schemas or interfaces.

ADB33 defines the distinction through compatibility of database technology and representation. Operating-system differences can occur but do not define heterogeneity. Homogeneous sites need not have identical schemas or automatic replication. Heterogeneous integration requires explicit mappings for names, types and semantics, rather than assuming that common connectivity alone reconciles their meanings.

Primary note proof

Study-note section ADB33

> A distributed database contains logically related data across networked sites, managed as a coordinated system. A homogeneous system uses compatible DBMS technology across sites; a heterogeneous system integrates differing DBMSs, data models, schemas or interfaces. Different operating systems are possible but do not define the distinction. Same DBMS does not imply identical local schemas, automatic replication or immediate synchronization.

Study-note section ADB33

> ODBC and JDBC provide connectivity interfaces; they do not automatically solve semantic differences or create one distributed transaction.

Study-note section ADB33

> Heterogeneous design must reconcile naming, types, units, identifiers, query capabilities and transaction semantics.

Question sources

Advanced Database Systems review questions · Question 1

Question 130 | NS0052

Why is data fragmentation useful in distributed databases?

Hint

Identify whether rows or columns are split and reverse the split to reconstruct the original relation.

Answer: Fragmentation improves locality, manageable placement and parallelism by splitting data across useful site boundaries.

ADB36 splits rows with predicates and columns with projections while preserving reconstruction through unions or key joins. This can place frequently used data near its consumers and allow independent work on pieces. Correct fragments must preserve completeness and required disjointness. Fragmentation alone creates no spare copy, so losing the only site containing a fragment still makes it unavailable.

Primary note proof

Study-note section ADB36

> Horizontal fragmentation selects row subsets by predicates; their union reconstructs the relation. Check completeness so every original row is represented and disjointness if no overlap is intended. Define an explicit fragment for NULL/other values when needed. Vertical fragmentation projects column subsets and repeats a key or row identifier so joining on it reconstructs the original rows without spurious matches.

Study-note section ADB36

> Partitioning improves locality and parallelism but alone creates no spare copy.

Study-note section ADB36

> Losing the only site containing a fragment makes that fragment unavailable, even while other sites continue.

Question sources

Advanced Database Systems review questions · Question 2

Question 131 | NS0053

What is the purpose of two-phase locking (2PL) in concurrency control?

Hint

Track the first lock release and the transaction-completion boundary.

Answer: 2PL guarantees conflict serializability by separating lock acquisition from release.

During the growing phase a transaction acquires or upgrades locks; after it releases any lock, the shrinking phase forbids acquiring new ones. For well-formed transactions this guarantees conflict serializability. Basic 2PL can still deadlock and permit cascading aborts, so strict or conservative variants add different protections. It is distinct from distributed two-phase commit.

Primary note proof

Study-note section ADB12

> Basic 2PL has a growing phase that acquires/upgrades locks and a shrinking phase that releases/downgrades them. Once any lock is released, no new lock may be acquired. The lock point is the instant the final lock is obtained. 2PL guarantees conflict serializability for well-formed transactions, but can deadlock and basic 2PL alone need not prevent cascading aborts.

Study-note section ADB12

> Two-phase locking orders access to data; two-phase commit coordinates a distributed commit decision.

Study-note section ADB12

> Strict 2PL retains exclusive locks until commit/abort.

Question sources

Advanced Database Systems review questions · Question 3

Question 132 | NS0054

Why is write-ahead logging important for database recovery?

Hint

Track durable-write ordering and distinguish reversing incomplete work from installing logged effects.

Answer: WAL makes recovery information durable before its changed data pages, enabling safe undo/redo after crashes.

ADB27 requires needed update logs to reach stable storage before corresponding changed pages. A durable commit also forces required log records, including commit. Recovery can then use before-images for undo and after-images for redo if buffered data was lost. WAL orders durable writes; modifying an in-memory buffer before the log flush does not itself violate it.

Primary note proof

Study-note section ADB27

> Write-ahead logging requires the update log needed for recovery to reach stable storage before the corresponding changed data page reaches disk. To acknowledge a durable commit, force the transaction's required log records, including its commit record, to stable storage. A buffer can be changed before that log flush; WAL orders durable writes, not every CPU assignment.

Study-note section ADB27

> Redo installs logged after-images when necessary, usually forward.

Study-note section ADB27

> Undo restores before-images of incomplete effects, usually traversing that transaction's updates backward.

Question sources

Advanced Database Systems review questions · Question 4

Question 133 | NS0055

How does a data warehouse differ from an operational database?

Hint

Distinguish operational transactions, analytical workloads and physical storage layout.

Answer: A warehouse integrates historical data for analysis; an operational database serves frequent business transactions.

OLTP handles account updates and other frequent operational transactions, while OLAP scans and summarizes large datasets. A warehouse commonly integrates sources through extraction, transformation and loading for historical analysis. These are workload tendencies rather than absolute restrictions: operational databases may retain history, and warehouses may receive updates. Schema and storage choices should follow the actual workload.

Primary note proof

Study-note section ADB41

> OLTP handles frequent operational transactions, such as account updates; OLAP scans and summarizes large datasets for analysis. A warehouse integrates data for historical analysis, often through extraction, transformation and loading. These are workload tendencies: OLTP can retain history and warehouses can be updated.

Question sources

Advanced Database Systems review questions · Question 5

Question 134 | NS0056

What does ACID stand for in the context of database transactions?

A. Atomicity, Consistency, Isolation, Durability

B. Accuracy, Consistency, Integrity, Durability

C. Atomicity, Concurrency, Isolation, Data

D. Availability, Consistency, Isolation, Durability

Hint

Track the transaction's guarantee or lifecycle boundary described by the scenario.

Answer A: Atomicity, Consistency, Isolation, Durability.

ADB06 names all four ACID properties and assigns distinct roles: all-or-none effects, preserved invariants, controlled interference and durable commits. Only A lists those names in the correct order. Accuracy, integrity, concurrency, data and availability are related database concepts but do not replace the letters of this established transaction acronym.

Why each choice is right or wrong

A - Correct: It lists the four ACID properties in the proper acronym order.

B - Incorrect: Accuracy and Integrity replace Atomicity and Isolation, changing the defined acronym.

C - Incorrect: Concurrency and Data incorrectly replace Consistency and Durability.

D - Incorrect: Availability is not the A in the ACID transaction acronym.

Primary note proof

Study-note section ADB06

> A transaction is a logical unit of database work, including read-only work. Atomicity means all effects or none; consistency means correct work preserves integrity rules; isolation controls concurrent interference; durability preserves committed effects despite failure. A DBMS cannot automatically make incorrect business logic consistent.

Question sources

Advanced Database Systems review questions · Question 1

Question 135 | NS0057

Which ACID property ensures that a transaction is treated as an indivisible unit - either all steps succeed or none are applied?

A. Consistency

B. Isolation

C. Atomicity

D. Durability

Hint

Track the transaction's guarantee or lifecycle boundary described by the scenario.

Answer C: Atomicity.

The question specifies indivisibility of the transaction effects: partial success must not remain if the transaction fails. ADB06 assigns that guarantee to atomicity. Consistency concerns valid invariants, isolation controls interference, and durability protects already committed work. Those properties support correctness too, but none directly means all-or-none effects.

Why each choice is right or wrong

A - Incorrect: Consistency concerns preserving integrity rules rather than specifically making effects indivisible.

B - Incorrect: Isolation controls interactions between concurrent transactions rather than partial transaction application.

C - Correct: Atomicity applies every transaction effect together or discards the incomplete work.

D - Incorrect: Durability protects committed effects after failure rather than defining all-or-none completion.

Primary note proof

Study-note section ADB06

> A transaction is a logical unit of database work, including read-only work. Atomicity means all effects or none; consistency means correct work preserves integrity rules; isolation controls concurrent interference; durability preserves committed effects despite failure. A DBMS cannot automatically make incorrect business logic consistent.

Question sources

Advanced Database Systems review questions · Question 2

Question 136 | NS0058

Account A = 5,000 Birr, Account B = 8,000 Birr. After transferring 750 Birr from A to B, which values maintain CONSISTENCY?

A. A = 4,000, B = 9,000

B. A = 4,250, B = 8,750

C. A = 5,750, B = 7,250

D. A = 4,250, B = 8,000

Hint

Track the transaction's guarantee or lifecycle boundary described by the scenario.

Answer B: A = 4,250 Birr and B = 8,750 Birr.

The requested transfer subtracts 750 from 5000 and adds 750 to 8000, giving 4250 and 8750. The invariant total remains 13000. A and C also sum to 13000, but implement a different amount or the reverse direction. Preserving the total alone does not implement the specified successful transfer; D loses the credit.

Why each choice is right or wrong

A - Incorrect: The sum remains 13000, but the changes transfer 1000 rather than the requested 750.

B - Correct: It debits 750 from A, credits 750 to B and preserves the 13000 total.

C - Incorrect: It preserves the total but transfers 750 in the reverse direction.

D - Incorrect: It debits A without crediting B, reducing the total to 12250.

Primary note proof

Study-note section ADB06

> A transaction is a logical unit of database work, including read-only work. Atomicity means all effects or none; consistency means correct work preserves integrity rules; isolation controls concurrent interference; durability preserves committed effects despite failure. A DBMS cannot automatically make incorrect business logic consistent.

Study-note section ADB06

> Unchanged or reverse-transfer balances can also preserve that sum; only the requested debit/credit implements the specified successful transfer.

Study-note section ADB06

> A=5,000 and B=8,000 become 4,250 and 8,750 after transferring 750 from A to B.

Question sources

Advanced Database Systems review questions · Question 3

Question 137 | NS0059

Which ACID property guarantees that committed transaction changes persist even after a system crash?

A. Atomicity

B. Consistency

C. Isolation

D. Durability

Hint

Track the transaction's guarantee or lifecycle boundary described by the scenario.

Answer D: Durability.

ADB06 defines durability as preserving committed effects despite failure. A system may leave data pages buffered at commit provided durable recovery information can restore the changes after a crash. Atomicity controls partial outcomes, consistency protects declared invariants and isolation controls concurrent interference; they do not name this persistence guarantee.

Why each choice is right or wrong

A - Incorrect: Atomicity means all-or-none effects, not specifically persistence after a successful commit.

B - Incorrect: Consistency concerns valid integrity rules before and after correct work.

C - Incorrect: Isolation controls concurrent interference rather than persistence across a crash.

D - Correct: Durability ensures committed changes survive failures through the supported recovery mechanisms.

Primary note proof

Study-note section ADB06

> A transaction is a logical unit of database work, including read-only work. Atomicity means all effects or none; consistency means correct work preserves integrity rules; isolation controls concurrent interference; durability preserves committed effects despite failure. A DBMS cannot automatically make incorrect business logic consistent.

Question sources

Advanced Database Systems review questions · Question 4

Question 138 | NS0060

In the Read_item(X) operation, what is the THIRD and final step?

A. Store the updated block back to disk

B. Find the disk block address containing X

C. Copy the disk block into main memory buffer

D. Copy item X from the buffer to the program variable named x

Hint

Trace movement between program variables, buffers and disk, or the meaning of a recorded transaction event.

Answer D: Copy X from the buffer into the program variable x.

ADB07 first locates the page containing X, brings it into a buffer if absent and then copies X into a program variable. Thus D is the final conceptual read step. Locating and loading precede it, and storing an updated block to disk belongs to writing/flushing rather than completing read_item. A buffer hit can avoid physical I/O.

Why each choice is right or wrong

A - Incorrect: A read does not update and write the block back to disk.

B - Incorrect: Locating the containing page is the first conceptual step, not the final one.

C - Incorrect: Loading the page into a buffer precedes copying the item into the program variable.

D - Correct: The final read step copies the requested item from its buffer into x.

Primary note proof

Study-note section ADB07

> read_item(X) locates X's page, brings it into a buffer if absent, and copies X into a program variable. write_item(X) copies the new program value into the buffered page, marking it dirty. Writing that page to disk can occur later according to the buffer policy; write_item is not inherently an immediate disk flush. Insert and delete also modify data; sorting is a query-processing operation rather than a primitive item update.

Question sources

Advanced Database Systems review questions · Question 5

Question 139 | NS0061

A transaction that has started and is currently executing its operations is in which state?

A. Committed

B. Partially Committed

C. Active

D. Failed

Hint

Track the transaction's guarantee or lifecycle boundary described by the scenario.

Answer C: Active.

ADB06 defines Active as the state while transaction operations are executing. Partially committed follows completion of the last operation but precedes assured durable commitment. Committed means commitment succeeded, while Failed means execution encountered a failure. Merely starting and continuing its operations therefore places this transaction in Active.

Why each choice is right or wrong

A - Incorrect: Committed requires successful commitment, which has not occurred while operations are still executing.

B - Incorrect: Partially committed follows the last operation rather than ordinary ongoing execution.

C - Correct: Active is the state during execution of the transaction operations.

D - Incorrect: Failed requires an execution failure, which the stem does not report.

Primary note proof

Study-note section ADB06

> Active means operations are executing. Partially committed means the last operation finished but durable commitment is not yet assured. Committed means commitment succeeded. A failure leads to Failed, then Aborted after rollback; a transaction may terminate or be restarted as a new attempt. Concurrency control primarily enforces isolation; recovery supports atomicity and durability. Transaction management is the broader subsystem, so both it and recovery management can be legitimate answers to broad responsibility questions.

Question sources

Advanced Database Systems review questions · Question 6

Question 140 | NS0062

Which transaction state means all operations executed successfully but the commit has NOT been finalized yet?

A. Active

B. Partially Committed

C. Committed

D. Aborted

Hint

Track the transaction's guarantee or lifecycle boundary described by the scenario.

Answer B: Partially committed.

Finishing all operations does not yet establish durable commitment. ADB06 names this intermediate state Partially committed. The transaction becomes Committed only after commitment succeeds, or can fail before that boundary. Active describes operations still running, while Aborted means rollback completed, so neither matches successful operations awaiting finalized commit.

Why each choice is right or wrong

A - Incorrect: Active means operations are still executing, whereas the last operation has finished here.

B - Correct: Partially committed means execution finished but durable commitment is not yet assured.

C - Incorrect: Committed requires the commit itself to have succeeded, which the stem excludes.

D - Incorrect: Aborted follows rollback rather than successful execution awaiting a commit decision.

Primary note proof

Study-note section ADB06

> Active means operations are executing. Partially committed means the last operation finished but durable commitment is not yet assured. Committed means commitment succeeded. A failure leads to Failed, then Aborted after rollback; a transaction may terminate or be restarted as a new attempt. Concurrency control primarily enforces isolation; recovery supports atomicity and durability. Transaction management is the broader subsystem, so both it and recovery management can be legitimate answers to broad responsibility questions.

Question sources

Advanced Database Systems review questions · Question 7

Question 141 | NS0063

What does the log record [abort, T] indicate?

A. Transaction T has just started execution

B. Transaction T committed successfully

C. Transaction T was aborted and ALL its changes must be discarded

D. Transaction T read a data item

Hint

Trace movement between program variables, buffers and disk, or the meaning of a recorded transaction event.

Answer C: T is aborting/aborted and its transaction effects must be discarded.

ADB07 includes ABORT among conceptual log records and warns that it can mark the start of rollback rather than prove every undo step is already complete. C is correct because it says the changes must be discarded, not that all undo has finished. START, COMMIT and ordinary read activity have different meanings.

Why each choice is right or wrong

A - Incorrect: A START record, rather than ABORT, marks beginning transaction execution.

B - Incorrect: COMMIT records successful completion; ABORT means the opposite outcome.

C - Correct: Abort requires discarding transaction effects, though this record need not prove all undo is already complete.

D - Incorrect: The record denotes abort handling rather than a read_item operation.

Primary note proof

Study-note section ADB07

> A conceptual log can contain START, UPDATE(T,X,old,new), COMMIT, ABORT and END records. Before-images support undo; after-images support redo. Real systems may use physical or logical records, and need not log every read. COMMIT records successful completion; an ABORT record can mark the start of rollback rather than prove every undo step is complete.

Question sources

Advanced Database Systems review questions · Question 8

Question 142 | NS0064

Which of the following is NOT one of the four basic transaction operations on a database?

A. Read

B. Write

C. Sort

D. Delete

Hint

Trace movement between program variables, buffers and disk, or the meaning of a recorded transaction event.

Answer C: Sort.

ADB07 distinguishes read_item and write_item and notes that inserts and deletes also modify data. Sorting is instead an operation used in query processing, not a primitive item update in this classification. The exact count four is a teaching convention, but the note directly supplies the relevant distinction that singles out Sort.

Why each choice is right or wrong

A - Incorrect: Reading is an explicitly defined primitive database item operation.

B - Incorrect: Writing is an explicitly defined primitive database item modification operation.

C - Correct: Sorting is a query-processing operation rather than the primitive item access/update category.

D - Incorrect: Delete modifies stored data and belongs with the listed primitive data operations.

Primary note proof

Study-note section ADB07

> read_item(X) locates X's page, brings it into a buffer if absent, and copies X into a program variable. write_item(X) copies the new program value into the buffered page, marking it dirty. Writing that page to disk can occur later according to the buffer policy; write_item is not inherently an immediate disk flush. Insert and delete also modify data; sorting is a query-processing operation rather than a primitive item update.

Question sources

Advanced Database Systems review questions · Question 9

Question 143 | NS0065

The Isolation property of ACID ensures that concurrent transactions:

A. Always read the same data at the same time

B. Do not interfere with each other; each executes independently

C. Commit in the same order they started

D. Always complete successfully without any errors

Hint

Track the transaction's guarantee or lifecycle boundary described by the scenario.

Answer B: Concurrent work is isolated from improper interference.

ADB06 defines isolation as controlling interference between concurrent transactions. B captures logical independence under the specified isolation guarantee; it does not mean transactions literally use separate hardware or never wait. Isolation does not require identical reads, start-order commits or universal successful completion. Strong serializable isolation makes behavior equivalent to some serial order.

Why each choice is right or wrong

A - Incorrect: Isolation does not require all transactions to read identical values at the same time.

B - Correct: Isolation controls interference so concurrent transactions retain the promised logical execution semantics.

C - Incorrect: Isolation does not require commit order to match transaction start order.

D - Incorrect: Conflicts and failures can still cause aborts; isolation is not a success guarantee.

Primary note proof

Study-note section ADB06

> A transaction is a logical unit of database work, including read-only work. Atomicity means all effects or none; consistency means correct work preserves integrity rules; isolation controls concurrent interference; durability preserves committed effects despite failure. A DBMS cannot automatically make incorrect business logic consistent.

Study-note section ADB09

> A serializable schedule is equivalent to some serial order; it may interleave transactions.

Study-note section ADB09

> A serial schedule executes each transaction's operations consecutively.

Question sources

Advanced Database Systems review questions · Question 10

Question 144 | NS0066

In a simplified teaching sequence, write_item(X) updates a buffered page and then the buffer manager immediately flushes that page, after required WAL records are durable. What is the final physical step of this specified sequence?

A. Copy item X to program variable

B. Find the disk block address

C. Store the updated buffer block back to disk

D. Read the old value of X first

Hint

Trace movement between program variables, buffers and disk, or the meaning of a recorded transaction event.

Answer C: C. Store the updated buffer block back to disk

After X's program value has been copied into the buffered page, the specified sequence completes by writing the changed page back to disk. That is C. In ordinary buffering this flush may be deferred, but the question explicitly includes it. Locating a page or reading its old value occurs before or separately from the final physical output, and copying into a program variable describes reading.

Why each choice is right or wrong

A - Incorrect: Copying into a program variable is a read operation.

B - Incorrect: The page address is located before the final output.

C - Correct: The explicitly included flush stores the updated buffered page on disk.

D - Incorrect: Reading the old value is not the final physical output step.

Primary note proof

Study-note section ADB07

> read_item(X) locates X's page, brings it into a buffer if absent, and copies X into a program variable. write_item(X) copies the new program value into the buffered page, marking it dirty. Writing that page to disk can occur later according to the buffer policy; write_item is not inherently an immediate disk flush. Insert and delete also modify data; sorting is a query-processing operation rather than a primitive item update.

Study-note section ADB27

> A buffer can be changed before that log flush; WAL orders durable writes, not every CPU assignment.

Study-note section ADB27

> To acknowledge a durable commit, force the transaction's required log records, including its commit record, to stable storage.

Question sources

Advanced Database Systems review questions · Question 11

Question 145 | NS0067

A transaction that encountered an error during execution and could not complete is in which state?

A. Aborted

B. Failed

C. Terminated

D. Partially Committed

Hint

Track the transaction's guarantee or lifecycle boundary described by the scenario.

Answer B: Failed.

ADB06 places a transaction in Failed when an error prevents successful execution. After rollback removes its effects it reaches Aborted. The stem reports the execution error but does not say rollback has completed, so Failed is the precise state. Partially committed follows successful final operation execution, not an error that prevents completion.

Why each choice is right or wrong

A - Incorrect: Aborted requires completed rollback, which is not stated after the execution error.

B - Correct: Failed is the immediate state when an error prevents completing the transaction.

C - Incorrect: Termination is later lifecycle handling rather than the immediate error state.

D - Incorrect: Partially committed follows completion of the last operation rather than failed execution.

Primary note proof

Study-note section ADB06

> Active means operations are executing. Partially committed means the last operation finished but durable commitment is not yet assured. Committed means commitment succeeded. A failure leads to Failed, then Aborted after rollback; a transaction may terminate or be restarted as a new attempt. Concurrency control primarily enforces isolation; recovery supports atomicity and durability. Transaction management is the broader subsystem, so both it and recovery management can be legitimate answers to broad responsibility questions.

Question sources

Advanced Database Systems review questions · Question 12

Question 146 | NS0068

Transaction log records serve primarily for which purpose?

A. Speeding up query execution

B. Encrypting sensitive data

C. Enabling database recovery after failures by recording all changes

D. Enforcing access control permissions

Hint

Trace movement between program variables, buffers and disk, or the meaning of a recorded transaction event.

Answer C: Enable recovery by recording the information needed to undo or redo changes.

ADB07 records starts, updates, commits and aborts, with before-images for undo and after-images for redo. That makes recovery the primary purpose among the choices. Actual log formats may be physical or logical and need not record every read, so all changes should be understood as the change information required by the recovery design, not every operation indiscriminately.

Why each choice is right or wrong

A - Incorrect: The primary log purpose here is recovery rather than speeding query execution.

B - Incorrect: Transaction logging does not inherently encrypt the stored sensitive data.

C - Correct: Logged update and transaction-state information supports recovery of valid committed state after failures.

D - Incorrect: Access privileges control authorization; transaction log records are not themselves that enforcement mechanism.

Primary note proof

Study-note section ADB07

> A conceptual log can contain START, UPDATE(T,X,old,new), COMMIT, ABORT and END records. Before-images support undo; after-images support redo. Real systems may use physical or logical records, and need not log every read. COMMIT records successful completion; an ABORT record can mark the start of rollback rather than prove every undo step is complete.

Study-note section ADB24

> A user who can view but cannot change a record has restricted access privileges.

Study-note section ADB24

> Authentication establishes identity; authorization/access control determines permitted actions.

Question sources

Advanced Database Systems review questions · Question 13

Question 147 | NS0069

Which processing type uses multiple CPUs to execute different transactions simultaneously, achieving higher throughput?

A. Sequential processing

B. Interleaved processing

C. Parallel processing

D. Batch processing

Hint

Distinguish overlapping dependent operators, independent workers and reused cached objects.

Answer C: Parallel processing.

ADB22 distinguishes concurrency by interleaving on one CPU from actual simultaneous work on multiple cores. The stem explicitly uses multiple CPUs to execute different transactions at the same time, making Parallel the correct classification. Batch describes grouping work, and sequential processing performs work in order; neither guarantees the stated simultaneous execution.

Why each choice is right or wrong

A - Incorrect: Sequential processing does not execute different transactions simultaneously on multiple CPUs.

B - Incorrect: Interleaving alternates execution and need not provide simultaneous CPU work.

C - Correct: Multiple CPUs working simultaneously provide parallel execution.

D - Incorrect: Batch describes grouped submission or handling, not necessarily simultaneous multi-CPU execution.

Primary note proof

Study-note section ADB22

> Materialization stores an intermediate result before the next operator consumes it. Pipelining passes tuples as they become available, overlapping producer and consumer work and reducing temporary I/O. A sort is normally blocking; a hash join must build its hash table before probing can output, though later probe/output can stream. Pipelining does not require separate CPUs.

Study-note section ADB22

> Interleaving on one CPU is concurrency; simultaneous cores provide parallelism.

Study-note section ADB22

> Parallel execution uses multiple workers, for example partitioned scans/joins, independent subplans or operator pipelines.

Question sources

Advanced Database Systems review questions · Question 14

Question 148 | NS0070

Why are transactions important in database systems?

A. They make queries run faster

B. They ensure the database remains consistent and reliable through ACID properties

C. They allow the database to store more data

D. They simplify the SQL syntax for users

Hint

Track the transaction's guarantee or lifecycle boundary described by the scenario.

Answer B: Transactions support consistent, reliable work through ACID guarantees.

ADB06 groups operations into a logical unit with all-or-none effects, invariant preservation, isolation and durable commits. These guarantees support consistent and reliable database behavior when application logic is correct. They do not inherently speed queries, expand storage capacity or simplify syntax. In particular a DBMS cannot make an incorrect business operation consistent merely by wrapping it in a transaction.

Why each choice is right or wrong

A - Incorrect: Transactions can add coordination costs and do not inherently make queries faster.

B - Correct: ACID guarantees support valid and recoverable logical work, provided business logic is correct.

C - Incorrect: Transaction semantics do not increase the database's physical storage capacity.

D - Incorrect: Grouping work atomically does not inherently simplify the SQL language for users.

Primary note proof

Study-note section ADB06

> A transaction is a logical unit of database work, including read-only work. Atomicity means all effects or none; consistency means correct work preserves integrity rules; isolation controls concurrent interference; durability preserves committed effects despite failure. A DBMS cannot automatically make incorrect business logic consistent.

Question sources

Advanced Database Systems review questions · Question 15

Question 149 | NS0071

T1 reads balance=$500 and adds $100, planning to write $600. T2 reads the same $500, adds $200, and writes $700. T1 then writes $600. What problem occurred?

A. Dirty Read

B. Lost Update (Write-Write Problem)

C. Incorrect Summary Problem

D. Deadlock

Hint

Trace which transaction wrote each value and whether an overwrite or mixed-version read occurs.

Answer B: Lost update: T1 overwrites T2’s increment with its stale calculation.

Both transactions read 500. T2 writes 700 after adding 200, but T1 then writes its previously computed 600, erasing T2’s increment. A serial execution would produce 800. This matches the lost-update trace in ADB08; no waiting cycle or aggregate calculation is described, and reading an uncommitted value is not the stated cause.

Why each choice is right or wrong

A - Incorrect: Neither transaction is described as reading the other's uncommitted write.

B - Correct: T1's stale write of 600 overwrites T2's added 200; the correct combined result is 800.

C - Incorrect: No aggregate over mutually inconsistent versions is being calculated.

D - Incorrect: No circular waiting or blocked resource requests are present.

Primary note proof

Study-note section ADB08

> Lost update: T1 and T2 both read 500; T2 adds 200 and writes 700; T1 adds 100 to its stale value and writes 600. Correct serial execution yields 800. Dirty read: T2 reads a value written by uncommitted T1; if T1 aborts, dependent work must be reconsidered. Reading one's own changes is not a dirty read.

Study-note section ADB13

> Deadlock requires a waiting cycle: T1 holds X and wants Y; T2 holds Y and wants X.

Study-note section ADB08

> Incorrect summary mixes mutually inconsistent versions: a transfer moves 10 from A=100 to B=100; a sum reading old A=100 and new B=110 gets 210 instead of the invariant 200.

Question sources

Advanced Database Systems review questions · Question 16

Question 150 | NS0072

A dirty read occurs when transaction T1 reads data that:

A. T1 itself wrote earlier in the same transaction

B. T2 modified but has NOT yet committed, and T2 may later abort

C. Was permanently deleted from the database

D. Was last read more than one hour ago

Hint

Trace which transaction wrote each value and whether an overwrite or mixed-version read occurs.

Answer B: Read another transaction’s uncommitted modification.

ADB08 defines dirty read as consuming a value written by an uncommitted other transaction. If that writer aborts, the dependent read used a value that should not survive. Reading one’s own changes is allowed and is not this anomaly; the age of a value or a completed permanent deletion does not define dirty reading.

Why each choice is right or wrong

A - Incorrect: Reading changes made earlier by the same transaction is not a dirty read.

B - Correct: The read depends on T2's uncommitted update, which may later need undo.

C - Incorrect: Permanent deletion is not the defining uncommitted-value dependency.

D - Incorrect: Elapsed time since a read does not determine whether the writer committed.

Primary note proof

Study-note section ADB08

> Lost update: T1 and T2 both read 500; T2 adds 200 and writes 700; T1 adds 100 to its stale value and writes 600. Correct serial execution yields 800. Dirty read: T2 reads a value written by uncommitted T1; if T1 aborts, dependent work must be reconsidered. Reading one's own changes is not a dirty read.

Study-note section ADB08

> A phantom means repeating a predicate query finds a changed qualifying set after another transaction inserts, deletes or changes matching rows.

Study-note section ADB08

> A single committed update from B=20 to B=50 does not alone prove an invalid summary of 90.

Question sources

Advanced Database Systems review questions · Question 17

Question 151 | NS0073

Which lock type allows MULTIPLE transactions to simultaneously READ a data item?

A. Exclusive Lock

B. Write Lock

C. Shared Lock

D. Binary Lock

Hint

Compare access permissions and same-item compatibility before granting a lock request.

Answer C: Shared lock.

ADB11 states that a shared lock permits reading and multiple shared holders can coexist on the same item. Exclusive/write locks conflict with another transaction’s shared or exclusive lock on that item. Thus shared locking provides the requested concurrent-reader behavior. A generic binary locked/unlocked label does not establish shared-reader compatibility in the supplied model.

Why each choice is right or wrong

A - Incorrect: An exclusive lock conflicts with other transactions' read locks on the same item.

B - Incorrect: A write/exclusive lock does not grant multiple independent readers the requested shared ownership.

C - Correct: Shared locks are compatible with other shared locks, permitting multiple readers.

D - Incorrect: The binary label does not provide the explicit S/S compatibility defined in the note.

Primary note proof

Study-note section ADB11

> A shared (S) lock permits reading; multiple S locks on the same item can coexist. An exclusive (X) lock permits its holder to read and write and conflicts with another S or X on that item. Locks on different items do not conflict merely because one is exclusive. These are the basic lock-based rules; multiversion systems can permit additional snapshot-reader behavior.

Study-note section ADB-S04

> Shared/exclusive locking adds modes so multiple shared readers can coexist while incompatible exclusive access is excluded.

Study-note section ADB11

> One transaction may request a lock on an already locked item: it is granted if compatible, otherwise waits or aborts under the policy.

Question sources

Advanced Database Systems review questions · Question 18

Question 152 | NS0074

In Two-Phase Locking (2PL), a transaction can acquire new locks ONLY during which phase?

A. Shrinking Phase

B. Termination Phase

C. Growing Phase

D. Validation Phase

Hint

Track the first lock release and the transaction-completion boundary.

Answer C: Growing phase.

Basic 2PL separates acquiring/upgrading locks from releasing/downgrading them. ADB12 permits acquisition only in the growing phase; after any release, no new lock may be acquired. Termination is a transaction boundary and validation belongs to a different control approach. The growing/shrinking rule is what distinguishes 2PL from unrestricted use of locks.

Why each choice is right or wrong

A - Incorrect: The shrinking phase releases or downgrades locks and forbids new acquisitions.

B - Incorrect: Termination is not the 2PL phase in which new locks are acquired.

C - Correct: Growing permits acquiring and upgrading locks before any release begins.

D - Incorrect: Validation is an optimistic-control stage, not the lock-acquisition phase of 2PL.

Primary note proof

Study-note section ADB12

> Basic 2PL has a growing phase that acquires/upgrades locks and a shrinking phase that releases/downgrades them. Once any lock is released, no new lock may be acquired. The lock point is the instant the final lock is obtained. 2PL guarantees conflict serializability for well-formed transactions, but can deadlock and basic 2PL alone need not prevent cascading aborts.

Study-note section ADB12

> Two-phase locking orders access to data; two-phase commit coordinates a distributed commit decision.

Study-note section ADB16

> Optimistic/validation control reads and computes privately, validates its read/write sets against overlapping transactions, then publishes if validation succeeds; otherwise it retries.

Question sources

Advanced Database Systems review questions · Question 19

Question 153 | NS0075

What does Two-Phase Locking (2PL) guarantee that locking alone does NOT guarantee?

A. That no deadlocks will occur

B. Serializability - results equivalent to some serial execution

C. That all transactions complete without aborting

D. That every transaction reads the most current data

Hint

Track the first lock release and the transaction-completion boundary.

Answer B: Conflict serializability for well-formed transactions.

ADB12 explicitly guarantees conflict serializability for well-formed 2PL transactions. Locking without its phase discipline need not provide that ordering guarantee. Basic 2PL can still deadlock and may permit cascading aborts, so it does not guarantee successful completion. Nor does serializability require every read to observe the latest wall-clock update.

Why each choice is right or wrong

A - Incorrect: Basic 2PL can deadlock, so deadlock freedom is not its general guarantee.

B - Correct: The phase discipline guarantees conflict-serializable schedules for well-formed transactions.

C - Incorrect: Deadlock resolution or failures can still abort transactions.

D - Incorrect: Serializability does not require every read to see the newest wall-clock version.

Primary note proof

Study-note section ADB12

> Basic 2PL has a growing phase that acquires/upgrades locks and a shrinking phase that releases/downgrades them. Once any lock is released, no new lock may be acquired. The lock point is the instant the final lock is obtained. 2PL guarantees conflict serializability for well-formed transactions, but can deadlock and basic 2PL alone need not prevent cascading aborts.

Study-note section ADB12

> Two-phase locking orders access to data; two-phase commit coordinates a distributed commit decision.

Study-note section ADB12

> Strict 2PL retains exclusive locks until commit/abort.

Question sources

Advanced Database Systems review questions · Question 20

Question 154 | NS0076

What is a deadlock in database systems?

A. A transaction that executes too slowly

B. A circular wait where each transaction holds a resource another needs, and none can proceed

C. A type of hardware failure causing data loss

D. When a transaction violates the ACID consistency property

Hint

Distinguish a waiting cycle, a long wait and indefinite unfair postponement.

Answer B: A circular wait among transactions holding resources needed by others.

ADB13 defines deadlock through a waiting cycle: each participant holds a resource another needs, so none can advance without an intervention. Slow work alone can still make progress and is not deadlock. Hardware loss and consistency violations are distinct problems that do not require a resource-wait cycle.

Why each choice is right or wrong

A - Incorrect: A slow transaction may still make progress and need not participate in a wait cycle.

B - Correct: Circular hold-and-wait prevents the involved transactions from progressing without intervention.

C - Incorrect: Hardware failure is a different failure category and does not define a lock wait cycle.

D - Incorrect: A consistency violation concerns invalid data states rather than necessarily circular waiting.

Primary note proof

Study-note section ADB13

> Deadlock requires a waiting cycle: T1 holds X and wants Y; T2 holds Y and wants X. In a wait-for graph, an edge Ti→Tj means Ti waits for a lock held by Tj. A cycle indicates deadlock under the ordinary lock-wait model. Abort a suitable victim, undo its effects and release its locks; repeat if other cycles remain. Aborting every deadlocked transaction also breaks cycles but wastes more work.

Study-note section ADB13

> A timeout aborts long waits but may mistake slow progress for deadlock.

Study-note section ADB26

> Transaction failures include invalid operations, constraint violations and concurrency-control aborts.

Question sources

Advanced Database Systems review questions · Question 21

Question 155 | NS0077

In the Wait-Die deadlock prevention strategy, when a YOUNGER transaction needs a resource held by an OLDER transaction, the younger transaction:

A. Wounds (aborts) the older transaction

B. Waits for the older transaction to release the resource

C. Is immediately aborted and restarted

D. Receives the resource immediately due to higher priority

Hint

Identify requester and holder ages before applying the protocol's action.

Answer C: Abort the younger requester; retry with its original timestamp.

The requester is younger and the resource holder older. ADB14 says wait-die permits an older requester to wait but aborts a younger requester needing an older holder. C therefore gives the correct action. Restart should retain the original timestamp to improve relative priority; immediately aborted does not require an immediate successful retry or resource grant.

Why each choice is right or wrong

A - Incorrect: Wait-die does not let the younger requester abort the older holder.

B - Incorrect: In wait-die, the younger requester dies rather than waiting for the older holder.

C - Correct: The younger requester is aborted and may restart using its original timestamp.

D - Incorrect: The older holder retains priority; the younger requester does not receive the resource immediately.

Primary note proof

Study-note section ADB14

> A smaller timestamp means an older transaction. In wait-die, an older requester may wait for a younger holder; a younger requester needing an older holder aborts itself. In wound-wait, an older requester aborts the younger holder; a younger requester waits for the older holder. Always identify requester versus holder before applying the names.

Question sources

Advanced Database Systems review questions · Question 22

Question 156 | NS0078

In the Wound-Wait strategy, when an OLDER transaction needs a resource held by a YOUNGER transaction:

A. The older transaction waits for the younger

B. The older transaction wounds (aborts) the younger transaction

C. Both transactions are simultaneously aborted

D. A deadlock detection algorithm runs

Hint

Identify requester and holder ages before applying the protocol's action.

Answer B: The older requester aborts the younger holder.

ADB14 distinguishes wound-wait from wait-die: an older requester wounds the younger holder, while a younger requester waits for an older holder. Here the requester is explicitly older, so B applies. The rule prevents waiting cycles through age-based action; it does not require detecting an existing deadlock first or aborting both participants.

Why each choice is right or wrong

A - Incorrect: An older requester wounds the younger holder rather than waiting under wound-wait.

B - Correct: The older requester causes the younger resource holder to abort and release its lock.

C - Incorrect: The protocol aborts the younger holder, not both transactions.

D - Incorrect: This is a prevention action based on ages, not a requirement to run cycle detection first.

Primary note proof

Study-note section ADB14

> A smaller timestamp means an older transaction. In wait-die, an older requester may wait for a younger holder; a younger requester needing an older holder aborts itself. In wound-wait, an older requester aborts the younger holder; a younger requester waits for the older holder. Always identify requester versus holder before applying the names.

Study-note section ADB13

> A cycle indicates deadlock under the ordinary lock-wait model.

Study-note section ADB13

> A no-wait policy aborts immediately on an incompatible lock request and needs no age timestamp.

Question sources

Advanced Database Systems review questions · Question 23

Question 157 | NS0079

Optimistic concurrency control is BEST suited for environments where:

A. Transactions frequently write to the same data items

B. Write operations always conflict with read operations

C. Conflicts between transactions are rare (read-heavy workloads)

D. All transactions must complete in strict timestamp order

Hint

Consider conflicts, private work and validation costs, or lock-management overhead.

Answer C: Conflicts between transactions are rare (read-heavy workloads)

Optimistic concurrency control lets transactions read and compute privately, then validates overlapping read/write activity before publishing changes. When conflicts are rare, most work can commit without being discarded. Frequent competing writes or persistent read/write conflicts instead lead to costly retries. Strict timestamp completion describes a separate ordering constraint; it does not supply the low-conflict condition that makes optimistic execution suitable. Read-heavy activity is useful here only insofar as actual conflicts remain uncommon.

Why each choice is right or wrong

A - Incorrect: Incorrect: frequent competing writes cause validation failures and discarded work.

B - Incorrect: Incorrect: persistent read/write conflicts increase retry costs rather than favoring optimistic execution.

C - Correct: Correct: rare conflicts allow most private work to validate and commit.

D - Incorrect: Incorrect: a required completion order does not imply low contention; optimistic suitability depends on conflicts and retry cost.

Primary note proof

Study-note section ADB16

> Optimistic/validation control reads and computes privately, validates its read/write sets against overlapping transactions, then publishes if validation succeeds; otherwise it retries. It works well when conflicts are uncommon, but high contention wastes work on aborts.

Question sources

Advanced Database Systems review questions · Question 24

Question 158 | NS0080

Lock upgrade refers to changing a lock from:

A. Exclusive → Shared

B. Shared → Exclusive

C. No lock → Shared

D. Exclusive → No lock

Hint

Compare access permissions and same-item compatibility before granting a lock request.

Answer B: Shared → Exclusive.

ADB11 explicitly names S→X an upgrade and X→S a downgrade. The stronger exclusive lock permits writing and can be granted only after conflicting other holders leave. Acquiring a new shared lock is initial acquisition rather than conversion, while releasing an exclusive lock is unlocking. Thus B alone names a lock upgrade.

Why each choice is right or wrong

A - Incorrect: Exclusive-to-shared weakens permissions and is a downgrade.

B - Correct: Shared-to-exclusive strengthens the held lock to permit writing, subject to compatibility.

C - Incorrect: No-lock-to-shared is initial acquisition, not conversion of an already held lock.

D - Incorrect: Exclusive-to-no-lock is release rather than upgrade.

Primary note proof

Study-note section ADB11

> A transaction must own the appropriate lock before access and can release only its own locks. S→X is an upgrade, possible only after conflicting other holders leave. X→S is a downgrade. The lock manager decides requests; the lock table stores granted locks and waiting requests. One transaction may request a lock on an already locked item: it is granted if compatible, otherwise waits or aborts under the policy. No double-locking is not a prohibition on shared readers.

Question sources

Advanced Database Systems review questions · Question 25

Question 159 | NS0081

Which trace demonstrates an incorrect-summary anomaly? The intended anomaly is a mixed-version aggregate, distinct from a nonrepeatable read.

A. Two transactions both delete the same record simultaneously

B. Initially A=B=100. During T2's transfer of 10 from A to B, T1 sums old A=100 and new B=110, returning 210 although the total-balance invariant is 200.

C. A transaction reads uncommitted data from another transaction

D. A transaction fails to acquire all necessary locks

Hint

Trace which transaction wrote each value and whether an overwrite or mixed-version read occurs.

Answer B: B. Initially A=B=100. During T2's transfer of 10 from A to B, T1 sums old A=100 and new B=110, returning 210 although the total-balance invariant is 200.

The transfer preserves the total balance at 200, but T1 combines the pre-transfer debit balance with the post-transfer credit balance. Its computed 100+110=210 is not a valid summary of a consistent state. This is an incorrect-summary anomaly. Dirty reading is defined by an uncommitted dependency, and lock failure or simultaneous deletion alone does not establish this mixed aggregate.

Why each choice is right or wrong

A - Incorrect: Concurrent deletion alone does not specify an inconsistent aggregate.

B - Correct: The mixed old/new balances yield 210 instead of the invariant 200.

C - Incorrect: Reading another transaction's uncommitted value defines a dirty read.

D - Incorrect: Failure to acquire locks concerns scheduling rather than this aggregate result.

Primary note proof

Study-note section ADB08

> Lost update: T1 and T2 both read 500; T2 adds 200 and writes 700; T1 adds 100 to its stale value and writes 600. Correct serial execution yields 800. Dirty read: T2 reads a value written by uncommitted T1; if T1 aborts, dependent work must be reconsidered. Reading one's own changes is not a dirty read.

Study-note section ADB08

> Incorrect summary mixes mutually inconsistent versions: a transfer moves 10 from A=100 to B=100; a sum reading old A=100 and new B=110 gets 210 instead of the invariant 200.

Study-note section ADB08

> A single committed update from B=20 to B=50 does not alone prove an invalid summary of 90.

Question sources

Advanced Database Systems review questions · Question 26

Question 160 | NS0082

Starvation in a database system occurs when:

A. A transaction consumes excessive memory resources

B. A transaction is repeatedly bypassed by higher-priority transactions and never executes

C. A deadlock persists longer than the timeout period

D. The transaction log becomes completely full

Hint

Distinguish a waiting cycle, a long wait and indefinite unfair postponement.

Answer B: Indefinite postponement while other transactions keep progressing.

ADB13 defines starvation as indefinite postponement while other work proceeds, without requiring any waiting cycle. Repeatedly favoring higher-priority work can prevent a transaction from executing, matching B. Memory consumption, a full log or a long deadlock are different resource/failure conditions; none alone defines the fairness failure of starvation.

Why each choice is right or wrong

A - Incorrect: Excessive memory use is a resource problem rather than the definition of indefinite postponement.

B - Correct: Repeated bypass by other transactions can indefinitely postpone this transaction while work continues.

C - Incorrect: Deadlock requires a waiting cycle; starvation can occur without one.

D - Incorrect: A full log can block work but does not itself define unfair indefinite postponement.

Primary note proof

Study-note section ADB13

> Deadlock requires a waiting cycle: T1 holds X and wants Y; T2 holds Y and wants X. In a wait-for graph, an edge Ti→Tj means Ti waits for a lock held by Tj. A cycle indicates deadlock under the ordinary lock-wait model. Abort a suitable victim, undo its effects and release its locks; repeat if other cycles remain. Aborting every deadlocked transaction also breaks cycles but wastes more work.

Study-note section ADB13

> Starvation is indefinite postponement while other work proceeds, without a required cycle.

Study-note section ADB13

> Fair queues, sensible victim selection and retaining original transaction timestamps on retry reduce starvation; deadlock freedom alone does not prove fairness.

Question sources

Advanced Database Systems review questions · Question 27

Question 161 | NS0083

Which concurrency control technique assigns a unique start-time value to each transaction and uses this to order execution and resolve conflicts?

A. Two-Phase Locking

B. Shadow Paging

C. Timestamp-Based Concurrency Control

D. Optimistic Concurrency Control

Hint

Compare the transaction timestamp with the item's recorded read and write timestamps.

Answer C: Timestamp-based concurrency control.

ADB15 assigns TS(T) to each transaction and compares it with item read_TS and write_TS values. Those tests reject operations that would violate timestamp order, so C matches the start-time ordering technique. 2PL orders locking, optimistic control validates private work, and shadow paging is a recovery/storage technique rather than this conflict-ordering protocol.

Why each choice is right or wrong

A - Incorrect: 2PL orders lock acquisition and release rather than defining the timestamp validity tests.

B - Incorrect: Shadow paging preserves page versions for recovery rather than ordering concurrent transaction operations by timestamp.

C - Correct: Timestamp ordering compares transaction timestamps with item read/write timestamps to resolve conflicts.

D - Incorrect: Optimistic control validates private read/write work rather than being defined by these timestamp-order tests.

Primary note proof

Study-note section ADB15

> Assign each transaction TS(T). For item X track read_TS(X), the largest timestamp of a successful reader, and write_TS(X), that of its latest successful writer. A read by T aborts if TS(T)<write_TS(X); otherwise it succeeds and updates read_TS. A write aborts if TS(T)<read_TS(X) or TS(T)<write_TS(X); otherwise it succeeds and sets write_TS. These tests preserve timestamp order.

Study-note section ADB16

> Multiversion control keeps versions so a reader can use an appropriate snapshot.

Study-note section ADB29

> Redo-only and NO-UNDO/REDO mean the same thing, so those cannot be separate unique answers.

Related reading (context, not primary note proof)

Study-note section ADB12

Question sources

Advanced Database Systems review questions · Question 28

Question 162 | NS0084

A well-formed transaction must follow which rule regarding locking?

A. Lock all items at the end of the transaction

B. Lock a data item BEFORE reading or writing it

C. Lock items only when modifying them, not when reading

D. Acquire all locks in alphabetical order by item name

Hint

Compare access permissions and same-item compatibility before granting a lock request.

Answer B: Acquire the appropriate lock before accessing the item.

ADB11 requires ownership of an appropriate lock before access and permits releasing only one's own locks. Reads therefore need shared or suitable stronger locks in this basic model; writes need exclusive ownership. Alphabetical acquisition may be a separate prevention convention, but it is not the general well-formedness rule and locks cannot be postponed until after access.

Why each choice is right or wrong

A - Incorrect: Locking only at the end leaves the earlier accesses unprotected.

B - Correct: A well-formed transaction holds an appropriate lock before reading or writing an item.

C - Incorrect: Basic lock-based access also requires an appropriate read lock, not only locks for writes.

D - Incorrect: A fixed resource order can help prevention, but alphabetical order is not the general well-formedness definition.

Primary note proof

Study-note section ADB11

> A shared (S) lock permits reading; multiple S locks on the same item can coexist. An exclusive (X) lock permits its holder to read and write and conflicts with another S or X on that item. Locks on different items do not conflict merely because one is exclusive. These are the basic lock-based rules; multiversion systems can permit additional snapshot-reader behavior.

Study-note section ADB11

> A transaction must own the appropriate lock before access and can release only its own locks.

Study-note section ADB13

> Aborting every deadlocked transaction also breaks cycles but wastes more work.

Question sources

Advanced Database Systems review questions · Question 29

Question 163 | NS0085

Lock timeout as a deadlock solution works by:

A. Detecting cycles in the wait-for graph

B. Building a priority queue of all waiting transactions

C. Automatically aborting a transaction that has waited too long for a lock

D. Locking all required data items before execution begins

Hint

Distinguish a waiting cycle, a long wait and indefinite unfair postponement.

Answer C: Abort a transaction after its lock wait exceeds the timeout.

ADB13 describes timeout as aborting long waits, while warning it may mistake slow progress for deadlock. C directly states that mechanism. Detecting cycles is a different method; acquiring all needed locks first is conservative locking; a priority queue alone neither defines a timeout nor guarantees elimination of waiting cycles.

Why each choice is right or wrong

A - Incorrect: Cycle detection is graph-based deadlock detection rather than a wait-duration timeout.

B - Incorrect: A priority queue alone does not enforce the stated wait-duration abort policy.

C - Correct: The policy aborts work whose lock wait exceeds the chosen threshold.

D - Incorrect: Obtaining all locks before execution is conservative locking, not timeout handling.

Primary note proof

Study-note section ADB13

> Deadlock requires a waiting cycle: T1 holds X and wants Y; T2 holds Y and wants X. In a wait-for graph, an edge Ti→Tj means Ti waits for a lock held by Tj. A cycle indicates deadlock under the ordinary lock-wait model. Abort a suitable victim, undo its effects and release its locks; repeat if other cycles remain. Aborting every deadlocked transaction also breaks cycles but wastes more work.

Study-note section ADB13

> A timeout aborts long waits but may mistake slow progress for deadlock.

Study-note section ADB12

> Conservative/static 2PL obtains all needed locks before execution and does not begin while only a subset is available, preventing hold-and-wait deadlock.

Question sources

Advanced Database Systems review questions · Question 30

Question 164 | NS0086

What are the three phases of query processing in the correct order?

A. Optimization, Parsing, Evaluation

B. Parsing & Translation, Optimization, Evaluation

C. Evaluation, Translation, Optimization

D. Parsing, Evaluation, Optimization

Hint

Separate query representation, strategy selection and execution.

Answer B: Parsing/translation → optimization → evaluation.

ADB17 checks grammar and semantics, constructs a logical representation, chooses an equivalent efficient execution plan and evaluates it. B groups parsing and translation into the first phase and preserves that dependency order. Plans cannot sensibly be evaluated before construction and selection, and optimization does not precede understanding the query's syntax and meaning.

Why each choice is right or wrong

A - Incorrect: Optimization cannot precede parsing and understanding the query in the stated pipeline.

B - Correct: It preserves analysis/translation, plan optimization and then execution/evaluation.

C - Incorrect: Evaluation cannot be the first phase before the query is represented and planned.

D - Incorrect: It executes before selecting the optimized plan, reversing optimization and evaluation.

Primary note proof

Study-note section ADB17

> Parsing checks SQL grammar; semantic analysis resolves names, types and access permissions. Translation constructs a logical representation, typically relational algebra or a logical query tree. Optimization chooses equivalent operations, join order and physical access methods. Evaluation executes that plan and returns results. Not every implementation exposes exactly the same phase boundaries.

Study-note section ADB17

> Query processing is the whole activity; selecting a suitable efficient strategy is optimization.

Study-note section ADB17

> DDL is not a mandatory stage before each SELECT, so authentication→DDL→DML permutations do not describe the processing sequence.

Question sources

Advanced Database Systems review questions · Question 31

Question 165 | NS0087

During query translation, SQL is typically converted into which internal representation for processing?

A. Machine code instructions

B. Binary decision trees

C. Relational algebra expressions

D. Compressed byte code

Hint

Separate query representation, strategy selection and execution.

Answer C: Relational algebra expressions or a logical query tree.

ADB17 states that translation constructs a logical representation, typically relational algebra or a logical query tree. This allows equivalent rewrites and plan choice before physical execution. Machine code or bytecode may appear in particular execution implementations, but they are not the general logical translation target asked for here; a binary decision tree is also not the defined representation.

Why each choice is right or wrong

A - Incorrect: Machine code is not the logical relational representation described for query translation.

B - Incorrect: A binary decision tree is not the note's general query-algebra representation.

C - Correct: Relational algebra expresses the logical operators that can be rewritten and optimized.

D - Incorrect: Compressed bytecode is not the stated general logical query representation.

Primary note proof

Study-note section ADB17

> Parsing checks SQL grammar; semantic analysis resolves names, types and access permissions. Translation constructs a logical representation, typically relational algebra or a logical query tree. Optimization chooses equivalent operations, join order and physical access methods. Evaluation executes that plan and returns results. Not every implementation exposes exactly the same phase boundaries.

Study-note section ADB17

> A query tree has base relations at leaves and operators at internal nodes; a query graph emphasizes relations and predicates.

Study-note section ADB17

> A physical execution plan adds scan/index choices and algorithms.

Question sources

Advanced Database Systems review questions · Question 32

Question 166 | NS0088

The query optimizer's primary goal is to:

A. Ensure queries return results in sorted order

B. Find an execution plan that minimizes the overall cost of retrieving data

C. Maximize the number of indexes used in the query

D. Ensure all tables are accessed in the order written in SQL

Hint

Identify the resource objective, counts and unit costs before comparing execution strategies.

Answer B: Choose a low-cost equivalent execution plan.

ADB19 estimates resource costs such as I/O, CPU, memory, temporary storage and communication for candidate plans. Optimization compares equivalent ways to return the same result and chooses a suitable low-cost strategy. It does not seek index count, force textual table order or impose sorting that the query never requested. The estimate need not prove a global real-world minimum.

Why each choice is right or wrong

A - Incorrect: Sorting is required only when query semantics need it, not as the universal optimizer goal.

B - Correct: The optimizer seeks an efficient equivalent plan under the selected resource-cost model.

C - Incorrect: More indexes used does not necessarily mean lower cost or better execution.

D - Incorrect: Equivalent join reordering can reduce cost; SQL textual order need not dictate access order.

Primary note proof

Study-note section ADB19

> A cost model estimates resources for a candidate plan: page I/O, CPU, memory, temporary storage and network traffic. Catalog statistics include row/page counts, distinct values and distributions. Selection with fraction s predicts s×N rows. For non-NULL equijoin keys, a common estimate is $|R|\times|S|/\max(V(R,k),V(S,k))$, assuming uniform values and containment of the smaller distinct-value domain within the larger. Adjust counts for NULLs; if either non-NULL input is empty, the result is zero. Skew, correlations or incomplete domain overlap can invalidate this estimate; known disjoint domains give zero matches.

Study-note section ADB23

Avoid universal rules that joins always beat subqueries, functions can never use indexes or more indexes always improve performance.

Study-note section ADB18

Cost-based optimization estimates candidate plans instead of relying on rules alone.

Question sources

Advanced Database Systems review questions · Question 33

Question 167 | NS0089

In the textbook local rotating-disk cost model, data is not memory-resident and query execution is disk-bound; client/network and CPU costs are negligible by comparison. Which component dominates the estimated query cost?

A. CPU processing time

B. Disk I/O time (seek time + transfer time)

C. Memory allocation overhead

D. Network latency to the client

Hint

Identify the resource objective, counts and unit costs before comparing execution strategies.

Answer B: B. Disk I/O time (seek time + transfer time)

The specified disk-bound model estimates the cost of seeks and transferred blocks. Because CPU, memory-management and network costs are negligible by assumption, disk I/O dominates this query's estimated cost. This is a contextual model rather than a universal fact about all databases: memory-resident or distributed workloads can have different dominant resources. The answer follows the scenario's stated objective.

Why each choice is right or wrong

A - Incorrect: CPU cost is negligible in the specified model.

B - Correct: Seek and transfer time dominate the stated disk-bound workload.

C - Incorrect: Memory-management overhead is negligible here.

D - Incorrect: Client/network cost is negligible in this local scenario.

Primary note proof

Study-note section ADB19

> For a simple rotating-disk model, cost = seeks×seek_time + transferred_blocks×block_transfer_time. Five seeks at 5 ms plus ten blocks at 1 ms cost 35 ms. Disk I/O often dominates textbook local-disk examples; CPU can dominate in-memory work and network can dominate distributed plans. State the assumed cost objective before ranking strategies.

Question sources

Advanced Database Systems review questions · Question 34

Question 168 | NS0090

In the disk I/O cost formula Cost = (S x tS) + (B x tT), what does 'B' represent?

A. Block size in bytes

B. Number of disk blocks transferred

C. Buffer pool size

D. Binary search operations

Hint

Identify the resource objective, counts and unit costs before comparing execution strategies.

Answer B: The number of transferred disk blocks.

ADB19 computes disk cost as seeks times seek duration plus transferred blocks times per-block transfer time. Therefore B in the formula is a block count, making B×tT the total transfer time. Block size, buffer capacity and search-operation count are different quantities and would not have the units required by this expression.

Why each choice is right or wrong

A - Incorrect: Block size is bytes per block rather than the number multiplied by per-block transfer time.

B - Correct: B counts transferred blocks, so B×tT gives their total transfer time.

C - Incorrect: Buffer-pool capacity is not the transferred-block count in this formula.

D - Incorrect: Binary-search operation count is not the disk-block transfer term.

Primary note proof

Study-note section ADB19

> For a simple rotating-disk model, cost = seeks×seek_time + transferred_blocks×block_transfer_time. Five seeks at 5 ms plus ten blocks at 1 ms cost 35 ms. Disk I/O often dominates textbook local-disk examples; CPU can dominate in-memory work and network can dominate distributed plans. State the assumed cost objective before ranking strategies.

Question sources

Advanced Database Systems review questions · Question 35

Question 169 | NS0091

The UNDO operation in database recovery is used to:

A. Re-apply changes of committed transactions not yet written to disk

B. Create new checkpoint entries in the log

C. Reverse changes made by incomplete or aborted transactions

D. Transfer data from cache to permanent disk storage

Hint

Track durable-write ordering and distinguish reversing incomplete work from installing logged effects.

Answer C: Reverse incomplete or aborted transaction effects.

ADB27 uses undo to restore before-images of incomplete effects, usually traversing a transaction’s updates backward. This removes changes that must not survive. Reapplying committed changes is redo, checkpoint records bound recovery searches, and transferring dirty buffers to storage is page flushing. Only C describes undo rather than another recovery or storage operation.

Why each choice is right or wrong

A - Incorrect: Reapplying missing committed updates is redo rather than undo.

B - Incorrect: Checkpoint creation records recovery state and is not reversal of incomplete effects.

C - Correct: Undo restores old values to remove incomplete or aborted transaction changes.

D - Incorrect: Writing a buffer to disk is flushing rather than restoring before-images.

Primary note proof

Study-note section ADB27

> Undo restores before-images of incomplete effects, usually traversing that transaction's updates backward. Redo installs logged after-images when necessary, usually forward. Setting X to its logged after-value is idempotent; blindly replaying X=X+10 twice is not. In a simple undo/redo teaching model, undo losers and redo winners. ARIES has a different redo phase that repeats history before undoing losers.

Study-note section ADB30

> A checkpoint records enough durable recovery state to avoid scanning all old history.

Study-note section ADB30

> In a simple quiescent/checkpoint exercise, specified flushing may make earlier committed work unnecessary to redo.

Related reading (context, not primary note proof)

Study-note section ADB07

Question sources

Advanced Database Systems review questions · Question 36

Question 170 | NS0092

The REDO operation in database recovery is used to:

A. Abort all active transactions found in the log

B. Reverse changes made by failed transactions

C. Re-apply changes of committed transactions not yet written to disk

D. Create shadow copies of database pages

Hint

Track durable-write ordering and distinguish reversing incomplete work from installing logged effects.

Answer C: Reapply required logged after-images, including committed changes missing from pages.

ADB27 describes redo as installing logged after-images when necessary. In the simple teaching model it preserves committed work not yet on disk, matching C. ARIES may repeat history more broadly before loser undo, so C describes the ordinary purpose rather than every algorithm's full phase. Aborting transactions and reversing failed changes are different actions.

Why each choice is right or wrong

A - Incorrect: Aborting active transactions is not the operation of applying logged after-images.

B - Incorrect: Reversing incomplete effects is undo rather than redo.

C - Correct: Redo can restore committed changes whose data pages were not durable at the crash.

D - Incorrect: Shadow-page creation is a separate copy-on-write technique rather than logged redo.

Primary note proof

Study-note section ADB27

> Undo restores before-images of incomplete effects, usually traversing that transaction's updates backward. Redo installs logged after-images when necessary, usually forward. Setting X to its logged after-value is idempotent; blindly replaying X=X+10 twice is not. In a simple undo/redo teaching model, undo losers and redo winners. ARIES has a different redo phase that repeats history before undoing losers.

Study-note section ADB29

> Shadow/copy-on-write update writes a new location while preserving the committed version.

Study-note section ADB29

> Shadow paging keeps an unchanged committed page map and a modified map; commit durably installs a new root/map pointer atomically after required pages are durable.

Question sources

Advanced Database Systems review questions · Question 37

Question 171 | NS0093

What is the fundamental durable-write ordering rule of write-ahead logging? In B, 'actual data changes' means writing the corresponding changed data page to persistent storage, not modifying a volatile buffer.

A. Write data to disk before creating the log record

B. Log records must be written to stable storage BEFORE making the actual data changes

C. All transactions must commit before any log entries are written

D. Log records are written only after a system crash occurs

Hint

Track durable-write ordering and distinguish reversing incomplete work from installing logged effects.

Answer B: B. Log records must be written to stable storage BEFORE making the actual data changes

WAL requires the recovery log for an update to reach stable storage before its corresponding changed page is written to disk. A volatile buffer may already contain the change, so this rule does not order every CPU assignment after a log flush. A reverses the required durable order; C and D postpone logs until too late to support recovery of earlier persistent changes.

Why each choice is right or wrong

A - Incorrect: Data-before-log reverses WAL's required durable ordering.

B - Correct: With the defined durable-write scope, the log reaches stable storage first.

C - Incorrect: Update logs may need to be durable before commit and before data flushing.

D - Incorrect: Recovery requires logs that were durable before the crash.

Primary note proof

Study-note section ADB27

> Write-ahead logging requires the update log needed for recovery to reach stable storage before the corresponding changed data page reaches disk. To acknowledge a durable commit, force the transaction's required log records, including its commit record, to stable storage. A buffer can be changed before that log flush; WAL orders durable writes, not every CPU assignment.

Study-note section ADB27

> Setting X to its logged after-value is idempotent; blindly replaying X=X+10 twice is not.

Study-note section ADB27

> Redo installs logged after-images when necessary, usually forward.

Question sources

Advanced Database Systems review questions · Question 38

Question 172 | NS0094

In a simple quiescent checkpoint exercise, all transactions have completed and the required log/data pages are flushed at the checkpoint. How does that checkpoint reduce later recovery search work?

A. Preventing all types of hardware failures

B. Encrypting log records for faster access

C. Providing a known consistent state so recovery can start from there instead of the log beginning

D. Automatically committing all active transactions periodically

Hint

Identify which history a recovery boundary can safely exclude and whether active work spans it.

Answer C: C. Providing a known consistent state so recovery can start from there instead of the log beginning

The quiescent checkpoint supplies a durable boundary for the simplified exercise. With no active transaction spanning it and the required pages flushed, recovery need not scan all earlier history to redo those completed changes. C captures that bounded search. Checkpointing does not prevent hardware failure, gain its benefit from encryption or automatically commit active transactions. Fuzzy checkpoints require different starting-point qualifications.

Why each choice is right or wrong

A - Incorrect: Recording recovery state does not prevent hardware failures.

B - Incorrect: Encryption is not the mechanism reducing log-search work.

C - Correct: The specified durable checkpoint bounds the history needed in this exercise.

D - Incorrect: Transactions have completed here; a checkpoint does not automatically commit active work.

Primary note proof

Study-note section ADB30

> A checkpoint records enough durable recovery state to avoid scanning all old history. In a simple quiescent/checkpoint exercise, specified flushing may make earlier committed work unnecessary to redo. Active transactions can span the checkpoint, so their relevant earlier updates can still need undo. Do not assume every transaction before a checkpoint needs no processing.

Study-note section ADB30

> Recovery may start analysis at the checkpoint but redo from an earlier required log position.

Study-note section ADB30

> A checkpoint is neither a full backup nor an automatic commit of active transactions.

Question sources

Advanced Database Systems review questions · Question 39

Question 173 | NS0095

In deferred update (No-Undo) recovery, actual database modifications are written to disk:

A. Immediately as each SQL statement executes

B. Only AFTER the transaction successfully commits

C. When a checkpoint operation is triggered

D. At regular 5-minute intervals regardless of transaction state

Hint

Separate update timing from update location and follow the commit boundary.

Answer B: After successful commit, in the deferred-update model.

ADB29 keeps uncommitted changes outside the persistent database. Only committed effects may therefore be installed in its actual database pages, which is the property B expresses. This does not require every committed page to be flushed immediately. Checkpoints and periodic timers cannot independently authorize writing uncommitted changes while retaining the claimed No-Undo model.

Why each choice is right or wrong

A - Incorrect: Immediate per-statement persistent writes can expose uncommitted effects and do not define deferred update.

B - Correct: The model does not install uncommitted effects in the persistent database; committed changes can be written later.

C - Incorrect: A checkpoint alone does not make an uncommitted transaction eligible for persistent installation.

D - Incorrect: A fixed timer cannot ignore transaction commit status while preserving deferred-update semantics.

Primary note proof

Study-note section ADB29

> Deferred update keeps uncommitted changes outside the persistent database; in the usual no-force setting it is NO-UNDO/REDO. Redo-only and NO-UNDO/REDO mean the same thing, so those cannot be separate unique answers. Immediate update allows persistent changes before commit and therefore may require undo; it need not flush every write_item immediately.

Study-note section ADB29

> Shadow/copy-on-write update writes a new location while preserving the committed version.

Study-note section ADB29

> Shadow paging keeps an unchanged committed page map and a modified map; commit durably installs a new root/map pointer atomically after required pages are durable.

Question sources

Advanced Database Systems review questions · Question 40

Question 174 | NS0096

Shadow paging recovery technique preserves the original database pages by:

A. Creating a backup on a separate server

B. Writing all modifications to NEW shadow pages, keeping originals intact until commit

C. Encrypting pages before any modification

D. Storing pages in sorted order for faster access

Hint

Separate update timing from update location and follow the commit boundary.

Answer B: Write changed data to new pages while preserving the committed page map.

ADB29 preserves the committed version and writes changed data at new locations. Shadow paging keeps the old page map plus a modified map; commit atomically installs the new durable root after needed pages are durable. B captures the copy-on-write preservation, although the unchanged old map is the shadow rather than the name of each newly modified page.

Why each choice is right or wrong

A - Incorrect: A separate-server backup is not the page-map copy-on-write mechanism of shadow paging.

B - Correct: Changes use new pages, preserving the originals until the new committed map is safely installed.

C - Incorrect: Encryption does not preserve the old page mapping or provide the stated rollback mechanism.

D - Incorrect: Sorting pages is an access-layout choice rather than preserving committed copies.

Primary note proof

Study-note section ADB29

> In-place update overwrites the original location. Shadow/copy-on-write update writes a new location while preserving the committed version. Shadow paging keeps an unchanged committed page map and a modified map; commit durably installs a new root/map pointer atomically after required pages are durable. Before commit, a crash uses the old map. It is an

alternative to conventional log-based recovery, with allocation, fragmentation and concurrency costs; it is not primarily a special action done only during recovery.

Study-note section ADB26

A full backup copies the database to separate storage; scheduled backups plus archived logs support restoration to a chosen recoverable point.

Study-note section ADB26

Rollback handles failed/uncommitted work; redo preserves committed work missing from pages; checkpoints reduce log-search work; backups provide another stored copy.

Related reading (context, not primary note proof)

Study-note section ADB24

Question sources

Advanced Database Systems review questions · Question 41

Question 175 | NS0097

Which type of database failure is caused by accidental deletion of important data by a user?

A. Hardware failure

B. Natural disaster

C. Software error

D. Human error

Hint

Identify what failed, what durable resources survive and which restoration action is required.

Answer D: Human error.

The described cause is an accidental user action, not faulty hardware, a natural event or a software defect. ADB26 treats human mistakes separately and notes they may need point-in-time restoration before a bad committed operation. Ordinary crash redo would otherwise preserve a committed deletion rather than recognize the user’s intention.

Why each choice is right or wrong

A - Incorrect: No hardware malfunction is stated; the cause is the user's mistaken deletion.

B - Incorrect: A natural disaster is not the cause described in the prompt.

C - Incorrect: The software may have executed the requested deletion correctly; the stated mistake belongs to the user.

D - Correct: Accidental deletion by a user is a human error.

Primary note proof

Study-note section ADB26

> Transaction failures include invalid operations, constraint violations and concurrency-control aborts. Enforcing concurrency can deliberately abort work; it does not prevent every transaction failure. A system crash loses volatile memory while disks may survive. Media failure damages persistent storage and normally requires restoring a backup, then replaying available archived logs. Human mistakes may require point-in-time restoration before the bad committed operation.

Study-note section ADB-S05

> An accidental user deletion is human error even if the software executes the requested command correctly.

Study-note section ADB-S05

> A software failure originates in erroneous program behavior, such as a logical programming defect, invalid operation or operating-system fault.

Question sources

Advanced Database Systems review questions · Question 42

Question 176 | NS0098

The transaction log records 'before and after values' for data modifications primarily to support:

A. Query optimization

B. User access control

C. UNDO (restore old value) and REDO (apply new value) operations during recovery

D. Database compression and storage efficiency

Hint

Track durable-write ordering and distinguish reversing incomplete work from installing logged effects.

Answer C: Undo with old values and redo with logged new values.

ADB27 restores before-images when undoing incomplete work and installs after-images when redoing logged effects. Recording both values therefore supports reversal and reapplication after failure. Query costing uses catalog statistics, access control uses privileges, and compression is a different storage concern; none explains the specific recovery value pair as directly.

Why each choice is right or wrong

A - Incorrect: Query optimization estimates plan cost rather than restoring old/new transaction values.

B - Incorrect: Access control checks privileges rather than using before/after images to authorize users.

C - Correct: Old values support reversal and new values support necessary reapplication during recovery.

D - Incorrect: Recording two values can add storage overhead and is not primarily a compression mechanism.

Primary note proof

Study-note section ADB27

> Undo restores before-images of incomplete effects, usually traversing that transaction's updates backward. Redo installs logged after-images when necessary, usually forward. Setting X to its logged after-value is idempotent; blindly replaying X=X+10 twice is not. In a simple undo/redo teaching model, undo losers and redo winners. ARIES has a different redo phase that repeats history before undoing losers.

Study-note section ADB19

> A cost model estimates resources for a candidate plan: page I/O, CPU, memory, temporary storage and network traffic.

Study-note section ADB19

> Catalog statistics include row/page counts, distinct values and distributions.

Related reading (context, not primary note proof)

Study-note section ADB24

Question sources

Advanced Database Systems review questions · Question 43

Question 177 | NS0099

Which type of distributed database uses the SAME DBMS software at every site?

A. Heterogeneous distributed database

B. Homogeneous distributed database

C. Middleware-based database

D. Partially replicated database

Hint

Separate coordinated network placement from engine compatibility and semantic integration.

Answer B: Homogeneous distributed database.

ADB33 identifies homogeneous systems by compatible DBMS technology across sites. Using the same DBMS software fits that classification. Heterogeneous systems integrate differing engines, models or interfaces. Middleware describes integration architecture and partial replication describes placement of copies, so neither substitutes for the homogeneity classification asked for here.

Why each choice is right or wrong

A - Incorrect: Heterogeneous systems integrate differing database technologies rather than the same DBMS throughout.

B - Correct: Using the same DBMS at each site fits homogeneous distributed database technology.

C - Incorrect: Middleware describes communication/integration responsibilities, not whether DBMS technology is the same.

D - Incorrect: Partial replication describes where selected copies reside rather than which DBMS software sites use.

Primary note proof

Study-note section ADB33

> A distributed database contains logically related data across networked sites, managed as a coordinated system. A homogeneous system uses compatible DBMS technology across sites; a heterogeneous system integrates differing DBMSs, data models, schemas or interfaces. Different operating systems are possible but do not define the distinction. Same DBMS does not imply identical local schemas, automatic replication or immediate synchronization.

Study-note section ADB37

> Full replication places the whole database at every relevant site; partial replication copies selected fragments to selected sites; nonredundant allocation stores each fragment once.

Study-note section ADB34

> These describe communication responsibilities, not fragmentation types.

Question sources

Advanced Database Systems review questions · Question 44

Question 178 | NS0100

Horizontal fragmentation divides a table based on:

A. Splitting columns into separate subsets

B. Splitting rows into subsets based on a condition

C. Combining two tables into one larger table

D. Replicating the table to multiple sites

Hint

Identify whether rows or columns are split and reverse the split to reconstruct the original relation.

Answer B: Split rows by predicates.

ADB36 defines horizontal fragmentation as selecting row subsets using predicates and reconstructing the relation by union. Column subsets belong to vertical fragmentation. Combining tables is not fragmentation, and copying a whole table is replication. Thus B identifies both the item being split and the rule used to decide fragment membership.

Why each choice is right or wrong

A - Incorrect: Column splitting is vertical fragmentation rather than horizontal fragmentation.

B - Correct: Horizontal fragments contain rows selected by stated predicates.

C - Incorrect: Combining tables increases the combined relation rather than splitting one table into row subsets.

D - Incorrect: Replicating copies preserves the whole table at more sites rather than partitioning its rows.

Primary note proof

Study-note section ADB36

> Horizontal fragmentation selects row subsets by predicates; their union reconstructs the relation. Check completeness so every original row is represented and disjointness if no overlap is intended. Define an explicit fragment for NULL/other values when needed. Vertical fragmentation projects column subsets and repeats a key or row identifier so joining on it reconstructs the original rows without spurious matches.

Study-note section ADB37

> Full replication places the whole database at every relevant site; partial replication copies selected fragments to selected sites; nonredundant allocation stores each fragment once.

Study-note section ADB37

> Full replication does not inherently mean every copy is updated simultaneously; its synchronization rule must be stated.

Question sources

Advanced Database Systems review questions · Question 45

Question 179 | NS0101

In vertical fragmentation, why must the PRIMARY KEY be included in every fragment?

A. To speed up INSERT operations

B. To prevent duplicate rows

C. To enable reconstruction of the original table by joining fragments on the primary key

D. To ensure proper replication across sites

Hint

Identify whether rows or columns are split and reverse the split to reconstruct the original relation.

Answer C: A repeated key or row identifier lets vertical pieces join back losslessly.

ADB36 repeats a key or row identifier across vertical fragments so attributes from the same original row can be matched during reconstruction. C states that purpose. The general requirement is a suitable identifier, not necessarily the particular declared primary key if another row identifier is used. It is unrelated to mandatory replication or inherently faster inserts.

Why each choice is right or wrong

A - Incorrect: Faster insertion is not why vertical fragments share a row identifier.

B - Incorrect: Avoiding duplicate values is not sufficient to align column pieces from the same original row.

C - Correct: The shared key identifies matching original rows when the column fragments are joined.

D - Incorrect: Replication copies data and is distinct from reconstructing vertical column fragments.

Primary note proof

Study-note section ADB36

> Horizontal fragmentation selects row subsets by predicates; their union reconstructs the relation. Check completeness so every original row is represented and disjointness if no overlap is intended. Define an explicit fragment for NULL/other values when needed. Vertical fragmentation projects column subsets and repeats a key or row identifier so joining on it reconstructs the original rows without spurious matches.

Study-note section ADB36

> Hybrid fragmentation combines row and column splits in either suitable order.

Study-note section ADB36

> Reconstruct by reversing the operations: key joins for corresponding vertical pieces and unions for horizontal pieces.

Question sources

Advanced Database Systems review questions · Question 46

Question 180 | NS0102

Which data replication scheme stores each data fragment at ONLY ONE site with NO copies?

A. Full replication

B. Partial replication

C. No replication (non-redundant allocation)

D. Hybrid replication

Hint

Separate copy placement, propagation timing and update-maintenance cost.

Answer C: No replication, or nonredundant allocation.

ADB37 explicitly calls storing each fragment once nonredundant allocation. Full replication places the whole database at every relevant site, while partial replication copies selected fragments to selected sites. A hybrid can mix strategies, but the stem specifies exactly one location and no copies for every fragment, so C is the precise classification.

Why each choice is right or wrong

A - Incorrect: Full replication stores copies throughout the relevant sites rather than one copy per fragment.

B - Incorrect: Partial replication still copies selected fragments and therefore does not mean no copies.

C - Correct: Nonredundant allocation stores each fragment at one site without replicas.

D - Incorrect: A hybrid can combine policies, but the stated universal no-copy arrangement is specifically nonreplicated.

Primary note proof

Study-note section ADB37

> Full replication places the whole database at every relevant site; partial replication copies selected fragments to selected sites; nonredundant allocation stores each fragment once. Copies improve read locality and can improve availability but require storage and update propagation. They can also spread mistakes, so replication does not replace independent backups.

Study-note section ADB37

> Full replication does not inherently mean every copy is updated simultaneously; its synchronization rule must be stated.

Study-note section ADB37

> Snapshot replication transfers a copy at intervals; incremental replication transfers changes.

Question sources

Advanced Database Systems review questions · Question 47

Question 181 | NS0103

Transparency in distributed databases means that:

A. All data is encrypted and transparent to hackers

B. The distribution complexity is hidden from users who interact as if using a single database

C. Users can see all technical details of how data is distributed

D. All sites must use the same operating system

Hint

Identify exactly which detail is hidden from the user.

Answer B: Hide distribution details behind a single logical database experience.

ADB35 defines transparency through which distribution details are hidden: sites, fragment reconstruction or replica selection/maintenance. Together these can let clients work with a single logical database abstraction. B captures that broad meaning. Transparency is not encryption, disclosure of every technical detail or a requirement that operating systems be identical.

Why each choice is right or wrong

A - Incorrect: Encryption protects content; transparency here concerns hiding distribution complexity from legitimate users.

B - Correct: Distribution details can be hidden so users work with one logical database abstraction.

C - Incorrect: Transparency hides selected implementation details rather than exposing all of them.

D - Incorrect: Operating-system uniformity does not define distribution transparency.

Primary note proof

Study-note section ADB35

> Location transparency hides which site holds a named object. Fragmentation transparency hides the existence and reconstruction of fragments: users query the whole logical relation. Replication transparency hides which copy is used and how copies are maintained. The broad single-logical-database experience may involve all three.

Study-note section ADB33

> Different operating systems are possible but do not define the distinction.

Study-note section ADB24

> Encryption protects stored or transmitted content; integrity constraints restrict valid data; auditing records actions.

Question sources

Advanced Database Systems review questions · Question 48

Question 182 | NS0104

Hybrid fragmentation combines which two fragmentation types?

A. Replication and Partitioning

B. Horizontal and Vertical fragmentation

C. Client-Server and Middleware architectures

D. Homogeneous and Heterogeneous distribution

Hint

Identify whether rows or columns are split and reverse the split to reconstruct the original relation.

Answer B: Horizontal and vertical fragmentation.

ADB36 defines hybrid fragmentation as combining row and column splits in a suitable order. Reconstructing reverses those operations using unions for horizontal pieces and key joins for corresponding vertical pieces. Replication, deployment architectures and DBMS homogeneity are different design dimensions rather than the two fragmentation types combined by hybrid fragmentation.

Why each choice is right or wrong

A - Incorrect: Replication copies data and is not the second fragmentation dimension in the hybrid definition.

B - Correct: Hybrid fragmentation combines horizontal row splits with vertical column splits.

C - Incorrect: Client-server and middleware classify architectures rather than fragmentation operations.

D - Incorrect: Homogeneous/heterogeneous classifies system technology compatibility rather than row/column splitting.

Primary note proof

Study-note section ADB36

> Horizontal fragmentation selects row subsets by predicates; their union reconstructs the relation. Check completeness so every original row is represented and disjointness if no overlap is intended. Define an explicit fragment for NULL/other values when needed. Vertical fragmentation projects column subsets and repeats a key or row identifier so joining on it reconstructs the original rows without spurious matches.

Study-note section ADB36

> Hybrid fragmentation combines row and column splits in either suitable order.

Study-note section ADB36

> Reconstruct by reversing the operations: key joins for corresponding vertical pieces and unions for horizontal pieces.

Question sources

Advanced Database Systems review questions · Question 49

Question 183 | NS0105

With full replication and synchronous propagation before acknowledgment, which listed disadvantage specifically concerns maintaining copies during an update-heavy workload? Assume usable replicas can serve reads.

A. Data becomes unavailable when any site fails

B. Updates incur propagation and coordination overhead because changes must reach the required copies before acknowledgment.

C. It requires all sites to use the same DBMS software

D. Queries can only be answered from the primary site

Hint

Separate copy placement, propagation timing and update-maintenance cost.

Answer B: B. Updates incur propagation and coordination overhead because changes must reach the required copies before acknowledgment.

Full replication stores the entire database at each relevant site, so updates create propagation and coordination work. The stated synchronous policy places that work before acknowledgment, adding update latency in the update-heavy scenario. This is the disadvantage described by B. Usable copies can serve reads and improve availability; full replication neither implies identical DBMS software nor restricts queries to one primary site.

Why each choice is right or wrong

A - Incorrect: Usable replicas can keep data available after one site fails.

B - Correct: The stated synchronous policy adds propagation and coordination work before acknowledgment.

C - Incorrect: Full replication is a copy-placement policy, not a requirement to standardize every DBMS.

D - Incorrect: Usable replicas can serve reads in the stated scenario.

Primary note proof

Study-note section ADB37

> Full replication places the whole database at every relevant site; partial replication copies selected fragments to selected sites; nonredundant allocation stores each fragment once. Copies improve read locality and can improve availability but require storage and update propagation. They can also spread mistakes, so replication does not replace independent backups.

Study-note section ADB37

> Eager/synchronous replication coordinates propagation before the specified commit/acknowledgment point, increasing update latency.

Study-note section ADB37

> Full replication does not inherently mean every copy is updated simultaneously; its synchronization rule must be stated.

Question sources

Advanced Database Systems review questions · Question 50

Question 184 | NS0106

What does ACID stand for in database transactions?

A. Atomicity, Concurrency, Isolation, Durability

B. Atomicity, Consistency, Isolation, Durability

C. Availability, Consistency, Integrity, Durability

D. Atomicity, Correctness, Isolation, Distribution

Hint

Track the transaction's guarantee or lifecycle boundary described by the scenario.

Answer B: Atomicity, Consistency, Isolation, Durability.

ADB06 gives all-or-none effects, preservation of declared rules, controlled interference and persistence after failure as the four ACID properties. B names them correctly. The other options substitute concurrency, availability, integrity, correctness or distribution for the defined terms, changing the acronym rather than describing an equivalent expansion.

Why each choice is right or wrong

A - Incorrect: Concurrency incorrectly replaces Consistency in the acronym.

B - Correct: The expansion exactly matches the four ACID property names.

C - Incorrect: Availability and Integrity replace Atomicity and Isolation, which are the defined terms.

D - Incorrect: Correctness and Distribution do not replace Consistency and Durability in ACID.

Primary note proof

Study-note section ADB06

> A transaction is a logical unit of database work, including read-only work. Atomicity means all effects or none; consistency means correct work preserves integrity rules; isolation controls concurrent interference; durability preserves committed effects despite failure. A DBMS cannot automatically make incorrect business logic consistent.

Question sources

Advanced Database Systems review questions · Question 1

Question 185 | NS0107

Which ACID property ensures that either ALL operations of a transaction complete or NONE do?

A. Consistency

B. Isolation

C. Atomicity

D. Durability

Hint

Track the transaction's guarantee or lifecycle boundary described by the scenario.

Answer C: Atomicity.

The requested property concerns whether partial transaction effects can survive. ADB06 assigns all-or-none application to atomicity. A correct transaction also preserves consistency, concurrency needs isolation and completed commits need durability, but those are different guarantees. C is therefore the property matching the explicit ALL or NONE condition.

Why each choice is right or wrong

A - Incorrect: Consistency concerns preservation of integrity rules rather than the indivisible effect boundary itself.

B - Incorrect: Isolation governs concurrent interference rather than all-or-none transaction effects.

C - Correct: Atomicity makes the transaction effects succeed together or be removed together.

D - Incorrect: Durability protects committed effects rather than defining partial-success handling.

Primary note proof

Study-note section ADB06

> A transaction is a logical unit of database work, including read-only work. Atomicity means all effects or none; consistency means correct work preserves integrity rules; isolation controls concurrent interference; durability preserves committed effects despite failure. A DBMS cannot automatically make incorrect business logic consistent.

Question sources

Advanced Database Systems review questions · Question 2

Question 186 | NS0108

If A=5000 and B=8000, and 750 is transferred from A to B, what values satisfy the Consistency property?

A. A=4250, B=8750, sum=13000

B. A=4250, B=8000, sum=12250

C. A=5000, B=8750, sum=13750

D. A=5000, B=8000, sum=13000

Hint

Track the transaction's guarantee or lifecycle boundary described by the scenario.

Answer A: A=4250, B=8750, total=13000.

Subtracting 750 from A gives 4250 and adding it to B gives 8750; their total remains 13000. A implements both the specified operation and its total-balance invariant. B and C apply only one side. D preserves the initial total but does not perform the requested transfer, so invariant preservation alone does not make it the successful-transfer result.

Why each choice is right or wrong

A - Correct: It performs the 750 debit and credit and preserves the total of 13000.

B - Incorrect: The debit occurs without its credit, reducing the total to 12250.

C - Incorrect: The credit occurs without its debit, increasing the total to 13750.

D - Incorrect: It preserves the starting total but leaves both accounts unchanged rather than performing the transfer.

Primary note proof

Study-note section ADB06

> A transaction is a logical unit of database work, including read-only work. Atomicity means all effects or none; consistency means correct work preserves integrity rules; isolation controls concurrent interference; durability preserves committed effects despite failure. A DBMS cannot automatically make incorrect business logic consistent.

Study-note section ADB06

> Unchanged or reverse-transfer balances can also preserve that sum; only the requested debit/credit implements the specified successful transfer.

Study-note section ADB06

> Both balances total 13,000.

Question sources

Advanced Database Systems review questions · Question 3

Question 187 | NS0109

Which ACID property ensures concurrent transactions do not interfere with each other?

A. Atomicity

B. Durability

C. Consistency

D. Isolation

Hint

Track the transaction's guarantee or lifecycle boundary described by the scenario.

Answer D: Isolation.

ADB06 assigns concurrent-interference control to isolation. That is the distinguishing phrase in the stem. Atomicity handles partial effects, durability handles committed persistence, and consistency means correct work preserves declared rules. Different isolation levels provide different detailed guarantees, so this classification does not imply that all implementations offer serializability by default.

Why each choice is right or wrong

A - Incorrect: Atomicity governs partial effects within a transaction rather than concurrent interference.

B - Incorrect: Durability concerns persistence of committed changes after failures.

C - Incorrect: Consistency concerns declared integrity rules under correct business logic.

D - Correct: Isolation controls interference among concurrently executing transactions.

Primary note proof

Study-note section ADB06

> A transaction is a logical unit of database work, including read-only work. Atomicity means all effects or none; consistency means correct work preserves integrity rules; isolation controls concurrent interference; durability preserves committed effects despite failure. A DBMS cannot automatically make incorrect business logic consistent.

Question sources

Advanced Database Systems review questions · Question 4

Question 188 | NS0110

Which ACID property guarantees committed changes survive system crashes?

A. Atomicity

B. Consistency

C. Isolation

D. Durability

Hint

Track the transaction's guarantee or lifecycle boundary described by the scenario.

Answer D: Durability.

ADB06 defines durability by persistence of committed effects despite failure. Recovery information can provide this even when changed data pages were buffered at the instant of commit. All-or-none application, invariant preservation and concurrent isolation serve different transaction guarantees, so only durability matches survival of successful commits after a crash.

Why each choice is right or wrong

A - Incorrect: Atomicity concerns all-or-none application rather than the persistence of completed commits.

B - Incorrect: Consistency concerns validity of declared invariants rather than crash survival of commits.

C - Incorrect: Isolation controls concurrent interactions rather than persistence after a crash.

D - Correct: Durability preserves committed effects across system failures.

Primary note proof

Study-note section ADB06

> A transaction is a logical unit of database work, including read-only work. Atomicity means all effects or none; consistency means correct work preserves integrity rules; isolation controls concurrent interference; durability preserves committed effects despite failure. A DBMS cannot automatically make incorrect business logic consistent.

Question sources

Advanced Database Systems review questions · Question 5

Question 189 | NS0111

A transaction that has executed all operations but NOT YET committed is in which state?

A. Active

B. Partially Committed

C. Committed

D. Failed

Hint

Track the transaction's guarantee or lifecycle boundary described by the scenario.

Answer B: Partially committed.

ADB06 places a transaction in Partially committed after its last operation finishes but before durable commitment is assured. The stem states exactly that boundary. Active means operations are still executing; Committed needs successful commit; Failed needs an error. Finishing the operation list alone does not establish the committed state.

Why each choice is right or wrong

A - Incorrect: Active describes ongoing operation execution, not the interval after the last operation finishes.

B - Correct: The last operation finished, but commitment is not yet assured.

C - Incorrect: The stem explicitly says the transaction has not yet committed.

D - Incorrect: No execution or commit failure is reported.

Primary note proof

Study-note section ADB06

> Active means operations are executing. Partially committed means the last operation finished but durable commitment is not yet assured. Committed means commitment succeeded. A failure leads to Failed, then Aborted after rollback; a transaction may terminate or be restarted as a new attempt. Concurrency control primarily enforces isolation; recovery supports atomicity and durability. Transaction management is the broader subsystem, so both it and recovery management can be legitimate answers to broad responsibility questions.

Question sources

Advanced Database Systems review questions · Question 6

Question 190 | NS0112

In the Aborted state, what happens to all changes made by the transaction?

A. Changes are permanently saved

B. All changes are rolled back restoring the database to its pre-transaction state

C. The transaction waits for resources

D. The transaction restarts automatically

Hint

Track the transaction's guarantee or lifecycle boundary described by the scenario.

Answer B: Its effects have been rolled back; other committed transactions remain.

ADB06 reaches Aborted after rollback. Thus the aborted transaction’s own changes are removed rather than permanently saved. Restoring pre-transaction state must be understood relative to its effects, not erasing unrelated concurrent commits. A restart can be a new attempt, but is not automatic merely because the aborted state was reached.

Why each choice is right or wrong

A - Incorrect: Permanent saving is a committed outcome, not an aborted outcome.

B - Correct: Rollback removes this transaction's effects while retaining other transactions' legitimate committed work.

C - Incorrect: Waiting for a lock describes a blocked executing transaction rather than completed rollback.

D - Incorrect: An aborted transaction may be retried, but automatic restart is not guaranteed.

Primary note proof

Study-note section ADB06

> Active means operations are executing. Partially committed means the last operation finished but durable commitment is not yet assured. Committed means commitment succeeded. A failure leads to Failed, then Aborted after rollback; a transaction may terminate or be restarted as a new attempt. Concurrency control primarily enforces isolation; recovery supports atomicity and durability. Transaction management is the broader subsystem, so both it and recovery management can be legitimate answers to broad responsibility questions.

Study-note section ADB27

> Undo restores before-images of incomplete effects, usually traversing that transaction's updates backward.

Study-note section ADB27

> Write-ahead logging requires the update log needed for recovery to reach stable storage before the corresponding changed data page reaches disk.

Question sources

Advanced Database Systems review questions · Question 7

Question 191 | NS0113

Which log record signals successful completion of transaction T?

A. [start_transaction, T]

B. [abort, T]

C. [write_item, T, X, old, new]

D. [commit, T]

Hint

Trace movement between program variables, buffers and disk, or the meaning of a recorded transaction event.

Answer D: [commit, T].

ADB07 identifies COMMIT as the record of successful transaction completion. START begins work, UPDATE records a data change and ABORT marks failed termination/rollback handling. A data write by itself does not prove the enclosing transaction committed, and an abort record can begin rollback rather than confirm it has completed.

Why each choice is right or wrong

A - Incorrect: The start record indicates beginning work rather than successful completion.

B - Incorrect: Abort records failure/rollback handling instead of successful commitment.

C - Incorrect: An update record describes one changed item, not successful transaction completion.

D - Correct: The commit record signals successful completion of transaction T.

Primary note proof

Study-note section ADB07

> A conceptual log can contain START, UPDATE(T,X,old,new), COMMIT, ABORT and END records. Before-images support undo; after-images support redo. Real systems may use physical or logical records, and need not log every read. COMMIT records successful completion; an ABORT record can mark the start of rollback rather than prove every undo step is complete.

Question sources

Advanced Database Systems review questions · Question 8

Question 192 | NS0114

The Read_item(X) command transfers data in which order?

A. Disk -> Program variable -> Buffer

B. Buffer -> Disk -> Program variable

C. Disk -> Buffer -> Program variable

D. Program variable -> Buffer -> Disk

Hint

Trace movement between program variables, buffers and disk, or the meaning of a recorded transaction event.

Answer C: Disk page → buffer → program variable.

ADB07 locates X's page, loads it into a buffer if absent and copies the item from that buffer into the program variable. C gives that conceptual data movement order. A cached page may avoid the physical disk read, but the program still reads through the buffer. The reverse direction describes a write path rather than read_item.

Why each choice is right or wrong

A - Incorrect: The page is buffered before the item is copied to the program variable.

B - Incorrect: A read does not first send the buffer to disk before obtaining the variable value.

C - Correct: The page enters the buffer if needed, then its item is copied into the program variable.

D - Incorrect: Program-variable-to-buffer-to-disk describes writing, not reading into a variable.

Primary note proof

Study-note section ADB07

> read_item(X) locates X's page, brings it into a buffer if absent, and copies X into a program variable. write_item(X) copies the new program value into the buffered page, marking it dirty. Writing that page to disk can occur later according to the buffer policy; write_item is not inherently an immediate disk flush. Insert and delete also modify data; sorting is a query-processing operation rather than a primitive item update.

Study-note section ADB07

> Real systems may use physical or logical records, and need not log every read.

Study-note section ADB07

> Before-images support undo; after-images support redo.

Question sources

Advanced Database Systems review questions · Question 9

Question 193 | NS0115

In a multi-user system, which mechanisms does the DBMS use to manage concurrent access?

A. Only backup systems

B. Locks, timestamps, and scheduling algorithms

C. Physical user separation

D. Only file system permissions

Hint

Compare access permissions and same-item compatibility before granting a lock request.

Answer B: Locks, timestamp rules and transaction scheduling.

ADB11 defines compatible shared/exclusive locks and ADB15 orders conflicting operations with timestamp tests. These are actual concurrency-control mechanisms that constrain transaction schedules. Backups provide copies for recovery, and file permissions determine access rather than safe interleavings. Physical separation of people also does not coordinate their concurrent database operations.

Why each choice is right or wrong

A - Incorrect: Backups support restoration rather than scheduling safe concurrent reads and writes.

B - Correct: Locks and timestamp rules control conflicting accesses and permissible schedules.

C - Incorrect: Separating users physically does not coordinate their concurrent operations on shared database items.

D - Incorrect: File permissions alone do not enforce isolation among authorized concurrent transactions.

Primary note proof

Study-note section ADB11

> A shared (S) lock permits reading; multiple S locks on the same item can coexist. An exclusive (X) lock permits its holder to read and write and conflicts with another S or X on that item. Locks on different items do not conflict merely because one is exclusive. These are the basic lock-based rules; multiversion systems can permit additional snapshot-reader behavior.

Study-note section ADB26

> Transaction failures include invalid operations, constraint violations and concurrency-control aborts.

Study-note section ADB09

> Two operations conflict when they belong to different transactions, access the same item and at least one writes.

Related reading (context, not primary note proof)

Study-note section ADB15

Study-note section ADB24

Question sources

Advanced Database Systems review questions · Question 10

Question 194 | NS0116

The Lost Update problem is also called:

A. Read-Read Problem

B. Write-Write Problem

C. Read-Write Problem

D. Phantom Read Problem

Hint

Trace which transaction wrote each value and whether an overwrite or mixed-version read occurs.

Answer B: Write-write problem, as shorthand for a lost-update overwrite.

ADB08 illustrates both transactions reading 500, one writing 700 and the other later overwriting it with stale 600. The conflict is between their writes, which explains the offered write-write shorthand. This is not a claim that every pair of writes loses an update: the stale calculation and overwrite are essential. Read/read and phantom behavior describe different situations.

Why each choice is right or wrong

A - Incorrect: Two reads alone do not overwrite and lose an update.

B - Correct: The stale write overwrites another write, motivating this write-write shorthand.

C - Incorrect: The defining loss is the later stale overwrite, not merely an arbitrary read/write pair.

D - Incorrect: A phantom changes a predicate query's qualifying row set rather than overwriting one balance.

Primary note proof

Study-note section ADB08

> Lost update: T1 and T2 both read 500; T2 adds 200 and writes 700; T1 adds 100 to its stale value and writes 600. Correct serial execution yields 800. Dirty read: T2 reads a value written by uncommitted T1; if T1 aborts, dependent work must be reconsidered. Reading one's own changes is not a dirty read.

Question sources

Advanced Database Systems review questions · Question 11

Question 195 | NS0117

A Dirty Read occurs when:

A. A transaction reads only committed data

B. A transaction reads data modified by another uncommitted transaction

C. Two transactions read the same record simultaneously

D. A transaction writes invalid format data

Hint

Trace which transaction wrote each value and whether an overwrite or mixed-version read occurs.

Answer B: Reading another transaction’s uncommitted data.

ADB08 defines dirty read through another transaction’s uncommitted write. The value can disappear if its writer aborts, leaving dependent work based on invalid data. Reading committed data or two readers accessing one item is not inherently dirty. Invalid-format writes concern data validity rather than whether the read-from transaction has committed.

Why each choice is right or wrong

A - Incorrect: Reading only committed values avoids the defining uncommitted-writer dependency.

B - Correct: The read consumes another transaction's modification before that writer commits.

C - Incorrect: Multiple readers alone do not create an uncommitted data dependency.

D - Incorrect: Invalid format concerns validation or integrity rather than the definition of a dirty read.

Primary note proof

Study-note section ADB08

> Lost update: T1 and T2 both read 500; T2 adds 200 and writes 700; T1 adds 100 to its stale value and writes 600. Correct serial execution yields 800. Dirty read: T2 reads a value written by uncommitted T1; if T1 aborts, dependent work must be reconsidered. Reading one's own changes is not a dirty read.

Question sources

Advanced Database Systems review questions · Question 12

Question 196 | NS0118

Which trace demonstrates an incorrect-summary anomaly, meaning an aggregate that mixes mutually inconsistent versions? Treat nonrepeatable read as a separate anomaly.

A. A transaction reads data after another commits

B. Initially A=B=100. T2 transfers 10 from A to B while T1 reads old A=100 and new B=110, reporting 210 rather than the invariant total 200.

C. Two transactions delete the same record

D. A transaction reads its own uncommitted data

Hint

Trace which transaction wrote each value and whether an overwrite or mixed-version read occurs.

Answer B: B. Initially A=B=100. T2 transfers 10 from A to B while T1 reads old A=100 and new B=110, reporting 210 rather than the invariant total 200.

The transfer subtracts and adds the same amount, preserving a total of 200. T1 instead adds an old A balance to a new B balance and obtains 210, combining versions that do not form a consistent summary. That is the incorrect-summary anomaly. Reading committed data, deleting a record or reading one's own uncommitted changes alone does not establish this aggregate defect.

Why each choice is right or wrong

A - Incorrect: A read after another commit is not by itself an inconsistent aggregate.

B - Correct: 100+110=210 mixes versions and violates the preserved total 200.

C - Incorrect: Concurrent deletions alone do not show this summary anomaly.

D - Incorrect: Reading one's own changes is not the stated mixed-version aggregate.

Primary note proof

Study-note section ADB08

> Lost update: T1 and T2 both read 500; T2 adds 200 and writes 700; T1 adds 100 to its stale value and writes 600. Correct serial execution yields 800. Dirty read: T2 reads a value written by uncommitted T1; if T1 aborts, dependent work must be reconsidered. Reading one's own changes is not a dirty read.

Study-note section ADB08

> Incorrect summary mixes mutually inconsistent versions: a transfer moves 10 from A=100 to B=100; a sum reading old A=100 and new B=110 gets 210 instead of the invariant 200.

Study-note section ADB08

> A single committed update from B=20 to B=50 does not alone prove an invalid summary of 90.

Question sources

Advanced Database Systems review questions · Question 13

Question 197 | NS0119

A Shared Lock allows:

A. Only one transaction to read an item

B. Multiple transactions to read simultaneously but not write

C. One transaction to read and write exclusively

D. Multiple transactions to write simultaneously

Hint

Compare access permissions and same-item compatibility before granting a lock request.

Answer B: Compatible readers, with no writing under a shared lock.

ADB11 permits multiple shared locks on one item, each for reading. Writing requires a suitable exclusive lock, which conflicts with other shared holders. Thus B describes shared-lock behavior in the basic lock-based model. Exclusive read/write ownership and multiple simultaneous writers are not shared locking; multiversion snapshot rules are a separate model.

Why each choice is right or wrong

A - Incorrect: More than one transaction may hold compatible shared read locks on the same item.

B - Correct: Shared locks permit multiple readers but do not authorize writes under that lock mode.

C - Incorrect: Sole read/write ownership describes an exclusive lock.

D - Incorrect: Shared locks do not allow multiple transactions to write simultaneously.

Primary note proof

Study-note section ADB11

> A shared (S) lock permits reading; multiple S locks on the same item can coexist. An exclusive (X) lock permits its holder to read and write and conflicts with another S or X on that item. Locks on different items do not conflict merely because one is exclusive. These are the basic lock-based rules; multiversion systems can permit additional snapshot-reader behavior.

Study-note section ADB11

> One transaction may request a lock on an already locked item: it is granted if compatible, otherwise waits or aborts under the policy.

Study-note section ADB11

> No double-locking is not a prohibition on shared readers.

Question sources

Advanced Database Systems review questions · Question 14

Question 198 | NS0120

An Exclusive Lock allows:

A. Multiple transactions to read concurrently

B. Multiple transactions to write simultaneously

C. Only one transaction to both read and write, blocking all other access

D. Multiple readers and one writer simultaneously

Hint

Compare access permissions and same-item compatibility before granting a lock request.

Answer C: The exclusive holder may read and write; conflicting access to that item is blocked.

ADB11 permits an exclusive lock holder to read and write and makes that item's X lock conflict with another S or X. C is correct in this basic model. Blocking all other access means conflicting access to the same item, not the entire database; locks on other items remain independent and multiversion systems can have additional snapshot-reader behavior.

Why each choice is right or wrong

A - Incorrect: Other transactions' shared reads conflict with an exclusive lock on the same item in this model.

B - Incorrect: Two exclusive writers cannot hold compatible locks on the same item.

C - Correct: One holder can read/write the locked item while incompatible same-item accesses wait or abort.

D - Incorrect: Concurrent same-item shared readers conflict with this exclusive writer under the basic rules.

Primary note proof

Study-note section ADB11

> A shared (S) lock permits reading; multiple S locks on the same item can coexist. An exclusive (X) lock permits its holder to read and write and conflicts with another S or X on that item. Locks on different items do not conflict merely because one is exclusive. These are the basic lock-based rules; multiversion systems can permit additional snapshot-reader behavior.

Study-note section ADB11

> One transaction may request a lock on an already locked item: it is granted if compatible, otherwise waits or aborts under the policy.

Study-note section ADB11

> S→X is an upgrade, possible only after conflicting other holders leave.

Question sources

Advanced Database Systems review questions · Question 15

Question 199 | NS0121

In Two-Phase Locking (2PL), during the Growing Phase a transaction:

A. Releases locks only

B. Acquires locks without releasing any

C. Acquires and releases locks freely

D. Makes no lock requests

Hint

Track the first lock release and the transaction-completion boundary.

Answer B: Acquire or upgrade locks without releasing them.

ADB12 defines growing as the acquisition/upgrade phase and shrinking as the release/downgrade phase. Once any lock is released, no further acquisition is allowed. B therefore matches growing. Freely mixing acquisition and release would abandon the two-phase discipline that guarantees conflict serializability for well-formed transactions.

Why each choice is right or wrong

A - Incorrect: Releasing locks belongs to shrinking rather than growing.

B - Correct: Growing acquires or upgrades locks before any release occurs.

C - Incorrect: Freely acquiring after release violates the defining 2PL phase restriction.

D - Incorrect: Growing is precisely the phase in which lock requests may be made.

Primary note proof

Study-note section ADB12

> Basic 2PL has a growing phase that acquires/upgrades locks and a shrinking phase that releases/downgrades them. Once any lock is released, no new lock may be acquired. The lock point is the instant the final lock is obtained. 2PL guarantees conflict serializability for well-formed transactions, but can deadlock and basic 2PL alone need not prevent cascading aborts.

Study-note section ADB12

> Two-phase locking orders access to data; two-phase commit coordinates a distributed commit decision.

Study-note section ADB12

> Conservative/static 2PL obtains all needed locks before execution and does not begin while only a subset is available, preventing hold-and-wait deadlock.

Question sources

Advanced Database Systems review questions · Question 16

Question 200 | NS0122

Which concurrency control technique uses start-times to order transaction execution?

A. Locking

B. Optimistic Concurrency Control

C. Timestamp-based Concurrency Control

D. Shadow Paging

Hint

Compare the transaction timestamp with the item's recorded read and write timestamps.

Answer C: Timestamp-based concurrency control.

ADB15 assigns each transaction a timestamp and checks reads and writes against item read/write timestamps. These checks preserve timestamp order and can abort stale operations. Locking instead uses ownership compatibility, optimistic control validates private work and shadow paging concerns recovery page maps. Only C names the start-time ordering technique described.

Why each choice is right or wrong

A - Incorrect: Locking uses lock compatibility and protocols rather than being defined by transaction start-time ordering.

B - Incorrect: Optimistic control validates private read/write sets rather than applying these timestamp-order tests.

C - Correct: Timestamp-based control orders valid conflicting operations using transaction timestamps.

D - Incorrect: Shadow paging preserves committed page maps for recovery rather than ordering concurrent operations.

Primary note proof

Study-note section ADB15

> Assign each transaction TS(T). For item X track read_TS(X), the largest timestamp of a successful reader, and write_TS(X), that of its latest successful writer. A read by T aborts if TS(T)<write_TS(X); otherwise it succeeds and updates read_TS. A write aborts if TS(T)<read_TS(X) or TS(T)<write_TS(X); otherwise it succeeds and sets write_TS. These tests preserve timestamp order.

Study-note section ADB16

> Optimistic/validation control reads and computes privately, validates its read/write sets against overlapping transactions, then publishes if validation succeeds; otherwise it retries.

Study-note section ADB29

> Shadow/copy-on-write update writes a new location while preserving the committed version.

Related reading (context, not primary note proof)

Study-note section ADB11

Question sources

Advanced Database Systems review questions · Question 17

Question 201 | NS0123

Optimistic Concurrency Control (OCC) is best suited for:

A. High-conflict write-heavy workloads

B. Read-heavy workloads where conflicts are rare

C. Single-user database systems

D. Distributed transactions only

Hint

Consider conflicts, private work and validation costs, or lock-management overhead.

Answer B: Read-heavy, low-conflict workloads.

ADB16 computes privately, validates and publishes, retrying failed validation. Low-conflict workloads let most work succeed; high write contention wastes computation on aborts. B states that criterion explicitly. Single-user systems do not need intertransaction conflict control, and OCC is not restricted to distributed transactions. Actual conflict frequency matters more than the read-heavy label alone.

Why each choice is right or wrong

A - Incorrect: High conflicts cause validation failures and repeated wasted work.

B - Correct: Rare conflicts allow optimistic private work to validate successfully with few retries.

C - Incorrect: A single-user setting lacks the concurrent conflict problem motivating this choice.

D - Incorrect: Optimistic control is not limited to distributed transaction environments.

Primary note proof

Study-note section ADB16

> Optimistic/validation control reads and computes privately, validates its read/write sets against overlapping transactions, then publishes if validation succeeds; otherwise it retries. It works well when conflicts are uncommon, but high contention wastes work on aborts. Multiversion control keeps versions so a reader can use an appropriate snapshot. Snapshot isolation is not automatically serializable: concurrent writes to different rows can violate a shared invariant.

Question sources

Advanced Database Systems review questions · Question 18

Question 202 | NS0124

Deadlock occurs when:

A. One transaction waits for a resource held by no one

B. Two or more transactions each wait for resources held by the other in a circular chain

C. A transaction commits too slowly

D. Multiple transactions read identical data

Hint

Distinguish a waiting cycle, a long wait and indefinite unfair postponement.

Answer B: A circular resource-wait chain.

ADB13 requires a waiting cycle: participants hold resources needed by others and cannot make progress without a victim release or another intervention. Waiting for an unheld resource does not state such a cycle. Slow commit and simultaneous reads can occur without deadlock; compatible shared readers in particular need not block one another.

Why each choice is right or wrong

A - Incorrect: A resource held by no one does not create the stated circular hold-and-wait dependency.

B - Correct: Each participant waits for another holder in a cycle, preventing independent progress.

C - Incorrect: A slow commit may still progress and need not form a waiting cycle.

D - Incorrect: Compatible shared reads of the same data do not inherently deadlock.

Primary note proof

Study-note section ADB13

> Deadlock requires a waiting cycle: T1 holds X and wants Y; T2 holds Y and wants X. In a wait-for graph, an edge Ti→Tj means Ti waits for a lock held by Tj. A cycle indicates deadlock under the ordinary lock-wait model. Abort a suitable victim, undo its effects and release its locks; repeat if other cycles remain. Aborting every deadlocked transaction also breaks cycles but wastes more work.

Study-note section ADB13

> A timeout aborts long waits but may mistake slow progress for deadlock.

Study-note section ADB11

> No double-locking is not a prohibition on shared readers.

Question sources

Advanced Database Systems review questions · Question 19

Question 203 | NS0125

In the Wait-Die protocol, when a YOUNGER transaction requests a resource held by an OLDER transaction:

A. The younger transaction dies (aborts)

B. The older transaction dies

C. The younger transaction waits

D. Both transactions abort

Hint

Identify requester and holder ages before applying the protocol's action.

Answer A: The younger requester aborts.

The requester is younger and the holder older. ADB14 makes that requester die in wait-die; only an older requester may wait for a younger holder. On retry the aborted transaction retains its original timestamp. Wounding a holder belongs to a different protocol, and both participants need not be aborted.

Why each choice is right or wrong

A - Correct: Wait-die aborts the younger requester when the needed resource is held by an older transaction.

B - Incorrect: The older holder keeps its resource; this protocol does not kill it for a younger requester.

C - Incorrect: Waiting is allowed for an older requester facing a younger holder, not this case.

D - Incorrect: The policy aborts the younger requester, not both participants.

Primary note proof

Study-note section ADB14

> A smaller timestamp means an older transaction. In wait-die, an older requester may wait for a younger holder; a younger requester needing an older holder aborts itself. In wound-wait, an older requester aborts the younger holder; a younger requester waits for the older holder. Always identify requester versus holder before applying the names.

Study-note section ADB14

> Retain the original timestamp when restarting an aborted transaction so it gains relative priority as new transactions arrive.

Study-note section ADB14

> In wait-die, an older transaction may wait for a younger one; a younger transaction requesting a resource held by an older one aborts.

Question sources

Advanced Database Systems review questions · Question 20

Question 204 | NS0126

In the Wound-Wait protocol, when an OLDER transaction requests a resource held by a YOUNGER transaction:

A. The older transaction waits

B. The younger is wounded (aborted), allowing the older to proceed

C. Both transactions are aborted

D. A new transaction takes over

Hint

Identify requester and holder ages before applying the protocol's action.

Answer B: Abort the younger holder so the older requester can proceed.

ADB14 says an older requester wounds a younger holder, while a younger requester waits. B is therefore the rule for the given ages. The protocol uses priority to prevent cycles rather than arbitrarily aborting both or handing the work to a new transaction. Any retry should preserve the original timestamp to reduce starvation.

Why each choice is right or wrong

A - Incorrect: An older requester wounds the younger holder rather than waiting under this policy.

B - Correct: The younger holder is aborted, releasing the resource for the older requester.

C - Incorrect: Aborting both is unnecessary and is not the wound-wait rule.

D - Incorrect: No replacement transaction takes over; the older requester continues after the conflicting holder releases.

Primary note proof

Study-note section ADB14

> A smaller timestamp means an older transaction. In wait-die, an older requester may wait for a younger holder; a younger requester needing an older holder aborts itself. In wound-wait, an older requester aborts the younger holder; a younger requester waits for the older holder. Always identify requester versus holder before applying the names.

Study-note section ADB14

> Retain the original timestamp when restarting an aborted transaction so it gains relative priority as new transactions arrive.

Study-note section ADB14

> In wait-die, an older transaction may wait for a younger one; a younger transaction requesting a resource held by an older one aborts.

Question sources

Advanced Database Systems review questions · Question 21

Question 205 | NS0127

Lock Timeout as a deadlock solution works by:

A. Building and analyzing wait-for graphs

B. Aborting any transaction that waits longer than a specified time limit

C. Locking all items before a transaction starts

D. Assigning age-based priorities

Hint

Distinguish a waiting cycle, a long wait and indefinite unfair postponement.

Answer B: Abort a transaction whose wait exceeds the configured limit.

ADB13 defines timeout by excessive wait duration and warns it can mistake slow progress for deadlock. B matches that mechanism. Wait-for graphs detect cycles, conservative locking obtains all locks before execution and age priorities define wait-die/wound-wait decisions. Those are distinct policies rather than implementations of a time limit.

Why each choice is right or wrong

A - Incorrect: Graph analysis detects cycles rather than deciding from elapsed lock-wait time.

B - Correct: Timeout aborts a waiting transaction after its configured wait limit is exceeded.

C - Incorrect: Preacquiring all locks is conservative locking rather than timeout handling.

D - Incorrect: Age-based priorities define other prevention policies, not an elapsed-wait threshold.

Primary note proof

Study-note section ADB13

> Deadlock requires a waiting cycle: T1 holds X and wants Y; T2 holds Y and wants X. In a wait-for graph, an edge Ti→Tj means Ti waits for a lock held by Tj. A cycle indicates deadlock under the ordinary lock-wait model. Abort a suitable victim, undo its effects and release its locks; repeat if other cycles remain. Aborting every deadlocked transaction also breaks cycles but wastes more work.

Study-note section ADB13

> A timeout aborts long waits but may mistake slow progress for deadlock.

Study-note section ADB12

> Conservative/static 2PL obtains all needed locks before execution and does not begin while only a subset is available, preventing hold-and-wait deadlock.

Related reading (context, not primary note proof)

Study-note section ADB14

Question sources

Advanced Database Systems review questions · Question 22

Question 206 | NS0128

A schedule is serializable if:

A. All transactions execute one after another with no overlap

B. Its concurrent execution produces the same result as some serial execution of those transactions

C. All transactions commit at the same time

D. No two transactions access the same table

Hint

Distinguish transaction ordering, conflict conditions and full execution equivalence.

Answer B: Equivalent behavior to some serial execution, even if interleaved.

ADB09 defines a serializable schedule as equivalent to a serial order while permitting interleaving. B matches when same result means the required full transaction equivalence, not an accidental equality of one final value. A describes a serial schedule, which is a special case but not the general definition. Commit simultaneity and disjoint tables are not required.

Why each choice is right or wrong

A - Incorrect: This defines serial execution, a stricter special case that omits permitted serializable interleavings.

B - Correct: Serializable behavior is equivalent to some serial ordering; coincidental equality of one value alone is insufficient.

C - Incorrect: Simultaneous commits do not establish the required transaction-execution equivalence.

D - Incorrect: Serializable transactions may access the same tables if their operations are correctly ordered.

Primary note proof

Study-note section ADB09

> A serial schedule executes each transaction's operations consecutively. A serializable schedule is equivalent to some serial order; it may interleave transactions. Equality of one final value is insufficient evidence because different executions can accidentally coincide. Two operations conflict when they belong to different transactions, access the same item and at least one writes. Read/read pairs do not conflict.

Question sources

Advanced Database Systems review questions · Question 23

Question 207 | NS0129

Lock Upgrade refers to:

A. Releasing an exclusive lock to a shared lock

B. Converting a shared (read) lock to an exclusive (write) lock

C. Removing all locks at commit

D. Granting a lock to multiple transactions

Hint

Compare access permissions and same-item compatibility before granting a lock request.

Answer B: Convert Shared to Exclusive.

ADB11 identifies S→X as an upgrade, possible only after incompatible other holders leave. It strengthens an existing read lock to permit writing. X→S is a downgrade, releasing all locks is transaction cleanup and granting compatible readers is shared acquisition. Only B names the requested conversion of a held lock.

Why each choice is right or wrong

A - Incorrect: Exclusive-to-shared is a downgrade rather than an upgrade.

B - Correct: Shared-to-exclusive strengthens the lock to permit writing when compatibility allows.

C - Incorrect: Removing locks is release rather than conversion to a stronger mode.

D - Incorrect: Granting compatible shared readers is not the upgrade of one existing lock.

Primary note proof

Study-note section ADB11

> A transaction must own the appropriate lock before access and can release only its own locks. S→X is an upgrade, possible only after conflicting other holders leave. X→S is a downgrade. The lock manager decides requests; the lock table stores granted locks and waiting requests. One transaction may request a lock on an already locked item: it is granted if compatible, otherwise waits or aborts under the policy. No double-locking is not a prohibition on shared readers.

Question sources

Advanced Database Systems review questions · Question 24

Question 208 | NS0130

Starvation in concurrency control means:

A. A transaction holding too many locks

B. A transaction is perpetually delayed and never executes due to other transactions always taking priority

C. The database runs out of storage space

D. A transaction commits before completing all operations

Hint

Distinguish a waiting cycle, a long wait and indefinite unfair postponement.

Answer B: Indefinite postponement caused by repeated priority to other work.

ADB13 defines starvation as indefinite postponement while other transactions progress, without requiring a deadlock cycle. B states that repeated bypass precisely. Holding many locks can create contention but does not itself prove starvation. Storage exhaustion and premature commit are different failures, so neither supplies the scheduling-fairness definition.

Why each choice is right or wrong

A - Incorrect: Holding many locks describes resource use rather than being perpetually denied execution.

B - Correct: Repeated priority to others can indefinitely postpone the transaction while other work continues.

C - Incorrect: Running out of storage is a capacity failure rather than the defined scheduling starvation.

D - Incorrect: Premature commit concerns transaction correctness rather than indefinite postponement.

Primary note proof

Study-note section ADB13

> Fixed resource ordering and conservative 2PL prevent cycles. A no-wait policy aborts immediately on an incompatible lock request and needs no age timestamp. A timeout aborts long waits but may mistake slow progress for deadlock. Starvation is indefinite postponement while other work proceeds, without a required cycle. Fair queues, sensible victim selection and retaining original transaction timestamps on retry reduce starvation; deadlock freedom alone does not prove fairness.

Question sources

Advanced Database Systems review questions · Question 25

Question 209 | NS0131

The first step in SQL query processing is:

A. Optimization

B. Evaluation

C. Parsing and Translation

D. Result Delivery

Hint

Separate query representation, strategy selection and execution.

Answer C: Parsing and translation.

ADB17 first checks syntax and semantics and constructs a logical query representation, before optimization and evaluation. C groups those initial activities. Result delivery follows execution, while optimization needs an understood query to compare valid plans. The phase grouping is conventional, but the ordering dependency is explicit in the complete note.

Why each choice is right or wrong

A - Incorrect: Optimization follows understanding and representing the query rather than preceding it.

B - Incorrect: Evaluation executes a selected plan and is not the first processing activity.

C - Correct: Parsing/translation establishes query meaning and logical representation before optimization.

D - Incorrect: Results can be delivered only after the required evaluation produces them.

Primary note proof

Study-note section ADB17

> Parsing checks SQL grammar; semantic analysis resolves names, types and access permissions. Translation constructs a logical representation, typically relational algebra or a logical query tree. Optimization chooses equivalent operations, join order and physical access methods. Evaluation executes that plan and returns results. Not every implementation exposes exactly the same phase boundaries.

Study-note section ADB17

> Query processing is the whole activity; selecting a suitable efficient strategy is optimization.

Study-note section ADB17

> DDL is not a mandatory stage before each SELECT, so authentication→DDL→DML permutations do not describe the processing sequence.

Question sources

Advanced Database Systems review questions · Question 26

Question 210 | NS0132

SQL queries are internally translated into:

A. Machine code

B. Relational algebra

C. Python scripts

D. XML documents

Hint

Separate query representation, strategy selection and execution.

Answer B: Relational algebra.

ADB17 translates a query into relational algebra or a logical query tree for equivalent rewrites and plan selection. B names that logical representation. A particular engine may later compile execution code, but machine code, Python scripts and XML documents are not the general logical translation target taught here. Logical meaning precedes implementation-specific execution choices.

Why each choice is right or wrong

A - Incorrect: Machine code may be an implementation detail but is not the stated logical translation target.

B - Correct: Relational algebra represents the logical operations used for rewriting and planning.

C - Incorrect: Python scripts are not the general internal representation specified here.

D - Incorrect: XML documents are not the defined general relational query representation.

Primary note proof

Study-note section ADB17

> Parsing checks SQL grammar; semantic analysis resolves names, types and access permissions. Translation constructs a logical representation, typically relational algebra or a logical query tree. Optimization chooses equivalent operations, join order and physical access methods. Evaluation executes that plan and returns results. Not every implementation exposes exactly the same phase boundaries.

Study-note section ADB17

> A physical execution plan adds scan/index choices and algorithms.

Study-note section ADB17

> A query tree has base relations at leaves and operators at internal nodes; a query graph emphasizes relations and predicates.

Question sources

Advanced Database Systems review questions · Question 27

Question 211 | NS0133

What does query optimization aim to minimize?

A. The number of tables referenced

B. The overall cost (time and resources) of executing the query

C. The number of join operations

D. The character length of the SQL query

Hint

Identify the resource objective, counts and unit costs before comparing execution strategies.

Answer B: Overall execution cost under the chosen resource model.

ADB19 measures candidate plans using I/O, CPU, memory, temporary storage and network traffic. The aim is a suitable low-cost equivalent plan, not syntactic brevity or indiscriminate removal of joins and tables. Required tables and semantics must be preserved; even fewer operations do not necessarily imply lower runtime or resource cost.

Why each choice is right or wrong

A - Incorrect: Required tables cannot be discarded merely to reduce the table count.

B - Correct: Optimization compares equivalent plans using estimated time and resource costs.

C - Incorrect: Join count alone ignores access paths, cardinalities and the cost of each join.

D - Incorrect: Short SQL text does not necessarily produce a cheaper execution plan.

Primary note proof

Study-note section ADB19

> A cost model estimates resources for a candidate plan: page I/O, CPU, memory, temporary storage and network traffic. Catalog statistics include row/page counts, distinct values and distributions. Selection with fraction s predicts s×N rows. For non-NULL equijoin keys, a common estimate is $|R|\times|S|/\max(V(R,k),V(S,k))$, assuming uniform values and containment of the smaller distinct-value domain within the larger. Adjust counts for NULLs; if either non-NULL input is empty, the result is zero. Skew, correlations or incomplete domain overlap can invalidate this estimate; known disjoint domains give zero matches.

Study-note section ADB19

> Disk I/O often dominates textbook local-disk examples; CPU can dominate in-memory work and network can dominate distributed plans.

Study-note section ADB19

> For a simple rotating-disk model, cost = seeks×seek_time + transferred_blocks×block_transfer_time.

Question sources

Advanced Database Systems review questions · Question 28

Question 212 | NS0134

The dominant cost factor in query execution is typically:

A. CPU processing time

B. Network transmission time

C. Disk I/O time (seek + transfer)

D. Memory allocation time

Hint

Identify the resource objective, counts and unit costs before comparing execution strategies.

Answer C: Disk I/O in the conventional local-disk query-cost model.

ADB19 says disk I/O often dominates textbook local-disk examples, matching the question's typical teaching model. C includes both seek and transfer work. This is a contextual tendency, not a universal claim: CPU can dominate in-memory work and communication can dominate distributed plans. The answer should retain that local-disk qualification rather than extend it to every system.

Why each choice is right or wrong

A - Incorrect: CPU can dominate in-memory work but is not the typical local-disk-model answer.

B - Incorrect: Network cost can dominate distributed plans rather than the conventional local-disk model.

C - Correct: Seek and transfer I/O often dominate the conventional disk-based cost model.

D - Incorrect: Memory allocation is not the dominant term specified for the textbook local-disk model.

Primary note proof

Study-note section ADB19

> For a simple rotating-disk model, cost = seeks×seek_time + transferred_blocks×block_transfer_time. Five seeks at 5 ms plus ten blocks at 1 ms cost 35 ms. Disk I/O often dominates textbook local-disk examples; CPU can dominate in-memory work and network can dominate distributed plans. State the assumed cost objective before ranking strategies.

Question sources

Advanced Database Systems review questions · Question 29

Question 213 | NS0135

If a query requires 5 seeks (tS=5ms each) and transfers 10 blocks (tT=1ms each), what is the disk I/O cost?

A. 50ms

B. 35ms

C. 15ms

D. 25ms

Hint

Identify the resource objective, counts and unit costs before comparing execution strategies.

Answer B: 35 ms.

ADB19 adds seeks times seek duration to blocks times per-block transfer duration. Five seeks cost 5×5=25 ms and ten block transfers cost 10×1=10 ms. Their sum is 35 ms. The terms must be added, not multiplied together or considered separately; this is the supplied simple disk model rather than a measured universal query runtime.

Why each choice is right or wrong

A - Incorrect: Fifty does not equal the sum of 25 ms seeking and 10 ms transfer.

B - Correct: Five times five plus ten times one gives 35 ms.

C - Incorrect: Fifteen omits the correct five-seek multiplication.

D - Incorrect: Twenty-five counts only seek time and omits ten milliseconds of transfer.

Primary note proof

Study-note section ADB19

> For a simple rotating-disk model, cost = seeks×seek_time + transferred_blocks×block_transfer_time. Five seeks at 5 ms plus ten blocks at 1 ms cost 35 ms. Disk I/O often dominates textbook local-disk examples; CPU can dominate in-memory work and network can dominate distributed plans. State the assumed cost objective before ranking strategies.

Question sources

Advanced Database Systems review questions · Question 30

Question 214 | NS0136

Database recovery restores the database after failure to:

A. Its state at database creation

B. A consistent and correct state, undoing incomplete transactions and reapplying committed ones

C. The state at the last user login

D. An empty state for fresh start

Hint

Identify what failed, what durable resources survive and which restoration action is required.

Answer B: A valid recovered state preserving durable commits and removing incomplete effects.

ADB26 defines restart recovery by preserving durable commits and removing incomplete effects after failure. B matches the simple undo/redo teaching model. The detailed work depends on buffer policy and algorithm; not every committed update needs physical redo if already installed. Recovery does not reset the database to creation, last login or an empty replacement state.

Why each choice is right or wrong

A - Incorrect: Returning to creation would discard legitimate later durable commits.

B - Correct: Recovery preserves committed work and removes incomplete effects to restore valid state.

C - Incorrect: User login time is not the transaction recovery boundary.

D - Incorrect: Emptying the database would destroy committed data rather than recover it.

Primary note proof

Study-note section ADB26

> Transaction failures include invalid operations, constraint violations and concurrency-control aborts. Enforcing concurrency can deliberately abort work; it does not prevent every transaction failure. A system crash loses volatile memory while disks may survive. Media failure damages persistent storage and normally requires restoring a backup, then replaying available archived logs. Human mistakes may require point-in-time restoration before the bad committed operation.

Study-note section ADB26

> Restart recovery restores a valid database after a crash while preserving durable commits and removing incomplete effects.

Study-note section ADB27

> In a simple undo/redo teaching model, undo losers and redo winners.

Question sources

Advanced Database Systems review questions · Question 31

Question 215 | NS0137

Which type of failure occurs when DBMS software bugs cause unexpected behavior?

A. Hardware Failure

B. Natural Disaster

C. Software Error

D. Network Failure

Hint

Classify the stated cause rather than inferring it from the observed symptom.

Answer C: Software error.

The stem directly identifies DBMS software bugs as the cause. That is a software error rather than failed hardware, a natural event or broken communication. ADB26 separates transaction/system/media failure concerns so the recovery resource can be chosen appropriately; an observed crash alone would not identify its cause, but this question explicitly supplies it.

Why each choice is right or wrong

A - Incorrect: The stated cause is faulty software behavior rather than a malfunctioning hardware component.

B - Incorrect: No natural event is described; the prompt names a software bug.

C - Correct: Unexpected behavior caused by DBMS bugs is a software error.

D - Incorrect: No failed network connection is given as the cause of the behavior.

Primary note proof

Study-note section ADB-S05

> A software failure originates in erroneous program behavior, such as a logical programming defect, invalid operation or operating-system fault. A hardware failure originates in malfunctioning physical equipment; loss of disk contents is media failure. An accidental user deletion is human error even if the software executes the requested command correctly. Physical catastrophes such as fire can also cause failure. The observed symptom of a crash does not alone identify which cause occurred.

Study-note section ADB26

> Generic recovery-manager terminology should not be mistaken for an exact MySQL component specification.

Study-note section ADB26

Enforcing concurrency can deliberately abort work; it does not prevent every transaction failure.

Question sources

Advanced Database Systems review questions · Question 32

Question 216 | NS0138

What does WAL require? In B, 'corresponding data changes' specifically means durable output of the changed data page; volatile buffer changes may occur earlier.

A. Data written to disk before the log record

B. Log records written to stable storage BEFORE corresponding data changes

C. Logs written only after transaction commits

D. Checkpoints before every write operation

Hint

Track durable-write ordering and distinguish reversing incomplete work from installing logged effects.

Answer B: B. Log records written to stable storage BEFORE corresponding data changes

The update log needed for recovery must be stable before the changed data page becomes persistent. B states that order under the question's explicit durable-write meaning. The buffer can be modified earlier. Data-before-log reverses the rule, waiting until after commit is not the required logging policy and checkpointing before every write is not a WAL requirement.

Why each choice is right or wrong

A - Incorrect: The durable log must precede the changed page, not follow it.

B - Correct: With the stated scope, stable logs precede corresponding durable page output.

C - Incorrect: Update logging is not deferred until after commit.

D - Incorrect: WAL does not require a checkpoint for every write.

Primary note proof

Study-note section ADB27

> Write-ahead logging requires the update log needed for recovery to reach stable storage before the corresponding changed data page reaches disk. To acknowledge a durable commit, force the transaction's required log records, including its commit record, to stable storage. A buffer can be changed before that log flush; WAL orders durable writes, not every CPU assignment.

Study-note section ADB27

> Setting X to its logged after-value is idempotent; blindly replaying X=X+10 twice is not.

Study-note section ADB27

> Redo installs logged after-images when necessary, usually forward.

Question sources

Advanced Database Systems review questions · Question 33

Question 217 | NS0139

The Redo operation during recovery:

A. Reverses incomplete transactions

B. Re-applies committed transactions whose changes were not yet persisted to disk

C. Creates new checkpoints

D. Locks data items during the recovery process

Hint

Track durable-write ordering and distinguish reversing incomplete work from installing logged effects.

Answer B: Reapply missing logged committed effects in the simple undo/redo model.

ADB27 uses redo to install logged after-images when necessary. B describes preserving committed work missing from disk pages in the simple teaching model. It does not mean re-running application side effects or blindly adding an amount twice. ARIES has a broader repeat-history phase before undo, but that does not make reversal, checkpoint creation or lock acquisition the definition of redo.

Why each choice is right or wrong

A - Incorrect: Reversing incomplete changes is undo rather than redo.

B - Correct: Redo installs required logged effects missing from data pages, preserving committed work in the simple model.

C - Incorrect: Checkpoint creation records recovery state rather than reapplying update after-images.

D - Incorrect: Locking may coordinate access but is not the operation of logged redo.

Primary note proof

Study-note section ADB27

> Undo restores before-images of incomplete effects, usually traversing that transaction's updates backward. Redo installs logged after-images when necessary, usually forward. Setting X to its logged after-value is idempotent; blindly replaying X=X+10 twice is not. In a simple undo/redo teaching model, undo losers and redo winners. ARIES has a different redo phase that repeats history before undoing losers.

Study-note section ADB30

> In a simple quiescent/checkpoint exercise, specified flushing may make earlier committed work unnecessary to redo.

Study-note section ADB30

> Recovery may start analysis at the checkpoint but redo from an earlier required log position.

Related reading (context, not primary note proof)

Study-note section ADB11

Question sources

Advanced Database Systems review questions · Question 34

Question 218 | NS0140

The Undo operation during recovery:

A. Re-applies committed transactions

B. Reverses changes of incomplete/aborted transactions using before-images from the log

C. Writes the WAL to stable storage

D. Creates shadow page copies

Hint

Track durable-write ordering and distinguish reversing incomplete work from installing logged effects.

Answer B: Restore before-images of incomplete or aborted work.

ADB27 restores before-images when undoing incomplete effects, normally following that transaction's updates backward. B states both the affected work and the supporting log information. Applying committed after-images is redo, forcing logs is a WAL durability action, and copying pages is part of a different update/recovery approach. None is the reversal operation itself.

Why each choice is right or wrong

A - Incorrect: Reapplying committed effects is the redo purpose in the simple model.

B - Correct: Undo restores logged old values to remove incomplete or aborted transaction effects.

C - Incorrect: Forcing the log supports durable ordering but does not itself reverse data changes.

D - Incorrect: Shadow-page copies preserve versions instead of defining logged before-image undo.

Primary note proof

Study-note section ADB27

> Undo restores before-images of incomplete effects, usually traversing that transaction's updates backward. Redo installs logged after-images when necessary, usually forward. Setting X to its logged after-value is idempotent; blindly replaying X=X+10 twice is not. In a simple undo/redo teaching model, undo losers and redo winners. ARIES has a different redo phase that repeats history before undoing losers.

Study-note section ADB29

It is an alternative to conventional log-based recovery, with allocation, fragmentation and concurrency costs; it is not primarily a special action done only during recovery.

Study-note section ADB29

Shadow/copy-on-write update writes a new location while preserving the committed version.

Question sources

Advanced Database Systems review questions · Question 35

Question 219 | NS0141

Shadow Paging recovery technique works by:

A. Using timestamps to sequence recovery

B. Writing changes to shadow (copy) pages, keeping originals intact, then swapping on commit

C. Using transaction logs for all rollbacks

D. Taking checkpoints every transaction

Hint

Separate update timing from update location and follow the commit boundary.

Answer B: Copy changed pages and atomically install the new durable map on commit.

ADB29 keeps the committed page map unchanged while modifications use new locations and a modified map. Commit durably installs the new root/map pointer after required pages are durable. B captures that preservation-and-switch mechanism. Timestamp ordering, mandatory per-transaction checkpoints and universal log-based rollback are not the defining shadow-paging steps.

Why each choice is right or wrong

A - Incorrect: Timestamp ordering controls concurrent operations rather than defining shadow page-map replacement.

B - Correct: Copy-on-write preserves originals and commit safely installs the new page map.

C - Incorrect: Shadow paging is an alternative to conventional log-based recovery, not mandatory logged rollback for all changes.

D - Incorrect: A checkpoint every transaction is not the mechanism that preserves the old page map.

Primary note proof

Study-note section ADB29

In-place update overwrites the original location. Shadow/copy-on-write update writes a new location while preserving the committed version. Shadow paging keeps an unchanged committed page map and a modified map; commit durably installs a new root/map pointer atomically after required pages are durable. Before commit, a crash uses the old map. It is an

> alternative to conventional log-based recovery, with allocation, fragmentation and concurrency costs; it is not primarily a special action done only during recovery.

Study-note section ADB30

> Do not assume every transaction before a checkpoint needs no processing.

Study-note section ADB30

> A checkpoint records enough durable recovery state to avoid scanning all old history.

Related reading (context, not primary note proof)

Study-note section ADB15

Question sources

Advanced Database Systems review questions · Question 36

Question 220 | NS0142

A checkpoint in database recovery helps because:

A. It stops all transactions

B. Recovery can start from the checkpoint state rather than processing the entire log from the beginning

C. It creates a full database backup copy

D. It grants exclusive locks to all active transactions

Hint

Identify which history a recovery boundary can safely exclude and whether active work spans it.

Answer B: A checkpoint supplies recovery state that avoids scanning all historical logs from the beginning.

ADB30 uses durable checkpoint state to avoid processing all old history. B describes that benefit if start means entering recovery analysis, not assuming every earlier update is irrelevant. Active transactions can span a checkpoint and fuzzy-checkpoint redo may require earlier log positions. A checkpoint is not a full backup, universal stop or lock grant.

Why each choice is right or wrong

A - Incorrect: Fuzzy checkpoints permit ongoing transactions, so stopping all work is not required.

B - Correct: Recorded recovery state provides a bounded starting point, while earlier necessary undo/redo must still be considered.

C - Incorrect: A checkpoint stores recovery metadata and is not a full separate database backup.

D - Incorrect: Checkpointing does not grant every active transaction exclusive locks.

Primary note proof

Study-note section ADB30

> A checkpoint records enough durable recovery state to avoid scanning all old history. In a simple quiescent/checkpoint exercise, specified flushing may make earlier committed work unnecessary to redo. Active transactions can span the checkpoint, so their relevant earlier updates can still need undo. Do not assume every transaction before a checkpoint needs no processing.

Study-note section ADB30

> Recovery may start analysis at the checkpoint but redo from an earlier required log position.

Study-note section ADB30

> A checkpoint is neither a full backup nor an automatic commit of active transactions.

Related reading (context, not primary note proof)

Study-note section ADB11

Question sources

Advanced Database Systems review questions · Question 37

Question 221 | NS0143

Under conventional deferred update with no-force, which recovery classifications describe the policy? Select all that apply. Interpret NO UNDO / REDO as 'no undo, redo required'.

A. UNDO/REDO

B. UNDO only

C. REDO only

D. NO UNDO / REDO

Hint

Separate update timing from update location and follow the commit boundary.

Answer C, D: C. REDO only; D. NO UNDO / REDO

Because uncommitted changes have not reached the persistent database, crash recovery does not need to undo them there. No-force permits committed changes to remain uninstalled, so redo may be required. REDO only and NO UNDO / REDO express the same classification under the stated notation. Undo-only and undo/redo both assert an undo requirement that this deferred model avoids.

Why each choice is right or wrong

A - Incorrect: Usual deferred update does not require undo of uncommitted persistent database changes.

B - Incorrect: Undo only gives the opposite recovery requirement from the usual deferred no-force model.

C - Correct: REDO only is the usual deferred-update recovery classification.

D - Correct: NO UNDO/REDO is another spelling of the same redo-only requirement.

Primary note proof

Study-note section ADB29

> Deferred update keeps uncommitted changes outside the persistent database; in the usual no-force setting it is NO-UNDO/REDO. Redo-only and NO-UNDO/REDO mean the same thing, so those cannot be separate unique answers. Immediate update allows persistent changes before commit and therefore may require undo; it need not flush every write_item immediately.

Study-note section ADB28

> Force writes a transaction's updated data pages at commit; no-force permits committed dirty pages to remain buffered, hence recovery may need redo.

Study-note section ADB28

> Steal permits a page with uncommitted changes to be written to disk; hence recovery may need undo.

Question sources

Advanced Database Systems review questions · Question 38

Question 222 | NS0144

Which data update strategy writes changes to a SEPARATE disk location preserving the original?

A. Immediate Update

B. Deferred Update

C. Shadow Update

D. In-Place Update

Hint

Separate update timing from update location and follow the commit boundary.

Answer C: Shadow update, or copy-on-write.

ADB29 distinguishes where an update is written from when it may become persistent. Shadow/copy-on-write uses a new location while retaining the committed version, matching C. Immediate and deferred classify commit timing, not necessarily a separate location. In-place update overwrites the original location, which directly contradicts the preservation condition in the stem.

Why each choice is right or wrong

A - Incorrect: Immediate update concerns allowing persistent changes before commit rather than requiring new locations.

B - Incorrect: Deferred update concerns withholding uncommitted persistent effects rather than necessarily copying pages.

C - Correct: Shadow/copy-on-write preserves the original and writes the changed value at a separate location.

D - Incorrect: In-place update overwrites the original location rather than preserving it intact.

Primary note proof

Study-note section ADB29

> In-place update overwrites the original location. Shadow/copy-on-write update writes a new location while preserving the committed version. Shadow paging keeps an unchanged committed page map and a modified map; commit durably installs a new root/map pointer atomically after required pages are durable. Before commit, a crash uses the old map. It is an alternative to conventional log-based recovery, with allocation, fragmentation and concurrency costs; it is not primarily a special action done only during recovery.

Study-note section ADB29

> Immediate update allows persistent changes before commit and therefore may require undo; it need not flush every write_item immediately.

Study-note section ADB29

> Deferred update keeps uncommitted changes outside the persistent database; in the usual no-force setting it is NO-UNDO/REDO.

Question sources

Advanced Database Systems review questions · Question 39

Question 223 | NS0145

In the course's conceptual transaction-log model supporting undo of incomplete changes and redo of committed changes, what value information does a write-operation record store?

A. Only new (after-image) values

B. Only old (before-image) values

C. Both old (before-image) AND new (after-image) values

D. Only transaction IDs and timestamps

Hint

Trace movement between program variables, buffers and disk, or the meaning of a recorded transaction event.

Answer C: C. Both old (before-image) AND new (after-image) values

The given UPDATE record contains both the old and new values. The old value supplies a before-image for undo, while the new value supplies an after-image for redo. Therefore the record stores both kinds of image. Real systems can use other physical or logical formats, but that variation does not alter the explicit conceptual record being examined here.

Why each choice is right or wrong

A - Incorrect: The given format includes old as well as new, so after-images alone are incomplete.

B - Incorrect: The format includes new as well as old, so before-images alone are incomplete.

C - Correct: Both before-image and after-image fields are present.

D - Incorrect: Transaction identifiers alone omit the explicitly supplied value fields.

Primary note proof

Study-note section ADB07

> A conceptual log can contain START, UPDATE(T,X,old,new), COMMIT, ABORT and END records. Before-images support undo; after-images support redo. Real systems may use physical or logical records, and need not log every read. COMMIT records successful completion; an ABORT record can mark the start of rollback rather than prove every undo step is complete.

Study-note section ADB27

> Undo restores before-images of incomplete effects, usually traversing that transaction's updates backward.

Study-note section ADB27

> In a simple undo/redo teaching model, undo losers and redo winners.

Question sources

Advanced Database Systems review questions · Question 40

Question 224 | NS0146

A distributed database is best described as:

A. A single database on one powerful server

B. Multiple logically related databases across networked computers, managed transparently

C. A fully replicated database at every network location

D. A web-based file storage system

Hint

Separate coordinated network placement from engine compatibility and semantic integration.

Answer B: Logically related data across networked sites under coordinated database management.

ADB33 defines logically related data across networked sites managed as a coordinated system. B matches that architecture and its logical abstraction. Full replication is only one placement choice, not a defining requirement. A single powerful server is centralized, and generic web file storage does not establish coordinated database semantics across related distributed data.

Why each choice is right or wrong

A - Incorrect: A database confined to one server is centralized rather than distributed across networked sites.

B - Correct: Networked, logically related data with coordinated management fits the distributed database definition.

C - Incorrect: A distributed database need not replicate every row at every network location.

D - Incorrect: Generic web file storage does not by itself establish coordinated distributed database management.

Primary note proof

Study-note section ADB33

> A distributed database contains logically related data across networked sites, managed as a coordinated system. A homogeneous system uses compatible DBMS technology across sites; a heterogeneous system integrates differing DBMSs, data models, schemas or interfaces. Different operating systems are possible but do not define the distinction. Same DBMS does not imply identical local schemas, automatic replication or immediate synchronization.

Study-note section ADB37

> Full replication does not inherently mean every copy is updated simultaneously; its synchronization rule must be stated.

Study-note section ADB37

> Full replication places the whole database at every relevant site; partial replication copies selected fragments to selected sites; nonredundant allocation stores each fragment once.

Question sources

Advanced Database Systems review questions · Question 41

Question 225 | NS0147

A homogeneous distributed database system requires:

A. Different DBMS at each site

B. Same DBMS software at all sites

C. No network between sites

D. Full independence of each site

Hint

Separate coordinated network placement from engine compatibility and semantic integration.

Answer B: The same compatible DBMS technology at the sites.

ADB33 defines homogeneity through compatible DBMS technology across sites. B is the listed form of that condition. It does not imply identical local schemas, replication or immediate synchronization. Different DBMSs describe heterogeneity, while removing the network or demanding full independence contradicts coordinated distributed management rather than defining homogeneity.

Why each choice is right or wrong

A - Incorrect: Different DBMS technologies characterize heterogeneous integration rather than homogeneity.

B - Correct: The same DBMS software supplies the compatible database technology described by homogeneous systems.

C - Incorrect: Distributed sites need network communication for coordinated management.

D - Incorrect: Full local independence is an autonomy choice rather than a homogeneity requirement.

Primary note proof

Study-note section ADB33

> A distributed database contains logically related data across networked sites, managed as a coordinated system. A homogeneous system uses compatible DBMS technology across sites; a heterogeneous system integrates differing DBMSs, data models, schemas or interfaces. Different operating systems are possible but do not define the distinction. Same DBMS does not imply identical local schemas, automatic replication or immediate synchronization.

Study-note section ADB34

> These describe communication responsibilities, not fragmentation types.

Study-note section ADB34

State how much schema, transaction and administrative autonomy local sites retain.

Question sources

Advanced Database Systems review questions · Question 42

Question 226 | NS0148

Heterogeneous distributed databases use which standards for inter-database communication?

A. Same DBMS software only

B. Direct SQL between databases

C. ODBC and JDBC generic connectivity

D. LAN protocols exclusively

Hint

Separate coordinated network placement from engine compatibility and semantic integration.

Answer C: ODBC and JDBC connectivity interfaces.

ADB33 explicitly names ODBC and JDBC as connectivity interfaces for differing systems. C therefore identifies the offered communication interfaces. They do not automatically reconcile schemas, units or transaction semantics and do not create a distributed transaction by themselves. Identical DBMS software is not heterogeneity, and generic LAN protocols do not replace database-level connectivity interfaces.

Why each choice is right or wrong

A - Incorrect: Requiring the same DBMS removes the differing-engine situation rather than identifying its connectivity interfaces.

B - Incorrect: Direct SQL alone does not identify the generic cross-system connectivity standards named in the note.

C - Correct: ODBC and JDBC provide generic database connectivity while semantic mappings remain necessary.

D - Incorrect: LAN protocols alone do not supply the database API/interface compatibility described.

Primary note proof

Study-note section ADB33

> Heterogeneous design must reconcile naming, types, units, identifiers, query capabilities and transaction semantics. ODBC and JDBC provide connectivity interfaces; they do not automatically solve semantic differences or create one distributed transaction. Locality, expansion and replicated availability are potential benefits. Distribution adds communication, coordination and security costs; a site outage can still make needed data unavailable if no usable replica exists.

Question sources

Advanced Database Systems review questions · Question 43

Question 227 | NS0149

Horizontal fragmentation divides a database table by:

A. Columns (attributes)

B. Rows based on a condition or criterion

C. Both rows and columns simultaneously

D. Database schemas

Hint

Identify whether rows or columns are split and reverse the split to reconstruct the original relation.

Answer B: Rows selected by conditions.

ADB36 defines horizontal fragmentation by selecting row subsets with predicates. B directly states that operation. Column division is vertical fragmentation, and combining both dimensions is hybrid fragmentation. Schema names and geographic placement can influence a design, but are not the definition of what is split by horizontal fragmentation.

Why each choice is right or wrong

A - Incorrect: Splitting attributes is vertical rather than horizontal fragmentation.

B - Correct: Horizontal fragmentation partitions rows according to stated predicates or criteria.

C - Incorrect: Splitting both dimensions combines horizontal and vertical operations in hybrid fragmentation.

D - Incorrect: Schemas are not the row units divided by the defined horizontal operation.

Primary note proof

Study-note section ADB36

> Horizontal fragmentation selects row subsets by predicates; their union reconstructs the relation. Check completeness so every original row is represented and disjointness if no overlap is intended. Define an explicit fragment for NULL/other values when needed. Vertical fragmentation projects column subsets and repeats a key or row identifier so joining on it reconstructs the original rows without spurious matches.

Study-note section ADB36

> Hybrid fragmentation combines row and column splits in either suitable order.

Study-note section ADB36

> Reconstruct by reversing the operations: key joins for corresponding vertical pieces and unions for horizontal pieces.

Question sources

Advanced Database Systems review questions · Question 44

Question 228 | NS0150

To reconstruct a horizontally fragmented table, which operation is used?

A. JOIN

B. UNION

C. INTERSECTION

D. DIFFERENCE

Hint

Identify whether rows or columns are split and reverse the split to reconstruct the original relation.

Answer B: UNION.

Horizontal fragments contain selected subsets of the original relation's rows. ADB36 reconstructs the relation by their union, assuming completeness and the intended overlap rules. Joining is used to align vertical column pieces by a key; intersection would keep only shared rows and difference would remove rows, so neither reconstructs all horizontal fragments.

Why each choice is right or wrong

A - Incorrect: Key joins reconstruct matching vertical column pieces, not ordinary horizontal row partitions.

B - Correct: Union collects the rows from every complete horizontal fragment.

C - Incorrect: Intersection keeps only common rows and would discard rows unique to individual fragments.

D - Incorrect: Difference removes rows instead of recombining all fragment members.

Primary note proof

Study-note section ADB36

> Horizontal fragmentation selects row subsets by predicates; their union reconstructs the relation. Check completeness so every original row is represented and disjointness if no overlap is intended. Define an explicit fragment for NULL/other values when needed. Vertical fragmentation projects column subsets and repeats a key or row identifier so joining on it reconstructs the original rows without spurious matches.

Study-note section ADB36

> Reconstruct by reversing the operations: key joins for corresponding vertical pieces and unions for horizontal pieces.

Study-note section ADB-S01

> A relation is represented by a table of tuples.

Question sources

Advanced Database Systems review questions · Question 45

Question 229 | NS0151

Vertical fragmentation divides a table by:

A. Rows

B. Columns (attributes), with primary key repeated in each fragment

C. Number of concurrent transactions

D. Geographic location of data

Hint

Identify whether rows or columns are split and reverse the split to reconstruct the original relation.

Answer B: Column subsets with a repeated key or row identifier.

ADB36 splits a relation by columns and repeats a key or row identifier so the pieces can be joined without spurious matches. B describes that usual primary-key form. Rows are split horizontally; transaction counts and geography concern workload or placement rather than the attribute-level split defining vertical fragmentation. The shared identifier can be an appropriate equivalent key.

Why each choice is right or wrong

A - Incorrect: Row subsets define horizontal rather than vertical fragmentation.

B - Correct: Vertical fragments contain column subsets plus a repeated identifier for reconstruction.

C - Incorrect: Concurrent transaction count is a workload property rather than the dimension being split.

D - Incorrect: Geographic placement does not define the column projection used for vertical fragments.

Primary note proof

Study-note section ADB36

> Horizontal fragmentation selects row subsets by predicates; their union reconstructs the relation. Check completeness so every original row is represented and disjointness if no overlap is intended. Define an explicit fragment for NULL/other values when needed. Vertical fragmentation projects column subsets and repeats a key or row identifier so joining on it reconstructs the original rows without spurious matches.

Study-note section ADB36

> Hybrid fragmentation combines row and column splits in either suitable order.

Study-note section ADB36

> Reconstruct by reversing the operations: key joins for corresponding vertical pieces and unions for horizontal pieces.

Question sources

Advanced Database Systems review questions · Question 46

Question 230 | NS0152

Full replication in distributed databases has which disadvantage?

A. Low data availability

B. Every update must be applied to all copies, creating high overhead

C. Fast read performance

D. Simple concurrency control

Hint

Separate copy placement, propagation timing and update-maintenance cost.

Answer B: Propagating each update across all copies adds maintenance overhead.

ADB37 says copies improve locality and can improve availability but require storage and update propagation. B names that maintenance burden for full replication. Propagation timing may be synchronous or asynchronous, so the answer does not imply every copy is updated simultaneously. Fast reads are a possible benefit, and concurrency control becomes more involved rather than inherently simple.

Why each choice is right or wrong

A - Incorrect: Usable replicas can improve availability rather than inherently making it low.

B - Correct: All copies must eventually reflect relevant updates, creating propagation and coordination overhead.

C - Incorrect: Fast reads are a potential benefit rather than the listed disadvantage.

D - Incorrect: Maintaining consistent copies does not inherently simplify concurrency control.

Primary note proof

Study-note section ADB37

> Full replication places the whole database at every relevant site; partial replication copies selected fragments to selected sites; nonredundant allocation stores each fragment once. Copies improve read locality and can improve availability but require storage and update propagation. They can also spread mistakes, so replication does not replace independent backups.

Study-note section ADB37

> Full replication does not inherently mean every copy is updated simultaneously; its synchronization rule must be stated.

Study-note section ADB37

> Lazy/asynchronous replication propagates later and may expose stale reads or need conflict resolution.

Question sources

Advanced Database Systems review questions · Question 47

Question 231 | NS0153

Fragmentation transparency in distributed databases means:

A. Users can see all the fragmentation details

B. Users interact with the database as a single entity, unaware of fragmentation existence

C. Only DBAs know about fragments

D. Fragments are listed as separate tables in the schema

Hint

Identify exactly which detail is hidden from the user.

Answer B: Users query the logical relation without knowing its fragments.

ADB35 defines fragmentation transparency as hiding the existence and reconstruction of fragments. B states that user-facing abstraction directly. It does not require literally only DBAs to know the implementation; developers and administrators may also need that knowledge. Exposing fragment tables or all fragmentation details to users would make fragmentation visible instead of transparent.

Why each choice is right or wrong

A - Incorrect: Showing all fragmentation details is the opposite of hiding them from ordinary queries.

B - Correct: Users operate on the whole logical relation without managing its fragment reconstruction.

C - Incorrect: Transparency describes the user abstraction, not exclusive knowledge restricted to DBAs alone.

D - Incorrect: Naming fragments separately exposes fragmentation rather than concealing it from the querying user.

Primary note proof

Study-note section ADB35

> Location transparency hides which site holds a named object. Fragmentation transparency hides the existence and reconstruction of fragments: users query the whole logical relation. Replication transparency hides which copy is used and how copies are maintained. The broad single-logical-database experience may involve all three.

Study-note section ADB35

> If users explicitly name a fragment but need not specify its site, fragmentation is visible while location can remain transparent.

Study-note section ADB35

> Hiding this column split from queries is fragmentation transparency; the split itself is a data-design operation.

Question sources

Advanced Database Systems review questions · Question 48

Question 232 | NS0154

The Middleware architecture in distributed DBMS uses:

A. Direct client-to-server connections

B. All servers collaborating on every query

C. A dedicated middleware server that mediates between clients and multiple independent database servers

D. A single centralized database server

Hint

Identify which tier submits, mediates or executes a request.

Answer C: Middleware mediates between clients and independent database servers.

ADB34 lets middleware translate requests, locate data, coordinate operations and combine results across independent servers. C describes that mediating tier. The logical responsibility does not require exactly one physical machine in every implementation. Direct connections omit this mediator, universal server collaboration is a different arrangement, and one centralized server is not the stated distributed middleware design.

Why each choice is right or wrong

A - Incorrect: Direct client-server links alone omit the middleware mediation that defines the requested architecture.

B - Incorrect: Every server need not participate in every query; relevant sources depend on the request.

C - Correct: A middleware tier mediates client requests across multiple independent database servers.

D - Incorrect: One centralized database server does not describe mediation across independent distributed servers.

Primary note proof

Study-note section ADB34

> In client/server architecture, clients submit requests while servers manage shared data, execute operations and enforce supported integrity/transaction rules. In collaborating-server designs, servers cooperate on subqueries and transactions. Middleware can translate requests, locate data, coordinate operations and combine results across independent servers. These describe communication responsibilities, not fragmentation types.

Question sources

Advanced Database Systems review questions · Question 49

Question 233 | NS0155

Hybrid fragmentation combines which two techniques?

A. Full replication and no replication

B. Horizontal fragmentation and vertical fragmentation

C. Locking and timestamp-based concurrency control

D. Client-server and middleware architectures

Hint

Identify whether rows or columns are split and reverse the split to reconstruct the original relation.

Answer B: Horizontal and vertical fragmentation.

ADB36 explicitly defines hybrid fragmentation as combining row and column splits in an appropriate order. B names those two operations. Replication changes copy placement, locking and timestamps control concurrent access, and client-server/middleware describe architecture responsibilities. They can coexist with hybrid fragmentation but are not its two component fragmentation techniques.

Why each choice is right or wrong

A - Incorrect: Full/no replication concerns copies rather than the row and column splits of hybrid fragmentation.

B - Correct: Hybrid fragmentation combines horizontal row subsets with vertical column subsets.

C - Incorrect: Locking and timestamps are concurrency-control mechanisms, not fragmentation types.

D - Incorrect: These are architecture forms rather than the two data-fragmentation operations.

Primary note proof

Study-note section ADB36

> Horizontal fragmentation selects row subsets by predicates; their union reconstructs the relation. Check completeness so every original row is represented and disjointness if no overlap is intended. Define an explicit fragment for NULL/other values when needed. Vertical fragmentation projects column subsets and repeats a key or row identifier so joining on it reconstructs the original rows without spurious matches.

Study-note section ADB36

> Hybrid fragmentation combines row and column splits in either suitable order.

Study-note section ADB34

> These describe communication responsibilities, not fragmentation types.

Question sources

Advanced Database Systems review questions · Question 50

Question 234 | NS0286

In client-server database architecture, what is the primary role of the server?

A. Provide the GUI for end users

B. Initiate all network connections and poll clients for updates

C. Store and manage shared data, enforce ACID properties, and process client requests

D. Cache all user sessions locally for offline access

Hint

Identify which tier submits, mediates or executes a request.

Answer C: Manage shared data, process requests and enforce supported transaction/integrity guarantees.

ADB34 assigns clients request submission and servers shared-data management, operation execution and supported integrity/transaction enforcement. C matches those responsibilities. User interfaces usually belong to clients, while initiating all connections, polling every client or caching all sessions for offline use are not the server role defined by this architecture. Guarantees still depend on supported mechanisms and correct application use.

Why each choice is right or wrong

A - Incorrect: The user-facing GUI is normally a client responsibility rather than the database server's primary role.

B - Incorrect: The server need not initiate every connection or poll clients for every update.

C - Correct: Shared-data management, query execution and supported integrity/transaction enforcement are server duties.

D - Incorrect: Caching every session for offline access is not the defined database-server responsibility.

Primary note proof

Study-note section ADB34

> In client/server architecture, clients submit requests while servers manage shared data, execute operations and enforce supported integrity/transaction rules. In collaborating-server designs, servers cooperate on subqueries and transactions. Middleware can translate requests, locate data, coordinate operations and combine results across independent servers. These describe communication responsibilities, not fragmentation types.

Study-note section ADB34

> Calling a system heterogeneous does not require all sites to surrender autonomy or to copy every row everywhere.

Study-note section ADB34

> A tightly integrated distributed system can present one global schema and shared control.

Related reading (context, not primary note proof)

Study-note section ADB06

Question sources

Computer Science Exit Exam · 2018 · Question 3

Question 235 | NS0288

In two-phase locking (2PL), during which phase may a transaction acquire locks but not release any?

A. Growing phase

B. Commit phase

C. Validation phase

D. Shrinking phase

Hint

Track the first lock release and the transaction-completion boundary.

Answer A: Growing phase.

ADB12 allows acquiring or upgrading locks during growing and releasing or downgrading them during shrinking. Once any lock is released, a transaction may not acquire another. A is therefore the phase described. Commit is a transaction event, validation belongs to optimistic control and shrinking has the opposite lock-release role.

Why each choice is right or wrong

A - Correct: Growing permits acquisitions and upgrades before any release starts.

B - Incorrect: Commit is not the general 2PL phase for new lock acquisition.

C - Incorrect: Validation is an optimistic-control stage rather than the 2PL growing phase.

D - Incorrect: Shrinking releases or downgrades locks and forbids acquiring new ones.

Primary note proof

Study-note section ADB12

> Basic 2PL has a growing phase that acquires/upgrades locks and a shrinking phase that releases/downgrades them. Once any lock is released, no new lock may be acquired. The lock point is the instant the final lock is obtained. 2PL guarantees conflict serializability for well-formed transactions, but can deadlock and basic 2PL alone need not prevent cascading aborts.

Study-note section ADB12

> Two-phase locking orders access to data; two-phase commit coordinates a distributed commit decision.

Study-note section ADB16

> Optimistic/validation control reads and computes privately, validates its read/write sets against overlapping transactions, then publishes if validation succeeds; otherwise it retries.

Question sources

Computer Science Exit Exam · 2018 · Question 5

Question 236 | NS0306

Assume that we are able to specify that Mr. Getahun can view the database record, but cannot change the value of the record. Which security management technique was used in this scenario?

A. Access Control

B. Availability

C. Non-repudiation

D. Integrity

Hint

Identify whether the scenario concerns identity, permission, disclosure or valid values.

Answer A: Access control.

ADB24 explicitly describes a user allowed to view but not change a record as having restricted access privileges. That is authorization/access control. Integrity concerns valid values, availability concerns readiness for use and non-repudiation concerns attributable actions rather than whether a particular read or write is permitted. A matches the actual permission distinction.

Why each choice is right or wrong

A - Correct: Access control grants reading while denying modification for the specified user.

B - Incorrect: Availability concerns service readiness rather than the read-versus-write privilege distinction.

C - Incorrect: Non-repudiation does not define whether this user is authorized to modify a record.

D - Incorrect: Integrity restricts valid data states rather than assigning user-specific read/update permissions.

Primary note proof

Study-note section ADB24

> Authentication establishes identity; authorization/access control determines permitted actions. Encryption protects stored or transmitted content; integrity constraints restrict valid data; auditing records actions. A user who can view but cannot change a record has restricted access privileges. A view can restrict visible rows/columns, but its privilege and execution rules must support that restriction.

Study-note section ADB-S03

> Neither property specifies which particular user has permission to change a database row; that is the separate authorization decision.

Study-note section ADB-S03

> Availability concerns keeping services and resources accessible to their authorized users.

Question sources

Computer Science Exit Exam · 2018 · Question 27

Question 237 | NS0307

Suppose, a developer proposes using deferred update with no checkpoints in a high-transaction OLTP system. What is the most serious drawback?

A. Log scans become prohibitively expensive after long uptime

B. Increased disk I/O due to frequent page copying

C. Shared locks cannot be used

D. View serializability cannot be ensured

Hint

Identify which history a recovery boundary can safely exclude and whether active work spans it.

Answer A: Long-running log scans can make recovery expensive.

ADB30 warns that without checkpoints or another valid truncation boundary, a long-running system may scan expensive amounts of log history. Deferred update removes uncommitted persistent effects but does not remove that search problem. Page copying belongs to shadow approaches, while shared locks and serializability are independent concurrency concerns rather than consequences of omitting checkpoints.

Why each choice is right or wrong

A - Correct: High transaction volume and long uptime can produce costly recovery log scans without a valid boundary.

B - Incorrect: Frequent copy-on-write pages characterize shadow updating rather than the absence of checkpoints in deferred update.

C - Incorrect: Omitting checkpoints does not inherently prohibit shared locks.

D - Incorrect: View serializability is a concurrency-order property, not inherently lost by this checkpoint omission.

Primary note proof

Study-note section ADB30

> A checkpoint records enough durable recovery state to avoid scanning all old history. In a simple quiescent/checkpoint exercise, specified flushing may make earlier committed work unnecessary to redo. Active transactions can span the checkpoint, so their relevant earlier updates can still need undo. Do not assume every transaction before a checkpoint needs no processing.

Study-note section ADB30

> Without checkpoints or another valid truncation boundary, long-running systems may need expensive log scans; deferred update does not avoid that problem.

Study-note section ADB29

> Shadow/copy-on-write update writes a new location while preserving the committed version.

Related reading (context, not primary note proof)

Study-note section ADB11

Study-note section ADB09

Question sources

Computer Science Exit Exam · 2018 · Question 28

Question 238 | NS0321

Which listed techniques use transaction logs for recovery under the course model? Interpret Deferred Database Modification as conventional logged deferred update with no-force. Select all that apply.

A. Recovery in Multi-database Systems

B. ARIES Recovery Algorithm

C. Shadow Paging Technique

D. Deferred Database Modification

Hint

Separate update timing from update location and follow the commit boundary.

Answer B, D: B. ARIES Recovery Algorithm; D. Deferred Database Modification

ARIES relies on WAL and log-driven analysis, redo and undo. Conventional logged deferred update also uses recorded updates for redo of committed work, with no undo of uncommitted persistent changes. Both therefore belong to the requested category. Shadow paging preserves old page mappings instead, while recovery in multidatabase systems names an environment rather than a particular log-based technique.

Why each choice is right or wrong

A - Incorrect: Multidatabase recovery describes an environment rather than one specific recovery technique.

B - Correct: ARIES explicitly uses WAL and log-driven analysis, redo and undo.

C - Incorrect: Shadow paging preserves committed page maps rather than being the conventional log-based technique.

D - Correct: Deferred modification can use logged changes for redo after commitment.

Primary note proof

Study-note section ADB29

Deferred update keeps uncommitted changes outside the persistent database; in the usual no-force setting it is NO-UNDO/REDO. Redo-only and NO-UNDO/REDO mean the same thing, so those cannot be separate unique answers. Immediate update allows persistent changes before commit and therefore may require undo; it need not flush every write_item immediately.

Study-note section ADB31

ARIES uses WAL, page log sequence numbers (pageLSN), a transaction table and a dirty-page table.

Study-note section ADB29

It is an alternative to conventional log-based recovery, with allocation, fragmentation and concurrency costs; it is not primarily a special action done only during recovery.

Question sources

Computer Science Exit Exam · 2018 · Question 46

Question 239 | NS0348

Which type of fragmentation divides a relation into subrelations containing subsets of its columns, repeating a key or row identifier so the original rows can be reconstructed?

A. Replication

B. Location

C. Horizontal

D. Vertical

Hint

Identify whether rows or columns are split and reverse the split to reconstruct the original relation.

Answer D: D. Vertical

Vertical fragmentation divides a relation by columns. Repeating a key or row identifier allows corresponding pieces to be joined back into the original rows without spurious matches. Horizontal fragmentation divides rows instead. Replication creates copies, while location transparency hides where data resides. Hiding a column split would be fragmentation transparency, but the question asks for the split operation itself.

Why each choice is right or wrong

A - Incorrect: Replication copies data rather than dividing its columns.

B - Incorrect: Location transparency hides sites rather than splitting a relation.

C - Incorrect: Horizontal fragmentation selects row subsets.

D - Correct: Vertical fragmentation projects column subsets with a reconstruction identifier.

Primary note proof

Study-note section ADB36

> Horizontal fragmentation selects row subsets by predicates; their union reconstructs the relation. Check completeness so every original row is represented and disjointness if no overlap is intended. Define an explicit fragment for NULL/other values when needed. Vertical fragmentation projects column subsets and repeats a key or row identifier so joining on it reconstructs the original rows without spurious matches.

Study-note section ADB35

> Hiding this column split from queries is fragmentation transparency; the split itself is a data-design operation.

Study-note section ADB35

> Replication transparency hides which copy is used and how copies are maintained.

Related reading (context, not primary note proof)

When overloading a function, what must be true?

A. The names should be different with different number and/or types of parameters.

B. None of the choices are correct

C. The names should be different with the same number and/or types of parameters.

D. The names should be the same with different number and/or types of parameters.

E. The names should be the same with the same number and/or types of parameters.

Hint

Compare names and parameter signatures before considering return types or access modifiers.

Answer D: The names should be the same with different number and/or types of parameters.

Overloads retain the method name and change parameter count or parameter types; return type alone cannot distinguish them.

Why each choice is right or wrong

A - Incorrect: Different names do not overload one function

B - Incorrect: D satisfies the overloading rule, so the statement that none of the choices is correct is false.

C - Incorrect: Different names define separate methods

D - Correct: Same name plus different parameter list meets the definition

E - Incorrect: Same name and same parameter signature cannot distinguish overloads

Primary note proof

Study-note section OOP12

> Overloaded methods share a name but have different parameter types, counts or type order. Return type alone is insufficient in Java and C++. Overloads can also arise through inherited methods; “same class only” is a teaching simplification. f(int), f(double) and f(int,int) are distinct, but changing a parameter name does not create an overload.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Object Oriented Programming module | PDF page 11 | lines 7-18

Method Overloading
• Is a process of having the same name for different methods as long as their parameter list or data types in the parameter list is different?
• The return type alone is insufficient to distinguish two versions of a method.
• Parameters are key identifiers of OM.
• Is one of the ways that Java supports polymorphism

Question sources

Mock exam 4 · Question 15

Question 2 | Q00983

Which of the following statement about function overloading is TRUE?

A. Overload function have same name but different parameters/type

B. Overload function is not supported

C. .
Overload function must have different return type

D. Overload function must have the same number of parameters

Hint

Compare names and parameter signatures before considering return types or access modifiers.

Answer A: Overload function have same name but different parameters/type

The test examples vary both argument counts and types while retaining test as the name.

Why each choice is right or wrong

A - Correct: Matches the definition

B - Incorrect: Overloading is explicitly supported

C - Incorrect: Return type alone is insufficient

D - Incorrect: test() and test(int,int) show that equal counts are not required

Primary note proof

Study-note section OOP12

Overloaded methods share a name but have different parameter types, counts or type order. Return type alone is insufficient in Java and C++. Overloads can also arise through inherited

methods; “same class only” is a teaching simplification. f(int), f(double) and f(int,int) are distinct, but changing a parameter name does not create an overload.

Study-note section OOP12

The compiler selects the applicable signature from the declared argument types and conversions. int arguments usually choose an exact int overload rather than a wider double overload. A return type is not part of an ordinary Java method signature.

Computer Science Exit Exam · 2018 · Question 96

Question 3 | Q01000

Which generation of programming languages stated for high-level languages like C++, Java, Python?

A. 2nd generation

B. 3rd generation

C. 4th generation

D. None of the above

Hint

Separate language-generation classification, translation strategy and portability assumptions.

Answer B: Third generation.

OOP39 explicitly places general-purpose high-level languages such as C++, Java and Python in the third generation. This taxonomy concerns historical language classification, not whether a language is object oriented or interpreted. Thus the third-generation option applies to all the examples named in the question.

Why each choice is right or wrong

A - Incorrect: Second generation is not the category assigned to these general-purpose high-level examples in OOP39.

B - Correct: Third generation is the explicit conventional category assigned to C++, Java and Python.

C - Incorrect: Fourth generation does not match the explicit third-generation classification of the named examples.

D - Incorrect: The third-generation option is present, so none of the above cannot be correct.

Primary note proof

Study-note section OOP39

> Under the conventional introductory generation taxonomy, general-purpose high-level languages such as C++, Java, Python and Perl are third generation. The taxonomy is separate from object orientation and from compilation versus interpretation. Java source normally compiles to JVM bytecode, and a compatible JVM plus libraries supports portability across systems.

Question 4 | Q01143

In which generation that classifies and categorizes high-level language like C++, JAVA, Python, Perl.

A. a | First Generation Language x

B. i? Second Generation Language x

C. |@| Third Generation Language oS

D. | Fourth Generation Language x

Hint

Separate language-generation classification, translation strategy and portability assumptions.

Answer C: Third Generation Language.

C++, Java, Python and Perl are third-generation languages in this historical classification. Compilation versus interpretation and object orientation do not alter that historical classification.

Why each choice is right or wrong

A - Incorrect: First generation does not match the third-generation classification of the named high-level languages.

B - Incorrect: Second generation does not match the conventional category OOP39 assigns to these high-level examples.

C - Correct: The named general-purpose high-level languages are explicitly classified as third generation in OOP39.

D - Incorrect: Fourth generation is not the classification given for these examples in the complete note.

Primary note proof

Study-note section OOP39

> Under the conventional introductory generation taxonomy, general-purpose high-level languages such as C++, Java, Python and Perl are third generation. The taxonomy is separate from object orientation and from compilation versus interpretation. Java source normally compiles to JVM bytecode, and a compatible JVM plus libraries supports portability across systems.

Computer Science Exit Exam practice questions · Question 4

Question 5 | SM0073

What is the output of the following Java fragment code? int n = 6, m = 15, p = 3; n -= m; n *= p; System.out.print(n);

A. 27

B. 3

C. 24

D. -27

Hint

Respect operator grouping and operand types, then trace each operation in evaluation order.

Answer D: -27.

Start with n=6. The subtraction assignment n-=m computes 6-15, leaving n=-9. The multiplication assignment then uses that updated value: -9*3=-27. OOP23 includes this exact trace. The sign cannot become positive because only subtraction followed by multiplication by positive three occurs.

Why each choice is right or wrong

A - Incorrect: 27 discards the negative sign produced when 15 is subtracted from 6.

B - Incorrect: Three is the unchanged multiplier p, not the updated value of n that is printed.

C - Incorrect: 24 does not follow either the subtraction result -9 or its subsequent multiplication by 3.

D - Correct: The ordered updates yield n=-9 and then n=-27, which System.out.print outputs.

Primary note proof

Study-note section OOP23

> Java evaluates operands left to right while respecting precedence. With n=6,m=15,p=3, n-=m then n*=p leaves -27.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Object Oriented Programming module | PDF page 4 | lines 21-34

> ✓ Operators: Are symbols that take one or more arguments (operands) and operates on them to produce a result. An operator performs a function on one (Unary), two (Binary), or three operands (Ternary). Java has one ternary operator, ?:, which is a short-hand if-else statement. E.g. c=x?w:s; Operators can be Arithmetic, Logical, assignment, Relational, conditional, Increment,

Question 6 | SM0098

What is the output of the following Java fragment code? int[] list = new int[4]; int sum = 0; for(int i = 0; i < list.length; i++) { list[i] = i * 3; sum += list[i]; } System.out.print(sum);

A. 18

B. 6

C. 3

D. 36

Hint

Trace every element or API argument and distinguish copying values from aliasing a reference.

Answer A: 18.

The length-four array is visited at indices 0,1,2,3. Assigning i*3 stores 0,3,6,9. Starting sum at zero and adding each element gives 18, exactly the example in OOP27. The loop processes four elements, not merely the first one or an uninitialized default array.

Why each choice is right or wrong

A - Correct: All four assigned elements contribute: 0+3+6+9 equals the printed sum 18.

B - Incorrect: Six is one element's value, not the sum after all four iterations.

C - Incorrect: Three is the element assigned at index 1, rather than the full accumulator result.

D - Incorrect: 36 doubles the actual total; each of the four elements is added only once.

Primary note proof

Study-note section OOP27

> For int[] a=new int[4], setting a[i]=i*3 and accumulating yields 0+3+6+9=18.

Study-note section OOP26

> Valid indices are 0..a.length-1; an invalid access throws ArrayIndexOutOfBoundsException.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

National Computer Science Exit Exam · Question 42

National Computer Science Exit Exam

MOE Computer Science Exit Exam

Computer Science Exit Exam practice collection · Question 79

Question 7 | SS178

Consider the following program:

```
import java.util.Scanner;
public class Test {
public static void main(String[] args) {
Scanner scanner = new Scanner(System.in);
System.out.println("enter choice");
int choice = scanner.nextInt();
switch (choice) {
case 1: System.out.println("Hello");
case 2: System.out.println("you");
break;
default: System.out.println("welcome");
}
System.out.println("Goodbye");
}
}
```

After entering 1, what lines are printed following the initial “enter choice” prompt? Preserve letter case.

A. Hello
You welcome

B. Hello
You
Welcome
Goodbye

C. Hello
Goodbye

D. Hello
you
Goodbye

Hint

Trace condition tests, control transfers and printing as separate steps.

Answer D: Hello you Goodbye

Input 1 selects case 1, which prints Hello but has no break. Execution falls through to case 2 and prints you. Its break exits the switch before default, so welcome does not print. The final println outside the switch prints Goodbye. The requested output excludes the initial input prompt and preserves exact letter case.

Why each choice is right or wrong

A - Incorrect: This incorrectly includes welcome and omits the final Goodbye.

B - Incorrect: Default is skipped after case 2 breaks, so this includes an extra line.

C - Incorrect: Fall-through executes case 2, so omitting you is wrong.

D - Correct: The exact post-prompt lines are Hello, you and Goodbye.

Primary note proof

Study-note section OOP25

> break exits the loop; continue skips its remaining body and then runs a for update. Traditional colon-style switch labels fall through without break. Choice 1 printing Hello then case 2 printing you and breaking is followed by Goodbye outside the switch; default is skipped.

Computer Science model exam collection · Question 85

Computer Science model exam collection

Question 8 | Q00035

Which one of the following is false regarding Exceptions in Java?

A. We cannot create our own exception classes by extending Exception class

B. Exception class describes errors caused by your program and external circumstances

C. Runtime Exception class describes programming errors such as bad casting and numeric errors

D. All Java exception classes inherit directly or indirectly from Throwable class

Hint

Separate source errors from runtime exceptions and determine the hierarchy and checked obligation.

Answer A: We cannot create our own exception classes by extending Exception class

The prohibition on user-defined exceptions is false: an exception class can extend Throwable or a subclass. Its examples describe input, file and resource failures and runtime programming bugs.

Why each choice is right or wrong

A - Correct: Contradicts the explicit permission to define exception classes

B - Incorrect: Consistent with user, programmer and resource failures

C - Incorrect: Consistent with runtime programming bugs, though individual bad-cast examples are not enumerated

D - Incorrect: Matches the Throwable ancestry rule

Primary note proof

Study-note section OOP29

Throwable is the root of throwable values, with Exception and Error branches.
RuntimeException and Error subclasses are unchecked; other throwable classes are checked.
IOException, FileNotFoundException and SQLException are standard checked examples.
ArithmeticException, NullPointerException, ClassCastException and array bounds exceptions are

unchecked. A missing semicolon or undeclared variable is a compile-time source error, not a checked exception.

Study-note section OOP29

A custom exception can extend Exception or RuntimeException.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Object Oriented Programming module | PDF page 27 | lines 20-41

• An exception is an event, which occurs during the execution of a program, that disrupts the normal flow of the program's instructions.
• An exception is an indication of a problem that occurs during a program‟s execution.
• An exception is a runtime error.
• A Java exception is an instance of a class derived from Throwable.
• The Throwable class is contained in the java.lang package, and subclasses of Throwable are contained in various packages.
• Errors related to GUI components are included in the java.awt package; numeric exceptions are included in the java.lang package because they are related to the java.lang.Number class.
• You can create your own exception classes by extending Throwable or a subclass of Throwable.

Object Oriented Programming module | PDF page 27 | lines 42-54

• Exceptions occur for various reasons.
E.g.
• A user has entered invalid data.
• A file that needs to be opened cannot be found.
• A network connection has been lost in the middle of communications or the JVM has run out of memory.
• Some of these exceptions are caused by:
• User error,
• Programmer error,
• Physical resources that have failed in some manner.

Object Oriented Programming module | PDF page 28 | lines 65-79

✓ Unchecked exceptions: Is an exception that occurs at the time of execution, these are also called as Runtime Exceptions.
✓ These include programming bugs, such as logic errors or improper use of an API.
✓ Runtime exceptions are ignored at the time of compilation.
✓ For example, if you have declared an array of size 5 in your program, and trying to call the 6th element of the array then an ArrayIndexOutOfBoundsExceptione xception occurs.

MOE Computer Science Exit Exam · 2016 · Question 35

Mock exam 4 · Question 30

Question 9 | Q00067

Assuming there is a rectangle object, what getArea, getPerimeter can represent?

A. Attribute

B. Property

C. Data field

D. Behavior

Hint

Distinguish an object’s stored state, operations, identity and class definition.

Answer D: Behavior

getArea and getPerimeter describe operations performed by a rectangle, so they are behavior rather than its stored state.

Why each choice is right or wrong

A - Incorrect: An attribute stores state rather than performing this operation

B - Incorrect: Property here would mean stored/descriptive state, not the two operations

C - Incorrect: A data field stores a value; these are methods

D - Correct: Methods perform operations and express characteristic behavior

Primary note proof

Study-note section OOP01

An object has identity, state and behavior. State is stored in fields; behavior is provided by methods. A Rectangle object may hold width and height and answer getArea() or getPerimeter(). Two objects can have equal fields and still be distinct objects. A class defines their common structure and behavior; an object is a particular instance.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Object Oriented Programming module | PDF page 3 | lines 2-18

• Are the basic runtime entities in
an OO program.
• Are identifiable things or
individuals?
• Are of significance to the system
• Have states reflected in the
attributes (data) held about
the object
• Have characteristic behaviour
(i.e. functionality)
ह. Class:
• Is a blueprint for an object.
• is the definition of a set of objects
• which are all similar in terms of their
attributes
• A class consists of a class name, data
and methods.

Object Oriented Programming module | PDF page 10 | lines 62-72

Methods
• Are members of classes and do
operations.
• Allows different classes to
communicate each other.
• E.g. type name(parameter-
list)
{ // body of method
//....
return value; // if
type is not void

Question sources

MOE Computer Science Exit Exam · 2016 · Question 67

Question 10 | Q00068

Which one of the following is false about abstract classes and abstract methods?

A. We can create instances of abstract classes using the new operator

B. Implementation of abstract methods is provided by the subclasses

C. A class that contains abstract methods must be defined as abstract

D. Abstract methods are defined without implementation in the superclass

Hint

Check whether a class is concrete and whether every inherited abstract contract has an implementation.

Answer A: We can create instances of abstract classes using the new operator

The abstract-class example permits a concrete method but forbids new A(); subclasses supply the body for callme(). Thus instantiation is the false claim.

Why each choice is right or wrong

A - Correct: Direct new instantiation is forbidden

B - Incorrect: B supplies the implementation of callme in the example

C - Incorrect: An abstract method is an unimplemented requirement of an abstract class in this model

D - Incorrect: The example declares abstract void callme() without a body

Primary note proof

Study-note section OOP18

> An abstract class cannot be directly instantiated but can define fields, constructors, abstract methods and concrete methods. It need not contain an abstract method. An abstract method has no body; abstract and final conflict because an operation cannot require overriding while forbidding it.

Study-note section OOP18

> A concrete subclass must provide or inherit implementations of all required abstract methods; otherwise it must itself be abstract.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Object Oriented Programming module | PDF page 23 | lines 57-81

> Abstract Classes
> • A classes declared with abstract
> keyword and can‟t be instantiated.
> • Used to hide meaningless methods:
> • There can be no objects of an abstract

class. .:.
• An abstract class cannot be directly instantiated with the new operator.
• You cannot declare abstract constructors, or abstract static methods
• Syntax: abstract class class_name
Example:
abstract class A {
abstract void callme();
// concrete methods are still allowed in abstract classes
void callmetoo() {
System.out.println("This is a concrete method.");
}}
class B extends A {
void callme() {
System.out.println("B's implementation of callme.");
}}

Object Oriented Programming module | PDF page 24 | lines 63-73

Summery:
Abstract:
• Classes: declared with abstract keyword and can‟t be instantiated.
• Methods: without body (no implementation)
Final:
• Class: declared as final prevents inheritance.
• Method: declared as final prevents overriding that method.

Question sources

MOE Computer Science Exit Exam · 2016 · Question 68

Question 11 | Q00070

Which operator is used to create an array?

A. new

B. declare

C. static

D. construct

Hint

Check declared dimensions, initializer shape, fixed length and zero-based index bounds.

Answer A: new.

OOP26 shows int[] a=new int[5] as valid array creation. Here new is the allocation operator that creates the array object. The note also allows brace initializers without spelling new in declarations, so the answer identifies the operator rather than asserting that every array initializer must explicitly contain it.

Why each choice is right or wrong

A - Correct: new is the operator used in the note's explicit array-allocation form new int[5].

B - Incorrect: declare is not the allocation operator in the Java array-creation syntax shown in OOP26.

C - Incorrect: static controls class membership; it does not create an array object by itself.

D - Incorrect: construct is not the Java array-allocation operator used in the provided creation syntax.

Primary note proof

Study-note section OOP26

> int[] a=new int[5]; and int a[]={1,2,3}; are valid. int[] a={}; creates a zero-length array; explicit new is unnecessary in a declaration initializer.

Study-note section OOP07

> static gives one field per loaded class, shared by its instances.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Object Oriented Programming module | PDF page 8 | lines 43-55

> • a class declaration only creates a template; it does not create an actual object.
> • To actually create a Dog object, use the second statement.
> • Dog myDog; // Creates only the template
> • myDog = new Dog(); // create a Dog object called myDog
> • After this statement executes, myDog will be an instance of Dog.

Object Oriented Programming module | PDF page 6 | lines 4-17

Java has two basic data types
1. Primitive Data Types: are 8 in java (byte, short, int, long, float, double, char & Boolean)
2. Reference types: Arrays, classes, and interfaces, String)
• Note: Boolean type has a value true or false (there is no conversion b/n Boolean and other types).
• All non-primitive types are reference types, so all class types are reference types.
• All integers in Java are signed, Java doesn‟t support unsigned integers.

Question sources

MOE Computer Science Exit Exam · 2016 · Question 70

Computer Science Exit Exam practice questions · Question 37

Question 12 | Q00072

What does this valid Java loop print? Ignore only the trailing space.

```
for (int i = 2; i <= 11; i = i + 2) {
if (i % 4 == 0)
System.out.print(i * i + " ");
}
```

A. 16 64

B. 4163664100

C. 16644864

D. 4816644

Hint

Trace condition tests, control transfers and printing as separate steps.

Answer A: 16 64

The loop visits 2, 4, 6, 8 and 10. Only 4 and 8 have remainder zero when divided by 4, so their squares are the only values printed: 16 and 64. The string space separates the values. With valid Java capitalization, operators and parentheses, and ignoring the final space, the loop prints 16 64.

Why each choice is right or wrong

A - Correct: Only the qualifying values 4 and 8 print their squares, giving 16 64.

B - Incorrect: This includes squares from iterations where i is not divisible by four.

C - Incorrect: This adds values not printed by the two qualifying iterations.

D - Incorrect: This does not match the squares of 4 and 8.

Primary note proof

Study-note section OOP25

> while and for pre-test and may execute zero times; do-while post-tests and executes once.

Study-note section OOP23

> Java evaluates operands left to right while respecting precedence.

Study-note section OOP24

> Once a String operand is encountered, + concatenates in left-to-right groups: 1+2+"x" gives "3x", while "x"+1+2 gives "x12".

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Object Oriented Programming module | PDF page 4 | lines 21-34

> ✓ Operators: Are symbols that take one or more arguments (operands) and operates on them to produce a result. An operator performs a function on one (Unary), two (Binary), or three operands (Ternary). Java has one ternary operator, ?:, which is a short-hand if-else statement. > Labels: Java does not include a goto statement.

Instead of goto, Java allows you to combine break and continue with a label.

Question sources

MOE Computer Science Exit Exam · 2016 · Question 72

Question 13 | Q00127

Which valid Java declaration reproduces a ragged table with first row 12, -9, 8; second row 7, 14; and third row -32, -1, 0? The second row has two elements, not a third element containing zero.

A. double[][] table = {12, -9, 8, 7, 14, -32, -1, 0};

B. double[][] table = { {12, -9, 8}, {7,14,0}, {-32,-1,0}};

C. double[][] table = { { 12,-9,8} {7,14} {-32,-1,0}};

D. double[][] table = { {12, -9, 8},{7, 14},{-32, -1, 0} };

Hint

Check declared dimensions, initializer shape, fixed length and zero-based index bounds.

Answer D: Use rows {12,-9,8}, {7,14}, {-32,-1,0}.

Java represents a two-dimensional array as an array of row arrays, so the rows may have different lengths. The source table has lengths 3, 2 and 3. D supplies exactly those rows with comma-separated nested initializers. B is syntactically valid but adds an unwanted middle-row zero. A supplies scalar values where row arrays are needed, and C omits commas between its row initializers.

Why each choice is right or wrong

A - Incorrect: The declared double[][] requires row-array elements; a flat list of numeric scalars does not supply them.

B - Incorrect: Its second row contains an extra zero and therefore does not match the two-element row.

C - Incorrect: Missing commas between the row initializers make this declaration syntactically incorrect.

D - Correct: Its nested comma-separated rows match the required values and lengths 3, 2 and 3.

Primary note proof

Study-note section OOP26

int[] a=new int[5]; and int a[]={1,2,3}; are valid. int[] a={}; creates a zero-length array; explicit new is unnecessary in a declaration initializer.

Study-note section OOP26

Valid indices are 0..a.length-1; an invalid access throws ArrayIndexOutOfBoundsException. Java two-dimensional arrays are arrays of arrays and may be ragged: {{12,-9,8},{7,14},{-32,-1,0}} has row lengths 3,2,3. Java does not expose a portable physical contiguity guarantee, so a language-level answer should not rely on raw addresses.

Object Oriented Programming module | PDF page 6 | lines 4-17

Java has two basic data types
1. Primitive Data Types: are 8 in java
(byte, short, int, long, float, double,
char & Boolean)
2. Reference types: Arrays, classes,
and interfaces, String)
• Note: Boolean type has a value true or
false (there is no conversion b/n Boolean
and other types).
• All non-primitive types are reference
types, so all class types are reference
types.
• All integers in Java are signed, Java
doesn‟t support unsigned integers.

Question sources

Addis Ababa University mock exam · Question 29

Question 14 | Q00128

Which members are good candidates for static? PI is a shared mathematical constant; the salary display reads the receiver’s salary; the hypotenuse calculation uses only side-length parameters; each Student has its own name. Select all that apply.

A. The PI field of a circle class

B. A method that displays the salary of an Employee class

C. A method that calculates the hypotenuse of a right-angle triangle class

D. A name field of a Student class

E. All except B

Hint

Decide whether a member belongs to a class or an object, then check initialization and final restrictions.

Answer A, C: The PI field of a circle class; A method that calculates the hypotenuse of a right-angle triangle class

PI is one shared mathematical constant, so a static final field suits it. A hypotenuse utility that uses only parameters also needs no current object and can be static. Reading an employee receiver's salary requires that instance, and each student's name belongs to its own object. The aggregate option includes the instance name field, so it is not a correct complete selection.

Why each choice is right or wrong

A - Correct: PI is shared across circles and is a suitable static final constant.

B - Incorrect: The specified display reads receiver-specific salary state and should be an instance method.

C - Correct: The specified calculation uses only parameters and is suitable as a static utility.

D - Incorrect: Each student's separate name should be an instance field.

E - Incorrect: All except B still includes the per-student name field, so this set is wrong.

Primary note proof

Study-note section OOP07

> static gives one field per loaded class, shared by its instances. If count starts at zero and every constructor increments it, three creations leave count=3. Prefer ClassName.count and ClassName.utility(). A static method has no current instance, but can still use instance members through an explicit object reference.

Study-note section OOP07

> A shared mathematical PI is a good static final candidate; a student name normally belongs to an instance. A calculation using only parameters may be static.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Object Oriented Programming module | PDF page 5 | lines 39-61

> C. Class/Static variables
> • Are declared with the static keyword in a class, but outside a method, constructor or a block.
> • There would only be one copy of each class variable per class, regardless of how many objects are created from it.
> • Are rarely used other than being declared as constants. (public static final)
> • Are stored in the static memory.
> • Static variables are created when the program starts and destroyed

when the program stops.
• Visibility is similar to instance variables. However, most static variables are declared public
• Default values are same as instance variables.
• Static variables can be accessed by calling with the class name ClassName.VariableName.

Object Oriented Programming module | PDF page 14 | lines 2-19

Static methods and Final Variables
• A static method can access only static data.
• A static method can call only other static data (Static methods & variables), but can not call a non-static data from it.
• Static method is belongs to the class and not to the object.
• A static method can be accessed directly by the class name and doesn‟t need any object.
• i.e ClassName.methodName(args)
• A static method cannot refer to "this" or "super" keywords in anyway
• But can be overloaded since they are resolved using static binding by compiler at compile time.

Addis Ababa University mock exam · Question 30

Question 15 | Q00129

Here is the general syntax for method definition:
accessModifier returnType methodName(parameterList){
Java statements
return returnValue;
}
What is true for the accessModifier?

A. It must always be private or public.

B. It can be omitted, but if not omitted it must be private or public.

C. It can be omitted, but if not omitted there are several choices, including private and public

D. The access modifier must agree with the type of the return value.

E. All of the above

Hint

Locate the accessing code, declaring type, package and receiver before applying visibility rules.

Answer C: It can be omitted, but if not omitted there are several choices, including private and public

The access table includes default/no modifier, private, public and protected. Access controls visibility and has no dependency on return type.

Why each choice is right or wrong

A - Incorrect: Excludes protected and default

B - Incorrect: Allows omission but incorrectly excludes protected

C - Correct: Allows omission and the several listed access levels

D - Incorrect: Return type and visibility have different roles

E - Incorrect: A, B and D are false

Primary note proof

Study-note section OOP08

> For ordinary members: private restricts access to the declaring class/nest; no modifier grants package access; protected grants same-package access plus qualified subclass access; public is widest, provided the declaring type itself is accessible. Top-level classes/interfaces may be public or package-private, not protected/private. Member types have additional visibility possibilities.

Study-note section OOP11

> A method has modifiers, return type, name, parameter list and body: public int getAge(){return age;}.

Object Oriented Programming module | PDF page 13 | lines 62-73

Access Specifiers
Access level modifiers determine whether other classes can use a particular field or invoke a particular method.
Their are four types access levels:
1. No Modifier(Default): Visible to the package(source file), and it is called package-private
2. Private: Visible to the class only.
3. Public: Visible to the world.
4. Protected: Visible to the package and all subclasses.

Question sources

Addis Ababa University mock exam · Question 31

Question 16 | Q00130

What is the output of the following Java 17 code?

```
class FinalExam{
int num1;
public FinalExam() {
num1 = 4;
}
void display() {
System.out.println(num1) ;
}
}
class Final1 extends FinalExam{
int num=3;
public Final1() {
this(5);
num1 = num;
}
public Final1(int num) {
this.num = num * num;
}
}
public class Main{
public static void main(String[] args){
Final1 f = new Final1();
f.display();
}
}
```

A. 4

B. 25

C. 12

D. 20

Hint

Trace constructor delegation and initialization in the specified Java version.

Answer B: 25

Constructing Final1 first runs the parent constructor, setting num1 to 4. Subclass initialization sets num to 3. The delegated Final1(int) body receives 5 and sets num to 25. Control returns to the no-argument body, which assigns num1=num, replacing 4 with 25. display then prints inherited num1. Consistent subclass and constructor names make this an executable Java 17 trace.

Why each choice is right or wrong

A - Incorrect: 4 is the parent's initial num1 value, overwritten by the no-argument subclass body.

B - Correct: The delegated constructor sets num=25 and the caller copies it to num1.

C - Incorrect: 12 is not produced by squaring the delegated argument or by the assignments.

D - Incorrect: 20 is not produced by the constructor chain.

Primary note proof

Study-note section OOP10

Under Java 17 rules, an explicit this(args) or super(args) invocation must be the first constructor statement. this invokes another constructor in the same class; super invokes the immediate superclass constructor. A constructor cannot explicitly invoke both. If there is no explicit delegation, an implicit super() is inserted; a matching accessible no-argument parent constructor must exist.

Study-note section OOP10

Trace parent construction first, then subclass field initializers and instance blocks in order, then the relevant subclass constructor body. With consistent class and constructor names and this(5) chaining in the FinalExam example, the parent sets num1=4, the subclass initializes num=3, this(5) sets num=25, and the no-arg body sets num1=num, leaving 25.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Object Oriented Programming module | PDF page 12 | lines 24-47

Constructors
• Performs automatic initialization of objects. .:.
• Initializes an object immediately upon creation.
• Once defined, the constructor is automatically called immediately after the object is created, before the new operator completes.
• The default constructor automatically initializes all instance variables to zero and all object references to NULL.
• The default constructor is often sufficient for simple classes, but it usually won‟t do for more sophisticated ones.
• Once you define your own constructor, the default constructor is no longer used.
• Syntax:
• Have the same name with their class name.
• Have not return type, not even void.

Object Oriented Programming module | PDF page 19 | lines 43-54

When Constructors Are Called?
• In a class hierarchy, constructors are called in order of derivation, from superclass to subclass.
• Further, since super( ) must be the first statement executed in a subclass‟ constructor, this order is the same whether or not super( ) is used.
• If super( ) is not used, then the default or parameter less constructor of each superclass will be executed.

Question sources

Addis Ababa University mock exam · Question 32

Question 17 | Q00131

Which one of the following is important to implement dynamic Polymorphism?

A. Polymorphic variable

B. Method overriding

C. Inheritance

D. All of the above

Hint

Check what compiles from the declared type, then select behavior from the actual runtime class.

Answer D: All of the above

Dynamic dispatch uses an inheritance hierarchy, an overridden method and a superclass reference pointing at a subclass object. The question's polymorphic variable is that reference.

Why each choice is right or wrong

A - Incorrect: The superclass reference can hold a child object

B - Incorrect: Overriding supplies the subclass behavior

C - Incorrect: Inheritance supplies the superclass/subclass relation

D - Correct: All three participate in the cited dispatch model

Primary note proof

Study-note section OOP15

For Animal a=new Dog(), Animal is the declared type and Dog the actual type. The declared type determines which member operations compile. If fetch() exists only in Dog, a.fetch() fails compilation. For an eligible overridden sound(), a.sound() invokes Dog.sound() at runtime.

Study-note section OOP14

A subclass overrides an eligible inherited instance method with the same signature and a compatible return type; a covariant reference return may be a subtype.

Study-note section OOP13

class Dog extends Animal declares a subclass/derived/child of a superclass/base/parent.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Object Oriented Programming module | PDF page 22 | lines 37-53

• Dynamic method dispatch is the mechanism by which a call to an overridden method is resolved at run time, rather than compile time.
• Dynamic method dispatch is important because this is how Java implements run-time polymorphism
• When an overridden method is called through a superclass reference, Java determines which version of that method to execute based upon the type of the object being referred to at the time the call occurs.
• Thus, this determination is made at run time.
• Method Overriding is an example of runtime polymorphism.

Object Oriented Programming module | PDF page 25 | lines 17-37

• Polymorphism is the ability of an object to take on many forms.
• The most common use of polymorphism in OOP occurs when a parent class reference is used to refer to a child class object.
• Any Java object that can pass more than one IS-A test is considered to be polymorphic.
• In Java, all Java objects are polymorphic since any object will pass the IS-A test for their own type and for the class Object.

• Polymorphism is derived from 2 Greek words: poly and morphs.
• The word "poly" means many and "morphs" means forms. So polymorphism means many forms.
• polymorphism is the capability of an action or method to do different things based on the object that it is acting upon.

Object Oriented Programming module | PDF page 15 | lines 23-53

What is Inheritance?
• Inheritance is one of the cornerstones of object-oriented programming because it allows the creation of hierarchical classifications.
• Inheritance is the process where one class acquires the properties (methods and fields) of another.
• A class that is inherited is called a superclass.
• The class that does the inheriting is called a subclass.
• OR: The class which inherits the properties of other is known as subclass (derived class, child class) and
• The class whose properties are inherited is known as superclass (base class, parent class).
• Therefore, a subclass is a specialized version of a superclass.
• It inherits all of the instance variables and methods defined by the superclass and add its own, unique elements.
• The extends keyword: is the keyword used to inherit the properties of a class. Below given is the syntax of extends keyword.
• Sytax:
class Super{
.....}
class Sub extends Super{ }

Question sources

Addis Ababa University mock exam · Question 33

Question 18 | Q00132

An accessible parent declares public abstract int value(); and its direct child is non-abstract with no inherited implementation of that method. What must the child do?

A. A child must override an abstract method inherited from its parent by defining a method with the same signature and same return type

B. A child must define an additional method similar to the one inherited from its parent by defining a method with the same signature and different return type.

C. Achild must not define any method with the same signature as the parent's abstract method.

D. A non-abstract child must define an abstract method with the same signature and same return type as the parent's abstract method.

E. All of the above

Hint

Check whether a class is concrete and whether every inherited abstract contract has an implementation.

Answer A: A child must override an abstract method inherited from its parent by defining a method with the same signature and same return type

A concrete child must implement every outstanding abstract method. Here the inherited contract has no parameters and a primitive int return, so the child must supply a public concrete implementation of that same signature and return type. The covariant reference-return exception does not apply to primitive int. A different return type, refusing to implement the method, or declaring it abstract leaves the concrete-class requirement unsatisfied.

Why each choice is right or wrong

A - Correct: A concrete matching no-argument int implementation, with the required public access, satisfies the inherited contract.

B - Incorrect: A different return type cannot implement this primitive int-returning contract.

C - Incorrect: Omitting a matching implementation leaves an abstract obligation in the concrete child.

D - Incorrect: An abstract declaration supplies no implementation and cannot satisfy the concrete child’s obligation.

E - Incorrect: B, C and D fail the stated implementation requirement, so the aggregate cannot be correct.

Primary note proof

Study-note section OOP18

> A concrete subclass must provide or inherit implementations of all required abstract methods; otherwise it must itself be abstract. If parent declares abstract String welcome(), a String welcome() implementation is required; int welcome() is incompatible, and welcome(int) merely

adds an overload. A valid class can contain both the required implementation and an unrelated overload.

Study-note section OOP14

A subclass overrides an eligible inherited instance method with the same signature and a compatible return type; a covariant reference return may be a subtype. Visibility cannot become more restrictive, and checked exceptions cannot be broadened incompatibly.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Object Oriented Programming module | PDF page 23 | lines 57-81

Abstract Classes
• A classes declared with abstract
keyword and can‟t be instantiated.
• Used to hide meaningless methods:
• There can be no objects of an abstract
class. .:.
• An abstract class cannot be directly
instantiated with the new operator.
• You cannot declare abstract
constructors, or abstract static methods
• Syntax: abstract class class_name
Example:
abstract class A {
abstract void callme();
// concrete methods are still
allowed in abstract classes
void callmetoo() {
System.out.println("This is a
concrete method.");
}}
class B extends A {
void callme() {
System.out.println("B's
implementation of callme.");
}}

Object Oriented Programming module | PDF page 11 | lines 55-67

Method Overriding
In a class hierarchy, when a method in a
subclass has the same name and type
signature as a method in its superclass, this
is called method Overriding.
• the method in the subclass is said to
override the method in the
superclass.

• The Method in the super class is known as an overridden method which is called within a subclass.
• The version of the method defined by the superclass will be hidden.

Object Oriented Programming module | PDF page 31 | lines 9-30

• It provides total abstraction;
• Means all the methods in interface are declared with empty body and are public and all fields are public, static and final by default.
• A class that implement interface must implement all the methods declared in the interface.
• If a class implements an interface and does not provide method bodies for all functions specified in the interface, then class must be declared abstract.
Rules of Interface
• Variables declared in an interface are public, static & final by default.
• Java does not allow you to extend more than one class, However you can implement more than one interfaces in your class.
• class implements interface but an interface extends another interfaces.

Question sources

Addis Ababa University mock exam · Question 34

Mock exam 3 · Question 18

Question 19 | Q00133

Which of the following is true?

A. A child class can extend a parent or implement an interface, but not do both.

B. A child class can extend just one parent and can implement just one interface.

C. A child class can extend just one parent and can implement zero or more interfaces.

D. A child class can extend zero or more parents, and can implement zero or more interfaces.

Hint

Identify the subtype or ownership relationship and distinguish class inheritance from interface contracts.

Answer C: A child class can extend just one parent and can implement zero or more interfaces.

A Java class can extend one class and implement multiple interfaces.

Why each choice is right or wrong

A - Incorrect: No exclusive choice between extending and implementing is stated

B - Incorrect: Artificially limits interfaces to one

C - Correct: One direct superclass and zero or more interfaces matches the rule

D - Incorrect: Multiple direct parent classes are forbidden

Primary note proof

Study-note section OOP13

> class Dog extends Animal declares a subclass/derived/child of a superclass/base/parent. A class extends one direct class and can implement multiple interfaces. Single, multilevel and hierarchical inheritance mean one parent, a chain, and several children of one parent. Java does not permit class Dog extends Animal,Mammal.

Study-note section OOP19

> A class can extend a superclass and implement zero or more interfaces.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Question sources

Addis Ababa University mock exam · Question 35

Mock exam 4 · Question 27

Question 20 | Q00224

What will be the output of the program?

```
try {
int x = 0;
int y = 5 / x;
} catch (Exception e) {
System.out.println("Exception");
} catch (ArithmeticException ae) {
System.out.println("Arithmetic Exception");
}
System.out.println("finished");
```

A. Arithmetic Exception

B. finished

C. Exception

D. Compilation fails.

Hint

Check the thrown type and catch order before tracing propagation or handler output.

Answer D: Compilation fails because the subtype catch is unreachable.

Exception is caught before its subclass ArithmeticException. OOP30 says that a general catch before a subtype catch makes the latter unreachable and prevents compilation. The program therefore never executes the division or either print statement. Reasoning about which handler would run cannot bypass this compile-time restriction.

Why each choice is right or wrong

A - Incorrect: The ArithmeticException handler is unreachable at compile time, so it cannot print its message.

B - Incorrect: Compilation fails before execution; the statement following the catches never prints finished.

C - Incorrect: Although Exception could catch this runtime type, the illegal later catch prevents any execution.

D - Correct: The earlier Exception catch subsumes ArithmeticException, making the later handler unreachable and the program uncompilable.

Primary note proof

Study-note section OOP30

> Catch blocks are considered in source order. Place FileNotFoundException before IOException and IOException before Exception; a general catch before a subtype catch makes that later handler unreachable and prevents compilation.

Study-note section OOP29

> Throwable is the root of throwable values, with Exception and Error branches. RuntimeException and Error subclasses are unchecked; other throwable classes are checked. IOException, FileNotFoundException and SQLException are standard checked examples. ArithmeticException, NullPointerException, ClassCastException and array bounds exceptions are unchecked.

> }
> Catch(ExceptionType1 exOb) {
> //handler for ExceptionType1
> }
> Catch(ExceptionType2 exOb) {
> //handler for ExceptionType2
> }

Object Oriented Programming module | PDF page 27 | lines 20-41

> • An exception is an event, which occurs during the execution of a program, that disrupts the normal flow of the program's instructions.
> • An exception is an indication of a problem that occurs during a program‟s execution.
> • An exception is a runtime error.
> • A Java exception is an instance of a class derived from Throwable.

• The Throwable class is contained in the java.lang package, and subclasses of Throwable are contained in various packages.
• Errors related to GUI components are included in the java.awt package; numeric exceptions are included in the java.lang package because they are related to the java.lang.Number class.
• You can create your own exception classes by extending Throwable or a subclass of Throwable.

Question sources

Mock exam 4 · Question 26

Question 21 | Q00226

Which one of the following constant declaration statements is not possible in the Interface body?

A. static double PI = 3.14;

B. static final double PI = 3.14;

C. double PI = 3.14;

D. final double PI = 3.14;

E. None of the choices is correct

Hint

Identify the interface contract, effective modifiers and permitted implementation forms.

Answer E: None of the choices is correct

All interface fields are implicitly public, static and final; writing either, both or neither of static and final does not remove the implicit modifiers. Each PI declaration also has an initializer.

Why each choice is right or wrong

A - Incorrect: static is explicit and final implicit

B - Incorrect: Both static and final are explicit

C - Incorrect: Both modifiers are implicit

D - Incorrect: final is explicit and static implicit

E - Correct: All four declarations satisfy the rule, so no listed declaration is impossible

Primary note proof

Study-note section OOP19

No interface instance fields or constructors exist; fields are implicitly public static final.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Question 22 | Q00227

Which one of the following is wrong about Method Overriding?

A. Method overriding is one way of implementing polymorphism at run time.

B. Method overriding deals with methods with similar signatures in the base and derived classes.

C. Method overriding deals with implementing similar operations for different objects.

D. Method overriding is possible between any two classes.

Hint

Check inheritance, signature compatibility, visibility and eligibility for an override.

Answer D: Method overriding is possible between any two classes.

Overriding is a superclass/subclass relationship with matching method signatures and supports runtime dispatch, not a relationship between arbitrary unrelated classes.

Why each choice is right or wrong

A - Incorrect: Runtime polymorphism is an explicit purpose

B - Incorrect: Matches the hierarchy and signature rule

C - Incorrect: Different subclass implementations can specialize the inherited operation

D - Correct: Unrelated arbitrary classes do not establish overriding

Primary note proof

Study-note section OOP14

> A subclass overrides an eligible inherited instance method with the same signature and a compatible return type; a covariant reference return may be a subtype.

Study-note section OOP14

> Merely reusing a name in two unrelated classes does not establish overriding.

Study-note section OOP15

> For an eligible overridden sound(), a.sound() invokes Dog.sound() at runtime.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Object Oriented Programming module | PDF page 11 | lines 55-67

> Method Overriding
> In a class hierarchy, when a method in a subclass has the same name and type signature as a method in its superclass, this is called method Overriding.
> • the method in the subclass is said to override the method in the superclass.

> • Dynamic method dispatch is the mechanism by which a call to an overridden method is resolved at run time, rather than compile time.

• Dynamic method dispatch is important because this is how Java implements run-time polymorphism
• When an overridden method is called through a superclass reference, Java determines which version of that method to execute based upon the type of the object being referred to at the time the call occurs.
• Thus, this determination is made at run time.
• Method Overriding is an example of runtime polymorphism.

Question sources

Mock exam 4 · Question 29

Question 23 | Q00277

Public classes A, B and C are in three different packages, with C extending B and B extending A. From code declared inside C, accessing fields through this, which is the complete access set? Assume ordinary instance fields with distinct names, accessible public declaring types, and no hiding.

A. All fields declared in C, and only accessible inherited protected and public fields from A and B

B. Protected, default and public data only in C and B.

C. Any data in C and only public data in A and B.

D. Protected, default and public data only in C.

Hint

Locate the accessing code, declaring type, package and receiver before applying visibility rules.

Answer A: All fields declared in C, and only accessible inherited protected and public fields from A and B

Code inside C can access C’s own fields, including private ones. Across package boundaries it can also access inherited public and protected fields through its own inherited context, here represented by this. It cannot access package-private or private ancestor fields directly. Consequently A gives the complete set; the public-only choice is incomplete because qualifying protected inherited access is also permitted.

Why each choice is right or wrong

A - Correct: This includes C’s own fields and the inherited public/protected access permitted through this.

B - Incorrect: Package-private ancestor fields in different packages are not accessible, and A's inherited access is omitted.

C - Incorrect: This omits accessible inherited protected fields and therefore is not the complete set.

D - Incorrect: This omits C's own private access and permitted inherited ancestor access.

Primary note proof

Study-note section OOP08

> For ordinary members: private restricts access to the declaring class/nest; no modifier grants package access; protected grants same-package access plus qualified subclass access; public is widest, provided the declaring type itself is accessible. Top-level classes/interfaces may be public or package-private, not protected/private. Member types have additional visibility possibilities.

Study-note section OOP08

> Across packages, a subclass accessing a protected instance member must do so through its own inherited context or an appropriate subclass-typed receiver, not any arbitrary superclass object.

Question sources

Computer Science model exam · Question 8

University of Gondar model exam · Question 8

Question 24 | Q00278

Inside an instance method, which shown forms invoke an accessible no-argument non-static method? Methodname stands for a valid method name, Objectname for a compatible object reference, and Classname for a type name. Select all that apply.

A. Methodname()

B. Classname.methodname()

C. Objectname.methodname()

D. Variablename.methodname

Hint

Separate parameters from arguments and operations that read state from operations that change it.

Answer A, C: Methodname(); Objectname.methodname()

An unqualified call inside a suitable instance context uses implicit this, so Methodname() is valid. An object-qualified call explicitly supplies the receiver and is also valid. A type name alone cannot invoke a non-static method without an object. The final form lacks invocation parentheses and therefore does not invoke a method. These are deliberate syntax alternatives under the stated placeholder meanings.

Why each choice is right or wrong

A - Correct: The unqualified call uses implicit this in the stated instance context.

B - Incorrect: A class name alone does not provide the required instance receiver.

C - Correct: The object-qualified call supplies the instance receiver.

D - Incorrect: Without parentheses this form does not perform a method invocation.

Primary note proof

Study-note section OOP11

> A method has modifiers, return type, name, parameter list and body: public int getAge(){return age;}. A void method returns no value. Parameters name the inputs in the declaration; arguments supply values at a call. An instance method can be invoked as object.method(), or with an implicit this inside suitable instance context.

Study-note section OOP16

> Java this and super are unavailable as current-instance references in static context.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Object Oriented Programming module | PDF page 14 | lines 2-19

Static methods and Final Variables
• A static method can access only static data.
• A static method can call only other static data (Static methods & variables), but can not call a non-static data from it.
• Static method is belongs to the class and not to the object.
• A static method can be accessed directly by the class name and doesn‟t need any object.
• i.e ClassName.methodName(args)
• A static method cannot refer to "this" or "super" keywords in anyway
• But can be overloaded since they are resolved using static binding by compiler at compile time.

Object Oriented Programming module | PDF page 11 | lines 24-41

```
class OverloadDemo {
void test() {
System.out.println("No
parameters"); }
void test(int a) { // Overload
test for one integer parameter.
System.out.println("a: " + a); }
void test(int a, int b) { //
Overload test for two integer
parameters.
System.out.println("a and b: " +
a + " " + b); }
double test(double a) { //
overload test for a double
parameter
System.out.println("double a: "
+ a);
return a*a; } }
```

Question sources

Computer Science model exam · Question 9

University of Gondar model exam · Question 9

Question 25 | Q00279

In Java, Base declares an eligible instance method m(), Sub overrides it, and an object's exact runtime class is Sub. Inside an instance method declared in Sub, what happens on an unqualified call m()? Assume no further subclass or explicit super call.

A. The Compiler will choose randomly the method to be executed

B. It will always refer to the version of that method defined by the subclass

C. Compile time error will occur

D. It will always refer to the version of that method defined by the superclass

Hint

Check what compiles from the declared type, then select behavior from the actual runtime class.

Answer B: It will always refer to the version of that method defined by the subclass

The unqualified invocation uses the current Sub object as receiver. Since m is an eligible overridden instance method and the exact runtime class is Sub, dynamic dispatch selects Sub's implementation. The compiler does not choose randomly, and the valid declaration produces no compilation error. An explicit super.m() would request the parent version, but that is excluded by the specified call expression.

Why each choice is right or wrong

A - Incorrect: Dispatch follows the language's receiver and overriding rules, not random choice.

B - Correct: The exact Sub receiver dispatches the ordinary call to Sub.m().

C - Incorrect: The stated accessible, eligible declaration and call compile.

D - Incorrect: The superclass version would require a different dispatch situation such as explicit super.m().

Primary note proof

Study-note section OOP15

> For Animal a=new Dog(), Animal is the declared type and Dog the actual type. The declared type determines which member operations compile. If fetch() exists only in Dog, a.fetch() fails compilation. For an eligible overridden sound(), a.sound() invokes Dog.sound() at runtime.

Study-note section OOP16

> An unqualified instance call may dispatch dynamically; an explicit super call is different.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Object Oriented Programming module | PDF page 11 | lines 55-67

> Method Overriding
> In a class hierarchy, when a method in a
> subclass has the same name and type

signature as a method in its superclass, this is called method Overriding.
• the method in the subclass is said to override the method in the superclass.
• The Method in the super class is known as an overridden method which is called within a subclass.
• The version of the method defined by the superclass will be hidden.

Object Oriented Programming module | PDF page 17 | lines 51-74

The super keyword
• Since encapsulation is a primary attribute of OOP, Whenever a subclass needs to refer to its immediate superclass, it can do so by use of the keyword super.
• Super has two general forms.
1. Used to access parent class instance members.
2. Used to access parent class constructor.
1. Used to access parent class instance members.
• super acts somewhat like this, except that it always refers to the superclass of the subclass in which it is used.
• Super has the form: super.member Here, member can be either a method or an instance variable.
• Super is most applicable to resolve member hiding.
• super( ) must always be the first statement executed inside a subclass‟ constructor.

Computer Science model exam · Question 10

University of Gondar model exam · Question 10

Question 26 | Q00280

Which of the following statements not true?

A. A private member of a class cannot be accessed by the methods of the same class

B. A public member of a class can be accessed in all the packages

C. A private member of a class cannot be accessed from its derived class

D. A protected member of a class can be accessed from its derived class.

Hint

Locate the accessing code, declaring type, package and receiver before applying visibility rules.

Answer A: A private member of a class cannot be accessed by the methods of the same class

Private visibility is class-only, so methods of the declaring class can access that member. Public is world-visible; protected includes subclasses.

Why each choice is right or wrong

A - Correct: False: same-class methods have access

B - Incorrect: Public visibility includes other packages

C - Incorrect: A child cannot directly access a parent's private member

D - Incorrect: Protected includes subclass access

Primary note proof

Study-note section OOP08

> For ordinary members: private restricts access to the declaring class/nest; no modifier grants package access; protected grants same-package access plus qualified subclass access; public is widest, provided the declaring type itself is accessible. Top-level classes/interfaces may be public or package-private, not protected/private. Member types have additional visibility possibilities.

Study-note section OOP08

> Across packages, a subclass accessing a protected instance member must do so through its own inherited context or an appropriate subclass-typed receiver, not any arbitrary superclass object. protected therefore does not mean “subclasses only”: unrelated classes in the same package also have access. A class’s own main method can access private fields of an instance of that class.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Object Oriented Programming module | PDF page 13 | lines 62-73

> Access Specifiers
> Access level modifiers determine whether
> other classes can use a particular field or
> invoke a particular method.
> Their are four types access levels:

1. No Modifier(Default): Visible to the package(source file), and it is called package-private
2. Private: Visible to the class only.
3. Public: Visible to the world.
4. Protected: Visible to the package and all subclasses.

Object Oriented Programming module | PDF page 17 | lines 4-9

Member Access and Inheritance
• Although a subclass includes all of the members of its superclass, it cannot access those members of the superclass that have been declared as private.

Question sources

Computer Science model exam · Question 11

University of Gondar model exam · Question 11

Question 27 | Q00281

_____is one of the basic principles of object oriented programming that use one object in multiple forms.

A. Inheritance

B. Interface

C. Encapsulation

D. None of the above

Hint

Identify whether the emphasis is grouping state, hiding implementation, exposing essentials or varying behavior.

Answer D: None of the above

Taking many forms is polymorphism. It is not explicitly listed, so the none option is the correct selection.

Why each choice is right or wrong

A - Incorrect: Inheritance acquires parent properties

B - Incorrect: Interface defines a contract rather than naming the many-forms principle

C - Incorrect: Encapsulation groups and hides data

D - Correct: The principle is polymorphism

Primary note proof

Study-note section OOP02

> Inheritance forms a subtype relationship and may reuse implementation. Polymorphism lets code using a common type invoke behavior appropriate to different concrete objects.

Study-note section OOP02

> Encapsulation groups related state and operations and controls access.

Study-note section OOP19

> interface Payable{double getPaymentAmount();} declares an abstract public operation. class Invoice implements Payable must provide public double getPaymentAmount(), perhaps returning getQuantity()*getPricePerItem().

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Object Oriented Programming module | PDF page 3 | lines 58-64

> 2. Polymorphism:
> • The word polymorphism means the ability to take more than one form.
> • In terms of the OOP, this means that a particular operation may behave differently for different sub-classes of the same class.

Question sources

Computer Science model exam · Question 12

University of Gondar model exam · Question 12

Question 28 | Q00282

Consider the program:

public class Student {

int id;

int section;

void display() {

System.out.println("ID : " + id);
System.out.println("Section : " + section); }

public static void main(String[] args) {

/*Create an object*/ }}

Which of the following is a correct way to create an object in the main method of the above program?

A. Student stud = Student (3983,20);

B. Student stud;

C. Student stud=new Student ();

D. Student stud =new Student (3983,2);

Hint

Separate a reference declaration, object allocation, reference copying and changes to the shared object.

Answer C: Student stud=new Student ();

No constructor is declared in Student, so the default no-argument construction pattern applies. A reference declaration alone does not create an object.

Why each choice is right or wrong

A - Incorrect: Missing new and invokes an undeclared parameterized constructor

B - Incorrect: Declares only a reference

C - Correct: Uses new and the implicit no-argument constructor

D - Incorrect: No matching two-argument constructor is declared

Primary note proof

Study-note section OOP03

> Student s; declares a reference variable; it creates no Student object. Student s=new Student(); allocates and initializes an instance.

Study-note section OOP09

If a class declares no constructor, Java supplies a default constructor. If Circle(double r) is declared, new Circle() fails unless a no-argument constructor is also declared.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Object Oriented Programming module | PDF page 8 | lines 43-55

• a class declaration only creates a template; it does not create an actual object.
• To actually create a Dog object, use the second statement.
• Dog myDog; // Creates only the template
• myDog = new Dog(); // create a Dog object called myDog
• After this statement executes, myDog will be an instance of Dog.

Object Oriented Programming module | PDF page 12 | lines 24-47

Constructors
• Performs automatic initialization of objects. .:.
• Initializes an object immediately upon creation.
• Once defined, the constructor is automatically called immediately after the object is created, before the new operator completes.
• The default constructor automatically initializes all instance variables to zero and all object references to NULL.
• The default constructor is often sufficient for simple classes, but it usually won‟t do for more sophisticated ones.
• Once you define your own constructor, the default constructor is no longer used.
• Syntax:
• Have the same name with their class name.
• Have not return type, not even void.

University of Gondar model exam · Question 13

Question 29 | Q00431

Default, public , protected, private are?

A. Access Modifier

B. Non-access Modifiers

C. Both A and B

D. It's variable

Hint

Locate the accessing code, declaring type, package and receiver before applying visibility rules.

Answer A: Access Modifier

The access table names no modifier/default, public, protected and private as visibility levels.

Why each choice is right or wrong

A - Correct: They control accessibility

B - Incorrect: They are visibility modifiers rather than non-access properties such as static

C - Incorrect: No basis for classifying the same list as both

D - Incorrect: They are not a variable

Primary note proof

Study-note section OOP08

> For ordinary members: private restricts access to the declaring class/nest; no modifier grants package access; protected grants same-package access plus qualified subclass access; public is widest, provided the declaring type itself is accessible. Top-level classes/interfaces may be public or package-private, not protected/private. Member types have additional visibility possibilities.

Question 30 | Q00432

Java Source Code is compiled into _____.

A. .Obj

B. Source Code

C. Bytecode

D. .Exe

Hint

Check declaration order, exact case, package boundaries and the compile-versus-launch stage.

Answer C: Bytecode

The compiler produces intermediate Java bytecodes, explicitly described as platform-independent.

Why each choice is right or wrong

A - Incorrect: Not the compiler’s intermediate-language output

B - Incorrect: Input source is translated rather than simply reproduced

C - Correct: Matches the stated intermediate language

D - Incorrect: Not the compiler’s intermediate-language output

Primary note proof

Study-note section OOP28

Ordinary compilation uses javac Test.java, producing bytecode, then java Test launches the class.

Study-note section OOP39

Java source normally compiles to JVM bytecode, and a compatible JVM plus libraries supports portability across systems.

Module passages - related reading

Object-Oriented Programming practice questions · Question 2

Question 31 | Q00433

Single line comment starts with _____ in Java.

A. /**

B. //

C. /*

D. None of these

Hint

Check the lexical category and whether the notation names a value, a declaration or non-executed source text.

Answer B: //

// begins a single-line comment; /* and /** begin block comments.

Why each choice is right or wrong

A - Incorrect: Starts documentation-style block comments

B - Correct: The single-line delimiter

C - Incorrect: Starts a block comment

D - Incorrect: The required delimiter is listed as B

Primary note proof

Study-note section OOP-S01

> A single-line Java comment begins with // and continues to the end of that line. A block comment begins with /* and ends with */. A documentation comment begins with /** and ends with */ and can be processed by Javadoc. Comment text does not execute as program statements.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Object Oriented Programming module | PDF page 4 | lines 2-4

> single line comment //, 2 multiline
> comments /* .... */ and /** ....*/.
> The las one is used by javaDoc

Question 32 | Q00434

How to compile java code in command prompt?

A. javac filename.java

B. java filename.java

C. javac filename

D. java filename

Hint

Check declaration order, exact case, package boundaries and the compile-versus-launch stage.

Answer A: javac filename.java

The FileNotFound example shows C:\>javac FilenotFound_Demo.java, establishing the compiler command with a .java source filename.

Why each choice is right or wrong

A - Correct: Matches the javac compilation command

B - Incorrect: Uses java rather than the demonstrated compiler

C - Incorrect: Omits the .java source suffix

D - Incorrect: Uses the runtime command name rather than javac

Primary note proof

Study-note section OOP28

> Ordinary compilation uses javac Test.java, producing bytecode, then java Test launches the class. Modern Java can also launch a source file using java Test.java; distinguish source-file launch from running a compiled class.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Object Oriented Programming module | PDF page 28 | lines 54-64

> FileReader(file);
> 1 error

Question sources

Object-Oriented Programming practice questions · Question 4

Question 33 | Q00435

An ordinary class named filename has already been compiled to filename.class, is in the current directory with no package, and has a valid main method. Which command launches that compiled class? Use class launch, not source-file mode.

A. javac filename.java

B. java filename.java

C. javac filename

D. java filename

Hint

Check declaration order, exact case, package boundaries and the compile-versus-launch stage.

Answer D: java filename

The Java launcher takes the compiled class's name for ordinary class launch, so java filename runs the available main method. javac filename.java compiles a source file and is a separate step. Modern Java also supports source-file launch with a .java argument, but the revised question explicitly asks for the already compiled class. The compiler invocation without the source extension is not the requested launch either.

Why each choice is right or wrong

A - Incorrect: This compiles source rather than launching the existing compiled class.

B - Incorrect: This is source-file launch, excluded by the requested class-launch mode.

C - Incorrect: This is a compiler invocation rather than the requested class launch.

D - Correct: java filename launches the named compiled class.

Primary note proof

Study-note section OOP28

> Ordinary compilation uses javac Test.java, producing bytecode, then java Test launches the class. Modern Java can also launch a source file using java Test.java; distinguish source-file launch from running a compiled class.

Module passages - related reading

1 error

Question sources

Object-Oriented Programming practice questions · Question 5

Question 34 | Q00436

Java is case sensitive?

A. True

B. False

C. Depends On Complier

D. May be true or false

Hint

Check declaration order, exact case, package boundaries and the compile-versus-launch stage.

Answer A: True: Java is case sensitive.

OOP28 explicitly states that Java identifiers are case sensitive. Changing the capitalization of a name can therefore change what it denotes or make a reference unresolved. This is a language rule rather than a compiler preference, so the conditional or uncertain answers do not describe standard Java behavior.

Why each choice is right or wrong

A - Correct: True directly matches the note's explicit statement that Java identifiers are case sensitive.

B - Incorrect: False contradicts the explicit identifier case-sensitivity rule stated in OOP28.

C - Incorrect: Case sensitivity is a Java language rule, not an option depending on the compiler implementation.

D - Incorrect: The note states a definite language property rather than a true-or-false implementation-dependent possibility.

Primary note proof

Study-note section OOP28

> Java identifiers are case sensitive; $ is allowed but @ is not an identifier character.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Object Oriented Programming module | PDF page 4 | lines 11-20

> ✓ Reserved keywords: class, extends, implements, for... ✓ Identifiers: programmers given name; grade, gRade... ✓ Literals (Constants values): 55, 60.78, "Hi", „M"... Java language specifies five major types of literals => integer, floating, character, string & Boolean literals

Question sources

Object-Oriented Programming practice questions · Question 6

Question 35 | Q00437

Which is the most complete description of the standard introductory naming conventions and ordinary public-top-level-class file rule in Java? Treat "should" in A and B as style advice, not a syntax requirement, and "class" in C as the public top-level class in a .java source file.

A. For all class names the first letter should be in Upper Case.

B. All method names should start with a Lower Case letter.

C. Name of the program file should exactly match the class name.

D. All of the above

Hint

Check declaration order, exact case, package boundaries and the compile-versus-launch stage.

Answer D: All of the above

Capitalized class initials and lowercase method initials are conventional Java style, not universal syntax requirements. An ordinary public top-level class must match its source filename's base name. The scope makes A and B recommendations and C the specific file rule. Each is then true, but D is the most complete selection because it includes all three rather than one isolated part.

Why each choice is right or wrong

A - Incorrect: This is valid style advice but only one part of the complete set.

B - Incorrect: This is valid style advice but omits the other convention and file rule.

C - Incorrect: This is the file rule for the specified public top-level class but is incomplete alone.

D - Correct: All three are valid under the stated convention and file-rule scope.

Primary note proof

Study-note section OOP28

> For ordinary public top-level types, filename and type name match. Capitalized class names and lowercase method names are conventions, not universal syntax requirements.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Object-Oriented Programming practice questions · Question 7

Question 36 | Q00438

All Java components require names. Names used for classes, variables, and methods are called?

A. Variables

B. identifiers

C. Access Modifiers

D. Java Modifiers

Hint

Check the lexical category and whether the notation names a value, a declaration or non-executed source text.

Answer B: identifiers

Identifiers are programmer-given names. Names attached to classes, variables and methods serve that role.

Why each choice is right or wrong

A - Incorrect: A variable is one named entity, not the name category

B - Correct: Matches programmer-given names

C - Incorrect: Controls visibility rather than naming

D - Incorrect: Modifiers change declarations rather than supply their names

Primary note proof

Study-note section OOP-S01

An identifier is a programmer-chosen name for an entity such as a class, method or variable. A reserved keyword has a language-defined role and cannot be used as an ordinary identifier. A

literal writes a value directly, such as an integer, floating-point number, quoted character, quoted string or Boolean value.

Study-note section OOP08

For ordinary members: private restricts access to the declaring class/nest; no modifier grants package access; protected grants same-package access plus qualified subclass access; public is widest, provided the declaring type itself is accessible.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Question sources

Object-Oriented Programming practice questions · Question 8

Question 37 | Q00439

Which of the following is smallest integer data type ?

A. int

B. byte

C. short

D. long

Hint

Identify the primitive category, width and conversion rule before evaluating a declaration or expression.

Answer B: byte

The actual PDF page-six widening diagram orders byte -> short -> int -> long -> float (and onward to double); the text says widening requires the destination to be wider than the source. Among byte, short, int and long, byte is therefore the smallest in this module diagram. The diagram is a raster/embedded visual omitted from extracted text, so the exact textual citation supplies the associated width condition rather than fabricating a diagram quotation.

Why each choice is right or wrong

A - Incorrect: int appears after byte and short in the widening diagram

B - Correct: byte is the earliest/narrowest listed integer type in the diagram

C - Incorrect: short is wider than byte in the diagram

D - Incorrect: long appears after int in the diagram

Primary note proof

Study-note section OOP06

> Java has byte, short, int, long, float, double, char and boolean. Signed integer widths are 8,16,32,64 bits respectively. byte ranges from -128 to 127; short from -32768 to 32767.

types.
• All integers in Java are signed, Java doesn‟t support unsigned integers.

Question sources

Object-Oriented Programming practice questions · Question 10

Question 39 | Q00441

Integer Data type does not include following primitive data type _____.

A. long

B. byte

C. short

D. double

Hint

Identify the primitive category, width and conversion rule before evaluating a declaration or expression.

Answer D: double is not an integer primitive type.

OOP06 lists byte, short, int and long as the signed integer types with widths 8,16,32,64 bits. Of the supplied options, long, byte and short belong to that group. double represents floating-point values rather than an integer primitive, so it is the exception requested by the question.

Why each choice is right or wrong

A - Incorrect: long is the 64-bit signed integer primitive in the note's integer-width sequence.

B - Incorrect: byte is the 8-bit signed integer primitive with the stated range -128 to 127.

C - Incorrect: short is the 16-bit signed integer primitive with the stated range -32768 to 32767.

D - Correct: double belongs to the floating numeric types rather than the signed integer primitive group.

Primary note proof

Study-note section OOP06

Java has byte, short, int, long, float, double, char and boolean. Signed integer widths are 8,16,32,64 bits respectively.

Object Oriented Programming module | PDF page 6 | lines 4-17

Java has two basic data types
1. Primitive Data Types: are 8 in java (byte, short, int, long, float, double, char & Boolean)
2. Reference types: Arrays, classes, and interfaces, String)
• Note: Boolean type has a value true or false (there is no conversion b/n Boolean and other types).
• All non-primitive types are reference types, so all class types are reference types.
• All integers in Java are signed, Java doesn‟t support unsigned integers.

Object-Oriented Programming practice questions · Question 11

Question 40 | Q00442

Character data type cannot store following value.

A. Digit

B. Letter

C. Special Character

D. String

Hint

Identify the primitive category, width and conversion rule before evaluating a declaration or expression.

Answer D: String

Character literals such as 'M' represent individual characters, while strings such as "Hi" are sequences of characters. A whole String is not one char value.

Why each choice is right or wrong

A - Incorrect: A digit can be a single character, not a multi-character string

B - Incorrect: A letter is a single character, illustrated by M

C - Incorrect: A special symbol can be one character

D - Correct: A string is a sequence rather than one character

Primary note proof

Study-note section OOP06

char is an unsigned 16-bit UTF-16 code unit and can hold a digit, letter or symbol, not a whole String.

5. String Class:- Immutable Class created to manipulate strings(Sequence of chars).

Question sources

Object-Oriented Programming practice questions · Question 12

Question 41 | Q00443

Range of Byte Data Type is _____.

A. -128 to 128

B. -127 to 127

C. -127 to 128

D. -128 to 127

Hint

Identify the primitive category, width and conversion rule before evaluating a declaration or expression.

Answer D: -128 to 127, inclusive.

OOP06 states that byte ranges from -128 to 127. These inclusive endpoints provide 256 values for an 8-bit signed type. Options that include positive 128 exceed the upper endpoint, and those starting at -127 omit the lowest permitted value. Only D preserves both limits correctly.

Why each choice is right or wrong

A - Incorrect: The upper endpoint 128 is one greater than the largest byte value 127.

B - Incorrect: The lower endpoint -127 omits the valid minimum byte value -128.

C - Incorrect: Both endpoints are wrong: -128 is omitted and the invalid positive value 128 is included.

D - Correct: The inclusive limits -128 and 127 exactly match the byte range stated in OOP06.

Primary note proof

Study-note section OOP06

> byte ranges from -128 to 127; short from -32768 to 32767.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Question sources

Object-Oriented Programming practice questions · Question 13

Question 42 | Q00444

What is size of integer in Java Programming.

A. 1 Bytes

B. 2 Bytes

C. 4 Bytes

D. 8 Bytes

Hint

Identify the primitive category, width and conversion rule before evaluating a declaration or expression.

Answer C: 4 bytes (32 bits).

In OOP06's ordered list, int is the 32-bit signed integer type. Converting 32 bits at eight bits per byte gives four bytes. The question concerns Java's fixed int width rather than implementation-dependent C++ sizes. The one-, two- and eight-byte options correspond to different integer widths.

Why each choice is right or wrong

A - Incorrect: One byte corresponds to the 8-bit byte type, not the 32-bit Java int.

B - Incorrect: Two bytes correspond to the 16-bit short width, not the Java int width.

C - Correct: Java int has 32 bits, equivalent to four eight-bit bytes.

D - Incorrect: Eight bytes correspond to the 64-bit long width, rather than the Java int width.

Primary note proof

Study-note section OOP06

> Signed integer widths are 8,16,32,64 bits respectively.

Study-note section OOP-S02

> Java 17 float uses IEEE 754 binary32, and double uses binary64.

Question sources

Object-Oriented Programming practice questions · Question 14

Question 43 | Q00445

Which of the following data type(s) can store 64 bit Value.

A. boolean

B. int

C. float

D. long

Hint

Identify the primitive category, width and conversion rule before evaluating a declaration or expression.

Answer D: long is the 64-bit integer primitive.

OOP06 identifies long as the 64-bit signed integer primitive, following byte, short and int at 8,16 and 32 bits. That directly matches the question's storage-width interpretation. boolean represents logical values, int has only 32 bits, and float is not the stated 64-bit integer storage type.

Why each choice is right or wrong

A - Incorrect: boolean represents logical values rather than providing storage for an arbitrary 64-bit numeric value.

B - Incorrect: The note assigns int a 32-bit width, so it is not the 64-bit integer type.

C - Incorrect: float is a floating numeric type rather than the long integer type explicitly assigned 64 bits.

D - Correct: long is the 64-bit signed integer type identified here's width sequence.

Primary note proof

Study-note section OOP06

> Java has byte, short, int, long, float, double, char and boolean. Signed integer widths are 8,16,32,64 bits respectively.

Study-note section OOP-S02

> Java 17 float uses IEEE 754 binary32, and double uses binary64.

Question sources

Object-Oriented Programming practice questions · Question 15

Question 44 | Q00446

Short data type has a minimum value of _____.

A. -32768

B. -32767

C. 32768

D. 32767

Hint

Identify the primitive category, width and conversion rule before evaluating a declaration or expression.

Answer A: -32768.

OOP06 gives the Java short range as -32768 through 32767. The question asks for its minimum, so the negative lower endpoint is required. -32767 is one above the minimum; positive 32767 is the maximum, and positive 32768 is outside the stated range entirely.

Why each choice is right or wrong

A - Correct: -32768 is exactly the lower endpoint of the short range given in OOP06.

B - Incorrect: -32767 is representable but is one above the minimum short value.

C - Incorrect: 32768 is above the maximum short value and cannot be its minimum.

D - Incorrect: 32767 is the maximum short value, whereas the question asks for the minimum.

Primary note proof

Study-note section OOP06

byte ranges from -128 to 127; short from -32768 to 32767.

Question sources

Object-Oriented Programming practice questions · Question 16

Question 45 | Q00447

What default value does a Java boolean instance field receive before any explicit initializer or constructor assignment?

A. TRUE

B. false

C. null

D. garbage

Hint

Locate the declaration scope and check default initialization versus definite assignment.

Answer B: false

Java fields receive defined initial values before ordinary explicit initialization. For primitive boolean fields that value is false. true is the other Boolean value, null is a reference value rather than a Boolean value, and Java does not expose an uninitialized field as garbage. The question specifically selects an instance field, so local-variable definite-assignment rules do not change the answer.

Why each choice is right or wrong

A - Incorrect: true is not the default Boolean field value.

B - Correct: false is the default value of a boolean field.

C - Incorrect: null is a reference default and cannot be a primitive boolean value.

D - Incorrect: Java supplies a defined field default rather than a garbage value.

Primary note proof

Study-note section OOP05

> Java fields and array elements receive defaults: numeric zero, char '\u0000', boolean false and references null. A local int t; followed by printing t is a compilation error.

Module passages - related reading

Object-Oriented Programming practice questions · Question 17

Question 46 | Q00448

What will be the output of the program?

```
class Main {
public static void main(String args[]) {
int t;
System.out.println(t);
}
}
```

A. 0

B. garbage value

C. compiler error

D. runtime error

Hint

Locate the declaration scope and check default initialization versus definite assignment.

Answer C: compiler error

t is a local variable read before assignment. Local variables must be initialized before use and have no default value.

Why each choice is right or wrong

A - Incorrect: Incorrectly applies a field-style default

B - Incorrect: Locals cannot be read as an arbitrary garbage value

C - Correct: Violates the initialization-before-use requirement

D - Incorrect: The violation arises before execution rather than as a runtime failure

Primary note proof

Study-note section OOP05

> Locals occur in methods, constructors or blocks; they must be definitely assigned before use and cannot have public/private/protected modifiers.

Study-note section OOP05

> A local int t; followed by printing t is a compilation error.

Question sources

Object-Oriented Programming practice questions · Question 18

Question 47 | Q00449

What will be the output of the program?
class Test {
public static void main(String[] args) {
for(int i = 0; 0; i++)
{
System.out.println(""Hello"");
break;
}
}
}

A. Hello

B. Empty Output

C. Compiler error

D. Runtime error

Hint

Identify the primitive category, width and conversion rule before evaluating a declaration or expression.

Answer C: Compiler error.

The for condition is integer literal 0, whereas OOP06 explicitly says for(...;0;...) is invalid in Java. The doubled quotes around Hello are another source syntax defect. Compilation therefore fails before any loop or print can execute. Treating zero as a false Java condition would incorrectly import C++ numeric truth conversion.

Why each choice is right or wrong

A - Incorrect: No Hello output occurs because the invalid loop condition prevents compilation.

B - Incorrect: Zero is not a legal false condition in Java; this is a compile-time error rather than a valid zero-iteration loop.

C - Correct: The numeric condition and malformed quoted text are compile-time source defects.

D - Incorrect: The program fails translation before execution, so the relevant failure is not a runtime exception.

Primary note proof

Study-note section OOP06

> boolean does not convert to or from numeric truth values; if(0) and for(...;0;...) are invalid.

Study-note section OOP-S01

> An identifier is a programmer-chosen name for an entity such as a class, method or variable. A reserved keyword has a language-defined role and cannot be used as an ordinary identifier. A

literal writes a value directly, such as an integer, floating-point number, quoted character, quoted string or Boolean value.

Study-note section OOP-S03

A while header is while(condition). A basic for header is for(initialization; condition; update). A do-while statement places its condition after the body. An if selects its true branch or, when present, its else branch; only the selected branch executes.

Object-Oriented Programming practice questions · Question 19

Question 48 | Q00450

What will be the output of the program?

```
class mainclass {
public static void main(String args[])
{
boolean var1 = true;
boolean var2 = false;
if (var1)
System.out.println(var1);
else
System.out.println(var2);
}
}
```

A. 0

B. 1

C. true

D. FALSE

Hint

Respect operator grouping and operand types, then trace each operation in evaluation order.

Answer C: true

var1 is initialized to true, so the if body executes and prints var1. The else body is skipped, so var2 does not appear. Java's Boolean output is the lowercase word true, followed by the newline from println. It does not use numeric 1 or uppercase TRUE. Correcting C's case makes it the exact visible output rather than an approximate description.

Why each choice is right or wrong

A - Incorrect: The chosen true Boolean value does not print as numeric 0.

B - Incorrect: Java Boolean output is not encoded as numeric 1.

C - Correct: The true branch prints the lowercase word true.

D - Incorrect: The false value is not printed because the else branch is skipped.

Primary note proof

Study-note section OOP23

> Printing Boolean true gives lowercase true, not 1 or uppercase TRUE.

Study-note section OOP-S03

> A while header is while(condition). A basic for header is for(initialization; condition; update). A do-while statement places its condition after the body. An if selects its true branch or, when present, its else branch; only the selected branch executes.

3. Control flow statements: regulates the order of statements execution
Selection: the if() and switch() statements

Question sources

Object-Oriented Programming practice questions · Question 20

Question 49 | Q00451

What is the numerical value computed by the final expression, rounded to eight digits after the decimal point? This asks for the rounded value, not the exact unformatted console string.

```
class average {
public static void main(String args[])
{
double num[] = {5.5, 10.1, 11, 12.8, 56.9, 2.5};
double result;
result = 0;
for (int i = 0; i<6; ++i)
result = result + num[i];
System.out.print(result/6);
}
}
```

A. 16.34

B. 16.56666664

C. 16.46666667

D. 16.76666667

Hint

Trace every element or API argument and distinguish copying values from aliasing a reference.

Answer C: 16.46666667

The six listed numbers sum to 98.8 mathematically. Dividing by six gives approximately 16.4666666667, which rounds to 16.46666667 at eight decimal places. Small binary-double representation differences do not affect that rounding here. The original unformatted print call does not impose eight-place formatting, so the revised question explicitly requests a rounded numerical value rather than claiming this is its exact console string.

Why each choice is right or wrong

A - Incorrect: 16.34 is not the sum divided by six at the requested precision.

B - Incorrect: 16.56666664 differs from the computed mean before rounding.

C - Correct: 16.46666667 is the mean rounded to eight decimal places.

D - Incorrect: 16.76666667 does not match the computed mean.

Primary note proof

Study-note section OOP27

> For int[] a=new int[4], setting a[i]=i*3 and accumulating yields 0+3+6+9=18. To average an array, sum every element and divide by its length using floating arithmetic; handle zero length separately. Floating representations and printing can differ from a rounded mathematical result. For the six-value example, the mathematical average is 98.8/6, approximately 16.46666667; the exact printed string also depends on floating representation and formatting.

Study-note section OOP26

Valid indices are 0..a.length-1; an invalid access throws ArrayIndexOutOfBoundsException.

Object-Oriented Programming practice questions · Question 21

Question 50 | Q00452

What will be the output of the program?
class increment {
public static void main(String args[])
{
int g = 4;
System.out.print(++g * 8);
}
}

A. 32

B. 36

C. 40

D. 48

Hint

Track the old and updated values separately and distinguish a character operand from a string.

Answer C: 40.

The prefix increment changes g from 4 to 5 before its value is used in multiplication. The expression therefore computes 5*8=40 and prints that integer. This differs from postfix increment, which would supply the old value to the multiplication. Only one increment occurs in this expression.

Why each choice is right or wrong

A - Incorrect: 32 would multiply the old value 4 by 8, which does not respect prefix increment.

B - Incorrect: 36 is not the product of either the old value 4 or updated value 5 with 8.

C - Correct: Prefix increment supplies 5, so the printed product is 5 times 8, or 40.

D - Incorrect: 48 requires g to become 6, but the single increment changes it only from 4 to 5.

Primary note proof

Study-note section OOP24

> Starting x=5, printing x++ then ++x gives 5 then 7.

Study-note section OOP23

> Java evaluates operands left to right while respecting precedence.

Module passages - related reading

Question sources

Object-Oriented Programming practice questions · Question 22

Question 51 | Q00453

What will this program print when run on Java 17?

```
class area {
public static void main(String args[])
{
double r, pi, a;
r = 9.8;
pi = 3.14;
a = pi * r * r;
System.out.println(a);
}
}
```

A. 301.5656

B. 301

C. 301.56

D. 301.57

Hint

Read the cited conceptual rules, state the model, and apply them before comparing the alternatives.

Answer A: 301.5656

Java groups pi * r * r as (pi * r) * r and rounds each double multiplication using binary64 arithmetic. The resulting value has hexadecimal representation 0x1.2d90cb295e9e2p+8. Java 17's standard conversion prints that value as 301.5656, followed by println's line terminator. The supplementary Oracle rules establish the precise arithmetic and text conversion; no separate decimal-place formatting is applied.

Why each choice is right or wrong

A - Correct: 301.5656 is the standard Java 17 printed representation of the computed double.

B - Incorrect: There is no integer conversion that discards the fractional part.

C - Incorrect: The program does not truncate or format the result to two decimal places.

D - Incorrect: The program does not round its displayed output to two decimal places.

Primary note proof

Study-note section OOP-S02

> Java 17 float uses IEEE 754 binary32, and double uses binary64. Successive multiplications group from left to right. Each floating-point operation rounds to its representable result, using nearest-value rounding with ties to even; regrouping a product can change its result.

Study-note section OOP-S02

> PrintStream.print(double) converts the stored value through String.valueOf and Double.toString. For finite nonzero magnitudes from 0.001 inclusive to 10000000 exclusive, the standard decimal form uses at least one fractional digit and only the further digits needed to distinguish the value from adjacent doubles. println(double) also adds a line terminator. This is not fixed-decimal-place formatting.

Question 52 | Q00454

What will be the output of the program?

```
class increment {
public static void main(String args[])
{
int g = 6;
System.out.print(--g * 8);
}
}
```

A. 48

B. 40

C. 56

D. 44

Hint

Read the cited conceptual rules, state the model, and apply them before comparing the alternatives.

Answer B: 40.

The prefix decrement reduces g from 6 to 5 before multiplication uses it. The resulting integer expression is 5*8, which equals 40. The updated value is used immediately; it is not the old 6 and no later increment occurs. Thus the integer printed is 40.

Why each choice is right or wrong

A - Incorrect: 48 uses the old value 6, which would not reflect the prefix decrement before multiplication.

B - Correct: Prefix decrement supplies 5 to the multiplication, producing 5*8=40.

C - Incorrect: 56 uses 7, but decrement reduces the initial 6 instead of increasing it.

D - Incorrect: 44 is not 5 multiplied by 8 and does not follow the stated prefix update.

Primary note proof

Study-note section OOP-S03

> Prefix ++ and -- update a variable before supplying its value; postfix forms supply the old value before the update. Multiplication, division and remainder bind before addition and subtraction; same-level binary arithmetic groups left to right. Integer division truncates toward zero.

Study-note section OOP23

> Java evaluates operands left to right while respecting precedence.

> ✓ Operators: Are symbols that take one or more arguments (operands) and operates on them to produce a result. An operator performs a function on one (Unary), two (Binary), or three operands (Ternary). Java has one ternary operator, ?:, which is a short-hand if-else statement. E.g. c=x?w:s; Operators can be Arithmetic, Logical, assignment, Relational, conditional, Increment,

Question sources

Object-Oriented Programming practice questions · Question 24

Question 53 | Q00456

To declare more than one variable of the specified type, we can use a _____ list.

A. colon-separated

B. bracket-separated

C. comma-separated

D. None of the above

Hint

Locate the declaration scope and check default initialization versus definite assignment.

Answer C: A comma-separated declarator list.

OOP05 illustrates a declaration with int a=10,b=10, separating the declarators with a comma. The shared type applies to each name in that declaration. Colons and brackets serve other syntactic purposes and do not separate ordinary variable declarators in the example. The comma-separated option states the required list form.

Why each choice is right or wrong

A - Incorrect: A colon does not separate the ordinary variable declarators shown in the note's shared-type declaration.

B - Incorrect: Brackets describe array types or indexing rather than separating names in a declarator list.

C - Correct: The example int a=10,b=10 uses a comma between variable declarators sharing the type int.

D - Incorrect: Comma-separated is an offered and supported list form, so none of the above is false.

Primary note proof

Study-note section OOP05

> Initializers such as int a=10,b=10; assign initial values.

Object Oriented Programming module | PDF page 4 | lines 11-20

> ✓ Reserved keywords: class, extends, implements, for…
> ✓ Identifiers: programmers given name; grade, gRade…
> ✓ Literals (Constants values): 55, 60.78, "Hi", „M"… Java language specifies five major types of literals => integer,

floating, character, string &
Boolean literals

Question sources

Object-Oriented Programming practice questions · Question 26

Question 54 | Q00457

In the introductory grouping by declaration scope and class-versus-instance ownership, how many categories of Java variables are distinguished? Include parameter and block-local contexts within the local category.

A. 2

B. 3

C. 4

D. 5

Hint

Locate the declaration scope and check default initialization versus definite assignment.

Answer B: 3

The introductory grouping distinguishes local variables, instance fields and class/static fields. Locals belong to method, constructor or block execution; instance fields belong to individual objects; static fields belong to the class. This gives three categories. The question uses that teaching grouping rather than counting every variable category distinguished by the full language specification.

Why each choice is right or wrong

A - Incorrect: Two categories cannot account for all three of local, instance and class/static variables.

B - Correct: The specified introductory grouping contains local, instance and class/static categories: three.

C - Incorrect: Four exceeds the three categories in the specified grouping.

D - Incorrect: Five exceeds the three categories in the specified grouping.

Primary note proof

Study-note section OOP05

The introductory three-way grouping is local, instance and class/static variables.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Object Oriented Programming module | PDF page 4 | lines 59-73

There are three kinds of variables in Java:
A. Local variables:
• Local variables are declared in methods, constructors, or blocks.
• has only local scope
• Access modifiers cannot be used for local variables.
• They are visible only within the declared method, constructor, or block.
• Have not a default value
• Should be declared and initialized @ z first time.
• Declare before use anywhere in a method or block.

Object Oriented Programming module | PDF page 5 | lines 14-38

B. Instance variables:
• Are declared in a class, but outside a method, constructor or any block.
• Have default values.
• are variables which are bound to the object itself. Meaning=>
• Every instance of that class (object) has it's own copy of that variable
• Are created when an object is created with the use of the keyword 'new' and destroyed when the object is destroyed.
• Can be declared in class level before or after use.
• Access modifiers can be given for instance variables.
• Are visible for all methods, constructors and block in the class.
E.g. class MyClass {
float aFloat; }
NB: By default, a member declared within a class is an instance member.

Object Oriented Programming module | PDF page 5 | lines 39-61

C. Class/Static variables
• Are declared with the static

keyword in a class, but outside a method, constructor or a block.
• There would only be one copy of each class variable per class, regardless of how many objects are created from it.
• Are rarely used other than being declared as constants. (public static final)
• Are stored in the static memory.
• Static variables are created when the program starts and destroyed when the program stops.
• Visibility is similar to instance variables. However, most static variables are declared public
• Default values are same as instance variables.
• Static variables can be accessed by calling with the class name ClassName.VariableName.

Object-Oriented Programming practice questions · Question 27

Question 55 | Q00458

Local variables are declared in?

A. methods

B. constructors

C. blocks

D. All of the above

Hint

Locate the declaration scope and check default initialization versus definite assignment.

Answer D: All of the above

The local-variable definition explicitly includes methods, constructors and blocks.

Why each choice is right or wrong

A - Incorrect: One of the three listed contexts

B - Incorrect: One of the three listed contexts

C - Incorrect: One of the three listed contexts

D - Correct: Combines all three permitted contexts

Primary note proof

Study-note section OOP05

> Locals occur in methods, constructors or blocks; they must be definitely assigned before use and cannot have public/private/protected modifiers.

Module passages - related reading

> • Declare before use anywhere in a method or block.

Question sources

Object-Oriented Programming practice questions · Question 28

Question 56 | Q00459

Which qualifier is preferred for accessing an accessible Java static field to make its class-level ownership clear?

A. Object name

B. Class name

C. Function name

D. Can not say

Hint

Decide whether a member belongs to a class or an object, then check initialization and final restrictions.

Answer B: Class name

A static field belongs to the loaded class and is shared by its instances. ClassName.field makes that ownership explicit and is the recommended qualification. An object reference can sometimes qualify a static member, but it obscures the class-level nature and is not the preferred form asked for. Function names do not supply the owning type, and the style rule gives a definite answer.

Why each choice is right or wrong

A - Incorrect: Object qualification can be legal, but it is not the preferred class-ownership notation.

B - Correct: Class qualification is the preferred notation for a static field.

C - Incorrect: A function name does not identify the field's owning type as a qualifier.

D - Incorrect: The note provides a definite preferred class-qualified form.

Primary note proof

Study-note section OOP07

> static gives one field per loaded class, shared by its instances. If count starts at zero and every constructor increments it, three creations leave count=3. Prefer ClassName.count and ClassName.utility().

Study-note section OOP16

> With Animal a=new Dog(), a.staticMethod() resolves using Animal's compile-time type. Prefer Animal.staticMethod() for clarity.

Object Oriented Programming module | PDF page 5 | lines 39-61

> C. Class/Static variables
> • Are declared with the static keyword in a class, but outside a method, constructor or a block.
> • There would only be one copy of each class variable per class, regardless of how many objects are created from it.
> • Are rarely used other than being declared as constants. (public static final)
> • Are stored in the static memory.
> • Static variables are created when the program starts and destroyed when the program stops.
> • Visibility is similar to instance variables. However, most static

variables are declared public
• Default values are same as instance variables.
• Static variables can be accessed by calling with the class name ClassName.VariableName.

Object Oriented Programming module | PDF page 14 | lines 2-19

Static methods and Final Variables
• A static method can access only static data.
• A static method can call only other static data (Static methods & variables), but can not call a non-static data from it.
• Static method is belongs to the class and not to the object.
• A static method can be accessed directly by the class name and doesn‟t need any object.
• i.e ClassName.methodName(args)
• A static method cannot refer to "this" or "super" keywords in anyway
• But can be overloaded since they are resolved using static binding by compiler at compile time.

Question sources

Object-Oriented Programming practice questions · Question 29

Question 57 | Q00460

Which of the following is an Example of variable initialization?

A. int a, b, c;

B. int a = 10, b = 10;

C. int 10 = a;

D. None of the above

Hint

Locate the declaration scope and check default initialization versus definite assignment.

Answer B: int a = 10, b = 10;

The declaration double c = 8.4 illustrates assignment of an initial value at declaration; B follows the same type-name-equals-value pattern for a and b.

Why each choice is right or wrong

A - Incorrect: Declares variables without initial values

B - Correct: Assigns initial values 10 to named variables

C - Incorrect: Places a literal where the declared name belongs

D - Incorrect: B demonstrates initialization

Primary note proof

Study-note section OOP05

> Initializers such as int a=10,b=10; assign initial values.

Study-note section OOP-S01

> An identifier is a programmer-chosen name for an entity such as a class, method or variable. A reserved keyword has a language-defined role and cannot be used as an ordinary identifier. A literal writes a value directly, such as an integer, floating-point number, quoted character, quoted string or Boolean value.

Question 58 | Q00461

Access modifiers cannot be used for local variables.

A. Yes

B. No

C. Can be yes or no

D. Cannot say

Hint

Locate the declaration scope and check default initialization versus definite assignment.

Answer A: Yes

The local-variable section explicitly says access modifiers cannot be used for local variables.

Why each choice is right or wrong

A - Correct: Agrees with the rule

B - Incorrect: Contradicts the rule

C - Incorrect: The stated prohibition is not conditional

D - Incorrect: The rule gives a definite answer

Primary note proof

Study-note section OOP05

> Locals occur in methods, constructors or blocks; they must be definitely assigned before use and cannot have public/private/protected modifiers.

Object-Oriented Programming practice questions · Question 31

Question 59 | Q00462

Which of the following can be operands of arithmetic operators?

A. Characters

B. Boolean

C. Numeric

D. Both Numeric & Characters

Hint

Identify the primitive category, width and conversion rule before evaluating a declaration or expression.

Answer D: Both numeric values and characters can participate in arithmetic.

OOP06 states that arithmetic promotes char, byte and short to int in many expressions. Characters are therefore allowed alongside numeric operands. boolean does not convert to numeric truth values and is not an arithmetic operand. D gives the complete supported pair; A and C each mention only part of that operand domain.

Why each choice is right or wrong

A - Incorrect: Characters are permitted through promotion, but this option alone omits the also-permitted numeric operand category.

B - Incorrect: Java boolean does not convert to numeric values for arithmetic, as OOP06 explicitly states.

C - Incorrect: Numeric operands are permitted, but this option alone omits the also-permitted character category.

D - Correct: Both numeric and char operands are permitted; chars undergo numeric promotion for arithmetic.

Primary note proof

Study-note section OOP06

> Arithmetic promotes char, byte and short to int in many expressions. boolean does not convert to or from numeric truth values; if(0) and for(...;0;...) are invalid.

Java has two basic data types
1. Primitive Data Types: are 8 in java
(byte, short, int, long, float, double,
char & Boolean)
2. Reference types: Arrays, classes,
and interfaces, String)
• Note: Boolean type has a value true or
false (there is no conversion b/n Boolean
and other types).
• All non-primitive types are reference
types, so all class types are reference
types.
• All integers in Java are signed, Java
doesn‟t support unsigned integers.

Question sources

Object-Oriented Programming practice questions · Question 32

Question 60 | Q00463

Modulus operator, %, can be applied to which of these?

A. Both Integers and floating - point numbers

B. Integers

C. Floating - point numbers

D. None of the mentioned

Hint

Respect operator grouping and operand types, then trace each operation in evaluation order.

Answer A: Both integers and floating-point numbers in Java.

OOP23 explicitly contrasts Java with C++: Java % accepts floating-point operands as well as integers. This course's Java context therefore makes A the complete domain among the offered choices. B and C each name only one supported category. Importing C++'s integral-only restriction would give the wrong answer for Java.

Why each choice is right or wrong

A - Correct: Both integer and floating-point operands are accepted by Java's remainder operator according to OOP23.

B - Incorrect: Integers are allowed, but this option alone omits Java's also-supported floating-point operands.

C - Incorrect: Floating-point values are allowed, but this option alone omits the also-supported integer operands.

D - Incorrect: The note explicitly supports both supplied operand categories, so none of the mentioned is false.

Primary note proof

Study-note section OOP23

> Unlike C++, Java % also accepts floating-point operands.

Question 61 | Q00465

Evaluate the value of the expression?
6 - 2 + 10 % 4 + 7

A. 14

B. 12

C. 13

D. 10

Hint

Respect operator grouping and operand types, then trace each operation in evaluation order.

Answer C: 13.

The remainder operation is evaluated first: 10%4 is 2. The remaining additions and subtraction group left to right, yielding 6-2+2+7 = 4+2+7 = 13. OOP23 includes the same expression and result. No floating conversion or increment operation appears in this calculation.

Why each choice is right or wrong

A - Incorrect: 14 does not follow the remainder 10%4=2 and the resulting sum 6-2+2+7.

B - Incorrect: 12 is one below the computed total and does not respect the stated remainder result.

C - Correct: Evaluating 10%4 first gives 2; then 6-2+2+7 equals 13.

D - Incorrect: 10 omits or miscalculates part of the expression; the full integer evaluation gives 13.

Primary note proof

Study-note section OOP23

> Java evaluates operands left to right while respecting precedence.

Study-note section OOP23

> 6-2+10%4+7 is 13.

Study-note section OOP-S03

> Prefix ++ and -- update a variable before supplying its value; postfix forms supply the old value before the update. Multiplication, division and remainder bind before addition and subtraction; same-level binary arithmetic groups left to right. Integer division truncates toward zero.

Question sources

Object-Oriented Programming practice questions · Question 35

Question 62 | Q00466

What is the output of this program?

```
class Main {
public static void main(String args[])
{
double var1 = 2 + 4;
double var2 = var1 / 4;
int var3 = 2 + 4;
int var4 = var3 / 4;
System.out.print(var2 + " " + var4);
}
}
```

A. 0 1

B. 1 1

C. 1.5 1

D. 1.5 1.0

Hint

Respect operator grouping and operand types, then trace each operation in evaluation order.

Answer C: 1.5 1.

Both additions initially produce 6. Assigning one to double makes var1=6.0, so var1/4 gives 1.5. var3 remains int, so var3/4 truncates to integer 1. The string containing a space then concatenates their representations, producing 1.5 1 rather than giving the integer result a decimal suffix.

Why each choice is right or wrong

A - Incorrect: The double division of 6.0 by 4 yields 1.5, not zero.

B - Incorrect: The first quotient is floating point and retains .5 rather than becoming integer 1.

C - Correct: The double quotient prints 1.5, followed by the space and integer quotient 1.

D - Incorrect: var4 is int, so its string representation is 1 rather than 1.0.

Primary note proof

Study-note section OOP23

> Integer 6/4 is 1; double 6.0/4 is 1.5.

Study-note section OOP24

> Once a String operand is encountered, + concatenates in left-to-right groups: 1+2+"x" gives "3x", while "x"+1+2 gives "x12".

Study-note section OOP-S03

> A while header is while(condition). A basic for header is for(initialization; condition; update). A do-while statement places its condition after the body. An if selects its true branch or, when present, its else branch; only the selected branch executes.

Object-Oriented Programming practice questions · Question 36

Question 63 | Q00467

What will be the output of the program?

```
class Bitwise
{
public static void main(String [] args)
{
int x = 11 & 9;
int y = x ^ 3;
System.out.println( y | 12 );
}
}
```

A. 7

B. 0

C. 14

D. 8

Hint

Respect operator grouping and operand types, then trace each operation in evaluation order.

Answer C: 14.

The AND produces 11&9 = 1011&1001 = 1001, or 9. XOR with 3 gives 1001^0011 = 1010, or 10. OR with 12 then gives 1010|1100 = 1110, or 14. OOP23 explicitly provides this chain; these are integer bitwise operations, not Boolean short-circuit operations.

Why each choice is right or wrong

A - Incorrect: Seven has binary 0111, whereas the final OR produces 1110.

B - Incorrect: The final OR includes the set bits of 12, so it cannot produce zero.

C - Correct: The chain produces x=9, y=10 and final y|12=14.

D - Incorrect: Eight omits bits set by the final OR of binary 1010 and 1100.

Primary note proof

Study-note section OOP23

For bitwise values, write binary columns: 11&9=9; 9^3=10; 10|12=14.

Question sources

Object-Oriented Programming practice questions · Question 37

Question 64 | Q00468

What is the output of relational operators?

A. Integer

B. Boolean

C. Characters

D. Double

Hint

Read the cited conceptual rules, state the model, and apply them before comparing the alternatives.

Answer B: Boolean.

Relational expressions test a relation rather than return one of their numeric operands. In Java that truth result is Boolean, consistent with OOP06's prohibition on treating boolean as numeric truth values and OOP23's Boolean output discussion. Integer, character and double values can be compared in suitable expressions, but are not the comparison result type.

Why each choice is right or wrong

A - Incorrect: Java comparison results are logical values rather than integer truth codes such as zero and one.

B - Correct: A relational test yields the Boolean truth value true or false.

C - Incorrect: Characters can be compared, but a comparison does not return a character result.

D - Incorrect: Double operands may participate in comparisons, but their relation yields a Boolean rather than a double.

Primary note proof

Study-note section OOP-S03

> Java relational comparisons (<, <=, >, >=) and equality tests (==, !=) produce primitive boolean truth values. Their result is not an integer truth code or a value of the numeric operand type.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Question sources

Object-Oriented Programming practice questions · Question 38

Question 65 | Q00469

Which of these is returned by "greater than", "less than" and "equal to" operators?

A. Integers

B. Floating - point numbers

C. Boolean

D. None of the mentioned

Hint

Read the cited conceptual rules, state the model, and apply them before comparing the alternatives.

Answer C: Boolean true or false.

Greater-than, less-than and equality operators express truth tests. Java represents their results as Boolean values, not integers or floating-point numbers. OOP06 distinguishes boolean from numeric values, and OOP23 describes printing Boolean true as lowercase true. The operand type therefore does not become the result type of the test.

Why each choice is right or wrong

A - Incorrect: Java uses Boolean truth values for comparisons rather than returning integer zero or one.

B - Incorrect: Comparing floating operands still yields a truth value, not a floating-point numerical result.

C - Correct: Greater-than, less-than and equality comparisons return Boolean true or false.

D - Incorrect: Boolean is explicitly offered and is the appropriate logical result type, so none is false.

Primary note proof

Study-note section OOP-S03

Java relational comparisons (<, <=, >, >=) and equality tests (==, !=) produce primitive boolean truth values. Their result is not an integer truth code or a value of the numeric operand type.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

• All integers in Java are signed, Java doesn‟t support unsigned integers.

Question sources

Object-Oriented Programming practice questions · Question 39

Question 66 | Q00471

In Java, what type must expression1 have in the conditional expression expression1 ? expression2 : expression3?

A. Integer

B. Floating - point numbers

C. Boolean

D. None of the mentioned

Hint

Read the cited conceptual rules, state the model, and apply them before comparing the alternatives.

Answer C: Java requires boolean or Boolean for the first operand of ?: .

Java's conditional operator requires its first operand to have primitive boolean or boxed Boolean type. That condition chooses which of the other two expressions is evaluated; the unselected alternative is not evaluated. Integer and floating-point values are not accepted as numeric truth codes. The Boolean option therefore names the required logical category, and None is false because that category is offered.

Why each choice is right or wrong

A - Incorrect: Java integer values do not satisfy the JLS first-operand requirement of boolean or Boolean.

B - Incorrect: Floating-point values do not satisfy Java's Boolean conditional-operand requirement.

C - Correct: Boolean names the required logical category; Java accepts primitive boolean or boxed Boolean.

D - Incorrect: The Boolean category is offered and satisfies the JLS requirement, so none is false.

Primary note proof

Study-note section OOP-S03

> The conditional expression condition ? whenTrue : whenFalse requires a boolean or Boolean condition. It evaluates only the selected alternative. An integer or floating-point first operand is a compile-time error.

Study-note section OOP06

> boolean does not convert to or from numeric truth values; if(0) and for(...;0;...) are invalid.

> ✓ Operators: Are symbols that take one or more arguments (operands) and operates on them to produce a result. An operator performs a function on one (Unary), two (Binary), or three operands (Ternary). Java has one ternary operator, ?:, which is a short-hand if-else statement. E.g. c=x?w:s; Operators can be Arithmetic,

Logical, assignment,
Relational, conditional,
Increment,

Object Oriented Programming module | PDF page 6 | lines 4-17

Java has two basic data types
1. Primitive Data Types: are 8 in java
(byte, short, int, long, float, double,
char & Boolean)
2. Reference types: Arrays, classes,
and interfaces, String)
• Note: Boolean type has a value true or
false (there is no conversion b/n Boolean
and other types).
• All non-primitive types are reference
types, so all class types are reference
types.
• All integers in Java are signed, Java
doesn‟t support unsigned integers.

Question sources

Object-Oriented Programming practice questions · Question 41

Question 67 | Q00472

What is the value stored in x in following lines of code?
int x, y, z;
x = 0;
y = 1;
x = y = z = 8;

A. 0

B. 1

C. 9

D. 8

Hint

Read the cited conceptual rules, state the model, and apply them before comparing the alternatives.

Answer D: x becomes 8.

The last statement assigns 8 to z, then that same assigned value to y and then x. The earlier x=0 and y=1 values are overwritten, and no addition takes place. This follows assignment's value propagation rather than the left-to-right operand arithmetic discussed in OOP23. The final stored value of x is 8.

Why each choice is right or wrong

A - Incorrect: Zero is x's earlier value; the final chained assignment overwrites it with 8.

B - Incorrect: One is y's earlier value, which is also overwritten before x receives the chain's result.

C - Incorrect: The statement performs assignments, not addition of the earlier y value to 8.

D - Correct: The chain assigns 8 to z, then y and x, leaving x equal to 8.

Primary note proof

Study-note section OOP-S03

> Assignments group right to left: a=b=c assigns c to b, then the resulting value to a. A later assignment overwrites an earlier value. Compound assignments update the left variable using the indicated operation.

Question sources

Object-Oriented Programming practice questions · Question 42

Question 68 | Q00473

What is the output of this program?

```
class Main
{
public static void main(String args[])
{
int x = 8;
System.out.println(++x * 3 + " " + x);
}
}
```

A. 24 8

B. 24 9

C. 27 8

D. 27 9

Hint

Track the old and updated values separately and distinguish a character operand from a string.

Answer D: 27 9.

Prefix ++x changes x from 8 to 9 before multiplication, producing 27. Concatenating the string containing a space switches the remaining + operations to text concatenation. The later x still holds 9 because no further update occurs. Therefore the single println emits 27 9, followed by its newline.

Why each choice is right or wrong

A - Incorrect: Both values wrongly use the original x=8 despite the prefix increment before multiplication.

B - Incorrect: The final x is 9, but the product must also use updated 9 and become 27.

C - Incorrect: The product is 27, but x remains 9 rather than reverting to its original 8.

D - Correct: The prefix update gives 9, its product is 27, and concatenation then appends space and 9.

Primary note proof

Study-note section OOP24

> Starting x=5, printing x++ then ++x gives 5 then 7.

Study-note section OOP24

> Once a String operand is encountered, + concatenates in left-to-right groups: 1+2+"x" gives "3x", while "x"+1+2 gives "x12".

Question sources

Object-Oriented Programming practice questions · Question 43

Question 69 | Q00474

_____ are a sequence of characters.

A. Character

B. Strings

C. Integer

D. Classes

Hint

Read the cited conceptual rules, state the model, and apply them before comparing the alternatives.

Answer B: Strings

The String Class description explicitly equates strings with a sequence of chars.

Why each choice is right or wrong

A - Incorrect: A character is one element, not the named sequence type

B - Correct: The sequence-of-characters type

C - Incorrect: Integer represents a different primitive category

D - Incorrect: Class is the general blueprint concept rather than this sequence type

Primary note proof

Study-note section OOP-S04

> A String represents a sequence of UTF-16 code units. A single char represents one code unit rather than an entire String. String objects are immutable; changing a reference to another String does not modify the original text value.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Object Oriented Programming module | PDF page 9 | lines 14-16

> 5. String Class:- Immutable
> Class created to manipulate
> strings(Sequence of chars).

Question sources

Object-Oriented Programming practice questions · Question 44

Question 70 | Q00475

The String class is?

A. mutable

B. immutable

C. Both A and B

D. None of the above

Hint

Separate identity, content equality, immutable values and references that may be reassigned.

Answer B: immutable

String is immutable, unlike mutable classes whose state can change.

Why each choice is right or wrong

A - Incorrect: Contradicts the stated immutable classification

B - Correct: Matches the stated classification

C - Incorrect: The two opposite classifications do not both describe String here

D - Incorrect: B is directly supported

Primary note proof

Study-note section OOP22

> Java String objects are immutable. text += " World" assigns a reference to a new concatenated result and can print Hello World without mutating the original String object. final class String prevents subclassing; final alone does not make arbitrary objects immutable.

Question sources

Object-Oriented Programming practice questions · Question 45

Question 71 | Q00476

Methods used to obtain information about an object are known as?

A. string methods

B. class methods

C. object method

D. accessor methods

Hint

Separate parameters from arguments and operations that read state from operations that change it.

Answer D: Accessor methods.

OOP11 says an accessor or getter returns information, whereas a mutator or setter changes state. Methods used to obtain information about an object therefore have the specific name accessor methods. String, class and object describe other categories or associations and do not identify this information-reading responsibility.

Why each choice is right or wrong

A - Incorrect: String methods concern a particular class; the requested information-reading role applies to objects generally.

B - Incorrect: Class methods identify a class/static association, rather than the specific purpose of returning object information.

C - Incorrect: Object method is too general; object methods can either read or change state.

D - Correct: Accessor methods specifically return information about object state, matching the definition in OOP11.

Primary note proof

Study-note section OOP11

> An accessor/getter returns information; a mutator/setter changes state.

Study-note section OOP07

> Prefer ClassName.count and ClassName.utility().

• Every Dog object will contain its own copies of the instance variables breed, age, and color.
• To access these variables, you will use the dot (.) operator.
• The dot operator links the name of the object with the name of an instance variable.
• For example, to assign the age variable of myDog the value 10, you would use the following statement:
myDog.age = 10; //This is called

Question sources

Object-Oriented Programming practice questions · Question 46

Question 72 | Q00477

Which method returns the character at the specified index?

A. int compareTo(Object o)

B. int compareTo(String anotherString)

C. char charAt(int index)

D. int compareToIgnoreCase(String str)

Hint

Separate identity, content equality, immutable values and references that may be reassigned.

Answer C: char charAt(int index).

OOP22 explicitly says charAt(index) returns a char. C gives that operation's parameter and result type: an integer position selects a single character. The compareTo alternatives return int comparison results rather than the character at a position, so they do not satisfy the requested retrieval behavior.

Why each choice is right or wrong

A - Incorrect: This comparison signature takes an object rather than an index and returns int instead of a character.

B - Incorrect: This comparison signature takes another String and returns int, rather than retrieving a character by index.

C - Correct: charAt takes an integer index and returns the char at that position, matching OOP22.

D - Incorrect: This comparison signature takes a String, not an integer index, and does not return the indexed char.

Primary note proof

Study-note section OOP22

> charAt(index) returns a char; length() counts UTF-16 units; substring(begin,end) excludes end.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Object Oriented Programming module | PDF page 9 | lines 14-16

> 5. String Class:- Immutable
> Class created to manipulate
> strings(Sequence of chars).

Question sources

Object-Oriented Programming practice questions · Question 47

Question 73 | Q00478

Which of these methods of String class is used to obtain character at specified index?

A. char()

B. Charat()

C. charat()

D. charAt()

Hint

Separate identity, content equality, immutable values and references that may be reassigned.

Answer D: charAt (with an index argument).

The operation named in OOP22 is charAt(index), with a lowercase c and uppercase A. D alone preserves that exact Java method name. The options abbreviate away the index argument; an actual call needs it. Java's case sensitivity prevents Charat or charat from naming the same standard operation.

Why each choice is right or wrong

A - Incorrect: char is a primitive type keyword, not the indexed String character-access method name.

B - Incorrect: Charat has the wrong capitalization and does not name the charAt operation in OOP22.

C - Incorrect: charat lacks the uppercase A required by the case-sensitive standard method name.

D - Correct: charAt is the exact method name; a real invocation supplies an index inside the parentheses.

Primary note proof

Study-note section OOP22

> charAt(index) returns a char; length() counts UTF-16 units; substring(begin,end) excludes end.

Study-note section OOP28

> Java identifiers are case sensitive; $ is allowed but @ is not an identifier character.

Question sources

Object-Oriented Programming practice questions · Question 48

Question 74 | Q00480

Which Java loop form pre-tests its body condition and writes that condition alone in parentheses immediately after its loop keyword, rather than using a three-clause header or a post-test?

A. for

B. do-while

C. while

D. None of the above

Hint

Read the cited conceptual rules, state the model, and apply them before comparing the alternatives.

Answer C: while

A while loop tests its condition before every possible execution and has a condition-only header. A for loop is also a pre-test loop, but its ordinary header has initialization, condition and update clauses. A do-while loop tests after its body and therefore runs at least once. The added header and timing distinctions make while the unique match rather than relying on repetition alone.

Why each choice is right or wrong

A - Incorrect: A basic for uses the three-clause header excluded by the stem.

B - Incorrect: A do-while post-tests rather than pre-testing its first iteration.

C - Correct: while has the condition-only pre-test form described.

D - Incorrect: The while form satisfies the description, so none is incorrect.

Primary note proof

Study-note section OOP-S03

> A while header is while(condition). A basic for header is for(initialization; condition; update). A do-while statement places its condition after the body. An if selects its true branch or, when present, its else branch; only the selected branch executes.

Study-note section OOP25

> while and for pre-test and may execute zero times; do-while post-tests and executes once.

program java uses break and continue statements.
The break statement: used to exit a loop
The Continue Statement: used to force program to go back to the top of a loop
Labels: Java does not include a goto statement.
Instead of goto, Java allows you to combine break and continue with a label.

Question sources

Object-Oriented Programming practice questions · Question 50

Question 75 | Q00481

Which loop guaranteed to execute at least one time?

A. for

B. do-while

C. while

D. All of the above

Hint

Trace condition tests, control transfers and printing as separate steps.

Answer B: do-while.

OOP25 states that do-while post-tests and executes once, whereas for and while pre-test and may execute zero times. The mandatory first body execution is therefore specific to do-while among these forms. This guarantee concerns entering its body when the statement is reached, before deciding whether to repeat.

Why each choice is right or wrong

A - Incorrect: A for loop tests its condition before its first body execution and may execute zero times.

B - Correct: A do-while executes its body before testing the condition, guaranteeing the first body execution.

C - Incorrect: A while loop pre-tests; an initially false condition prevents all body executions.

D - Incorrect: For and while can execute zero times, so the first-execution guarantee does not apply to all forms.

Primary note proof

Study-note section OOP25

while and for pre-test and may execute zero times; do-while post-tests and executes once.

Question sources

Object-Oriented Programming practice questions · Question 51

Question 76 | Q00483

Which statement causes the loop to immediately jump to the next iteration of the loop?

A. Exit

B. Break

C. Jump

D. Continue

Hint

Trace condition tests, control transfers and printing as separate steps.

Answer D: Continue

continue skips the rest of the current iteration and proceeds to the loop's continuation step; break exits the loop. Thus continue matches moving to the next iteration.

Why each choice is right or wrong

A - Incorrect: Exit is not the named loop-jump statement here

B - Incorrect: break leaves the loop

C - Incorrect: Jump is a category, rather than the required keyword

D - Correct: continue advances control to loop continuation

Primary note proof

Study-note section OOP25

> break exits the loop; continue skips its remaining body and then runs a for update.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Object Oriented Programming module | PDF page 7 | lines 26-41

Question sources

Object-Oriented Programming practice questions · Question 54

Question 78 | Q00485

Java array is a collection of _____.

A. similar type of elements

B. different type of element

C. heterogeneous data

D. Both A and C

Hint

Check declared dimensions, initializer shape, fixed length and zero-based index bounds.

Answer A: Elements with a common declared component type.

OOP26 says array elements share a declared common component type, possibly a superclass or interface. That is the precise interpretation of similar type in A. Reference elements may point to different compatible runtime subclasses, but this does not give the array unrelated declared element types or make arbitrary heterogeneous data its defining property.

Why each choice is right or wrong

A - Correct: Similar type is accurate when understood as the array's single declared common component type.

B - Incorrect: The array does not assign an unrelated declared type to each element; compatible runtime subclasses are a separate issue.

C - Incorrect: Heterogeneous runtime objects may share one component type, but unrestricted heterogeneity is not the array's defining type rule.

D - Incorrect: Combining A with unrestricted heterogeneity obscures the single declared component type required by OOP26.

Primary note proof

Study-note section OOP26

> Elements have a declared common component type, which may be a superclass/interface.

Question sources

Object-Oriented Programming practice questions · Question 55

Question 79 | Q00486

Array data access using _____.

A. Operator

B. Variable

C. index

D. Pointer

Hint

Check declared dimensions, initializer shape, fixed length and zero-based index bounds.

Answer C: An index.

OOP26 defines valid array indices as zero through length-1. Selecting an array element therefore uses its index, as in a[i]. An operator participates in the syntax and a variable can hold the index, but neither term identifies the selection value as precisely. Java does not require a raw pointer to access an element.

Why each choice is right or wrong

A - Incorrect: Array-access syntax uses brackets, but operator is less specific than the index that selects the element.

B - Incorrect: A variable can store an index, but array selection also accepts other integer index expressions.

C - Correct: An index specifies the position of the requested element within the array’s valid bounds.

D - Incorrect: Java element access uses checked indices rather than requiring a programmer-visible raw pointer.

Primary note proof

Study-note section OOP26

Valid indices are 0..a.length-1; an invalid access throws ArrayIndexOutOfBoundsException.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Question sources

Object-Oriented Programming practice questions · Question 56

Question 80 | Q00487

Java Array can allocate _____.

A. Dynamic Memory

B. Static Memory

C. Both A and B

D. None of the above

Hint

Check declared dimensions, initializer shape, fixed length and zero-based index bounds.

Answer A: Dynamic allocation of an array object.

OOP26 shows array creation through new int[5] and describes the result as an array object with fixed length after creation. Allocation occurs when that creation expression executes, which is the dynamic-memory meaning of A. Fixed array length does not mean statically allocated storage, and a static reference does not change the array object into static memory.

Why each choice is right or wrong

A - Correct: The creation expression allocates an array object when executed, even though the created object’s length is fixed.

B - Incorrect: A fixed length does not imply static allocation; new creates an array object during execution.

C - Incorrect: Declaring a static reference does not supply a second static-allocation mechanism for the array object itself.

D - Incorrect: The valid new-array expression in OOP26 demonstrates dynamic allocation, so none is false.

Primary note proof

Study-note section OOP26

int[] a=new int[5]; and int a[]={1,2,3}; are valid. int[] a={}; creates a zero-length array; explicit new is unnecessary in a declaration initializer. int a[],b; makes only a an array; int[] c,d; makes both arrays. Array objects have fixed length after creation, although the reference may be reassigned.

Dog.

Question sources

Object-Oriented Programming practice questions · Question 57

Question 81 | Q00488

Which complete Java array declaration has an incorrect initializer syntax? Treat each option independently.

A. int[] arr = new int[5];

B. int arr[] = new int[5];

C. int arr[] = new int[5];

D. int arr[] = int[5] new;

Hint

Check declared dimensions, initializer shape, fixed length and zero-based index bounds.

Answer D: int arr[] = int[5] new;

Java permits array brackets on the declared type or after the variable name, and new int[5] allocates a five-element array. Thus A is valid, and B and its duplicate C are also valid declarations. D reverses the required allocation token order, putting new after int[5]. Replacing editorial periods with semicolons isolates the intended initializer-syntax error without treating punctuation noise as the tested concept.

Why each choice is right or wrong

A - Incorrect: Brackets on the type and new int[5] are valid.

B - Incorrect: Brackets after the variable name are legal with this allocation expression.

C - Incorrect: This duplicates B's valid declaration and is not an incorrect initializer.

D - Correct: The initializer must place new before int[5], so this token order is incorrect.

Primary note proof

Study-note section OOP26

int[] a=new int[5]; and int a[]={1,2,3}; are valid. int[] a={}; creates a zero-length array; explicit new is unnecessary in a declaration initializer. int a[],b; makes only a an array; int[] c,d; makes both arrays.

Question sources

Object-Oriented Programming practice questions · Question 58

Question 82 | Q00489

Index in array start with _____.

A. -1

B. 0

C. 1

D. infinite

Hint

Check declared dimensions, initializer shape, fixed length and zero-based index bounds.

Answer B: 0.

OOP26 states that valid array indices run from zero to length minus one. Thus the first element of any nonempty Java array has index 0. An empty array has no valid element index, but that does not change the language’s zero-based indexing convention requested by this question.

Why each choice is right or wrong

A - Incorrect: Negative one is below the valid lower bound and causes an invalid access when used.

B - Correct: Zero is the first valid index of a nonempty Java array.

C - Incorrect: One selects the second element when present; Java arrays do not use one-based indexing.

D - Incorrect: Infinity is not an array index; valid positions are finite integers below the fixed array length.

Primary note proof

Study-note section OOP26

> Valid indices are 0..a.length-1; an invalid access throws ArrayIndexOutOfBoundsException.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Object Oriented Programming module | PDF page 28 | lines 65-79

> ✓ Unchecked exceptions: Is an exception that occurs at the time of execution, these are also called as Runtime Exceptions.
> ✓ These include programming bugs, such as logic errors or improper use of an API.
> ✓ Runtime exceptions are ignored at the time of compilation.
> ✓ For example, if you have declared an array of size 5 in your program, and trying to call the 6th element of the array then an ArrayIndexOutOfBoundsExceptione xception occurs.

Question sources

Object-Oriented Programming practice questions · Question 59

Question 83 | Q00490

Which shown Java declarations create and initialize a one-dimensional int array? Zero-length arrays count. Treat the options independently. Select all that apply.

A. int arr [] [] = {1, 2, 3, 4};

B. int [] arr = (1, 2, 3);

C. int [] arr = {};

D. int arr [] = {1, 2, 3};

Hint

Check declared dimensions, initializer shape, fixed length and zero-based index bounds.

Answer C, D: int [] arr = {};; int arr [] = {1, 2, 3};

C creates an int array of length zero, and D creates one of length three initialized to 1, 2 and 3. Both declare, create and initialize a one-dimensional array. A declares two dimensions but supplies scalar elements instead of row arrays. B uses parentheses, which do not form an array initializer. Explicitly allowing zero length prevents incorrectly rejecting the valid empty array.

Why each choice is right or wrong

A - Incorrect: The flat int values do not initialize the declared int[][] component rows.

B - Incorrect: Parentheses do not provide a Java array initializer.

C - Correct: Empty braces validly create and initialize a zero-length int array.

D - Correct: The brace list validly creates and initializes a three-element int array.

Primary note proof

Study-note section OOP26

> int[] a=new int[5]; and int a[]={1,2,3}; are valid. int[] a={}; creates a zero-length array; explicit new is unnecessary in a declaration initializer. int a[],b; makes only a an array; int[] c,d; makes both arrays.

Study-note section OOP26

> Java two-dimensional arrays are arrays of arrays and may be ragged: {{12,-9,8},{7,14},{-32,-1,0}} has row lengths 3,2,3.

Question sources

Object-Oriented Programming practice questions · Question 60

Question 84 | Q00491

We can calculate the length of an array using _____.

A. sizeof(array)

B. array.len

C. array.length

D. array.sizeof()

Hint

Check declared dimensions, initializer shape, fixed length and zero-based index bounds.

Answer C: array.length.

OOP26 uses a.length as the fixed element count when defining valid indices. Therefore array.length is the correct Java expression for the length field of an array reference named array. This is a field access rather than a method invocation, and the other supplied spellings are not the array-length mechanism described in the note.

Why each choice is right or wrong

A - Incorrect: sizeof is not the Java array-length expression used in OOP26's index-bound rule.

B - Incorrect: The field name is length, not len, so this spelling does not retrieve array length.

C - Correct: Java arrays expose their fixed element count through the length field, without parentheses.

D - Incorrect: The note uses a length field; arrays do not expose the proposed sizeof method.

Primary note proof

Study-note section OOP26

> Array objects have fixed length after creation, although the reference may be reassigned.

Study-note section OOP26

> Valid indices are 0..a.length-1; an invalid access throws ArrayIndexOutOfBoundsException.

• All non-primitive types are reference types, so all class types are reference types.
• All integers in Java are signed, Java doesn‟t support unsigned integers.

Question sources

Object-Oriented Programming practice questions · Question 61

Question 85 | Q00492

Which is an inherent property of Java arrays? Here “Code Optimization” means a guarantee that merely introducing an array makes every algorithm run faster.

A. Code Optimization

B. Random access

C. Size No-Limit

D. Both A and B

Hint

Check declared dimensions, initializer shape, fixed length and zero-based index bounds.

Answer B: Random access is the concrete array advantage.

Arrays provide indexed random access, so B states the inherent capability. They have a fixed length after creation and are bounded by implementation limits and available resources, so unlimited size is false. An array is a storage structure, not a guarantee that every algorithm becomes faster: allocating an unused array cannot improve a computation that does not need it. A therefore fails the stated guarantee, and combining it with B does not make D correct.

Why each choice is right or wrong

A - Incorrect: The stated universal speedup does not follow from array storage; adding an unused allocation does not improve the algorithm’s required computation.

B - Correct: Indexed random access is a direct array capability.

C - Incorrect: Array length is fixed after creation and constrained by implementation limits and resources.

D - Incorrect: This conjunction includes the false universal optimization guarantee, even though random access itself is true.

Primary note proof

Study-note section OOP27

Random access is the reliable array advantage; size is bounded by implementation/resources, not unlimited.

Study-note section OOP26

Array objects have fixed length after creation, although the reference may be reassigned.

Study-note section OOP03

Student s=new Student(); allocates and initializes an instance.

doesn‟t support unsigned integers.

Question sources

Object-Oriented Programming practice questions · Question 62

Question 86 | Q00493

Which term describes the logical index order of a Java array, from 0 through length−1, rather than making any claim about physical RAM placement?

A. Random

B. Sequential

C. Sequential & Random

D. Binary search

Hint

Check declared dimensions, initializer shape, fixed length and zero-based index bounds.

Answer B: Sequential

Java arrays expose a logical sequence of indices starting at zero and ending at length minus one. Sequential describes that order. Random access describes the ability to choose an index directly, not a random logical ordering of elements or a portable physical-memory arrangement. Binary search is an algorithm rather than an ordering description. The revised question therefore tests index semantics without assuming exposed physical contiguity.

Why each choice is right or wrong

A - Incorrect: Random access does not mean that the logical index sequence is randomly ordered.

B - Correct: Sequential describes the logical index progression from 0 to length−1.

C - Incorrect: Combining access capability with ordering does not give the precise ordering term requested.

D - Incorrect: Binary search is an algorithm, not the array's logical index order.

Primary note proof

Study-note section OOP26

> Valid indices are 0..a.length-1; an invalid access throws ArrayIndexOutOfBoundsException.

Study-note section OOP27

> Random access is the reliable array advantage; size is bounded by implementation/resources, not unlimited.

Question sources

Object-Oriented Programming practice questions · Question 63

Question 87 | Q00494

What will be the output of the program?

```
class Main
{
public static void main(String args[]) {
int arr[] = {10, 20, 30, 40, 50};
for(int i=0; i < arr.length; i++)
{
System.out.print(" " + arr[i]);
}
}
}
```

A. 10 20 30 40 50

B. Compiler Error

C. 10 20 30 40

D. None of the above

Hint

Check declared dimensions, initializer shape, fixed length and zero-based index bounds.

Answer D: Exact output: " 10 20 30 40 50", with an initial space.

The loop visits all five indices, 0 through 4. Each print prepends the literal string containing one space, including before the first element. The exact output is therefore " 10 20 30 40 50" without a newline. A lists the correct numbers but omits that initial space. Under literal output matching, D is the offered exact answer.

Why each choice is right or wrong

A - Incorrect: The listed values are right, but the printed option omits the leading space emitted before 10.

B - Incorrect: The array declaration and traversal stay within indices 0 through 4, so no compilation error follows.

C - Incorrect: The last index 4 is visited and prints 50; this also omits the initial space.

D - Correct: None of the other options reproduces the exact leading-space output required by the literal code.

Primary note proof

Study-note section OOP26

> int[] a=new int[5]; and int a[]={1,2,3}; are valid.

Study-note section OOP26

> Valid indices are 0..a.length-1; an invalid access throws ArrayIndexOutOfBoundsException.

Study-note section OOP25

while and for pre-test and may execute zero times; do-while post-tests and executes once.

Study-note section OOP24

Once a String operand is encountered, + concatenates in left-to-right groups: 1+2+"x" gives "3x", while "x"+1+2 gives "x12".

Study-note section OOP-S02

PrintStream.print(double) converts the stored value through String.valueOf and Double.toString. For finite nonzero magnitudes from 0.001 inclusive to 10000000 exclusive, the standard decimal form uses at least one fractional digit and only the further digits needed to distinguish the value from adjacent doubles. println(double) also adds a line terminator. This is not fixed-decimal-place formatting.

The Continue Statement: used to
force program to go back to the top
of a loop
Labels: Java does not include a goto

statement.
Instead of goto, Java allows you to
combine break and continue with a
label.

Question sources

Object-Oriented Programming practice questions · Question 64

Question 88 | Q00495

Which of these is an incorrect Statement?

A. It is necessary to use new operator to initialize an array

B. Array can be initialized using comma separated expressions surrounded by curly braces

C. Array can be initialized when they are declared

D. None of the mentioned

Hint

Check declared dimensions, initializer shape, fixed length and zero-based index bounds.

Answer A: Explicit new is not necessary in a declaration initializer.

OOP26 explicitly states that new need not be written in a declaration initializer and shows both empty and nonempty brace forms. Thus A is the incorrect statement. B and C describe the valid brace-initializer form used at declaration. This does not imply that an existing array variable can later be assigned a bare brace list.

Why each choice is right or wrong

A - Correct: The claim is false: brace initialization at declaration creates an array without explicitly writing new.

B - Incorrect: This is a true description of the comma-separated brace initializer shown in OOP26.

C - Incorrect: This is true: the note's examples initialize arrays as part of their declarations.

D - Incorrect: A is an offered false statement, so it is incorrect to say none is incorrect.

Primary note proof

Study-note section OOP26

int[] a=new int[5]; and int a[]={1,2,3}; are valid. int[] a={}; creates a zero-length array; explicit new is unnecessary in a declaration initializer.

Question sources

Object-Oriented Programming practice questions · Question 65

Question 89 | Q00496

What is the type of variable "b" and "d" in the below snippet?
int a[], b;
int []c, d;

A. "b" and "d" are int

B. "b" and "d" are arrays of type int

C. "d" is int variable; and "b" is int array

D. "b" is int variable; and "d" is int array

Hint

Check declared dimensions, initializer shape, fixed length and zero-based index bounds.

Answer D: b is int; d is int[].

In int a[],b, the brackets belong only to a, leaving b as a scalar int. In int[] c,d, the brackets are part of the common type, so both c and d are int arrays. OOP26 gives these exact forms. The distinction depends on bracket placement rather than on the variable names.

Why each choice is right or wrong

A - Incorrect: b is scalar int, but d belongs to the common int[] type of the second declaration.

B - Incorrect: Only d is an array; the first declaration attaches brackets to a rather than to b.

C - Incorrect: This reverses the actual types: b is scalar int and d is int[].

D - Correct: Brackets after a leave b scalar, while brackets after int make both c and d arrays.

Primary note proof

Study-note section OOP26

int a[],b; makes only a an array; int[] c,d; makes both arrays.

Object-Oriented Programming practice questions · Question 66

Question 90 | Q00497

How to sort an array?

A. Array.sort()

B. Arrays.sort()

C. Collection.sort()

D. System.sort()

Hint

Trace every element or API argument and distinguish copying values from aliasing a reference.

Answer B: Arrays.sort(array).

OOP27 specifies java.util.Arrays.sort(a) for in-place sorting of an array. B names that method, with the argument omitted as shorthand in the options; a real invocation supplies the array. The other class/method combinations do not match the array-sorting API provided here.

Why each choice is right or wrong

A - Incorrect: The supplied class name Array does not match the java.util.Arrays class specified here.

B - Correct: Arrays.sort is the correct method name; actual use supplies the array argument as Arrays.sort(a).

C - Incorrect: Collection.sort is not the array-sorting API identified in OOP27.

D - Incorrect: System.sort is not the array-sorting API provided in the complete note.

Primary note proof

Study-note section OOP27

> java.util.Arrays.sort(a) sorts in place.

Question sources

Object-Oriented Programming practice questions · Question 67

Question 91 | Q00498

Which correctly spelled Java API copies a selected range from one existing array into another existing array? The parentheses in distractors stand for a method name, not a complete no-argument invocation.

A. System.arraycopy(src, srcPos, dst, dstPos, length)

B. Array.copy()

C. Arrays.copy()

D. Collection.copy()

Hint

Trace every element or API argument and distinguish copying values from aliasing a reference.

Answer A: System.arraycopy(src, srcPos, dst, dstPos, length)

System.arraycopy copies length elements from the supplied source position into a supplied destination array position. Its name uses lowercase c in copy. Arrays.copyOf is a different supported API that creates a copy, but Arrays.copy is not that method's name. The other printed names do not identify the requested array-copy API. Correcting A's spelling and supplying its arguments restores a usable exact choice.

Why each choice is right or wrong

A - Correct: This is the correctly spelled range-copy API for existing source and destination arrays.

B - Incorrect: Array.copy is not the supported API named here.

C - Incorrect: The supported creation API is Arrays.copyOf, not Arrays.copy.

D - Incorrect: Collection.copy is not the specified array-range-copy API.

Primary note proof

Study-note section OOP27

> System.arraycopy(src,srcPos,dst,dstPos,length) copies into an existing array; its exact spelling uses lowercase c. Arrays.copyOf(a,n) creates a copy. a=b merely aliases the same array.

Question sources

Object-Oriented Programming practice questions · Question 68

Question 92 | Q00499

Which named type categories can be directly declared as top-level members of a Java package? Subpackages are separately named packages, not automatically enclosed members. Select all that apply.

A. Classes

B. Sub Packages

C. Interfaces

D. All of the above

Hint

Check declaration order, exact case, package boundaries and the compile-versus-launch stage.

Answer A, C: Classes; Interfaces

A package organizes named types, including classes and interfaces, and provides a naming and access boundary. A subpackage is a separate package identity even when its name starts with the parent’s name. It does not automatically gain membership or access through that spelling. Consequently classes and interfaces are the direct type categories, while the all option wrongly includes subpackages in the same membership sense.

Why each choice is right or wrong

A - Correct: Classes can be top-level named types belonging to the package.

B - Incorrect: A subpackage is a separate named package rather than a directly declared type member.

C - Correct: Interfaces can be top-level named types belonging to the package.

D - Incorrect: All includes the separate-package category and is therefore too broad.

Primary note proof

Study-note section OOP28

package p; precedes imports; imports precede top-level type declarations. import p.*; imports accessible types from p as needed, not types in p.sub automatically. Packages organize names

and control access; hierarchical spelling does not grant special access between a package and its subpackages.

Object Oriented Programming module | PDF page 9 | lines 51-70

2.3. Source file declaration
rules
• These rules are essential when declaring classes, import statements and package statements in a source file.
1. There can be only one public class per source file.
2. A source file can have multiple nonpublic classes.
3. The public class name should be the name of the source file as well which should be appended by .java at the end.
For example: the class name is public class Employee{} then the source file should be as Employee.java.
• If the class is defined inside a package, then the package statement should be the first statement in the source file.

Question sources

Object-Oriented Programming practice questions · Question 70

Question 94 | Q00501

An _____ statement can be used to access the classes and interface of a different package from the current package.

A. instanceOf

B. import

C. extends

D. implement

Hint

Check declaration order, exact case, package boundaries and the compile-versus-launch stage.

Answer B: import

Import statements follow any package declaration and precede top-level type declarations; they come first when there is no package declaration. They bring external class/interface names into the source context.

Why each choice is right or wrong

A - Incorrect: instanceof is an object-type test, not an import

B - Correct: Matches the source-file import statement

C - Incorrect: extends defines inheritance

D - Incorrect: implement is not the import statement

Primary note proof

Study-note section OOP28

> package p; precedes imports; imports precede top-level type declarations. import p.*; imports accessible types from p as needed, not types in p.sub automatically. Packages organize names and control access; hierarchical spelling does not grant special access between a package and its subpackages.

package statement and the class declaration.
• If there are no package statements then the import statement should be the first line in the source file.
• Import and package statements will imply to all the classes present in the source file.
• It is not possible to declare different import and/or package statements to different classes in the source file.

Question sources

Object-Oriented Programming practice questions · Question 71

Question 95 | Q00502

Which of the following packages is used to includes classes to create user interface like Button and Checkbox?

A. java.lang

B. java.net

C. java.awt

D. java.io

Hint

Check declaration order, exact case, package boundaries and the compile-versus-launch stage.

Answer C: java.awt.

OOP28 explicitly identifies java.awt as including Button and Checkbox. The question names those UI classes, so the answer follows directly from their package membership. java.lang, networking and I/O packages serve other purposes and are not the package the note identifies for these two AWT controls.

Why each choice is right or wrong

A - Incorrect: java.lang is implicitly imported, but OOP28 locates Button and Checkbox in java.awt instead.

B - Incorrect: The named controls are AWT UI types, not networking types in the proposed java.net package.

C - Correct: OOP28 explicitly lists Button and Checkbox as classes included in java.awt.

D - Incorrect: java.io supplies input/output facilities rather than the two AWT controls named by the question.

Primary note proof

Study-note section OOP28

java.lang is implicitly imported; java.util supplies utilities; java.io supplies I/O; java.awt includes Button and Checkbox.

Study-note section OOP-S04

Calendar and Date are classes in java.util; Collection is an interface in that package. java.util also contains Arrays and Scanner. java.net supplies networking facilities; java.awt supplies the Button and Checkbox UI controls described in the package overview.

Object Oriented Programming module | PDF page 27 | lines 20-41

• An exception is an event, which occurs during the execution of a program, that disrupts the normal flow of the program's instructions.
• An exception is an indication of a problem that occurs during a program‟s execution.
• An exception is a runtime error.
• A Java exception is an instance of a class derived from Throwable.
• The Throwable class is contained in the java.lang package, and subclasses of Throwable are contained in various packages.
• Errors related to GUI components are included in the java.awt package; numeric exceptions are included in the java.lang package because they are related to the java.lang.Number class.
• You can create your own exception classes by extending Throwable or a subclass of Throwable.

Question sources

Object-Oriented Programming practice questions · Question 72

Question 96 | Q00503

Which of the following packages is used to includes utility classes like Calendar, Collection, Date?

A. java.lang

B. java.net

C. java.awt

D. java.util

Hint

Read the cited conceptual rules, state the model, and apply them before comparing the alternatives.

Answer D: java.util.

The question identifies Calendar, Collection and Date as utility types. OOP28 assigns utility facilities to java.util, in contrast to implicitly imported language facilities, AWT user-interface classes and I/O. Therefore java.util is the package category supported for the named utility examples, rather than the language, networking or UI alternatives.

Why each choice is right or wrong

A - Incorrect: java.lang supplies core language facilities; the utility package identified here is java.util.

B - Incorrect: java.net is the networking alternative, not the utility package identified in OOP28.

C - Incorrect: java.awt contains AWT UI controls, rather than the utility facilities requested by the question.

D - Correct: java.util is the note's explicit utility-package mapping for the class/interface examples in the stem.

Primary note proof

Study-note section OOP-S04

> Calendar and Date are classes in java.util; Collection is an interface in that package. java.util also contains Arrays and Scanner. java.net supplies networking facilities; java.awt supplies the Button and Checkbox UI controls described in the package overview.

Study-note section OOP28

> java.lang is implicitly imported; java.util supplies utilities; java.io supplies I/O; java.awt includes Button and Checkbox.

Question sources

Object-Oriented Programming practice questions · Question 73

Question 97 | Q00504

An accessible class declares an ordinary field. Which offered modifier choices permit another unrelated class in the same package to access that field directly? Choose the most complete answer; this asks about member modifiers, not top-level class modifiers.

A. Public

B. Protected

C. No Modifier

D. All of the mentioned

Hint

Locate the accessing code, declaring type, package and receiver before applying visibility rules.

Answer D: All of the mentioned

For ordinary members, public allows access, protected includes same-package access, and no modifier grants package access. All three listed choices therefore permit the unrelated same-package client to access the field. This does not claim that protected is legal on a top-level class, and class accessibility alone would not expose a private field. Under the explicitly member-level scope, D is the complete selection.

Why each choice is right or wrong

A - Incorrect: Public permits the access, but this is only one of the three valid modifier choices.

B - Incorrect: Protected includes same-package access, but this option alone is incomplete.

C - Incorrect: No modifier grants package access, but this option alone is incomplete.

D - Correct: All three listed member-modifier choices permit the specified same-package access.

Primary note proof

Study-note section OOP08

For ordinary members: private restricts access to the declaring class/nest; no modifier grants package access; protected grants same-package access plus qualified subclass access; public is widest, provided the declaring type itself is accessible.

Study-note section OOP08

protected therefore does not mean “subclasses only”: unrelated classes in the same package also have access.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Object Oriented Programming module | PDF page 13 | lines 62-73

Access Specifiers
Access level modifiers determine whether other classes can use a particular field or invoke a particular method.
Their are four types access levels:
1. No Modifier(Default): Visible to the package(source file), and it is called package-private
2. Private: Visible to the class only.
3. Public: Visible to the world.
4. Protected: Visible to the package and all subclasses.

Object Oriented Programming module | PDF page 9 | lines 51-70

2.3. Source file declaration rules
• These rules are essential when declaring classes, import statements and package statements in a source file.
1. There can be only one public class per source file.
2. A source file can have multiple nonpublic classes.
3. The public class name should be the name of the source file as well which should be appended by .java at the end.
For example: the class name is public class Employee{} then the source file should be as Employee.java.
• If the class is defined inside a package, then the package statement should be the first statement in the source file.

Question sources

Object-Oriented Programming practice questions · Question 74

Question 98 | Q00505

Which option is a syntactically complete Java on-demand import of accessible top-level types from package pkg, without importing subpackages automatically?

A. import pkg.

B. Import pkg.

C. import pkg.*;

D. Import pkg.*

Hint

Check declaration order, exact case, package boundaries and the compile-versus-launch stage.

Answer C: import pkg.*;

A type-import-on-demand statement uses lowercase import, the package name, a dot and wildcard, and a semicolon. import pkg.*; therefore supplies the complete syntax. It makes accessible types from pkg available as needed without automatically importing types from pkg.sub. A lacks the wildcard or type name, and capitalized Import is not the Java keyword in B or D.

Why each choice is right or wrong

A - Incorrect: The trailing dot lacks a wildcard or type name and a complete terminator.

B - Incorrect: Capitalized Import is not the keyword, and the target is incomplete.

C - Correct: This is the complete lowercase wildcard import statement.

D - Incorrect: Capitalized Import is not a Java keyword and the statement lacks its semicolon.

Primary note proof

Study-note section OOP28

> import p.*; imports accessible types from p as needed, not types in p.sub automatically.

Study-note section OOP28

> Java identifiers are case sensitive; $ is allowed but @ is not an identifier character.

> package statement and the class
> declaration.
> • If there are no package statements
> then the import statement should be
> the first line in the source file.
> • Import and package statements will
> imply to all the classes present in the

source file.
• It is not possible to declare different import and/or package statements to different classes in the source file.

Object Oriented Programming module | PDF page 27 | lines 20-41

• An exception is an event, which occurs during the execution of a program, that disrupts the normal flow of the program's instructions.
• An exception is an indication of a problem that occurs during a program‟s execution.
• An exception is a runtime error.
• A Java exception is an instance of a class derived from Throwable.
• The Throwable class is contained in the java.lang package, and subclasses of Throwable are contained in various packages.
• Errors related to GUI components are included in the java.awt package; numeric exceptions are included in the java.lang package because they are related to the java.lang.Number class.
• You can create your own exception classes by extending Throwable or a subclass of Throwable.

Object-Oriented Programming practice questions · Question 75

Question 99 | Q00506

Which of the following is false statement about package in java?

A. Packages are used for preventing naming conflicts

B. Providing controlled access: protected and default have package level access control.

C. Packages cannot be considered as data encapsulation

D. Both B and C

Hint

Check declaration order, exact case, package boundaries and the compile-versus-launch stage.

Answer C: The claim that packages cannot support encapsulation is false.

OOP28 says packages organize names and control access, while OOP08 defines package access and same-package protected access. These mechanisms can hide implementation types or members behind permitted boundaries, so C's categorical denial is false. A and B describe real package roles. D incorrectly includes the true package-access statement B among the false claims.

Why each choice is right or wrong

A - Incorrect: Organizing names into packages supports avoiding naming conflicts, so this is a true purpose rather than the false claim.

B - Incorrect: Default access is package access, and protected also grants same-package access; the statement is true.

C - Correct: Packages control access and can hide implementation types or members, contradicting this categorical denial of encapsulation.

D - Incorrect: B is supported by the access rules, so both B and C cannot be classified as false.

Primary note proof

Study-note section OOP28

> Packages organize names and control access; hierarchical spelling does not grant special access between a package and its subpackages.

Study-note section OOP08

> For ordinary members: private restricts access to the declaring class/nest; no modifier grants package access; protected grants same-package access plus qualified subclass access; public is widest, provided the declaring type itself is accessible.

Study-note section OOP08

> protected therefore does not mean "subclasses only": unrelated classes in the same package also have access.

Study-note section OOP02

> Information hiding keeps implementation decisions behind a stable interface.

Object-Oriented Programming practice questions · Question 76

Question 100 | Q00507

For a Java naming hierarchy such as p and p.q, what is the specific conventional term for packages such as p.q relative to p?

A. packages

B. nested packages sharing their parent's member-access scope

C. util subpackages

D. subpackages

Hint

Check declaration order, exact case, package boundaries and the compile-versus-launch stage.

Answer D: Subpackages.

The conventional term for p.q relative to p is subpackage. This is a naming hierarchy, not a lexical enclosing scope: the parent's import does not automatically import types from the subpackage, and their related names grant no special member access. Packages is only the broad category. The util qualifier would restrict the answer to a particular package family instead of naming the general relationship.

Why each choice is right or wrong

A - Incorrect: Packages names the broad category but does not identify the requested relationship to a parent name.

B - Incorrect: The naming hierarchy does not give a subpackage its parent's member-access scope.

C - Incorrect: The relationship applies to arbitrary package names, not just util subpackages.

D - Correct: Subpackages is the conventional term for the requested naming relationship.

Primary note proof

Study-note section OOP28

import p.*; imports accessible types from p as needed, not types in p.sub automatically. Packages organize names and control access; hierarchical spelling does not grant special access between a package and its subpackages.

Object-Oriented Programming practice questions · Question 77

Question 101 | Q00508

_____ can be defined as the process where one class acquires the properties (methods and fields) of another.

A. Overriding

B. Inheritance

C. Polymorphism

D. Abstraction

Hint

Identify the subtype or ownership relationship and distinguish class inheritance from interface contracts.

Answer B: Inheritance

Inheritance means acquiring another class's methods and fields.

Why each choice is right or wrong

A - Incorrect: Overrides a method rather than acquiring the class properties generally

B - Correct: Matches the definition word for word

C - Incorrect: Many forms is a different principle

D - Incorrect: Exposes essential information rather than acquiring class properties

Primary note proof

Study-note section OOP13

class Dog extends Animal declares a subclass/derived/child of a superclass/base/parent.

Study-note section OOP13

Use inheritance when a subtype can satisfy the parent's contract: Dog is an Animal.

Study-note section OOP02

Inheritance forms a subtype relationship and may reuse implementation. Polymorphism lets code using a common type invoke behavior appropriate to different concrete objects.

Study-note section OOP14

A subclass overrides an eligible inherited instance method with the same signature and a compatible return type; a covariant reference return may be a subtype.

Study-note section OOP02

Abstraction presents the essential operations while omitting details irrelevant to the caller.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Object Oriented Programming module | PDF page 15 | lines 23-53

What is Inheritance?
• Inheritance is one of the cornerstones of object-oriented programming because it allows the creation of hierarchical classifications.
• Inheritance is the process where one class acquires the properties (methods and fields) of another.
• A class that is inherited is called a superclass.
• The class that does the inheriting is called a subclass.
• OR: The class which inherits the properties of other is known as subclass (derived class, child class) and
• The class whose properties are inherited is known as superclass (base class, parent class).
• Therefore, a subclass is a specialized version of a superclass.
• It inherits all of the instance variables and methods defined by the superclass and add its own, unique elements.
• The extends keyword: is the keyword used to inherit the properties of a class. Below given is the syntax of extends keyword.
• Sytax:
class Super{

```
.....}
class Sub extends Super{ }
```

Question sources

Object-Oriented Programming practice questions · Question 78

Question 102 | Q00509

The class which inherits the properties of other is known as _____

A. superclass

B. parent class

C. subclass

D. None of the above

Hint

Identify the subtype or ownership relationship and distinguish class inheritance from interface contracts.

Answer C: subclass

The class that does the inheriting is explicitly called subclass, derived class or child class.

Why each choice is right or wrong

A - Incorrect: Superclass is the source class

B - Incorrect: Parent class is the source class

C - Correct: Subclass is the inheriting class

D - Incorrect: C identifies the inheriting class correctly

Primary note proof

Study-note section OOP13

class Dog extends Animal declares a subclass/derived/child of a superclass/base/parent.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Question 103 | Q00510

Subclass also known as ?

A. derived class

B. child class

C. base class

D. Both A and B

Hint

Identify the subtype or ownership relationship and distinguish class inheritance from interface contracts.

Answer D: Both A and B

Subclass, derived class and child class are synonyms; base class is a superclass synonym.

Why each choice is right or wrong

A - Incorrect: A valid subclass synonym

B - Incorrect: A valid subclass synonym

C - Incorrect: Names the superclass instead

D - Correct: Combines both valid synonyms

Primary note proof

Study-note section OOP13

> class Dog extends Animal declares a subclass/derived/child of a superclass/base/parent.

Object-Oriented Programming practice questions · Question 80

Question 104 | Q00511

_____ is the keyword used to inherit the properties of a class.

A. inherit

B. poly

C. extends

D. super

Hint

Identify the subtype or ownership relationship and distinguish class inheritance from interface contracts.

Answer C: extends

The inheritance syntax is class Sub extends Super.

Why each choice is right or wrong

A - Incorrect: Not the stated keyword

B - Incorrect: Not the stated keyword

C - Correct: Explicitly identified inheritance keyword

D - Incorrect: Refers to the superclass rather than declaring inheritance

Primary note proof

Study-note section OOP13

> class Dog extends Animal declares a subclass/derived/child of a superclass/base/parent.

Study-note section OOP16

> super.name selects a hidden superclass field; super.sound() directly requests the parent implementation.

class Sub extends Super{ }

Question sources

Object-Oriented Programming practice questions · Question 81

Question 105 | Q00512

The super keyword is similar to _____ keyword.

A. construct

B. this

C. class

D. extends

Hint

Distinguish the current instance, parent context, hidden fields and static dispatch.

Answer B: this

super accesses superclass members, while this refers to the current object; the comparison concerns member access, rather than distinct receiver objects.

Why each choice is right or wrong

A - Incorrect: construct is not the compared keyword

B - Correct: Explicitly named comparison

C - Incorrect: class defines a type rather than this-like access

D - Incorrect: extends establishes inheritance rather than member reference

Primary note proof

Study-note section OOP16

Java this denotes the current object; this.name=name distinguishes a field from a parameter. super.name selects a hidden superclass field; super.sound() directly requests the parent implementation. It does not create a second parent object. An unqualified instance call may dispatch dynamically; an explicit super call is different.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Object Oriented Programming module | PDF page 17 | lines 51-74

The super keyword
• Since encapsulation is a primary attribute of OOP, Whenever a subclass needs to refer to its immediate superclass, it can do so by use of the keyword super.
• Super has two general forms.
1. Used to access parent class instance members.
2. Used to access parent class constructor.
1. Used to access parent class instance members.
• super acts somewhat like this, except that it always refers to the superclass of the subclass in which it is used.
• Super has the form: super.member Here, member can be either a method or an instance variable.
• Super is most applicable to resolve member hiding.
• super( ) must always be the first statement executed inside a subclass‟ constructor.

Question sources

Object-Oriented Programming practice questions · Question 82

Question 106 | Q00513

Which of these is correct way of inheriting class A by class B?

A. class B + class A {}

B. class B inherits class A {}

C. class B extends A {}

D. class B extends class A {}

Hint

Identify the subtype or ownership relationship and distinguish class inheritance from interface contracts.

Answer C: class B extends A {}

The declared subclass comes first, followed by extends and the superclass name; the example is class Sub extends Super.

Why each choice is right or wrong

A - Incorrect: Plus is not the inheritance syntax

B - Incorrect: inherits is not the inheritance keyword

C - Correct: Correct order and single class keyword

D - Incorrect: Extra class before the parent violates the demonstrated form

Primary note proof

Study-note section OOP13

> class Dog extends Animal declares a subclass/derived/child of a superclass/base/parent.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Question sources

Object-Oriented Programming practice questions · Question 83

Question 107 | Q00514

A class which is declared with the _____ keyword is known as an abstract class in Java.

A. abstract

B. util

C. extends

D. None of the above

Hint

Check whether a class is concrete and whether every inherited abstract contract has an implementation.

Answer A: abstract

The abstract-class definition explicitly uses the abstract keyword.

Why each choice is right or wrong

A - Correct: Matches the definition

B - Incorrect: util is not the modifier

C - Incorrect: extends names an inheritance relation

D - Incorrect: A directly supplies the keyword

Primary note proof

Study-note section OOP18

> An abstract class cannot be directly instantiated but can define fields, constructors, abstract methods and concrete methods. It need not contain an abstract method. An abstract method has no body; abstract and final conflict because an operation cannot require overriding while forbidding it.

Study-note section OOP13

> class Dog extends Animal declares a subclass/derived/child of a superclass/base/parent.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Object Oriented Programming module | PDF page 23 | lines 57-81

> Abstract Classes
> • A classes declared with abstract
> keyword and can‟t be instantiated.
> • Used to hide meaningless methods:
> • There can be no objects of an abstract
> class. .:.
> • An abstract class cannot be directly
> instantiated with the new operator.
> • You cannot declare abstract
> constructors, or abstract static methods
> • Syntax: abstract class class_name
> Example:
> abstract class A {
> abstract void callme();
> // concrete methods are still
> allowed in abstract classes
> void callmetoo() {
> System.out.println("This is a
> concrete method.");
> }}
> class B extends A {
> void callme() {
> System.out.println("B's
> implementation of callme.");
> }}

Question sources

Object-Oriented Programming practice questions · Question 84

Question 108 | Q00515

A method which is declared as abstract and does not have implementation is known as an _____?

A. Abstract Interface

B. Abstract Thread

C. Abstract List

D. abstract Method

Hint

Check whether a class is concrete and whether every inherited abstract contract has an implementation.

Answer D: abstract Method

The summary says abstract methods have no body/implementation. That is the method kind described by the stem.

Why each choice is right or wrong

A - Incorrect: Confuses a method with an interface

B - Incorrect: Thread is not the unimplemented method category

C - Incorrect: List is not the unimplemented method category

D - Correct: Matches a method without implementation

Primary note proof

Study-note section OOP18

> An abstract method has no body; abstract and final conflict because an operation cannot require overriding while forbidding it.

Study-note section OOP19

> interface Payable{double getPaymentAmount();} declares an abstract public operation. class Invoice implements Payable must provide public double getPaymentAmount(), perhaps returning getQuantity()*getPricePerItem().

Object Oriented Programming module | PDF page 24 | lines 63-73

> Summery:
> Abstract:
> • Classes: declared with abstract
> keyword and can‟t be instantiated.
> • Methods: without body (no
> implementation)

Final:
• Class: declared as final prevents inheritance.
• Method: declared as final prevents overriding that method.

Question sources

Object-Oriented Programming practice questions · Question 85

Question 109 | Q00516

Which offered access modifier may be explicitly applied to an ordinary top-level Java interface? This is not a member interface nested in another type.

A. Public

B. private

C. Protected

D. All of the mentioned

Hint

Locate the accessing code, declaring type, package and receiver before applying visibility rules.

Answer A: Public

An ordinary top-level interface may be public or package-private. Of the explicit access modifiers listed, only public is permitted at top level. Private and protected can apply in some nested member contexts but are excluded by the stated declaration location. No modifier is the package-private alternative, though it is not one of the offered choices. Therefore the aggregate of all modifiers is false.

Why each choice is right or wrong

A - Correct: Public is permitted on an ordinary top-level interface.

B - Incorrect: Private is not a legal top-level interface modifier.

C - Incorrect: Protected is not a legal top-level interface modifier.

D - Incorrect: All includes the forbidden private and protected top-level modifiers.

Primary note proof

Study-note section OOP08

Top-level classes/interfaces may be public or package-private, not protected/private. Member types have additional visibility possibilities.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Object Oriented Programming module | PDF page 33 | lines 31-46

The d/c b/n Interface & Class
• You cannot instantiate an interface
• Interface has not constructor
• Methods in an interface are all abstract.
• Fields in an interface are all static and final
• An interface can extend multiple interfaces
Summery
• By default, methods in interface are public and abstract.
• Data members are public, static and final.
• An interface with empty body is called Tag/marker interface.

Question sources

Object-Oriented Programming practice questions · Question 86

Question 110 | Q00517

Which of these keywords is used by a class to use an interface defined previously?

A. Import

B. import

C. implements

D. Implements

Hint

Identify the interface contract, effective modifiers and permitted implementation forms.

Answer C: implements

A class implements an interface, while an interface extends another interface.

Why each choice is right or wrong

A - Incorrect: Import is neither the demonstrated spelling nor implementation keyword

B - Incorrect: import is a source naming facility, not implementation

C - Correct: Matches class implementation syntax

D - Incorrect: Capitalized form is not the stated keyword

Primary note proof

Study-note section OOP19
