array implementation, to add item it checks whether there is room at the rear or not. Therefore, even though there are free released spaces at the front ot the array the queue implementation might
generate overflow message. This is the key drawback to use simple array to implement Queue.

Data Structure and Algorithms module | PDF page 5 | lines 3-8

While adding a node to a list, the chain needs to be rearranged properly so that the each nodes are connected to each other. It is possible to add a node anywhere in the chain (at the start, middle or end). Let's consider adding a node at the end of the list:
Step 1: First we need to reserve a space for the new node using the keyword new.
Node *temp = new *Node; // Reserving a space for temporary pointer which points to new node;

University of Gondar model exam · Question 21

Question 23 | Q00291

For selection sort on n elements, n>=2, count only exchanges between distinct positions and omit the final one-element suffix. What is the maximum number of swaps?

A. n - 1

B. 1

C. n

D. n - 2

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer A: A. n - 1

Selection sort places the minimum remaining element into each successive position. After n-1 such placements, the last position is determined automatically. Each placement needs at most one exchange between distinct positions, so the maximum is n-1. This count excludes self-swaps and the redundant final-position call that some implementations include. The choice of input can require an exchange on every one of those meaningful passes.

Why each choice is right or wrong

A - Correct: There are n-1 meaningful placements, each requiring at most one exchange.

B - Incorrect: More than one exchange can be needed for larger n.

C - Incorrect: n counts an extra redundant final swap call under another convention.

D - Incorrect: n-2 omits a possible exchange on a meaningful pass.

Primary note proof

Study-note section DSA33

> At position i, scan the remaining suffix for its minimum, then exchange it with A[i]. There are n-1 meaningful placements and n(n-1)/2 comparisons regardless of initial order. At most n-1 exchanges of distinct positions are needed. A loop that also swaps the last item with itself can count n swap calls.

Computer Science model exam · Question 22

University of Gondar model exam · Question 22

Question 24 | Q00293

In an infix-to-prefix conversion algorithm that temporarily holds pending operators and parentheses using last-in, first-out access, which abstract data type supplies that access discipline?

A. Stack

B. Queue

C. Binary tree

D. Linked list

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer A: A. Stack

Pending operators must be retrieved in reverse order when grouping or precedence requires them to be emitted. A stack provides that last-in, first-out discipline. An expression tree is another possible representation for conversion, but it is not the requested pending-operator ADT in this specified algorithm. A queue retrieves the oldest entry first, while a linked list alone describes storage links without prescribing the needed access policy.

Why each choice is right or wrong

A - Correct: A stack retrieves the latest pending operator first.

B - Incorrect: A queue uses first-in, first-out access.

C - Incorrect: An expression tree can support another conversion method but is not this pending-operator ADT.

D - Incorrect: A linked list can implement storage but alone does not specify LIFO behavior.

Primary note proof

Study-note section DSA11

> Stack policy is LIFO, equivalently FILO. Push inserts, pop removes/returns top, and peek only observes. With zero-based occupied slots, top=-1 is empty and top=C-1 is full. Check before A[++top]=x or returning A[top--].

Study-note section DSA13

To evaluate postfix, push operands. At a binary operator, pop right operand first, then left, and push left op right. Build an expression tree for either prefix (preorder) or postfix (postorder); a stack is useful but is not the only possible conversion representation.

Question 25 | Q00294

Which one of the following is the process of inserting an element in the stack?

A. Insert

B. Add

C. Push

D. None of the above

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer C: Push

The stack terminology explicitly names adding an element Push. Evidence: assigned PDF pages 6.

Why each choice is right or wrong

A - Incorrect: Insert is a generic action rather than the given operation name. See assigned PDF 6.

B - Incorrect: Add is descriptive rather than the module stack name. See assigned PDF 6.

C - Correct: Push is defined as adding an element to the stack. See assigned PDF 6.

D - Incorrect: C is explicitly defined, so none is false. See assigned PDF 6.

Primary note proof

Study-note section DSA11

> Stack policy is LIFO, equivalently FILO. Push inserts, pop removes/returns top, and peek only observes. With zero-based occupied slots, top=-1 is empty and top=C-1 is full. Check before A[++top]=x or returning A[top--].

Computer Science model exam · Question 25

University of Gondar model exam · Question 25

Question 26 | Q00371

How many cases are there, which are used to compare various data structure's execution time in a relative manner?

A. 2

B. 3

C. 4

D. 5

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer B: Three: best, average, worst.

DSA05 names best, average, and worst as the ordinary cases for comparing costs on inputs of equal size. Average additionally needs an input distribution. Counting these cases gives three. This is a classification of input cases, rather than a count of resources, data structures, or asymptotic bound notations.

Why each choice is right or wrong

A - Incorrect: Two omits one of the three named categories: best, average, and worst case.

B - Correct: The note lists three ordinary fixed-size input cases: best, average, and worst.

C - Incorrect: Four does not match the three ordinary input-case categories listed in DSA05.

D - Incorrect: Five adds categories outside the stated best, average, and worst input-case classification.

Primary note proof

Study-note section DSA-S01

> Fix the input size before comparing cases. Best-case cost is the minimum resource use over legal inputs of that size; worst-case cost is the maximum. Average-case cost averages costs using a stated input distribution. These three input-case functions can each be described using upper, lower or tight asymptotic bounds; the case name does not select the bound notation.

> Algorithm analysis refers to the process of determining the amount of computing time and storage
> space required by different algorithms. It used to produce a function T (n) that describes the algorithm in terms of the operations performed in order to measure the complexityof the algorithm.
> Complexity Analysis is the systematic study of the cost of computation, measured either in time units or in operations performed, or in the amount of storage space required.

Question sources

Data Structures & Algorithms practice questions · Question 1

Question 27 | Q00372

Which case of data structure operation takes maximum time?

A. Worst Case

B. Average Case

C. Best Case

D. None of the above

Hint

Fix the input case and cost model, then count dominant work or simultaneously live storage.

Answer A: Worst case

DSA05 distinguishes best, average, and worst over inputs of the same size. Worst selects the largest runtime; best selects the smallest, while average takes an expectation under a distribution. Therefore Worst Case directly matches maximum time. This input-case distinction is independent of whether the resulting cost function is described with O, Ω, or Θ notation.

Why each choice is right or wrong

A - Correct: Worst case takes the maximum operation cost over valid inputs of the same size.

B - Incorrect: Average case computes an expected cost under a distribution instead of selecting the maximum.

C - Incorrect: Best case selects the minimum cost, the opposite extremum from the question.

D - Incorrect: Worst Case is offered and directly identifies the requested maximum-time input case.

Primary note proof

Study-note section DSA-S01

> Fix the input size before comparing cases. Best-case cost is the minimum resource use over legal inputs of that size; worst-case cost is the maximum. Average-case cost averages costs using a stated input distribution. These three input-case functions can each be described using upper, lower or tight asymptotic bounds; the case name does not select the bound notation.

Question sources

Data Structures & Algorithms practice questions · Question 2

Question 28 | Q00375

Which listed characteristic is a binary-tree shape condition rather than a general functional-correctness or resource-cost criterion for arbitrary data-structure operations? Interpret completeness as the complete-tree shape property.

A. Completeness

B. Correctness

C. Time Complexity

D. Space Complexity

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer A: A. Completeness

Correctness asks whether operations produce their specified results. Time and space complexity measure operation counts and memory use under a resource model. Completeness, under the explicit meaning supplied here, instead describes how a binary tree's levels are filled: earlier levels are full and the last fills from the left. It is a particular shape condition, rather than a universal assessment criterion for every data structure.

Why each choice is right or wrong

A - Correct: Completeness describes a particular binary-tree shape.

B - Incorrect: Correctness assesses whether an operation meets its specification.

C - Incorrect: Time complexity assesses operation cost.

D - Incorrect: Space complexity assesses memory cost.

Primary note proof

Study-note section DSA18

> Binary means at most two children. Full means each node has zero or two children. Complete means all earlier levels are filled and the last fills from left. Perfect means all leaves share a level and every internal node has two children. Balanced means height stays logarithmic under a stated rule; it does not require a perfect shape.

Study-note section DSA04

> Finiteness means termination after finitely many steps for every valid input. Definiteness means each instruction has one interpretation; effectiveness means each step is executable. Correctness means meeting the stated result for every valid input. A finite program can still return the wrong answer.

Study-note section DSA05

> Time counts chosen operations; space counts memory, including live recursive frames.

Question sources

Data Structures & Algorithms practice questions · Question 5

Question 29 | Q00377

Which abstract data types permit deleting an element at the front and inserting an element at the rear? Include types that also permit additional endpoint operations. Select all that apply.

A. Stacks

B. Queues

C. Deques

D. Binary search tree

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer B, C: B. Queues; C. Deques

An ordinary queue supplies exactly the stated FIFO operations: insertion at the rear and removal at the front. A deque allows insertion and removal at both ends, which includes those same two operations as a subset. The question explicitly includes types with additional endpoint capabilities, so both qualify. A stack exposes a single LIFO top, and a BST organizes access by keys rather than front and rear.

Why each choice is right or wrong

A - Incorrect: A stack exposes a single LIFO top rather than these FIFO endpoints.

B - Correct: A queue enqueues at rear and dequeues at front.

C - Correct: A deque includes both requested operations among its endpoint capabilities.

D - Incorrect: A BST uses key-based tree operations rather than front/rear endpoints.

Primary note proof

Study-note section DSA14

> An ordinary queue enqueues at rear, dequeues at front, and peeks at front. This is FIFO or first-come, first-served. A linked implementation with head and tail supports both operations in constant time: append at tail, remove at head. The first insertion sets both pointers; removing the last item clears both. With head alone, insertion must traverse to the tail.

Study-note section DSA16

> A deque permits both-end insertion/removal without guaranteeing middle access. Endpoint-linked operations are constant but middle indexing is linear. A circular-array deque may support indexed access. Dequeue names removal; deque names the structure.

Data Structures & Algorithms practice questions · Question 7

Question 30 | Q00379

Which algorithms have tight worst-case time Theta(n^2)? Use ordinary array comparison-sort implementations; radix sort uses counting-based passes with fixed digit count and fixed radix. Select all that apply.

A. Merge sort

B. Insertion sort

C. Quick sort

D. Radix sort

Hint

Fix the input case and cost model, then count dominant work or simultaneously live storage.

Answer B, C: B. Insertion sort; C. Quick sort

Insertion sort on reverse input shifts a growing sorted prefix, totaling quadratic work. Quicksort repeatedly choosing an extreme pivot also accumulates quadratic partition work. Ordinary merge sort instead performs linear work at logarithmically many levels. Under the explicitly fixed digit count and radix, radix sorting is linear in n. Tight bounds distinguish these actual growth rates from the looser quadratic upper bounds that faster algorithms also satisfy.

Why each choice is right or wrong

A - Incorrect: Ordinary merge sort has tight n log n worst time.

B - Correct: Reverse-order insertion gives quadratic shifts.

C - Correct: Repeated extreme quicksort pivots give quadratic work.

D - Incorrect: Fixed-width, fixed-radix counting passes give linear time.

Primary note proof

Study-note section DSA34

> Reverse order causes 1+2+...+(n-1) shifts: quadratic time.

Study-note section DSA36

> Balanced partitions give n log n work; repeated extreme pivots sum n+(n-1)+... to quadratic work.

Study-note section DSA37

> There are logarithmically many levels with linear merge work per level, giving n log n time even on sorted input unless an optimization skips merges.

Study-note section DSA39

> With d digits and radix r, counting-based passes take O(d(n+r)) time and O(n+r) auxiliary storage.

Data Structure and Algorithms module | PDF page 11 | lines 14-22

ii. Quick sort: is the fastest known algorithm. It uses divide and conquer strategy and in the worst case its complexity is O (n2). But its expected complexity is O(nlogn).
Algorithm:
1. Choose a pivot value (mostly the first element is taken as the pivot value)
2. Position the pivot element and partition the list so that:
• the left part has items less than or equal to the pivot value
• the right part has items greater than or equal to the pivot value
3. Recursively sort the left part
4. Recursively sort the right part

Data Structure and Algorithms module | PDF page 11 | lines 38-44

iv. Merge sort
Merge sort uses divide and conquer strategy and its time complexity is O(nlogn).
Algorithm:
1. Divide the array in to two halves.
2. Recursively sort the first n/2 items.
3. Recursively sort the last n/2 items.
4. Merge sorted items (using an auxiliary array).

Question sources

Data Structures & Algorithms practice questions · Question 9

Question 31 | Q00380

In which sorting algorithm does the largest element "bubble" to the end of the list at each pass?

A. Bubble sort

B. Selection sort

C. Insertion sort

D. Heap sort

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer A: Bubble sort

Repeated adjacent out-of-order swaps push the largest item toward the final position in a left-to-right pass. This is exactly the bubble-sort mechanism. Evidence: assigned PDF pages 4, 3, 11.

Why each choice is right or wrong

A - Correct: Adjacent comparisons bubble the largest to its proper end. See assigned PDF 4, 3, 3, 11.

B - Incorrect: Selection finds a minimum and swaps it into position rather than bubbling through adjacent pairs. See assigned PDF 4, 3, 3, 11.

C - Incorrect: Insertion inserts each new element into a sorted prefix. See assigned PDF 4, 3, 3, 11.

D - Incorrect: Heap sort removes a root maximum using tree adjustment. See assigned PDF 4, 3, 3, 11.

Primary note proof

Study-note section DSA32

> For ascending order, compare each adjacent pair and swap only when left>right. The largest remaining value moves to the final unsorted position after one left-to-right pass. Shrink the next pass by one position. Quadratic worst/average work comes from up to n(n-1)/2 pair comparisons.

Study-note section DSA33

> At position i, scan the remaining suffix for its minimum, then exchange it with A[i].

Study-note section DSA34

> For each remaining item, save its value, shift larger preceding values right, and insert it into the gap.

) and How many swaps? => O(n2
)

Data Structure and Algorithms module | PDF page 11 | lines 23-37

iii. Heap Sort
Heap sort operates by first converting the list in to a heap tree. Heap tree is a binary tree in which
each node has a value greater than both its children (if any). It uses a process called "adjust to accomplish its task (building a heap tree) whenever a value is larger than its parent. The time complexity of heap sort is O(nlogn).
Algorithm:
1. Construct a binary tree
• The root node corresponds to Data[0].
• If we consider the index associated with a particular node to be i, then the left child of this node corresponds to the element with index 2*i+1 and the right child corresponds to the element with index 2*i+2. If any or both of these elements do not exist in the array, then the corresponding child node does not exist either.
2. Construct the heap tree from initial binary tree using "adjust" process.
Sort by swapping the root value with the lowest, right most value and deleting the lowest, right most value and inserting the deleted value in the array in it proper position.

Question sources

Data Structures & Algorithms practice questions · Question 10

Question 32 | Q00381

Which algorithms have tight best-case time Theta(n)? Use early-exit bubble sort, ordinary quicksort, ordinary array mergesort without merge-skipping, and standard insertion sort. Select all that apply.

A. Bubble sort

B. Quick sort

C. Merge sort

D. Insertion sort

Hint

Fix the input case and cost model, then count dominant work or simultaneously live storage.

Answer A, D: A. Bubble sort; D. Insertion sort

Early-exit bubble sort terminates after one complete no-swap pass on already sorted input, so its best case is linear. Insertion sort also checks each new item once without shifting it on sorted input. Ordinary quicksort still partitions across logarithmically many balanced levels in its best case, and ordinary mergesort still performs its merges. Thus exactly the bubble and insertion implementations have the requested linear best case.

Why each choice is right or wrong

A - Correct: The no-swap early exit gives a linear sorted-input pass.

B - Incorrect: Ordinary quicksort has n log n best growth.

C - Incorrect: Without merge-skipping, mergesort still uses n log n work.

D - Correct: Sorted input needs one ordering check per insertion pass.

Primary note proof

Study-note section DSA32

> Early stopping makes a sorted input linear: one no-swap pass finishes.

Study-note section DSA34

> On sorted input each pass needs one ordering check and no shifts: linear time.

Study-note section DSA36

> Balanced partitions give n log n work; repeated extreme pivots sum n+(n-1)+... to quadratic work.

Study-note section DSA37

> There are logarithmically many levels with linear merge work per level, giving n log n time even on sorted input unless an optimization skips merges.

iv. Merge sort
Merge sort uses divide and conquer strategy and its time complexity is O(nlogn).
Algorithm:
1. Divide the array in to two halves.
2. Recursively sort the first n/2 items.
3. Recursively sort the last n/2 items.
4. Merge sorted items (using an auxiliary array).

Variant 1 | Alternative version 1

Which algorithms have tight best-case time Theta(n)? Use early-exit bubble sort, standard selection sort, ordinary array mergesort without merge-skipping, and standard insertion sort. Select all that apply.

A. Bubble sort

B. Selection sort

C. Merge sort

D. Insertion sort

Answer A, D: A. Bubble sort; D. Insertion sort

Early-exit bubble sort needs one no-swap pass on sorted input, while insertion sort performs one successful ordering check per new item with no shifts. Both have linear best time. Selection sort still scans every remaining suffix and makes quadratic comparisons, even on sorted input. Ordinary mergesort retains logarithmically many levels of merging. Consequently A and D are the complete selection for this variant.

Why each choice is right or wrong

A - Correct: An early-exit no-swap pass makes optimized bubble sort linear on sorted input.

B - Incorrect: Selection sort still scans each suffix and makes quadratic comparisons even when sorted.

C - Incorrect: Ordinary merge sorting does n log n work across input orders.

D - Correct: Insertion sort is linear on sorted input because each pass needs no shifts.

Primary note proof

Study-note section DSA32

> Early stopping makes a sorted input linear: one no-swap pass finishes.

Study-note section DSA34

> On sorted input each pass needs one ordering check and no shifts: linear time.

Study-note section DSA33

> There are n-1 meaningful placements and n(n-1)/2 comparisons regardless of initial order.

Study-note section DSA37

> There are logarithmically many levels with linear merge work per level, giving n log n time even on sorted input unless an optimization skips merges.

Question sources

Data Structures & Algorithms practice questions · Question 11

Computer Science MCQ practice collection · Question 454

Question 33 | Q00382

Which ordinary iterative array sorting implementations use constant auxiliary element storage? Use buffered mergesort for C. Select all that apply.

A. Bubble sort

B. Selection sort

C. Merge sort

D. Insertion sort

Hint

Apply the naming, type and syntax rules before deciding whether an option can be used as stated.

Answer A, B, D: A. Bubble sort; B. Selection sort; D. Insertion sort

Bubble sort reuses one temporary element for each adjacent swap. Selection sort retains the minimum position while scanning, then exchanges elements using the same fixed-size temporary storage. Insertion sort saves one item and shifts preceding entries within the original array before filling the gap. The indices and saved elements stay fixed in number as n grows, giving constant auxiliary storage for A, B and D. Buffered mergesort instead needs a linear auxiliary buffer.

Why each choice is right or wrong

A - Correct: Adjacent swaps reuse a single temporary element and a fixed number of indices.

B - Correct: The suffix scan retains a minimum index; the exchange needs only fixed-size temporary storage.

C - Incorrect: The specified buffered array mergesort allocates a linear auxiliary merge buffer.

D - Correct: One saved item and fixed-size indices suffice while larger entries shift within the original array.

Primary note proof

Study-note section DSA32

> For ascending order, compare each adjacent pair and swap only when left>right.

Study-note section DSA34

> For each remaining item, save its value, shift larger preceding values right, and insert it into the gap.

Study-note section DSA33

> At position i, scan the remaining suffix for its minimum, then exchange it with A[i].

Study-note section DSA37

> Ordinary array merging needs a linear auxiliary buffer.

B. Selection Sort
Loop through the list/array from i=0 to n-1 and select the smallest element in the list and swap this value with value at position i. Repeat this step for the rest of the items.
• How many comparisons? => O(n2
) and How many swaps? => O(n)

Data Structure and Algorithms module | PDF page 3 | lines 34-43

A. Insertion Sort
The most instinctive type of sorting algorithm; it finds the location for an element and move all others up, and insert the element to its right position. It starts with the left most two items and put
them in order. Then add 3rd
item to the relatively sorted portion and find its correct location
(relative to each other) swapping adjacent elements if they are out of order. In such it sorts all item
in the list.
• How many comparisons? => O(n2
) and How many swaps? => O(n2
)

Data Structure and Algorithms module | PDF page 11 | lines 38-44

iv. Merge sort
Merge sort uses divide and conquer strategy and its time complexity is O(nlogn).
Algorithm:
1. Divide the array in to two halves.
2. Recursively sort the first n/2 items.
3. Recursively sort the last n/2 items.
4. Merge sorted items (using an auxiliary array).

Question sources

Data Structures & Algorithms practice questions · Question 12

Question 34 | Q00383

Which sorting algorithm uses a pivot element to partition the list into two sublists?

A. Bubble sort

B. Selection sort

C. Quick sort

D. Insertion sort

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer C: Quick sort

The source quicksort procedure chooses a pivot and partitions around it before recursively sorting both sides. Evidence: assigned PDF pages 11, 4, 3.

Why each choice is right or wrong

A - Incorrect: Bubble uses adjacent exchanges without a pivot partition. See assigned PDF 11, 4, 3, 3.

B - Incorrect: Selection chooses the minimum for its next position. See assigned PDF 11, 4, 3, 3.

C - Correct: Quicksort explicitly chooses and positions a pivot. See assigned PDF 11, 4, 3, 3.

D - Incorrect: Insertion extends a sorted prefix rather than partitioning by a pivot. See assigned PDF 11, 4, 3, 3.

Primary note proof

Study-note section DSA36

> Choose a pivot, partition, then recursively sort the pieces. Balanced partitions give n log n work; repeated extreme pivots sum n+(n-1)+... to quadratic work. Expected n log n needs an input/random-pivot model. Random and median-of-three choices have different tradeoffs; neither is universally best.

Study-note section DSA32

> For ascending order, compare each adjacent pair and swap only when left>right.

Study-note section DSA34

> Begin with the first element already sorted.

Question sources

Data Structures & Algorithms practice questions · Question 13

Question 35 | Q00384

Which sorting implementations preserve the relative input order of equal keys? Use bubble sort with strict adjacent swaps, standard exchange-based selection sort, ordinary in-place quicksort, and mergesort with left-first tie handling. Select all that apply.

A. Bubble sort

B. Selection sort

C. Quick sort

D. Merge sort

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer A, D: A. Bubble sort; D. Merge sort

Strict bubble swaps never exchange equal adjacent keys, so equal records retain their input order. Left-first handling during merging likewise preserves the order of ties from the left and right runs. Standard selection sort can reverse ties through a distant minimum exchange, and ordinary quicksort partitioning does not guarantee stable order. The specified implementation details therefore make bubble and merge the two stable choices.

Why each choice is right or wrong

A - Correct: Strict adjacent swaps preserve equal-key order.

B - Incorrect: A distant minimum exchange can reverse equal records.

C - Incorrect: Ordinary in-place partitioning does not guarantee stability.

D - Correct: Taking the left run first on ties preserves equal-key order.

Primary note proof

Study-note section DSA32

> Strict swaps preserve equal-key order.

Study-note section DSA37

> With left-first tie handling, equal keys retain order.

Study-note section DSA33

> Selection suits expensive record moves with cheap key comparisons, not every large dataset. It is unstable: exchanging first 2a with 1 in [2a,2b,1] gives [1,2b,2a]. Constant extra element storage is shared by several sorts.

Study-note section DSA31

> stack usually log n average, n worst; unstable

Question sources

Data Structures & Algorithms practice questions · Question 14

Question 36 | Q00385

Which algorithm has tight Theta(n log n) time in both the average and worst cases? Use ordinary array implementations; radix sort uses fixed digit count and fixed radix.

A. Bubble sort

B. Selection sort

C. Merge sort

D. Radix sort

Hint

Fix the input case and cost model, then count dominant work or simultaneously live storage.

Answer C: C. Merge sort

Ordinary mergesort performs linear merging at each of logarithmically many levels, giving n log n work regardless of input order. Bubble and selection have quadratic average and worst time. Fixed-width, fixed-radix counting passes instead give radix sort linear time, so radix does not have the requested tight n log n growth. Specifying tight bounds excludes faster methods that would also satisfy the looser Big-O upper bound.

Why each choice is right or wrong

A - Incorrect: Bubble has quadratic average and worst time.

B - Incorrect: Selection makes quadratic comparisons in every order.

C - Correct: Ordinary mergesort has tight n log n average and worst time.

D - Incorrect: With fixed digits and radix, radix sorting has tight linear time.

Primary note proof

Study-note section DSA37

> There are logarithmically many levels with linear merge work per level, giving n log n time even on sorted input unless an optimization skips merges.

Study-note section DSA39

> With d digits and radix r, counting-based passes take O(d(n+r)) time and O(n+r) auxiliary storage.

Study-note section DSA32

> Quadratic worst/average work comes from up to n(n-1)/2 pair comparisons.

Study-note section DSA33

> There are n-1 meaningful placements and n(n-1)/2 comparisons regardless of initial order.

3. Recursively sort the left part
4. Recursively sort the right part

Variant 1 | Alternative version 1

Under ordinary array comparison-sort implementations, which algorithm has tight Theta(n log n) time in every input case? Exclude optimizations that skip work on already ordered input.

A. Bubble sort

B. Selection sort

C. Merge sort

D. Insertion sort

Answer C: C. Merge sort

Buffered mergesort has linear merge work at logarithmically many levels in every input case, giving tight n log n average and worst growth. Bubble, selection and insertion have quadratic worst time, and their usual average time is also quadratic. Quicksort's extreme partitions can violate the requested worst-case bound, whereas buffered mergesort meets it.

Why each choice is right or wrong

A - Incorrect: Bubble has quadratic average and worst time.

B - Incorrect: Selection always makes quadratic comparisons.

C - Correct: Mergesort has the required tight average and worst bounds.

D - Incorrect: Insertion has quadratic average and worst time.

Primary note proof

Study-note section DSA37

> There are logarithmically many levels with linear merge work per level, giving n log n time even on sorted input unless an optimization skips merges.

Study-note section DSA32

Computer Science MCQ practice collection · Question 438

Question 37 | Q00386

For a large array of nonnegative integer keys with fixed digit count and fixed radix, which listed ordinary algorithm can achieve linear time using counting-based digit passes and O(n+r) auxiliary storage?

A. Bubble sort

B. Selection sort

C. Radix sort

D. Insertion sort

Hint

Fix the input case and cost model, then count dominant work or simultaneously live storage.

Answer C: C. Radix sort

With digit count d and radix r fixed, the radix cost O(d(n+r)) reduces to linear growth in n. Its counting-based stable passes use auxiliary storage for output and digit counts. The key assumptions make this an eligible radix-sorting workload rather than an unspecified large-list claim. Bubble, selection and insertion use constant extra element storage in their ordinary forms and can require quadratic work.

Why each choice is right or wrong

A - Incorrect: Bubble uses adjacent comparisons and can require quadratic work.

B - Incorrect: Selection uses quadratic comparisons and constant extra element storage.

C - Correct: Radix uses the stated digit passes and auxiliary storage.

D - Incorrect: Insertion uses prefix shifts and can require quadratic work.

Primary note proof

Study-note section DSA39

> With d digits and radix r, counting-based passes take O(d(n+r)) time and O(n+r) auxiliary storage.

Study-note section DSA32

> For ascending order, compare each adjacent pair and swap only when left>right.

Study-note section DSA34

> For each remaining item, save its value, shift larger preceding values right, and insert it into the gap.

Study-note section DSA33

> At position i, scan the remaining suffix for its minimum, then exchange it with A[i].

Data Structures & Algorithms practice questions · Question 16

Question 38 | Q00387

Which listed sorting algorithm orders fixed-length strings by stably processing individual character positions, without using whole-string comparison operations? Assume an ordered finite character alphabet and LSD passes.

A. Bubble sort

B. Selection sort

C. Merge sort

D. Radix sort

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer D: D. Radix sort

Strings can be compared lexicographically, but the stated question asks for a digit-based mechanism rather than whole-key comparisons. LSD radix sorting treats each character position as a digit, stably sorting from the last position toward the first. Stability retains the ordering established by earlier passes. Bubble, selection and merge use comparisons between keys in their ordinary forms, so they do not implement this specified character-pass mechanism.

Why each choice is right or wrong

A - Incorrect: Ordinary bubble sort compares adjacent whole keys.

B - Incorrect: Ordinary selection chooses a minimum through key comparisons.

C - Incorrect: Ordinary merge compares the fronts of sorted key runs.

D - Correct: LSD radix uses stable character-position passes from least significant to most significant.

Primary note proof

Study-note section DSA39

> LSD radix sorting handles fixed-width digit keys by stably sorting least-significant digit first, then moving left. Stable intermediate passes preserve the ordering already established by less-significant digits. With d digits and radix r, counting-based passes take O(d(n+r)) time and O(n+r) auxiliary storage.

Study-note section DSA32

> For ascending order, compare each adjacent pair and swap only when left>right.

Study-note section DSA33

> At position i, scan the remaining suffix for its minimum, then exchange it with A[i].

Study-note section DSA37

> Split into halves, sort them, then merge by advancing the smaller current front.

4. Merge sorted items (using an auxiliary array).

Question sources

Data Structures & Algorithms practice questions · Question 17

Question 39 | Q00388

How many passes does an insertion sort algorithm consist of?

A. N

B. N-1

C. N+1

D. N2

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer B: N-1

The first element is already a sorted prefix. Each of the remaining N-1 elements is inserted once: the source starts with the first two, then adds the third, and so on. Evidence: assigned PDF pages 3.

Why each choice is right or wrong

A - Incorrect: N counts the initial singleton as an insertion pass. See assigned PDF 3.

B - Correct: There is one insertion for each position 2 through N. See assigned PDF 3.

C - Incorrect: N+1 adds two passes with no corresponding elements. See assigned PDF 3.

D - Incorrect: N squared is a work bound, not the count of outer passes. See assigned PDF 3.

Primary note proof

Study-note section DSA34

> Begin with the first element already sorted. For each remaining item, save its value, shift larger preceding values right, and insert it into the gap. That gives n-1 insertion passes. On sorted input each pass needs one ordering check and no shifts: linear time. Reverse order causes 1+2+...+(n-1) shifts: quadratic time.

Question 40 | Q00389

What is the running time of an insertion sort algorithm if the input is pre-sorted?

A. O(N2)

B. O(N log N)

C. O(N)

D. O(M log N)

Hint

Fix the input case and cost model, then count dominant work or simultaneously live storage.

Answer C: O(N)

For sorted input every new item already belongs after its predecessor. Each of N-1 prefix extensions needs constant comparison work and no shifts, giving Theta(N). Big-O choices are interpreted as tight orders. Evidence: assigned PDF pages 3.

Why each choice is right or wrong

A - Incorrect: Quadratic is the adverse-input bound, not the tight sorted-input cost. See assigned PDF 3.

B - Incorrect: N log N adds work not performed by this insertion process. See assigned PDF 3.

C - Correct: One constant check per extension gives linear work. See assigned PDF 3.

D - Incorrect: M is undefined and no M-dependent process is given. See assigned PDF 3.

Primary note proof

Study-note section DSA34

> Begin with the first element already sorted. For each remaining item, save its value, shift larger preceding values right, and insert it into the gap. That gives n-1 insertion passes. On sorted input each pass needs one ordering check and no shifts: linear time. Reverse order causes 1+2+...+(n-1) shifts: quadratic time.

Question 41 | Q00390

Which of the following examples represent the worst case input for an insertion sort?

A. array in sorted order

B. array sorted in reverse order

C. normal unsorted array

D. large array

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer B: array sorted in reverse order

Reverse order forces each inserted item to move through the whole preceding prefix. The movement total 1+2+...+(n-1)=n(n-1)/2 is quadratic. Evidence: assigned PDF pages 3.

Why each choice is right or wrong

A - Incorrect: Sorted input needs no shifts. See assigned PDF 3.

B - Correct: Each next element is smaller than every element in the prefix. See assigned PDF 3.

C - Incorrect: An arbitrary unsorted array need not maximize all insertion distances. See assigned PDF 3.

D - Incorrect: Large size alone does not determine relative ordering or maximal shifts. See assigned PDF 3.

Primary note proof

Study-note section DSA34

> Begin with the first element already sorted. For each remaining item, save its value, shift larger preceding values right, and insert it into the gap. That gives n-1 insertion passes. On sorted input each pass needs one ordering check and no shifts: linear time. Reverse order causes 1+2+...+(n-1) shifts: quadratic time.

Question sources

Data Structures & Algorithms practice questions · Question 20

Question 42 | Q00391

Which scenario specifically favors selection sort's small number of record exchanges, when records themselves are moved and comparisons are cheap? Interpret large values as large records and small keys as inexpensive comparison keys.

A. The input is already sorted

B. A large file has to be sorted

C. Large values need to be sorted with small keys

D. Small values need to be sorted with large keys

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer C: C. Large values need to be sorted with small keys

Selection sort scans suffixes and makes quadratic comparisons regardless of the initial order, but it performs at most one meaningful exchange per placement. That tradeoff can be useful when physically moving a large record is expensive while comparing its small key is cheap. A large file or sorted input alone does not offer this advantage. Expensive large-key comparisons instead make selection's many comparisons less attractive.

Why each choice is right or wrong

A - Incorrect: Sorted order does not reduce selection's quadratic comparison count.

B - Incorrect: Large file size alone does not identify the expensive-move advantage.

C - Correct: Large records with cheap keys match the many-comparisons/few-exchanges tradeoff.

D - Incorrect: Expensive comparisons with cheap moves do not favor that tradeoff.

Primary note proof

Study-note section DSA33

At position i, scan the remaining suffix for its minimum, then exchange it with A[i]. There are n-1 meaningful placements and n(n-1)/2 comparisons regardless of initial order. At most n-1 exchanges of distinct positions are needed. A loop that also swaps the last item with itself can count n swap calls.

Question sources

Data Structures & Algorithms practice questions · Question 21

Question 43 | Q00392

What is the advantage of selection sort over other sorting techniques?

A. It requires no additional storage space

B. It is scalable

C. It works best for inputs which are already sorted

D. It is faster than any other sorting technique

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer A: Constant extra element storage, conventionally called in-place sorting.

DSA33 says selection uses constant extra element storage, which is the conventional meaning of A's no-additional-storage phrasing. It still needs a few temporary values, so literally zero bytes would be inaccurate. Its quadratic comparisons do not improve on already sorted input, and the note gives no universal scalability or fastest-algorithm claim. A names the valid conventional benefit.

Why each choice is right or wrong

A - Correct: Interpreted conventionally as in-place, selection uses constant extra element storage rather than an auxiliary array.

B - Incorrect: Quadratic comparisons do not provide an unqualified scalability advantage for growing datasets.

C - Incorrect: Selection makes the same quadratic comparisons even on already sorted input.

D - Incorrect: No universal fastest claim follows; selection trades few moves for many comparisons.

Primary note proof

Study-note section DSA33

> Selection suits expensive record moves with cheap key comparisons, not every large dataset. It is unstable: exchanging first 2a with 1 in [2a,2b,1] gives [1,2b,2a]. Constant extra element storage is shared by several sorts.

Study-note section DSA33

> There are n-1 meaningful placements and n(n-1)/2 comparisons regardless of initial order.

iv. Merge sort
Merge sort uses divide and conquer strategy and its time complexity is O(nlogn).
Algorithm:
1. Divide the array in to two halves.
2. Recursively sort the first n/2 items.
3. Recursively sort the last n/2 items.
4. Merge sorted items (using an auxiliary array).

Question sources

Data Structures & Algorithms practice questions · Question 22

Question 44 | Q00393

What is an external sorting algorithm?

A. Algorithm that uses tape or disk during the sort

B. Algorithm that uses main memory during the sort

C. Algorithm that involves swapping

D. Algorithm that are considered 'in place'

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer A: Sorting using external storage such as disk or tape.

DSA37 defines external sorting through datasets beyond main memory and buffered disk runs. Option A captures this distinguishing external-storage use. Main memory may still hold buffers, but using it alone does not define external sorting. Swapping and being in place are separate implementation properties and do not identify whether the working dataset resides externally.

Why each choice is right or wrong

A - Correct: Tape or disk stores external runs when the working dataset does not fit wholly in main memory.

B - Incorrect: Main-memory use alone does not distinguish external sorting; external algorithms also use memory for buffers.

C - Incorrect: Swapping is an operation used by many sorts and does not define external storage use.

D - Incorrect: In-place concerns auxiliary element storage, independently of whether sorting accesses an external dataset.

Primary note proof

Study-note section DSA37

> Top-down mergesort recurses; bottom-up merges runs of widths 1,2,4,... iteratively. In-place merging variants exist with different tradeoffs; linear merge names an operation, not a universally standardized sort variant. Internal sorting fits the working dataset in memory. External sorting builds sorted runs and merges buffered streams from disk, aiming to reduce I/O. Reverse order alone does not characterize maximum merge comparisons.

Question 45 | Q00395

What is the worst case complexity of bubble sort?

A. O(nlogn)

B. O(logn)

C. O(n)

D. O(n2)

Hint

Fix the input case and cost model, then count dominant work or simultaneously live storage.

Answer D: O(n2)

An adversarial input requires repeated passes over adjacent pairs; the total comparisons and swaps are quadratic as stated in the module. Evidence: assigned PDF pages 4.

Why each choice is right or wrong

A - Incorrect: n log n understates the tight adverse-input work. See assigned PDF 4.

B - Incorrect: Logarithmic growth cannot account for repeated full passes. See assigned PDF 4.

C - Incorrect: Linear describes at most a single pass. See assigned PDF 4.

D - Correct: The source explicitly gives O(n2) comparisons and swaps. See assigned PDF 4.

Primary note proof

Study-note section DSA32

> For ascending order, compare each adjacent pair and swap only when left>right. The largest remaining value moves to the final unsorted position after one left-to-right pass. Shrink the next pass by one position. Quadratic worst/average work comes from up to n(n-1)/2 pair comparisons.

>) and How many swaps? => O(n2
>)

Question sources

Data Structures & Algorithms practice questions · Question 25

Question 46 | Q00396

What is the average case complexity of bubble sort?

A. O(nlogn)

B. O(logn)

C. O(n)

D. O(n2)

Hint

Fix the input case and cost model, then count dominant work or simultaneously live storage.

Answer D: O(n^2) under the usual average-case model.

DSA32 identifies quadratic average and worst work from repeated adjacent comparisons. Under the usual random-permutation average model, bubble sort therefore takes $\Theta(n^2)$, which implies $O(n^2)$. Early stopping makes an already sorted input linear, but that is the optimized best case rather than the ordinary average over input arrangements.

Why each choice is right or wrong

A - Incorrect: Quadratic average work grows faster than n log n, so this bound is too small.

B - Incorrect: Repeated adjacent passes do not have logarithmic average growth under the usual input model.

C - Incorrect: Linear work is the optimized sorted-input best case, not ordinary average-case bubble sorting.

D - Correct: Quadratic average work is bounded by $O(n^2)$, matching the adjacent-pass analysis in DSA32.

Primary note proof

Study-note section DSA32

> For ascending order, compare each adjacent pair and swap only when left>right. The largest remaining value moves to the final unsorted position after one left-to-right pass. Shrink the next pass by one position. Quadratic worst/average work comes from up to n(n-1)/2 pair comparisons.

Study-note section DSA-S01

> Fix the input size before comparing cases. Best-case cost is the minimum resource use over legal inputs of that size; worst-case cost is the maximum. Average-case cost averages costs using a stated input distribution. These three input-case functions can each be described using upper, lower or tight asymptotic bounds; the case name does not select the bound notation.

Data Structures & Algorithms practice questions · Question 26

Question 47 | Q00397

What is the auxiliary space complexity of merge sort?

A. O(1)

B. O(log n)

C. O(n)

D. O(n log n)

Hint

Fix the input case and cost model, then count dominant work or simultaneously live storage.

Answer C: O(n)

Merging both halves needs an auxiliary array holding up to n elements. Recursion contributes O(log n) frames, dominated by O(n) temporary element storage in the ordinary implementation. Evidence: assigned PDF pages 11.

Why each choice is right or wrong

A - Incorrect: Constant space contradicts the full merge array. See assigned PDF 11.

B - Incorrect: Logarithmic describes recursion depth alone. See assigned PDF 11.

C - Correct: A merge buffer proportional to n dominates auxiliary storage. See assigned PDF 11.

D - Incorrect: n log n counts cumulative work across levels, not simultaneously live storage when buffers are reused. See assigned PDF 11.

Primary note proof

Study-note section DSA37

Ordinary array merging needs a linear auxiliary buffer.

Study-note section DSA37

There are logarithmically many levels with linear merge work per level, giving n log n time even on sorted input unless an optimization skips merges.

Study-note section DSA07

An n-level ordinary recursion with constant live storage per level needs Theta(n) stack space.

iv. Merge sort
Merge sort uses divide and conquer strategy and its time complexity is O(nlogn).
Algorithm:
1. Divide the array in to two halves.
2. Recursively sort the first n/2 items.
3. Recursively sort the last n/2 items.
4. Merge sorted items (using an auxiliary array).

Question sources

Data Structures & Algorithms practice questions · Question 27

Question 48 | Q00398

What is the tightest listed worst-case time bound for ordinary array mergesort that performs all merges and does not skip already ordered runs? Interpret logarithms explicitly as parenthesized in the options.

A. O(n log n)

B. $O(n^2)$

C. $O(n^2 \log n)$

D. $O(n (\log n)^2)$

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer A: A. O(n log n)

Ordinary mergesort splits the array into logarithmically many levels and performs linear total merging work per level. It therefore has n log n worst-case growth under the specified implementation. Sorted input does not skip any merges here. The quadratic and $n^2 \log n$ choices are looser upper bounds, while $n(\log n)^2$ grows faster than n log n. Asking for the tightest listed bound selects A uniquely.

Why each choice is right or wrong

A - Correct: This matches the actual n log n growth.

B - Incorrect: Quadratic is a valid but looser upper bound.

C - Incorrect: $n^2 \log n$ is a valid but looser upper bound.

D - Incorrect: $n(\log n)^2$ grows faster and is a looser upper bound.

Primary note proof

Study-note section DSA37

> There are logarithmically many levels with linear merge work per level, giving n log n time even on sorted input unless an optimization skips merges.

Study-note section DSA06

> For eventually nonnegative functions, f(n)=O(g(n)) means f(n)≤c g(n) for some positive c beyond a threshold k. Omega reverses the inequality; Theta requires both. Little-o means f/g tends to zero; little-omega means it grows without bound. These relations can describe best-case, average-case, worst-case or space functions.

Question sources

Data Structures & Algorithms practice questions · Question 29

Question 50 | Q00400

Using the terminology of the course note, which listed phrase names the combining operation rather than a recognized organization or storage variant of mergesort?

A. in-place merge sort

B. bottom up merge sort

C. top down merge sort

D. linear merge sort

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer D: D. linear merge sort

Top-down mergesort recursively divides the sequence, while bottom-up mergesort iteratively combines runs of increasing widths. In-place variants change the storage tradeoff used while merging. Under the note's stated terminology, linear merge names the combining operation itself rather than a separate standardized sort variant. This is a distinction within the supplied naming convention, not a claim that no author could ever use that phrase differently.

Why each choice is right or wrong

A - Incorrect: In-place merging is a recognized storage variant.

B - Incorrect: Bottom-up mergesort is the iterative run-merging organization.

C - Incorrect: Top-down mergesort is the recursive organization.

D - Correct: Linear merge names the combining operation under the stated terminology.

Primary note proof

Study-note section DSA37

Top-down mergesort recurses; bottom-up merges runs of widths 1,2,4,... iteratively. In-place merging variants exist with different tradeoffs; linear merge names an operation, not a universally standardized sort variant. Internal sorting fits the working dataset in memory.

External sorting builds sorted runs and merges buffered streams from disk, aiming to reduce I/O. Reverse order alone does not characterize maximum merge comparisons.

3. Recursively sort the last n/2 items.
4. Merge sorted items (using an auxiliary array).

Question sources

Data Structures & Algorithms practice questions · Question 30

Question 51 | Q00401

Which of the following is not in place sorting algorithm by default?

A. merge sort

B. quick sort

C. heap sort

D. insertion sort

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer A: merge sort

The default merge algorithm explicitly uses an auxiliary array. The described partition, heap swaps and insertion can use the original array; recursion-stack use is distinct from requiring a second element array. Evidence: assigned PDF pages 11, 3.

Why each choice is right or wrong

A - Correct: Merge expressly allocates auxiliary array storage. See assigned PDF 11, 11, 11, 3.

B - Incorrect: Quicksort partitions in the existing array in its conventional form. See assigned PDF 11, 11, 11, 3.

C - Incorrect: Heap sorts by exchanging root and last within the array. See assigned PDF 11, 11, 11, 3.

D - Incorrect: Insertion rearranges the list in its existing slots. See assigned PDF 11, 11, 11, 3.

Primary note proof

Study-note section DSA37

Ordinary array merging needs a linear auxiliary buffer.

Study-note section DSA36

Quicksort normally rearranges in the same array but recursive storage can be linear in the worst case.

Study-note section DSA38

Building with bottom-up sinking is linear; repeated extraction gives O(n log n) worst time. Iterative sinking needs constant auxiliary storage. The method is generally unstable because long root-to-end exchanges can reorder equal keys. It is not uniquely the method for sorting by priorities: any comparison sort can compare a priority field. Heap extraction is its distinctive mechanism.

Study-note section DSA34

For each remaining item, save its value, shift larger preceding values right, and insert it into the gap.

iv. Merge sort
Merge sort uses divide and conquer strategy and its time complexity is O(nlogn).
Algorithm:
1. Divide the array in to two halves.
2. Recursively sort the first n/2 items.
3. Recursively sort the last n/2 items.
4. Merge sorted items (using an auxiliary array).

Data Structure and Algorithms module | PDF page 11 | lines 14-22

ii. Quick sort: is the fastest known algorithm. It uses divide and conquer strategy and in the worst case its complexity is O (n2). But its expected complexity is O(nlogn).
Algorithm:
1. Choose a pivot value (mostly the first element is taken as the pivot value)
2. Position the pivot element and partition the list so that:
• the left part has items less than or equal to the pivot value
• the right part has items greater than or equal to the pivot value
3. Recursively sort the left part
4. Recursively sort the right part

Data Structure and Algorithms module | PDF page 11 | lines 23-37

iii. Heap Sort
Heap sort operates by first converting the list in to a heap tree. Heap tree is a binary tree in which

each node has a value greater than both its children (if any). It uses a process called "adjust to accomplish its task (building a heap tree) whenever a value is larger than its parent. The time complexity of heap sort is O(nlogn).
Algorithm:
1. Construct a binary tree
• The root node corresponds to Data[0].
• If we consider the index associated with a particular node to be i, then the left child of this node corresponds to the element with index 2*i+1 and the right child corresponds to the element with index 2*i+2. If any or both of these elements do not exist in the array, then the corresponding child node does not exist either.
2. Construct the heap tree from initial binary tree using "adjust" process.
Sort by swapping the root value with the lowest, right most value and deleting the lowest, right most value and inserting the deleted value in the array in it proper position.

Data Structure and Algorithms module | PDF page 3 | lines 34-43

A. Insertion Sort
The most instinctive type of sorting algorithm; it finds the location for an element and move all others up, and insert the element to its right position. It starts with the left most two items and put
them in order. Then add 3rd
item to the relatively sorted portion and find its correct location
(relative to each other) swapping adjacent elements if they are out of order. In such it sorts all item
in the list.
• How many comparisons? => O(n2
) and How many swaps? => O(n2
)

Question sources

Data Structures & Algorithms practice questions · Question 31

Question 52 | Q00402

Which of the following is not a stable sorting algorithm?

A. Quick sort

B. Cocktail sort

C. Bubble sort

D. Merge sort

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer A: Standard quicksort is unstable.

The DSA31 sorting table identifies quicksort as unstable. Cocktail and bubble sorts preserve equal-key order when swapping only strict adjacent inversions. Ordinary merge sort preserves equal-key order when ties are taken from the left run first. Under these usual implementations, quicksort is the single listed algorithm that does not guarantee stability.

Why each choice is right or wrong

A - Correct: Standard quicksort partition exchanges can move equal keys past one another and do not guarantee stability.

B - Incorrect: Cocktail sort is stable with strict adjacent swaps, as described in DSA32.

C - Incorrect: Bubble sort preserves equal-key order when it swaps only strict adjacent inversions.

D - Incorrect: Merge sort preserves equal-key order by taking equal elements from the left run first.

Primary note proof

Study-note section DSA32

> Early stopping makes a sorted input linear: one no-swap pass finishes. A fixed pass schedule stays quadratic. Strict swaps preserve equal-key order. Cocktail sort runs bubble passes in both directions and is stable with strict swaps.

Study-note section DSA37

> With left-first tie handling, equal keys retain order.

Study-note section DSA31

> stack usually log n average, n worst; unstable

Question sources

Data Structures & Algorithms practice questions · Question 32

Question 53 | Q00403

Which specified sorting implementations avoid recursion? A is ordinary recursive quicksort; B is top-down recursive mergesort; C uses iterative heap sinking; D is bottom-up mergesort. Select all that apply.

A. quick sort

B. top-down merge sort

C. heap sort with iterative sinking

D. bottom up merge sort

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer C, D: C. heap sort with iterative sinking; D. bottom up merge sort

Bottom-up mergesort processes run widths 1, 2, 4 and so on in loops, without recursive splitting. Heapsort can also restore heap order with iterative sinking, making the specified C implementation nonrecursive. A and B are explicitly the recursive forms described in the note. The question fixes implementations because algorithm names alone do not force either recursive or iterative control flow.

Why each choice is right or wrong

A - Incorrect: The specified quicksort recursively sorts its partition ranges.

B - Incorrect: The specified top-down mergesort recursively sorts halves.

C - Correct: Iterative heap sinking requires no recursive calls.

D - Correct: Bottom-up run merging proceeds iteratively.

Primary note proof

Study-note section DSA37

> Top-down mergesort recurses; bottom-up merges runs of widths 1,2,4,... iteratively.

Study-note section DSA38

> Iterative sinking needs constant auxiliary storage.

Question sources

Data Structures & Algorithms practice questions · Question 33

Question 54 | Q00404

What is the worst case time complexity of a quick sort algorithm?

A. O(N)

B. O(N log N)

C. O(N2)

D. O(log N)

Hint

Fix the input case and cost model, then count dominant work or simultaneously live storage.

Answer C: O(N2)

The source states O(n^2) in the worst case. Repeated extreme pivots leave subproblems n-1,n-2,..., whose partition work sums quadratically. Evidence: assigned PDF pages 11.

Why each choice is right or wrong

A - Incorrect: Linear does not include repeated near-full partitions. See assigned PDF 11.

B - Incorrect: n log n is the expected, not worst, cost. See assigned PDF 11.

C - Correct: Unbalanced partitions give quadratic work. See assigned PDF 11.

D - Incorrect: Logarithmic describes neither partition scans nor their total. See assigned PDF 11.

Primary note proof

Study-note section DSA36

Choose a pivot, partition, then recursively sort the pieces. Balanced partitions give n log n work; repeated extreme pivots sum n+(n-1)+... to quadratic work. Expected n log n needs an input/random-pivot model. Random and median-of-three choices have different tradeoffs; neither is universally best.

Data Structures & Algorithms practice questions · Question 34

Question 55 | Q00405

For a strictly increasing array of at least five distinct keys, which listed pivot rule is deterministic and avoids choosing an extreme key on the first partition? Interpret median-of-three as the median of the first, middle and last keys.

A. first element

B. last element

C. median-of-three partitioning

D. random element

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer C: C. median-of-three partitioning

On a strictly increasing array, the first key is the minimum and the last key is the maximum, so those deterministic endpoint rules choose extremes. The median of the first, middle and last keys is the middle-position value, which is neither extreme for the stated size. A random element is not a deterministic rule and can choose an endpoint. This criterion selects C without claiming a universally best practical pivot strategy.

Why each choice is right or wrong

A - Incorrect: The first key is the minimum on this input.

B - Incorrect: The last key is the maximum on this input.

C - Correct: The sample median is the middle-position value and is not extreme.

D - Incorrect: Random selection is not deterministic and may choose an extreme.

Primary note proof

Study-note section DSA36

Choose a pivot, partition, then recursively sort the pieces. Balanced partitions give n log n work; repeated extreme pivots sum n+(n-1)+... to quadratic work. Expected n log n needs an input/random-pivot model. Random and median-of-three choices have different tradeoffs; neither is universally best.

D. O(log N)

Hint

Fix the input case and cost model, then count dominant work or simultaneously live storage.

Answer C: O(N log N)

Expected O(n log n) is explicitly given. Under ordinary nonadversarial/random-pivot assumptions this is the average runtime intended by the question. Evidence: assigned PDF pages 11.

Why each choice is right or wrong

A - Incorrect: Quadratic is the stated worst case. See assigned PDF 11.

B - Incorrect: Linear omits recursive partition levels. See assigned PDF 11.

C - Correct: Matches the stated expected n log n growth. See assigned PDF 11.

D - Incorrect: Logarithmic omits linear partition work. See assigned PDF 11.

Primary note proof

Study-note section DSA36

Choose a pivot, partition, then recursively sort the pieces. Balanced partitions give n log n work; repeated extreme pivots sum n+(n-1)+... to quadratic work. Expected n log n needs an input/random-pivot model. Random and median-of-three choices have different tradeoffs; neither is universally best.

Study-note section DSA-S01

Fix the input size before comparing cases. Best-case cost is the minimum resource use over legal inputs of that size; worst-case cost is the maximum. Average-case cost averages costs using a stated input distribution. These three input-case functions can each be described using upper, lower or tight asymptotic bounds; the case name does not select the bound notation.

Data Structure and Algorithms module | PDF page 11 | lines 14-22

ii. Quick sort: is the fastest known algorithm. It uses divide and conquer strategy and in the worst case its complexity is O (n2). But its expected complexity is O(nlogn).
Algorithm:
1. Choose a pivot value (mostly the first element is taken as the pivot value)
2. Position the pivot element and partition the list so that:
• the left part has items less than or equal to the pivot value
• the right part has items greater than or equal to the pivot value
3. Recursively sort the left part
4. Recursively sort the right part

Question sources

Data Structures & Algorithms practice questions · Question 36

Question 57 | Q00407

Which option gives the most complete set of the listed situations in which linear search can be an appropriate direct method? Select the combined answer rather than only one valid situation.

A. When the list has only a few elements

B. When performing a single search in an unordered list

C. Used all the time

D. When the list has only a few elements and When performing a single search in an unordered list

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer D: Both short lists and a single unsorted-list query favor scanning.

Linear scanning can suit a short list because setup costs may dominate, and it can answer a single unsorted query without first building an ordered index or sorting the data. These are two supported use cases, not conditions that must occur simultaneously. A and B each give one true but incomplete situation. D combines both, while the universal claim that scanning should be used all the time is false.

Why each choice is right or wrong

A - Incorrect: True but incomplete: a short list is one supported case, but this omits the single unsorted query.

B - Incorrect: True but incomplete: a single unsorted query is supported, but this omits the short-list case.

C - Incorrect: Linear search is not preferable for every workload or available representation.

D - Correct: The combined answer includes both supported situations.

Primary note proof

Study-note section DSA28

> For a single unsorted query, sorting first is rarely justified. Small lists may favour scanning because setup matters. Sorting does not avoid examining all values for mean, variance or arbitrary parity counts.

Question 58 | Q00408

What is the best case for linear search?

A. O(nlogn)

B. O(logn)

C. O(n)

D. O(1)

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer D: O(1)

An immediate match at the first list element takes one comparison. Treat complexity options as the tight order. Evidence: assigned PDF pages 3.

Why each choice is right or wrong

A - Incorrect: n log n is not the immediate-match cost. See assigned PDF 3.

B - Incorrect: Logarithmic is not needed for the first inspected item. See assigned PDF 3.

C - Incorrect: Linear is the complete-scan order. See assigned PDF 3.

D - Correct: The first-item match requires constant work. See assigned PDF 3.

Primary note proof

Study-note section DSA28

> Compare the target with successive elements until equal or exhausted. Unsorted data is allowed; sorted data is allowed too. A first-element match costs Theta(1). An absent target or last-position match needs n comparisons, giving Theta(n) worst time. Uniformly likely successful positions average (n+1)/2 comparisons, still linear.

Question 60 | Q00410

What is the worst case complexity of binary search using recursion?

A. O(nlogn)

B. O(logn)

C. O(n)

D. O(n2)

Hint

Fix the input case and cost model, then count dominant work or simultaneously live storage.

Answer B: O(logn)

Each recursive step halves the candidate interval; after k steps its size is at most n/2^k. Reaching size one requires about log2 n steps. Evidence: assigned PDF pages 3.

Why each choice is right or wrong

A - Incorrect: n log n overcounts a single search path. See assigned PDF 3.

B - Correct: Repeated halving gives logarithmic search depth. See assigned PDF 3.

C - Incorrect: Linear ignores the discarded half at every step. See assigned PDF 3.

D - Incorrect: Quadratic has no corresponding nested scan. See assigned PDF 3.

Primary note proof

Study-note section DSA29

On an ascending random-access sequence, set lo=0, hi=n-1. Compute mid=lo+(hi-lo)//2. Equality finishes; if target<A[mid], set hi=mid-1; otherwise set lo=mid+1. Stop unsuccessfully when lo>hi. Reverse comparisons for descending order. Comparable keys and valid finite bounds matter; fixed allocation before population is not an extra algorithmic requirement.

Study-note section DSA29

Worst probes are floor($\log_2 n$)+1 for n>0: seven for 100 keys, about twenty for one million. Iteration uses constant space; recursion uses logarithmic stack depth. Linked midpoint traversal

loses logarithmic total time. Boundary variants retain a candidate rather than stopping at equality.

• The computational time for this algorithm is proportional to log2 n.

Question sources

Data Structures & Algorithms practice questions · Question 40

Question 61 | Q00411

For recursive binary search on a sorted random-access array of n distinct keys, each stored key is equally likely to be the successful target. With constant-time comparisons, what is the tightest listed average-time upper bound?

A. O(nlogn)

B. O(logn)

C. O(n)

D. O(n2)

Hint

Fix the input case and cost model, then count dominant work or simultaneously live storage.

Answer B: B. O(logn)

Binary search repeatedly halves the remaining interval. Under equally likely successful keys, only a limited number can be found at shallow decision-tree levels, while a constant fraction require logarithmic depth. Together with the logarithmic upper bound, this gives Theta(log n) average probes. The larger displayed upper bounds are valid but loose; the requested tightest listed bound is therefore O(log n).

Why each choice is right or wrong

A - Incorrect: n log n is a looser upper bound on logarithmic average work.

B - Correct: log n is the tight average order under the stated successful-target distribution.

C - Incorrect: Linear is a valid but looser upper bound.

D - Incorrect: Quadratic is a valid but much looser upper bound.

Primary note proof

Study-note section DSA-S01

> For successful binary search with all stored positions equally likely, average probes have order Theta(log n). The probe decisions form a binary tree: only a bounded number of positions occur in shallow levels, while a constant fraction require logarithmic depth. Interval halving also gives the logarithmic upper bound. A distribution concentrating on an immediate midpoint hit would give a different average.

Study-note section DSA29

> On an ascending random-access sequence, set lo=0, hi=n-1. Compute mid=lo+(hi-lo)//2. Equality finishes; if target<A[mid], set hi=mid-1; otherwise set lo=mid+1. Stop unsuccessfully when lo>hi. Reverse comparisons for descending order. Comparable keys and valid finite bounds matter; fixed allocation before population is not an extra algorithmic requirement.

Question sources

Data Structures & Algorithms practice questions · Question 41

Question 62 | Q00412

Which task cannot directly use ordinary binary interval elimination under its stated conditions? The interval-union subtask in B uses a sorted array of interval endpoints; C has an ordered monotone good/bad boundary.

A. To find the lower/upper bound in an ordered sequence

B. Finding endpoint bounds in a sorted endpoint array while forming an interval union

C. Finding a monotone good/bad boundary during debugging

D. Directly searching an unordered list without sorting or an ordered index

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer D: D. Directly searching an unordered list without sorting or an ordered index

Binary search needs ordering that justifies rejecting one half of its candidate interval. Lower and upper bounds in an ordered sequence have that property. Searching sorted interval endpoints during an interval-union task also supplies an ordered subproblem, and a monotone debugging boundary permits the same halving logic. Direct searching in an unordered list supplies no such invariant, so a midpoint comparison cannot safely discard a half.

Why each choice is right or wrong

A - Incorrect: Boundary variants operate on the ordered candidate sequence.

B - Incorrect: The specified endpoint lookup is an ordered binary-search subtask.

C - Incorrect: The specified monotone good/bad boundary supports binary elimination.

D - Correct: An unordered list lacks the order needed to safely discard half after comparison.

Primary note proof

Study-note section DSA29

> On an ascending random-access sequence, set lo=0, hi=n-1. Compute mid=lo+(hi-lo)//2. Equality finishes; if target<A[mid], set hi=mid-1; otherwise set lo=mid+1. Stop unsuccessfully when lo>hi. Reverse comparisons for descending order. Comparable keys and valid finite bounds matter; fixed allocation before population is not an extra algorithmic requirement.

Study-note section DSA29

> Binary debugging needs an ordered good/bad boundary, not arbitrary fault locations.

Question sources

Data Structures & Algorithms practice questions · Question 42

Question 63 | Q00413

Which standard linear structure is defined by a chain of nodes, each containing a payload and one successor link, with a null successor ending an ordinary noncircular chain?

A. linked list

B. Array

C. Binary tree

D. None of these

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer A: A. linked list

The payload stores an item and the successor link connects its node to the next item's node. Following those links produces a linear sequence ending at null, which is the ordinary singly linked-list representation. An array instead reaches equal-sized positions by address arithmetic, and a binary tree has a branching parent/child contract rather than this one-successor sequence contract. The linked-list option is therefore the matching standard name.

Why each choice is right or wrong

A - Correct: A linked list represents its sequence through payload-plus-successor nodes.

B - Incorrect: An array uses indexed positions rather than this successor-chain representation.

C - Incorrect: A binary tree specifies up to two child branches rather than the stated linear successor contract.

D - Incorrect: The linked-list option supplies the matching structure.

Primary note proof

Study-note section DSA08

> A singly linked node contains data and next. Head points to the first node; null ends a noncircular chain.

Study-note section DSA02

> For equal-size elements, address(A[i]) = base + i × element_size under zero-based indexing.

Study-note section DSA18

> Binary means at most two children.

Data Structures & Algorithms practice questions · Question 43

Question 64 | Q00414

What is the time complexity to count the number of elements in the linked list?

A. O(1)

B. O(n)

C. O(logn)

D. None of the mentioned

Hint

Fix the input case and cost model, then count dominant work or simultaneously live storage.

Answer B: O(n)

Without a stored count, follow next pointers from start to NULL and increment once per visited node. Exactly n node visits are needed. Evidence: assigned PDF pages 5.

Why each choice is right or wrong

A - Incorrect: Constant time requires an additional maintained count. See assigned PDF 5.

B - Correct: Traversal visits every node once. See assigned PDF 5.

C - Incorrect: No halving shortcut exists in the next-pointer chain. See assigned PDF 5.

D - Incorrect: B supplies the traversal order. See assigned PDF 5.

Primary note proof

Study-note section DSA08

To display or count nodes, follow next from head until null, processing each node. Counting is Theta(n) unless size is maintained. An array-linked list still follows links unless separately position-indexed.

III. Displaying the list of Nodes
After adding nodes to the list, we need to display the list of nodes on the screen. Here are the steps required to display all nodes item in the list:
1. Set a temporary pointer to point to the same thing as the start pointer.
2. If the pointer points to NULL, display the message "End of list" and stop.
3. Otherwise, display the details of the node pointed to by the start pointer.
4. Make the temporary pointer point to the same thing as the next pointer of the node it is currently indicating.
5. Jump back to step 2.

Question sources

Data Structures & Algorithms practice questions · Question 44

Question 65 | Q00415

Linked lists are not suitable to for the implementation of?

A. Insertion sort

B. Radix sort

C. Polynomial manipulation

D. Binary search

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer D: Binary search loses its usual advantage on linked lists.

DSA29 explains that linked midpoint traversal loses logarithmic total time. That makes an ordinary linked list unsuitable for the usual efficient binary-search implementation, although an algorithm can still be written. The other tasks do not require constant-time midpoint access: insertion sort can relink nodes, polynomial terms can occupy nodes, and radix digit buckets can retain stable node sequences.

Why each choice is right or wrong

A - Incorrect: Insertion sorting can find an insertion location and relink nodes without requiring constant-time midpoint access.

B - Incorrect: Radix digit buckets can preserve node order across passes without a random-access midpoint operation.

C - Incorrect: Polynomial terms are explicitly listed as a linked-list application in DSA10.

D - Correct: Traversing to linked-list midpoints defeats the standard logarithmic total-time advantage of binary search.

Primary note proof

Study-note section DSA29

> Linked midpoint traversal loses logarithmic total time.

Study-note section DSA34

> Few inversions mean few shifts, favouring insertion for nearly sorted or small arrays. Shift only strictly larger keys for stability. A linked implementation saves array shifts but still must locate each insertion position.

Study-note section DSA10

> Lists suit changing sequences when references to insertion positions are already available. Finding a position is still linear. Lists can hold polynomial terms (coefficient, exponent), directory or block links, child lists in nonbinary trees, and hash chains. Browser history can use a doubly linked cursor. A playlist may be circular; airline seat lookup requires a specified seat-record model, not an automatic linked-list answer.

Study-note section DSA39

> Stable intermediate passes preserve the ordering already established by less-significant digits.

Data Structures & Algorithms practice questions · Question 45

Question 66 | Q00416

Which of these is an application of linked lists?

A. To implement file systems

B. For separate chaining in hash-tables

C. To implement non-binary trees

D. All of the mentioned

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer D: All listed applications.

DSA10 explicitly lists directory or block links, hash chains, and nonbinary-tree child lists as applications of linked nodes. These correspond to the three preceding options. Therefore All of the mentioned is the complete answer. The statement says linked lists can implement these components; it does not require every file system or tree representation to use them.

Why each choice is right or wrong

A - Incorrect: File-system directory or block links are valid uses, but this option omits the other supported applications.

B - Incorrect: Separate chaining uses linked bucket entries, but this is only one of the supported applications.

C - Incorrect: Child lists can represent nonbinary-tree children, alongside the other listed uses.

D - Correct: All three preceding options correspond to linked-record applications explicitly listed in DSA10.

Primary note proof

Study-note section DSA10

Lists suit changing sequences when references to insertion positions are already available. Finding a position is still linear. Lists can hold polynomial terms (coefficient, exponent), directory or block links, child lists in nonbinary trees, and hash chains. Browser history can use a doubly linked cursor. Question 67 | Q00417

In linked list each node contain minimum of two fields. One field is data field to store the data second field is?

A. Pointer to character

B. Pointer to integer

C. Pointer to node

D. Node

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer C: Pointer to node

The second minimum field points to the next node of the same node structure, alongside the payload. Evidence: assigned PDF pages 4.

Why each choice is right or wrong

A - Incorrect: A character pointer is not the next-node link unless the entire node type were a character, which it is not. See assigned PDF 4.

B - Incorrect: An integer pointer cannot stand for the described structured node link. See assigned PDF 4.

C - Correct: The link points to a node of the list. See assigned PDF 4.

D - Incorrect: The field is a pointer to a node, not a nested node stored by value. See assigned PDF 4.

Primary note proof

Study-note section DSA08

> A singly linked node contains data and next. Head points to the first node; null ends a noncircular chain. Empty means head==null. Nodes allocated as needed grow dynamically, with pointer overhead and no direct index arithmetic.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Question sources

Data Structures & Algorithms practice questions · Question 47

Question 68 | Q00418

For repeated queries for the item at logical position k, which listed representation gives constant-time lookup? A-C maintain ordinary links and endpoints only; D additionally maintains a random-access array mapping each logical position to its node. Ignore the cost of maintaining this index during updates.

A. Singly linked list

B. Doubly linked list

C. Circular linked list

D. Array implementation with a separate logical-position-to-node index

Hint

Fix the input case and cost model, then count dominant work or simultaneously live storage.

Answer D: D. Array implementation with a separate logical-position-to-node index

Ordinary singly, doubly and circular linked lists must follow links to reach a logical position, giving linear worst-case positional access. Storing nodes in an array alone does not change that. The explicit extra index in D is different: it maps each logical position directly to the corresponding node, so a random-access array lookup answers the query in constant time. Update costs are excluded by the stated workload.

Why each choice is right or wrong

A - Incorrect: Ordinary next-link traversal is linear in the worst case.

B - Incorrect: Using either endpoint still requires linear worst-case traversal.

C - Incorrect: Circular links do not supply a direct logical-position index.

D - Correct: The maintained position-to-node array permits direct indexed lookup.

Primary note proof

Study-note section DSA08

> To display or count nodes, follow next from head until null, processing each node. Counting is Theta(n) unless size is maintained. An array-linked list still follows links unless separately position-indexed.

Study-note section DSA02

> For equal-size elements, address(A[i]) = base + i × element_size under zero-based indexing. This arithmetic gives constant-time positional access in the usual RAM cost model. A row-major rectangular matrix uses base + (row × columns + column) × element_size.

Question 69 | Q00419

Linked list is considered as an example of _____ type of memory allocation.

A. Dynamic

B. Static

C. Compile time

D. None of the mentioned

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer A: Dynamic

Nodes are allocated with new as they are needed; the source explicitly calls linked-list stack memory dynamic. Evidence: assigned PDF pages 5, 6.

Why each choice is right or wrong

A - Correct: Node allocation occurs during execution. See assigned PDF 5, 6.

B - Incorrect: Static allocation is the contrasting array implementation. See assigned PDF 5, 6.

C - Incorrect: Compile-time allocation does not describe new-node creation. See assigned PDF 5, 6.

D - Incorrect: Dynamic is explicitly supported. See assigned PDF 5, 6.

Primary note proof

In Linked List implementation, a node carries information regarding

A. Data

B. Link

C. Data and Link

D. None of the mentioned

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer C: Data and Link

A node combines its payload with a next-node pointer. Neither field alone represents the complete linked-list node. Evidence: assigned PDF pages 4.

Why each choice is right or wrong

A - Incorrect: Data alone omits the next link. See assigned PDF 4.

B - Incorrect: A link alone omits the payload. See assigned PDF 4.

C - Correct: Both data and link are explicitly required. See assigned PDF 4.

D - Incorrect: C matches the stated two-field structure. See assigned PDF 4.

Primary note proof

Study-note section DSA08

> A singly linked node contains data and next. Head points to the first node; null ends a noncircular chain. Empty means head==null. Nodes allocated as needed grow dynamically, with pointer overhead and no direct index arithmetic.

Data Structures & Algorithms practice questions · Question 50

Question 71 | Q00421

Process of inserting an element in stack is called _____.

A. Create

B. Push

C. Evaluation

D. Pop

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer B: Push

The module defines push as adding an element to the stack top. Evidence: assigned PDF pages 6.

Why each choice is right or wrong

A - Incorrect: Create would initialize a structure, not name its insertion operation. See assigned PDF 6.

B - Correct: Push adds an element. See assigned PDF 6.

C - Incorrect: Evaluation is an application rather than insertion. See assigned PDF 6.

D - Incorrect: Pop removes an element. See assigned PDF 6.

Primary note proof

Study-note section DSA11

> Stack policy is LIFO, equivalently FILO. Push inserts, pop removes/returns top, and peek only observes. With zero-based occupied slots, top=-1 is empty and top=C-1 is full. Check before A[++top]=x or returning A[top--].

Data Structures & Algorithms practice questions · Question 51

Question 72 | Q00422

In a stack, if a user tries to remove an element from empty stack it is called _____.

A. Underflow

B. Empty collection

C. Overflow

D. Garbage Collection

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer A: Underflow

The stack pop code first tests empty at top==0. Removing from an empty structure is the underflow condition, explicitly named for dequeue and applied here to the same empty-removal failure. Evidence: assigned PDF pages 6, 7.

Why each choice is right or wrong

A - Correct: Underflow denotes attempting removal without an available element. See assigned PDF 6, 7.

B - Incorrect: Empty collection describes the state rather than the operation failure. See assigned PDF 6, 7.

C - Incorrect: Overflow concerns adding to a full structure. See assigned PDF 6, 7.

D - Incorrect: Garbage collection concerns reclaiming storage, not empty pop. See assigned PDF 6, 7.

Primary note proof

Study-note section DSA11

> Overflow is an attempted insertion into full storage; underflow is an attempted removal from empty storage. Merely checking isEmpty does not underflow.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Question 73 | Q00423

Process of removing an element from stack is called _____

A. Create

B. Push

C. Evaluation

D. Pop

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer D: Pop

The source names removing an element Pop and adding one Push. Evidence: assigned PDF pages 6.

Why each choice is right or wrong

A - Incorrect: Create does not remove the stack top. See assigned PDF 6.

B - Incorrect: Push adds rather than removes. See assigned PDF 6.

C - Incorrect: Evaluation uses stack operations but is not their deletion name. See assigned PDF 6.

D - Correct: Pop removes the current top. See assigned PDF 6.

Primary note proof

Study-note section DSA11

> Stack policy is LIFO, equivalently FILO. Push inserts, pop removes/returns top, and peek only observes. With zero-based occupied slots, top=-1 is empty and top=C-1 is full. Check before A[++top]=x or returning A[top--].

Question sources

Data Structures & Algorithms practice questions · Question 53

Question 74 | Q00424

A serial-storage interface restricts insertion and removal to the same current end: an item must be removed before any item stored earlier beneath it can be removed. Which ADT matches this restricted access policy?

A. Heap

B. Binary Tree

C. Array

D. Stack

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer D: D. Stack

The restriction makes the latest inserted item the next removable item. That is the stack's LIFO policy, with both push and pop acting at the top. Serial access alone would not establish this rule, so the same-end removal restriction is stated explicitly. A heap selects by priority, a binary tree supplies branching relationships, and an ordinary array permits indexed access rather than imposing this removal policy.

Why each choice is right or wrong

A - Incorrect: A heap selects an extreme priority rather than the latest insertion.

B - Incorrect: A binary tree supplies hierarchy rather than this same-end policy.

C - Incorrect: An array does not inherently impose this removal order.

D - Correct: A stack's push/pop policy matches the specified LIFO restriction.

Primary note proof

Study-note section DSA11

> Stack policy is LIFO, equivalently FILO. Push inserts, pop removes/returns top, and peek only observes. With zero-based occupied slots, top=-1 is empty and top=C-1 is full. Check before A[++top]=x or returning A[top--].

Study-note section DSA45

> ADTs do not force one representation, and serial-access memory is not inherently LIFO.

Question sources

Data Structures & Algorithms practice questions · Question 54

Question 75 | Q00425

A singly linked queue maintains only its front pointer and owns all its nodes. Emptying means immediately visiting and freeing every node. Which option gives the complete set of listed operations with tight worst-case linear time for n nodes?

A. Insertion

B. Deletion

C. To empty a queue

D. Both Insertion and To empty a queue

Hint

Fix the input case and cost model, then count dominant work or simultaneously live storage.

Answer D: D. Both Insertion and To empty a queue

Enqueue must traverse from the front to find the tail because no rear pointer is maintained. Emptying the owned queue must also visit and release all n nodes under the specified reclamation contract. Deleting one front node requires only a constant number of link and deallocation operations. Therefore both insertion and complete emptying are linear, and the aggregate option D is the complete selection.

Why each choice is right or wrong

A - Incorrect: Insertion is linear, but this omits the also-linear emptying operation.

B - Incorrect: A single front deletion is constant time.

C - Incorrect: Emptying is linear, but this omits insertion.

D - Correct: Both insertion and immediate full-node cleanup are linear.

Primary note proof

Study-note section DSA14

> An ordinary queue enqueues at rear, dequeues at front, and peeks at front. This is FIFO or first-come, first-served. A linked implementation with head and tail supports both operations in constant time: append at tail, remove at head. The first insertion sets both pointers; removing the last item clears both. With head alone, insertion must traverse to the tail.

Study-note section DSA09

> Deleting the tail of a singly linked list requires its predecessor, even when tail itself is known. Handle empty and single-node lists separately; after removing the only node, set both head and tail to null. To remove a known successor, bypass it before deallocation. Clearing an owned n-node chain visits and releases every node.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Data Structure and Algorithms module | PDF page 5 | lines 13-24

Step 3: Then add the node at the end of the list. For this we need to check whether the list is empty or not. If list is empty the new node will be the first (Start) node, otherwise navigate forward starting form the first node till last node found and add it next to this node which make the new node the last node.
if (start == NULL) // If list is empty, then new node become start node
start = temp;
else {
temp2 = start; // list not empty! Thus temp2 starts from first node
while (temp2->next!= NULL) { // till the current last node found navigates forward
temp2 = temp2->next; // Move to next link in chain
}
temp2->next = temp; // new node (temp) appended at the end of the list

Data Structure and Algorithms module | PDF page 8 | lines 35-37

III. Linked list implementation of enqueue and dequeue operations
Enqueue- is inserting a node at the end of a linked list
Dequeue- is deleting the first node in the list

Data Structure and Algorithms module | PDF page 5 | lines 35-41

IV. Deleting a node from the list
When a node is deleted, the space that it took up should be reclaimed. Otherwise the computer will eventually run out of memory space. This is done with the delete instruction:
delete temp; // Release the memory pointed to by temp
However, we can't just delete the nodes willy-nilly as it would break the chain. We need to reassign the pointers and then delete the node at the last moment. We can delete nodes at the start, middle or end of the list. Here let’s see the steps to delete at the end.

Data Structures & Algorithms practice questions · Question 55

Question 76 | Q00426

A linear list of elements in which deletion can be done from one end (front) and insertion can take place only at the other end (rear) is known as a ?

A. Queue

B. Stack

C. Tree

D. Linked list

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer A: Queue

The queue definition makes insertion rear-only and deletion front-only. A linked list can implement that policy, but does not by itself impose the two restrictions. Evidence: assigned PDF pages 7, 6, 4.

Why each choice is right or wrong

A - Correct: Matches the defined queue interface. See assigned PDF 7, 6, 4.

B - Incorrect: Stack uses one common endpoint for both operations. See assigned PDF 7, 6, 4.

C - Incorrect: Tree operations are not front/rear list operations. See assigned PDF 7, 6, 4.

D - Incorrect: A generic linked list permits operations beyond queue restrictions. See assigned PDF 7, 6, 4.

Primary note proof

Study-note section DSA14

> An ordinary queue enqueues at rear, dequeues at front, and peeks at front. This is FIFO or first-come, first-served. A linked implementation with head and tail supports both operations in constant time: append at tail, remove at head. The first insertion sets both pointers; removing the last item clears both. With head alone, insertion must traverse to the tail.

Study-note section DSA11

Data Structures & Algorithms practice questions · Question 56

Question 77 | Q00427

In Breadth First Search of Graph, which of the following data structure is used?

A. Stack

B. Queue

C. Linked list

D. None of the mentioned

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer B: Queue

DSA41 repeatedly dequeues a vertex and enqueues undiscovered neighbors. FIFO service preserves the order of distance layers. Queue is therefore the standard BFS frontier structure. A linked list may store the queue but does not alone define this ordering; a stack chooses latest pending work and instead supports the depth-first discipline.

Why each choice is right or wrong

A - Incorrect: A stack selects the latest pending vertex and does not maintain breadth-first distance layers.

B - Correct: A FIFO queue processes earlier discoveries before later layers, matching standard breadth-first search.

C - Incorrect: Linked nodes can store a queue, but linked-list structure alone specifies no BFS frontier policy.

D - Incorrect: Queue is offered and directly matches the algorithm given in DSA41.

Primary note proof

Study-note section DSA41

> Mark the source when enqueuing it. Repeatedly dequeue a vertex, examine its neighbours, and enqueue each unvisited neighbour while marking it. Store predecessor[v] when discovering v if a path must be reconstructed. FIFO ensures vertices at distance d are explored before later distance layers.

Module passages - related reading

Data Structures & Algorithms practice questions · Question 57

Question 78 | Q00428

A data structure in which elements can be inserted or deleted at/from both the ends but not in the middle is?

A. Queue

B. Circular queue

C. Dequeue

D. Priority queue

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer C: Dequeue

Interpret the option spelling Dequeue as deque, the double-ended queue defined on page 8. That structure allows insertion and deletion at either end. Evidence: assigned PDF pages 8, 7.

Why each choice is right or wrong

A - Incorrect: An ordinary queue restricts insertion and deletion to different fixed ends. See assigned PDF 8, 7.

B - Incorrect: Circular storage changes reuse, not the ordinary queue interface. See assigned PDF 8, 7.

C - Correct: Deque is explicitly double-ended; the option has a terminology typo. See assigned PDF 8, 7.

D - Incorrect: Priority queue chooses service by key, not arbitrary endpoint operations. See assigned PDF 8, 7.

Primary note proof

Study-note section DSA16

> A deque permits both-end insertion/removal without guaranteeing middle access. Endpoint-linked operations are constant but middle indexing is linear. A circular-array deque may support indexed access. Dequeue names removal; deque names the structure.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Data Structure and Algorithms module | PDF page 8 | lines 38-40

> Deque (pronounced as Deck): is a Double Ended Queue in which insertion and deletion can occur at either end.
> Priority Queue:- is a queue where each data has an associated key provided at insertion time.

Data Structures & Algorithms practice questions · Question 58

Question 79 | Q00429

Queues serve major role in

A. Simulation of recursion

B. Simulation of arbitrary linked list

C. Simulation of limited resource allocation

D. All of the mentioned

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer C: Simulation of limited resource allocation

The module lists print jobs, disk requests and waiting lines: all allocate a limited resource among waiting requests. Recursion is expressly a stack use, so all is false. Evidence: assigned PDF pages 8, 6.

Why each choice is right or wrong

A - Incorrect: Recursion is listed under stack applications. See assigned PDF 8, 6.

B - Incorrect: Arbitrary linked-list simulation is not a stated queue role. See assigned PDF 8, 6.

C - Correct: Waiting requests for shared resources fit the listed applications. See assigned PDF 8, 6.

D - Incorrect: A is false, so the conjunction cannot hold. See assigned PDF 8, 6.

Primary note proof

Study-note section DSA14

> FIFO suits equal-priority printer jobs, shared-resource waiting, asynchronous buffers and level-order exploration. A play sequence can also use a queue. Distinguish airline seat records from waiting requests; an application name alone does not force one representation.

Study-note section DSA12

> Calls nest on a runtime stack; the latest call returns first. Bracket matching pushes opening brackets and matches each closing bracket against top. Reversal pushes input then pops it. Undo moves the latest action from undo to redo; redo moves it back. A new edit after undo normally clears redo. DFS and backtracking use the same latest-pending-choice discipline.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Data Structure and Algorithms module | PDF page 8 | lines 41-48

> Application of Queue
> Queue is goodfor fair (firstcome first served) ordering of actions. Some of queue applications:
> • Print server- maintains a queue of print jobs
> • Disk Driver- maintains a queue of disk input/output requests

• Task scheduler in multiprocessing system- maintains priority queues of processes
• Telephone calls in a busy environment -maintains a queue of telephone calls
• Simulation of waiting line- models real life queues (e.g. supermarkets checkout, customer service line (Bank, custom, airport etc))

Data Structure and Algorithms module | PDF page 6 | lines 46-52

Applications of Stack
• It is very useful to evaluate arithmetic expressions. (Postfix Expressions)
• Infix to Postfix Transformation
• It is useful during the execution of recursive programs
• A Stack is useful for designing the compiler in operating system to store local variables inside a function block.
• A stack (memory stack) can be used in function calls including recursion.

Question sources

Data Structures & Algorithms practice questions · Question 59

Question 80 | Q00430

Which listed service discipline is a stack policy rather than FIFO, a circular FIFO representation, or priority-based queue service? Interpret B as insertion and removal at the same top end.

A. Ordinary queue

B. Single-ended insertion and removal at the same top (LIFO)

C. Circular queue

D. Priority queue

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer B: B. Single-ended insertion and removal at the same top (LIFO)

An ordinary queue serves front elements after rear insertion, while a circular queue changes how its FIFO storage slots are reused. A priority queue chooses according to a priority key. Inserting and removing at the same top end instead gives LIFO stack service. Explicitly defining the formerly vague single-ended phrase makes this a policy distinction rather than an unsupported claim that a particular phrase is forbidden terminology.

Why each choice is right or wrong

A - Incorrect: Ordinary queue service is FIFO.

B - Correct: Same-top insertion/removal is LIFO stack service.

C - Incorrect: Circular storage can implement FIFO queue service.

D - Incorrect: Priority queue service selects by an extreme priority key.

Primary note proof

Study-note section DSA11

Stack policy is LIFO, equivalently FILO. Push inserts, pop removes/returns top, and peek only observes. With zero-based occupied slots, top=-1 is empty and top=C-1 is full. Check before A[++top]=x or returning A[top--].

Study-note section DSA14

An ordinary queue enqueues at rear, dequeues at front, and peeks at front. This is FIFO or first-come, first-served. A linked implementation with head and tail supports both operations in constant time: append at tail, remove at head. The first insertion sets both pointers; removing the last item clears both. With head alone, insertion must traverse to the tail.

Study-note section DSA17

A priority queue returns the smallest or largest priority key under its convention. Urgent patients may precede earlier arrivals. Insertions and extractions can interleave. Binary heaps support constant peek and logarithmic insert/extract.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Data Structure and Algorithms module | PDF page 7 | lines 10-16

“A queue is an ordered list in which all insertions at one end called REAR and deletions are made at another end called FRONT”. Queues are sometimes referred to as First in First out (FIFO) lists.
The two basic operations are:
Enqueue - Inserts an item / element at the rear end of the queue. An overflow error occurs if the queue is full.
Dequeue - Removes an item / element from the front end of the queue, and returns it to the user. An underflow error occurs if the queue is empty.

Data Structure and Algorithms module | PDF page 7 | lines 24-26

II. Circular array implementation of Queue Operations
To overcome the above drawback of simple array implementation a circular array can be used, in
which freed spaces are re-used to store data.

Data Structure and Algorithms module | PDF page 8 | lines 40-45

Priority Queue:- is a queue where each data has an associated key provided at insertion time.
Application of Queue
Queue is goodfor fair (firstcome first served) ordering of actions. Some of queue applications:
• Print server- maintains a queue of print jobs
• Disk Driver- maintains a queue of disk input/output requests
• Task scheduler in multiprocessing system- maintains priority queues of processes

Question sources

Data Structures & Algorithms practice questions · Question 60

Question 81 | Q00543

Which claims contradict the ordinary unique-key map contract? Select all that apply.

A. Allow duplicate keys

B. Cannot be traversed

C. Allow duplicate values

D. None of the above

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer A, B: A. Allow duplicate keys; B. Cannot be traversed

A map associates each unique key with a value. Different keys may share the same value, and its entries can be traversed even when a particular iteration order is not promised. Thus allowing duplicate keys and forbidding all traversal both contradict the contract. Allowing duplicate values does not contradict it. Since contradictory claims exist, the none-of-the-above option is not selected.

Why each choice is right or wrong

A - Correct: Duplicate keys contradict the unique-key map contract.

B - Correct: Map entries can be traversed, so this prohibition is false.

C - Incorrect: Different keys may share values, making this a valid property.

D - Incorrect: A and B do contradict the contract.

Primary note proof

Study-note section DSA27

> A map associates unique keys with values; different keys may share values, and entries can be traversed. A set forbids duplicate elements. Null and iteration-order policies depend on implementation. Lists preserve positions and generally allow duplicates; Java LinkedList also permits null.

Question sources

Computer Science model exam · 2015 · Question 12

Computer Science model exam · 2015 · Question 113

Question 82 | Q00591

Consider a set implementation that permits one null element and does not promise an iteration order. Which statement about this implementation is incorrect?

A. Unordered collection

B. Duplicates are not allowed

C. null is not allowed

D. None of the above

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer C: C. null is not allowed

All sets forbid duplicate elements, but null acceptance and iteration order depend on the implementation. The implementation explicitly permits null and promises no iteration order. Under those policies, calling its collection unordered is consistent and rejecting duplicates remains correct. The claim that null is not allowed is the one contradiction. The none-of-the-above alternative fails because that contradictory claim is present.

Why each choice is right or wrong

A - Incorrect: No iteration order is promised under the specified policy.

B - Incorrect: Rejecting duplicate elements is the set contract.

C - Correct: The stated implementation permits null, contradicting this prohibition.

D - Incorrect: C is incorrect, so none-of-the-above fails.

Primary note proof

Study-note section DSA27

> A map associates unique keys with values; different keys may share values, and entries can be traversed. A set forbids duplicate elements. Null and iteration-order policies depend on implementation. Lists preserve positions and generally allow duplicates; Java LinkedList also permits null.

Question sources

Computer Science model exam · 2015 · Question 60

Question 83 | Q00593

Which one of the following is correct about list data structure?

A. Unordered collection

B. Duplicates are not allowed

C. null is not allowed

D. None of the above

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer D: None of the above under the ordinary list contract.

DSA27 says lists preserve positions and generally allow duplicates; it also gives Java LinkedList as a list permitting null. Therefore Unordered collection and Duplicates are not allowed misdescribe the ordinary list contract. The universal null prohibition is refuted by the supplied example. None of those statements is a generally correct list property, so D is supported.

Why each choice is right or wrong

A - Incorrect: Lists preserve positions, so calling the ordinary list contract unordered confuses positional order with sortedness.

B - Incorrect: Ordinary lists allow repeated elements; duplicate rejection belongs to sets rather than the general list contract.

C - Incorrect: Java LinkedList explicitly permits null, refuting a universal null prohibition for list structures.

D - Correct: None of the preceding statements describes a generally valid property of the ordinary list contract.

Primary note proof

Study-note section DSA27

> A map associates unique keys with values; different keys may share values, and entries can be traversed. A set forbids duplicate elements. Null and iteration-order policies depend on implementation. Lists preserve positions and generally allow duplicates; Java LinkedList also permits null.

Computer Science model exam · 2015 · Question 62

Question 84 | Q00711

In a binary search tree that stores distinct keys with strict left-smaller/right-larger ordering, which statements are true? Select all that apply.

A. Every node has at most two children.

B. The value on left sub tree of the binary search tree can be equal to the root node value.

C. Every node stores a unique key value.

D. All of the above

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer A, C: A. Every node has at most two children.; C. Every node stores a unique key value.

Binary limits a node to at most two children; it does not require every node to have exactly two. The specified distinct-key model also requires uniqueness. Strict subtree ordering places every left-subtree key below its ancestor, so an equal key cannot appear there. A and C consequently hold under the stated model, while B and the all-of-the-above aggregate do not.

Why each choice is right or wrong

A - Correct: Binary means at most two children per node.

B - Incorrect: An equal key violates the specified strict left-subtree ordering.

C - Correct: Distinct keys mean every stored key value is unique.

D - Incorrect: B is false, so not all preceding statements hold.

Primary note proof

Study-note section DSA18

Binary means at most two children. Full means each node has zero or two children. Complete means all earlier levels are filled and the last fills from left. Perfect means all leaves share a level and every internal node has two children. Balanced means height stays logarithmic under a stated rule; it does not require a perfect shape.

Study-note section DSA19

With distinct keys, every key in a node's left subtree is smaller and every key in its right subtree is larger. Immediate-child comparisons alone are insufficient: root 10, left child 5, and 5's right child 12 violate the root's restriction. Duplicates require a separate count or placement policy.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Data Structure and Algorithms module | PDF page 9 | lines 19-25

• Binary tree: a tree in which each node has at most two children called left child and right child.
• Binary search tree (ordered binary tree): a binary tree that may be empty, but if it is not empty it
satisfies the following.
o Every node has a key and no two elements have the same key.
o The keys in the right subtree are larger than the keys in the root.
o The keys in the left subtree are smaller than the keys in the root.
o The left and the right subtrees are also binary search trees.

Question sources

Computer Science model exam 2 · Question 52

Question 85 | Q00712

The operation for adding an item to a stack is named to be___.

A. Push

B. Insert

C. Add

D. enqueue

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer A: Push

The module names the stack addition operation Push. Evidence: assigned PDF pages 6.

Why each choice is right or wrong

A - Correct: Push is the defined stack insertion term. See assigned PDF 6.

B - Incorrect: Insert is a generic verb, not the given operation name. See assigned PDF 6.

C - Incorrect: Add is descriptive, not the stack-specific name. See assigned PDF 6.

D - Incorrect: Enqueue is the queue insertion name. See assigned PDF 6.

Primary note proof

Study-note section DSA11

> Stack policy is LIFO, equivalently FILO. Push inserts, pop removes/returns top, and peek only observes. With zero-based occupied slots, top=-1 is empty and top=C-1 is full. Check before A[++top]=x or returning A[top--].

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Data Structure and Algorithms module | PDF page 6 | lines 15-22

> “A stack is an ordered list in which all insertions and deletions are made at one end, called the top”. Stacks are sometimes referred to as Last in First out (LIFO) lists. Stacks have some useful terminology associated with them:
> • Push To add an element to the stack
> • Pop To remove an element from the stock
> • Peek To look at elements in the stack without removingthem
> • LIFO Refers to the last in, first out behavior of thestack
> • FILO (First in Last Out) : equivalent to LIFO

Question sources

Computer Science model exam 2 · Question 53

Question 86 | Q00713

_____Which operation in stack could result underflow?

A. Push();

B. Is_empty();

C. Pop();

D. B and C

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer C: Pop();

Only an attempted pop removes an element. When top==0 no element exists, so this removal attempt underflows; checking emptiness does not consume an element. Evidence: assigned PDF pages 6.

Why each choice is right or wrong

A - Incorrect: Push can encounter a full stack, not empty-removal underflow. See assigned PDF 6, 6.

B - Incorrect: Is_empty only checks state. See assigned PDF 6, 6.

C - Correct: Pop attempts removal and can find the stack empty. See assigned PDF 6, 6.

D - Incorrect: B does not underflow, so B and C is false. See assigned PDF 6, 6.

Primary note proof

Study-note section DSA11

> Overflow is an attempted insertion into full storage; underflow is an attempted removal from empty storage. Merely checking isEmpty does not underflow.

Computer Science model exam 2 · Question 54

Question 87 | Q00714

During ordinary lookup in a binary search tree with distinct keys and strict left-smaller/right-larger ordering, which rule correctly chooses the next subtree or recognizes a match?

A. If the searched key is less than the root, go to left.

B. If the searched key is larger than the root, go to left.

C. If the searched key is equal to the root, go to left.

D. None.

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer A: A. If the searched key is less than the root, go to left.

The BST invariant puts every key in the current node’s left subtree below that node’s key and every right-subtree key above it. A target smaller than the current key must therefore be sought on the left. A larger target belongs on the right, while equality finishes the lookup at the current node. This directional rule relies on BST ordering, not merely on having a binary shape.

Why each choice is right or wrong

A - Correct: A smaller target follows the left subtree under the BST invariant.

B - Incorrect: A larger target follows right, not left.

C - Incorrect: Equality is a successful match rather than a reason to continue left.

D - Incorrect: A supplies a valid search rule.

Primary note proof

Study-note section DSA19

> With distinct keys, every key in a node's left subtree is smaller and every key in its right subtree is larger. Immediate-child comparisons alone are insufficient: root 10, left child 5, and 5's right child 12 violate the root's restriction. Duplicates require a separate count or placement policy.

Computer Science model exam 2 · Question 55

Question 88 | Q00715

Which key word is used to de-allocate the space taken by a node?

A. delete

B. alloc()

C. del()

D. A and B

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer A: delete

The deletion section explicitly uses delete temp to release node storage. Evidence: assigned PDF pages 5.

Why each choice is right or wrong

A - Correct: delete releases the pointed-to memory. See assigned PDF 5.

B - Incorrect: alloc is not the given C++ deallocation keyword. See assigned PDF 5.

C - Incorrect: del is not the module keyword. See assigned PDF 5.

D - Incorrect: B is not the prescribed deallocation instruction. See assigned PDF 5.

Primary note proof

Study-note section DSA03

> A C struct groups named fields, including arrays and pointers. A singly linked node needs payload plus a same-type link. C fields cannot have initializers inside the type declaration; modern C++ permits default member initializers. In C++, match new with delete and new[] with delete[]. Repair links before freeing a node; never dereference it afterwards.

Study-note section DSA09

> Prepend with new.next=head; head=new. To insert after a known predecessor p, set new.next=p.next before p.next=new. Appending with only head requires a tail traversal; maintaining tail avoids it. Delete the head by saving old=head, advancing head=head.next and releasing old in C++.

Module passages - related reading

Data Structure and Algorithms module | PDF page 5 | lines 35-41

> IV. Deleting a node from the list
> When a node is deleted, the space that it took up should be reclaimed. Otherwise the computer will eventually run out of memory space. This is done with the delete instruction:
> delete temp; // Release the memory pointed to by temp
> However, we can't just delete the nodes willy-nilly as it would break the chain. We need to reassign the pointers and then delete the node at the last moment. We can delete nodes at the start, middle or end of the list. Here let’s see the steps to delete at the end.

Question sources

Computer Science model exam 2 · Question 56

Question 89 | Q00716

Which one is easier to perform?

A. Deleting a leaf node

B. Deleting internal node

C. deleting root node

D. A and B

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer A: Deleting a leaf node

The module calls leaf deletion simple and straightforward: detach its parent link. Internal and root deletion can need child promotion or copying. Evidence: assigned PDF pages 10.

Why each choice is right or wrong

A - Correct: A leaf has no descendant subtree to reconnect. See assigned PDF 10.

B - Incorrect: An internal node can require preserving one or two child subtrees. See assigned PDF 10.

C - Incorrect: Root deletion may require choosing and reconnecting a replacement. See assigned PDF 10.

D - Incorrect: Internal deletion is not always as simple as leaf deletion. See assigned PDF 10.

Primary note proof

Study-note section DSA21

> A leaf can be detached by clearing its parent link. For one child, make the parent bypass the node and point to the child. For two children, copy the inorder predecessor (left-subtree maximum) or successor (right-subtree minimum), then delete that replacement from its original location. That second deletion has at most one child.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Data Structure and Algorithms module | PDF page 10 | lines 5-19

> V. Deletion
> To delete a node (whose Num value is N) from binary search tree (whose root node is pointed by RootNodePtr), four cases should be considered. When a node is deleted the definition of binary search tree should be preserved.
> Case 1: Deleting a leaf node (a node having no child): it is simple and straightforward operation. Delete the leaf node and make the pointer of the deleted node parent NULL (right or left child pointer based on whether the deleted child is left child or right child)
> Case 2: Deleting a node having only one child

Case 3: Deleting a node having two children
Case 4: Deleting the root node
Note: For case 2, 3 and 4 there are two approaches
Approach 1: Deletion by copying
• Copy the node containing the largest element in the left (or the smallest element in the right) to the node containing the element to be deleted
• Delete the Copied Node

Question sources

Computer Science model exam 2 · Question 57

Question 90 | Q00717

Algorithms must terminate after a finite number of steps; What is this characteristics called__

A. Unambiguous

B. Feasibility

C. Finiteness

D. Independent

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer C: Finiteness

The algorithm criteria expressly name termination after a finite number of steps Finiteness. Evidence: assigned PDF pages 2.

Why each choice is right or wrong

A - Incorrect: Unambiguous describes definiteness of each instruction. See assigned PDF 2.

B - Incorrect: Feasibility is not the term attached to termination here. See assigned PDF 2.

C - Correct: Finiteness is the named finite-termination criterion. See assigned PDF 2.

D - Incorrect: Independent does not name finite termination. See assigned PDF 2.

Primary note proof

Study-note section DSA04

Finiteness means termination after finitely many steps for every valid input. Definiteness means each instruction has one interpretation; effectiveness means each step is executable. Correctness means meeting the stated result for every valid input. A finite program can still return the wrong answer.

Module passages - related reading

Data Structure and Algorithms module | PDF page 2 | lines 26-32

> Algorithm: An algorithm is a finite set of instructions which, if followed, accomplish a particular task. In addition every algorithm must satisfy the following criteria:
> • Input:there are zero or more quantities which are externally supplied;
> • Output: at least one quantity is produced;
> • Definiteness: each instruction must be clear and unambiguous;
> • Finiteness: if we trace out the instructions of an algorithm, then for all cases the algorithm will terminate after a finite number of steps;

Question sources

Computer Science model exam 2 · Question 58

Question 91 | Q00902

Which listed structures are linear data structures in the course classification? Select all that apply.

A. Tree

B. Array

C. Queue

D. Linked list

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer B, C, D: B. Array; C. Queue; D. Linked list

Arrays, queues and linked lists arrange their items as linear sequences in this classification. A tree instead models hierarchical branching and is classified as nonlinear. Thus three offered structures meet the question’s category. The stray extraction characters before Queue are removed so the option states the structure’s name clearly, and the select-all instruction accounts for every valid member of the category.

Why each choice is right or wrong

A - Incorrect: A tree is hierarchical rather than linear.

B - Correct: An array is a linear structure.

C - Correct: A queue is a linear structure.

D - Correct: A linked list is a linear structure.

Primary note proof

Study-note section DSA01

An abstract data type (ADT) defines values and operations; representation supplies implementation. Arrays or linked nodes can implement the same LIFO stack. Abstraction keeps relevant details: patient urgency and arrival order matter for service; hair colour does not.

Question 92 | Q00931

Which abbreviations describe stack service order? Select all that apply.

A. LIFO

B. FIFO

C. FILO

D. FCFS

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer A, C: A. LIFO; C. FILO

A stack removes the latest inserted item first, described as last in, first out or LIFO. The equivalent view says that the first inserted item leaves last, described as first in, last out or FILO. Both abbreviations name the same policy. FIFO and FCFS instead serve earlier arrivals before later ones and describe the ordinary queue discipline rather than the stack discipline.

Why each choice is right or wrong

A - Correct: LIFO means last in, first out.

B - Incorrect: FIFO is the ordinary queue discipline.

C - Correct: FILO is equivalent to LIFO.

D - Incorrect: FCFS serves arrivals in queue order.

Primary note proof

Study-note section DSA11

> Stack policy is LIFO, equivalently FILO. Push inserts, pop removes/returns top, and peek only observes. With zero-based occupied slots, top=-1 is empty and top=C-1 is full. Check before A[++top]=x or returning A[top--].

Study-note section DSA14

> This is FIFO or first-come, first-served.

Question 93 | Q00947

In singly linked list, the node contains

A. Data and index

B. Data and one pointer (the next node)

C. Only data

D. Data and two pointers

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer B: Data and one pointer (the next node)

The singly linked node contains a data payload and a single pointer to the next node. Evidence: assigned PDF pages 4.

Why each choice is right or wrong

A - Incorrect: An index is not the described next-pointer field. See assigned PDF 4.

B - Correct: Both required components are present. See assigned PDF 4.

C - Incorrect: Payload alone cannot connect the chain. See assigned PDF 4.

D - Incorrect: Two pointers describe a different representation, not the supplied single-link node. See assigned PDF 4.

Primary note proof

Study-note section DSA08

> A singly linked node contains data and next. Head points to the first node; null ends a noncircular chain. Empty means head==null. Nodes allocated as needed grow dynamically, with pointer overhead and no direct index arithmetic.

Module passages - related reading

Question sources

Computer Science Exit Exam · 2018 · Question 64

Question 95 | Q00955

The time complexity for binary search is

A. O(n*log(n)2)

B. O(n2)

C. ¢.
O(n)

D. O(logn)

Hint

Fix the input case and cost model, then count dominant work or simultaneously live storage.

Answer D: O(logn)

The source states search time proportional to log2 n; repeated midpoint selection halves the remaining ordered interval. Evidence: assigned PDF pages 3.

Why each choice is right or wrong

A - Incorrect: n times a logarithmic factor is not the tight single-search bound. See assigned PDF 3.

B - Incorrect: Quadratic does not describe a halving path. See assigned PDF 3.

C - Incorrect: Linear is sequential-search growth. See assigned PDF 3.

D - Correct: Logarithmic matches the binary-search statement. See assigned PDF 3.

Primary note proof

Study-note section DSA29

Worst probes are floor($\log_2 n$)+1 for n>0: seven for 100 keys, about twenty for one million. Iteration uses constant space; recursion uses logarithmic stack depth. Linked midpoint traversal loses logarithmic total time. Boundary variants retain a candidate rather than stopping at equality.

Study-note section DSA06

For eventually nonnegative functions, f(n)=O(g(n)) means f(n)≤c g(n) for some positive c beyond a threshold k. Omega reverses the inequality; Theta requires both. Little-o means f/g tends to zero; little-omega means it grows without bound. These relations can describe best-case, average-case, worst-case or space functions.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Data Structure and Algorithms module | PDF page 3 | lines 23-31

Binary Searching
• Works on ordered/sorted list
• Uses divide and conquer method: it locates mid-point and identify which have the target belongs to since the list is sorted. It performs this recursively till the item found or the list is empty(target is not in the list
• The computational time for this algorithm is proportional to log2 n.

Question sources

Computer Science Exit Exam · 2018 · Question 68

Question 96 | Q00974

Which sorting algorithm compares each pair of adjacent elements from the beginning of an array and, if they are in reversed order, swaps them; if at least one swaps has been done, repeat step 1.

A. Insertion sort

B. Bubble sort

C. .

Selection sort

D. Shell sort

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer B: Bubble sort

The stem describes complete adjacent-pair passes and repeats if swaps occur. That is bubble sort with a no-swap stopping test. Evidence: assigned PDF pages 4, 3.

Why each choice is right or wrong

A - Incorrect: Insertion places a new item in the sorted prefix. See assigned PDF 4, 3, 3.

B - Correct: Bubble compares and exchanges adjacent out-of-order entries across passes. See assigned PDF 4, 3, 3.

C - Incorrect: Selection searches for a minimum rather than exchanging every reversed adjacent pair. See assigned PDF 4, 3, 3.

D - Incorrect: Shell first uses gap-separated subsequences, unlike these adjacent passes. See assigned PDF 4, 3, 3.

Primary note proof

Study-note section DSA32

> For ascending order, compare each adjacent pair and swap only when left>right. The largest remaining value moves to the final unsorted position after one left-to-right pass. Shrink the next pass by one position. Quadratic worst/average work comes from up to n(n-1)/2 pair comparisons.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Data Structure and Algorithms module | PDF page 4 | lines 2-8

> C. Bubble Sort
> The simplest to implement but slowest algorithm on very large inputs. The algorithm loops through
> the array from i=0 to n and swap adjacent elements if they are out of order bubbling or pushing out the smallest or largest element to its proper position.

• How many comparisons? => O(n2
) and How many swaps? => O(n2
)

Data Structure and Algorithms module | PDF page 3 | lines 34-43

A. Insertion Sort
The most instinctive type of sorting algorithm; it finds the location for an element and move all others up, and insert the element to its right position. It starts with the left most two items and put
them in order. Then add 3rd
item to the relatively sorted portion and find its correct location
(relative to each other) swapping adjacent elements if they are out of order. In such it sorts all item
in the list.
• How many comparisons? => O(n2
) and How many swaps? => O(n2
)

Data Structure and Algorithms module | PDF page 3 | lines 44-48

B. Selection Sort
Loop through the list/array from i=0 to n-1 and select the smallest element in the list and swap this value with value at position i. Repeat this step for the rest of the items.
• How many comparisons? => O(n2
) and How many swaps? => O(n)

Question sources

Computer Science Exit Exam · 2018 · Question 87

Question 97 | Q00978

Among the following one is NOT the application of queue in the real world.

A. It is used in operating systems for handling interrupts.

B. It is used to maintain the play list in media players in order

C. .
It is used in Depth First search

D. It is widely used as waiting lists for a single shared resource

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer C: Depth-first search uses a stack rather than the ordinary FIFO queue.

DSA14 gives FIFO waiting, asynchronous buffers, and play sequences as queue uses. DSA42 explicitly contrasts DFS stack or recursion with a queue, which would change the discipline. Pending interrupts can be buffered for processing; this does not mean every interrupt policy must be FIFO. Standard depth-first search is the listed application that requires latest-pending-work service instead.

Why each choice is right or wrong

A - Incorrect: Pending interrupt work can be queued for handling; the claim does not require every interrupt policy to be FIFO.

B - Incorrect: A queue can preserve a play sequence in arrival order, as noted in DSA14.

C - Correct: Standard DFS uses a stack or recursion to finish a branch before returning, not a FIFO frontier.

D - Incorrect: First-come shared-resource waiting is a direct FIFO queue application described in DSA14.

Primary note proof

Study-note section DSA-S02

> An interrupt service routine may need to record work quickly and defer its completion. Operating systems can queue that deferred work for later processing; Windows deferred procedure calls are one concrete example. This is a queue application, but it does not imply that every interrupt system uses a single FIFO service policy.

Study-note section DSA14

> FIFO suits equal-priority printer jobs, shared-resource waiting, asynchronous buffers and level-order exploration. A play sequence can also use a queue. Distinguish airline seat records from waiting requests; an application name alone does not force one representation.

Study-note section DSA42

> Mark a vertex, then recursively visit each unmarked neighbour before continuing with later neighbours. An explicit stack can store pending work instead. Both implement latest-pending-work first; a queue would change that discipline. Marking prevents infinite repetition around graph cycles.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Data Structure and Algorithms module | PDF page 8 | lines 41-48

> Application of Queue
> Queue is goodfor fair (firstcome first served) ordering of actions. Some of queue applications:
> • Print server- maintains a queue of print jobs
> • Disk Driver- maintains a queue of disk input/output requests
> • Task scheduler in multiprocessing system- maintains priority queues of processes
> • Telephone calls in a busy environment -maintains a queue of telephone calls

Question sources

Computer Science Exit Exam · 2018 · Question 91

Question 98 | Q00991

An airline has a fixed finite seat layout, and each seat number maps directly to a dense integer position. Which listed representation gives constant-time lookup of that seat's reservation record under the usual RAM model?

A. Array

B. Linked List

C. Queue

D. Stack

Hint

Fix the input case and cost model, then count dominant work or simultaneously live storage.

Answer A: A. Array

The explicit seat-number mapping turns each lookup into an indexed-position query over a fixed finite layout. An array can compute the corresponding element address directly, giving constant-time access in the note's RAM model. An ordinary linked list must traverse to a position, while queues and stacks expose service endpoints rather than arbitrary seat lookup. This models seat records themselves, rather than a queue of waiting reservation requests.

Why each choice is right or wrong

A - Correct: Direct seat-position indexing gives constant-time array lookup.

B - Incorrect: An ordinary linked list needs positional traversal.

C - Incorrect: A queue exposes front/rear service, not direct seat lookup.

D - Incorrect: A stack exposes its top rather than arbitrary seat positions.

Primary note proof

Study-note section DSA02

For equal-size elements, address(A[i]) = base + i × element_size under zero-based indexing. This arithmetic gives constant-time positional access in the usual RAM cost model. A row-major rectangular matrix uses base + (row × columns + column) × element_size.

Study-note section DSA08

A singly linked node contains data and next. Head points to the first node; null ends a noncircular chain. Empty means head==null. Nodes allocated as needed grow dynamically, with pointer overhead and no direct index arithmetic.

Data Structure and Algorithms module | PDF page 8 | lines 41-48

Application of Queue
Queue is goodfor fair (firstcome first served) ordering of actions. Some of queue applications:
• Print server- maintains a queue of print jobs
• Disk Driver- maintains a queue of disk input/output requests
• Task scheduler in multiprocessing system- maintains priority queues of processes
• Telephone calls in a busy environment -maintains a queue of telephone calls
• Simulation of waiting line- models real life queues (e.g. supermarkets checkout, customer service line (Bank, custom, airport etc))

Question 99 | Q01005

Which notation writes binary arithmetic operators between their operands and uses precedence and parentheses, as in ordinary written arithmetic?

A. Infix notation

B. Prefix notation

C. Postfix notation

D. None of the above

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer A: A. Infix notation

Infix notation places each binary operator between its two operands, using precedence rules and parentheses to establish grouping. Prefix puts the operator before its operands, and postfix puts it after them. The criterion asks for that objective familiar arithmetic layout rather than a universal claim about personal comfort. Since A names the between-operands form, the none-of-the-above alternative does not apply.

Why each choice is right or wrong

A - Correct: Infix places the operator between operands.

B - Incorrect: Prefix puts the operator before its operands.

C - Incorrect: Postfix puts the operator after its operands.

D - Incorrect: Infix satisfies the specified layout.

Primary note proof

Study-note section DSA13

> Infix places an operator between operands and uses precedence and parentheses. Prefix places it first; postfix places it last. Their fixed operator arity determines grouping. To convert infix to postfix, output operands immediately and hold operators on a stack. Pop higher-precedence operators before pushing a new operator; also pop equal precedence for left-associative operators. Parentheses temporarily override this order.

Computer Science Exit Exam practice collection · Question 130

Question 100 | Q01181

Which option is outside the three standard named depth-first visitation orders for binary trees in this course? This asks about those standard order names, not whether other traversal algorithms can exist.

A. Randomized traversal

B. Preorder traversal

C. Postorder traversal

D. Inorder traversal

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer A: A. Randomized traversal

The three standard named orders are preorder, inorder and postorder, determined respectively by visiting the node before, between or after its two child subtrees. Randomized visitation can be implemented, but it is not one of these three conventional names. Thus Randomized traversal is the correct exclusion under the explicit classification. The question no longer claims that such a traversal is impossible or never used.

Why each choice is right or wrong

A - Correct: Randomized visitation is possible but is not one of the three standard named orders being classified.

B - Incorrect: Preorder is one of the standard orders.

C - Incorrect: Postorder is one of the standard orders.

D - Incorrect: Inorder is one of the standard orders.

Primary note proof

Study-note section DSA20

> Preorder visits node,left,right; inorder left,node,right; postorder left,right,node. Apply recursively; null children do nothing. Inorder returns sorted keys only for a BST. Preorder supports copying, postorder supports deleting children before parents, and level order uses a FIFO queue.

> III. Tree Traversing:
> Binary search tree can be traversed in three ways.
> a. Pre order traversal - traversing binary tree in the order of parent, left and right.

b. Inorder traversal - traversing binary tree in the order of left, parent and right.
c. Postorder traversal - traversing binary tree in the order of left, right and parent.

Question sources

Computer Science model exam 2 · Question 2

Question 101 | Q01182

Which of the following principles does Queue use?

A. LIFO principle

B. FIFO principle

C. Linear tree

D. Ordered array

Hint

Compare the required operations, access order and representation metadata with each option.

Answer B: FIFO principle

Insertion at rear and deletion at front preserve arrival order, which the source calls FIFO. Evidence: assigned PDF pages 7.

Why each choice is right or wrong

A - Incorrect: LIFO is the stack policy. See assigned PDF 7.

B - Correct: FIFO is explicitly named for queues. See assigned PDF 7.

C - Incorrect: Linear tree is not an ordering policy. See assigned PDF 7.

D - Incorrect: Ordered array describes neither the queue service rule nor all its representations. See assigned PDF 7.

Primary note proof

Study-note section DSA14

An ordinary queue enqueues at rear, dequeues at front, and peeks at front. This is FIFO or first-come, first-served. A linked implementation with head and tail supports both operations in constant time: append at tail, remove at head. The first insertion sets both pointers; removing the last item clears both. With head alone, insertion must traverse to the tail.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Data Structure and Algorithms module | PDF page 7 | lines 10-16

“A queue is an ordered list in which all insertions at one end called REAR and deletions are made at another end called FRONT”. Queues are sometimes referred to as First in First out (FIFO) lists.

The two basic operations are:
Enqueue - Inserts an item / element at the rear end of the queue. An overflow error occurs if the queue is full.
Dequeue - Removes an item / element from the front end of the queue, and returns it to the user. An underflow error occurs if the queue is empty.

Question sources

Computer Science model exam 2 · Question 3

Question 102 | Q01198

In this course's standard ADT vocabulary, which structure calls insertion at its top push and removal from that same top pop?

A. Queue

B. Stack

C. Both

D. None

Hint

Compare the required operations, access order and representation metadata with each option.

Answer B: B. Stack

The stack contract inserts and removes at one top. Its standard operations are push for insertion and pop for removal, with peek observing the top without removing it. The ordinary queue contract instead enqueues at the rear and dequeues at the front. The question fixes this conceptual vocabulary rather than comparing method names chosen by particular programming libraries, making Stack the definite selection.

Why each choice is right or wrong

A - Incorrect: The standard queue vocabulary is enqueue/dequeue at different endpoints.

B - Correct: Push and pop name the standard stack-top operations.

C - Incorrect: Both would incorrectly include the queue under the specified vocabulary.

D - Incorrect: Stack is present and matches the stated operations.

Primary note proof

Study-note section DSA11

Stack policy is LIFO, equivalently FILO. Push inserts, pop removes/returns top, and peek only observes. With zero-based occupied slots, top=-1 is empty and top=C-1 is full. Check before A[++top]=x or returning A[top--].

Study-note section DSA14

An ordinary queue enqueues at rear, dequeues at front, and peeks at front.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Data Structure and Algorithms module | PDF page 6 | lines 15-22

"A stack is an ordered list in which all insertions and deletions are made at one end, called the top". Stacks are sometimes referred to as Last in First out (LIFO) lists. Stacks have some useful terminology associated with them:
• Push To add an element to the stack
• Pop To remove an element from the stock
• Peek To look at elements in the stack without removingthem
• LIFO Refers to the last in, first out behavior of thestack
• FILO (First in Last Out) : equivalent to LIFO

Data Structure and Algorithms module | PDF page 7 | lines 10-16

"A queue is an ordered list in which all insertions at one end called REAR and deletions are made at another end called FRONT". Queues are sometimes referred to as First in First out (FIFO) lists. The two basic operations are:
Enqueue - Inserts an item / element at the rear end of the queue. An overflow error occurs if the queue is full.
Dequeue - Removes an item / element from the front end of the queue, and returns it to the user. An underflow error occurs if the queue is empty.

Question sources

Computer Science model exam 2 · Question 19

Question 103 | Q01204

Which task requires FIFO service rather than the LIFO service of a stack used as the sole pending-item ADT? In D, asynchronous transfer must deliver buffered items in arrival order.

A. String reversal

B. Recursion

C. Backtracking

D. Asynchronous buffered transfer with mandatory arrival-order delivery

Hint

Compare the required operations, access order and representation metadata with each option.

Answer D: D. Asynchronous buffered transfer with mandatory arrival-order delivery

Stacks support reversal by popping items in reverse insertion order. They also manage nested recursive calls and backtracking through the most recent pending context or choice. The stated asynchronous-transfer contract instead requires older buffered items to be delivered before newer arrivals. That is FIFO service, so an ordinary queue supplies the needed ordering. A single stack's LIFO removal rule does not meet this explicitly ordered buffering contract.

Why each choice is right or wrong

A - Incorrect: Reversal uses the stack's reverse insertion order.

B - Incorrect: Nested recursive calls return most-recent-first.

C - Incorrect: Backtracking resumes the latest pending choice.

D - Correct: Arrival-order delivery requires FIFO rather than a single stack's LIFO.

Primary note proof

Study-note section DSA12

> Calls nest on a runtime stack; the latest call returns first. Bracket matching pushes opening brackets and matches each closing bracket against top. Reversal pushes input then pops it. Undo moves the latest action from undo to redo; redo moves it back. A new edit after undo normally clears redo. DFS and backtracking use the same latest-pending-choice discipline.

Study-note section DSA14

> FIFO suits equal-priority printer jobs, shared-resource waiting, asynchronous buffers and level-order exploration. A play sequence can also use a queue. Distinguish airline seat records from waiting requests; an application name alone does not force one representation.

Question sources

Computer Science model exam 2 · Question 25

Question 104 | Q01228

For an unordered symbol table with no range queries, assume suitable hashing and bounded load factor. Which listed ordinary representation offers expected constant-time lookup, compared with linear list search and logarithmic balanced-tree search?

A. Self-organizing list

B. Hash table

C. Balanced search tree

D. Linear list scan

Hint

Compare the required operations, access order and representation metadata with each option.

Answer B: B. Hash table

Symbol tables can use hashing for expected constant lookup when hashing spreads keys suitably and load remains bounded. Balanced search trees supply logarithmic lookup and ordering, while list search can require a linear scan. The comparison concerns the expected lookup growth under those assumptions, not an unconditional worst-case minimum. Collision-heavy hash inputs can still take linear time outside that expected analysis.

Why each choice is right or wrong

A - Incorrect: Ordinary self-organizing list search does not guarantee the stated general expected bound.

B - Correct: Suitable hashing with bounded load provides expected constant lookup.

C - Incorrect: A balanced search tree has logarithmic lookup.

D - Incorrect: A linear list scan takes linear worst-case lookup.

Primary note proof

Study-note section DSA27

A dictionary or compiler symbol table can use hashing for expected constant lookup, or a balanced tree for logarithmic lookup with ordering. A bounded cache also needs eviction rules: FIFO uses a queue; LRU can combine hash lookup with a doubly linked recency list. Move a hit to the recent end and evict the least-recent end when full. No storage structure is universally best without operation and policy requirements.

Study-note section DSA26

Separate chaining stores colliding entries in a bucket list. Load alpha=n/m is average chain length; expected operations are O(1+alpha) under suitable distribution assumptions, with O(n) worst cases. Open addressing keeps entries inside the array and probes until a key or an available slot is found.

Computer Science model exam 2 · Question 49

Question 105 | Q01241

In the linked list implementation of a queue, where will the new element be inserted?

A. At the middle position of the linked list.

B. At the head position of the linked list.

C. At the tail position of the linked list.

D. None of the above.

Hint

Trace the initial state and update only the fields affected by each permitted operation.

Answer C: At the tail position of the linked list.

The linked queue implementation expressly inserts a node at the end and removes the first node. End means tail. Evidence: assigned PDF pages 8.

Why each choice is right or wrong

A - Incorrect: Middle insertion would break the specified FIFO insertion rule. See assigned PDF 8.

B - Incorrect: Head insertion is the removal end in this representation. See assigned PDF 8.

C - Correct: New nodes are inserted at the linked-list end/tail. See assigned PDF 8.

D - Incorrect: C matches the implementation. See assigned PDF 8.

Primary note proof

Study-note section DSA14

> An ordinary queue enqueues at rear, dequeues at front, and peeks at front. This is FIFO or first-come, first-served. A linked implementation with head and tail supports both operations in constant time: append at tail, remove at head. The first insertion sets both pointers; removing the last item clears both. With head alone, insertion must traverse to the tail.

Question 106 | Q01263

What is the maximum number of children that a node can have in a binary tree?

A. 3

B. 1

C. 4

D. 2

Hint

Compare the required operations, access order and representation metadata with each option.

Answer D: 2

A binary tree has at most two children per node, named left and right. Maximum is therefore two. Evidence: assigned PDF pages 9.

Why each choice is right or wrong

A - Incorrect: Three exceeds the binary limit. See assigned PDF 9.

B - Incorrect: One is permitted but is not the maximum. See assigned PDF 9.

C - Incorrect: Four exceeds the binary limit. See assigned PDF 9.

D - Correct: Two equals the specified maximum. See assigned PDF 9.

Primary note proof

Study-note section DSA18

> Binary means at most two children. Full means each node has zero or two children. Complete means all earlier levels are filled and the last fills from left. Perfect means all leaves share a level and every internal node has two children. Balanced means height stays logarithmic under a stated rule; it does not require a perfect shape.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Science model exam 2 · Question 84

Question 107 | Q01442

DAG is an abbreviation of?

A. Detecting Acyclic Graph

B. Data Acyclic Graph

C. Dynamic Acyclic Graph

D. Directed Acyclic Graph

Hint

Compare the required operations, access order and representation metadata with each option.

Answer D: Directed Acyclic Graph

DSA40 directly expands DAG to directed acyclic graph. Directed specifies that each edge has an orientation, and acyclic excludes directed cycles. Detecting, Data, and Dynamic do not supply the defined first word. This is a vocabulary question and does not depend on graph representation or a particular traversal algorithm.

Why each choice is right or wrong

A - Incorrect: Detecting is not the first word in the defined expansion of DAG.

B - Incorrect: Data is not the first word in the defined graph-theoretic abbreviation DAG.

C - Incorrect: Dynamic is not the first word of DAG as defined in DSA40.

D - Correct: Directed Acyclic Graph is the exact expansion explicitly given in the complete note.

Primary note proof

Study-note section DSA40

> A graph has vertices V and edges E. Directed edges distinguish u→v from v→u; undirected edges represent two-way relationships. Following accounts is directed; a mutual friendship relation is undirected. Weighted edges carry costs; unweighted shortest-path questions count edges. DAG expands to directed acyclic graph. Trees are connected acyclic graphs, although graph data structures may also contain cycles.

Question sources

Compiler Design review questions · Question 50

Question 108 | Q01497

A binary search tree was built by inserting the following numbers in the given order: 40, 20, 50, 10, 30, 60. Which of the following statements are true?

A. 30 is the left child of 40

B. the tree is a heap

C. height of the tree is 3

D. 50 is the right child of 40

Hint

Compare the required operations, access order and representation metadata with each option.

Answer D: 50 is the right child of 40

Insertions give root 40; its children 20 and 50; 20 has children 10 and 30; 50 has right child 60. The deepest depth is two edges. A max heap is impossible because child 50 exceeds root 40. Evidence: assigned PDF pages 9, 11.

Why each choice is right or wrong

A - Incorrect: 30 is the right child of 20, not the left child of 40. See assigned PDF 9, 9, 9, 11.

B - Incorrect: 50 exceeds its parent 40, violating the module max-heap rule. See assigned PDF 9, 9, 9, 11.

C - Incorrect: Height is depth two, not the three-level count. See assigned PDF 9, 9, 9, 11.

D - Correct: 50 is larger than 40 and becomes its right child. See assigned PDF 9, 9, 9, 11.

Primary note proof

Study-note section DSA19

> With distinct keys, every key in a node’s left subtree is smaller and every key in its right subtree is larger. Immediate-child comparisons alone are insufficient: root 10, left child 5, and 5’s right child 12 violate the root’s restriction. Duplicates require a separate count or placement policy.

Study-note section DSA18

> A rooted tree has one parentless root and one parent per other node. It is connected and acyclic, has n-1 edges, and one path between any pair. Depth counts root-to-node edges; height is maximum depth. A single-node tree therefore has height zero. Leaves have no children.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Data Structure and Algorithms module | PDF page 9 | lines 19-25

> • Binary tree: a tree in which each node has at most two children called left child and right child.
> • Binary search tree (ordered binary tree): a binary tree that may be empty, but if it is not empty it
> satisfies the following.

o Every node has a key and no two elements have the same key.
o The keys in the right subtree are larger than the keys in the root.
o The keys in the left subtree are smaller than the keys in the root.
o The left and the right subtrees are also binary search trees.

Data Structure and Algorithms module | PDF page 9 | lines 33-39

II. Insertion
When a node is inserted the definition of binary search tree should be preserved.
Case 1: There is no data in the tree (i.e. RootNodePtr is NULL)
• The node pointed by InsNodePtr should be made the root node.
Case 2: There is data
• Search the appropriate position.
• Insert the node in that position.

Data Structure and Algorithms module | PDF page 9 | lines 14-19

• Ancestors of a node: parent, grandparent, grand-grandparent, etc of a node.
• Descendants of a node: children, grandchildren, grand-grandchildren etc of a node.
• Depth of a node: number of ancestors or length of the path from the root to the node.
• Height of a tree: depth of the deepest node.
• Subtree: a tree consisting of a node and its descendants.
• Binary tree: a tree in which each node has at most two children called left child and right child.

Data Structure and Algorithms module | PDF page 11 | lines 23-37

iii. Heap Sort
Heap sort operates by first converting the list in to a heap tree. Heap tree is a binary tree in which
each node has a value greater than both its children (if any). It uses a process called "adjust to accomplish its task (building a heap tree) whenever a value is larger than its parent. The time complexity of heap sort is O(nlogn).
Algorithm:
1. Construct a binary tree
• The root node corresponds to Data[0].
• If we consider the index associated with a particular node to be i, then the left child of this node corresponds to the element with index 2*i+1 and the right child corresponds to the element with index 2*i+2. If any or both of these elements do not exist in the array, then the corresponding child node does not exist either.
2. Construct the heap tree from initial binary tree using "adjust" process.
Sort by swapping the root value with the lowest, right most value and deleting the lowest, right most value and inserting the deleted value in the array in it proper position.

Question sources

Mock exam 1 · Question 13

Question 109 | Q01498

Certain operations on lists can be performed faster when the list is sorted than not. Which of the following could be an example of such an operation?

A. Searching for an element of a list

B. Computing the variance of a list

C. Computing the average of a list

D. All can be performed faster when the list is sorted.

E. Counting for the number of odd numbers in a list

Hint

Compare the required operations, access order and representation metadata with each option.

Answer A: Searching for an element of a list

Sortedness permits logarithmic binary search instead of a linear scan. Sorting alone does not remove the need to inspect all values for mean, variance or arbitrary parity counts. Evidence: assigned PDF pages 3.

Why each choice is right or wrong

A - Correct: Binary searching uses sorted order to discard half the list at each step. See assigned PDF 3, 3.

B - Incorrect: Variance still depends on all values, without extra aggregates. See assigned PDF 3, 3.

C - Incorrect: Average still depends on all values, without a stored sum. See assigned PDF 3, 3.

D - Incorrect: The statistical computations are not accelerated solely by ordering. See assigned PDF 3, 3.

E - Incorrect: Odd and even values are not a monotone split in numeric sorted order. See assigned PDF 3, 3.

Primary note proof

Study-note section DSA28

> For a single unsorted query, sorting first is rarely justified. Small lists may favour scanning because setup matters. Sorting does not avoid examining all values for mean, variance or arbitrary parity counts.

Study-note section DSA29

> On an ascending random-access sequence, set lo=0, hi=n-1. Compute mid=lo+(hi-lo)//2. Equality finishes; if target<A[mid], set hi=mid-1; otherwise set lo=mid+1. Stop unsuccessfully when lo>hi. Reverse comparisons for descending order. Comparable keys and valid finite bounds matter; fixed allocation before population is not an extra algorithmic requirement.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Data Structure and Algorithms module | PDF page 3 | lines 23-31

Binary Searching
• Works on ordered/sorted list
• Uses divide and conquer method: it locates mid-point and identify which have the target belongs to since the list is sorted. It performs this recursively till the item found or the list is empty(target is not in the list
• The computational time for this algorithm is proportional to log2 n.

Data Structure and Algorithms module | PDF page 3 | lines 16-22

Linear/Sequential searching
• Works with unsorted List
• Loop through the list starting at the first element
• Time is proportional to the size of input (n) and we call this time complexity O(n).

Question sources

Mock exam 1 · Question 14

Question 110 | Q01499

For the values 5 3 8 9 1 7 0 2 6 4, which offered arrays satisfy the final-pivot partition condition for pivot 5: all smaller values precede it and all larger values follow it? Do not require a particular partition algorithm or internal ordering. Select all that apply.

A. 3 1 0 2 4 5 8 9 7 6

B. None of the choices are correct

C. 4 2 3 0 1 5 7 9 6 8

D. 0 3 4 2 1 5 7 9 6 8

E. 3 1 0 2 4 5 8 9 6 7

F. 5 3 4 2 1 0 7 9 6 8

Hint

Compare the required operations, access order and representation metadata with each option.

Answer A, C, D, E: A. 3 1 0 2 4 5 8 9 7 6; C. 4 2 3 0 1 5 7 9 6 8; D. 0 3 4 2 1 5 7 9 6 8; E. 3 1 0 2 4 5 8 9 6 7

There are five values below 5 and four values above it, so a final-position pivot must occupy index five in zero-based order. A, C, D and E each place precisely the smaller group before that pivot and the larger group after it. Their internal subgroup orders need not agree because only the partition invariant is requested. F leaves smaller values after an initial pivot and fails the condition.

Why each choice is right or wrong

A - Correct: All five smaller values precede 5 and all larger ones follow.

B - Incorrect: Several offered arrays satisfy the condition.

C - Correct: This array satisfies the smaller/pivot/larger grouping.

D - Correct: This array also satisfies the grouping despite different internal order.

E - Correct: The right-side permutation does not violate the grouping.

F - Incorrect: Smaller values after the leading 5 violate its final-position condition.

Primary note proof

Study-note section DSA36

> In the ten-distinct-value example, a final pivot 5 has five smaller values before it and four larger after it. Internal orders depend on the partition algorithm; several candidate arrays can satisfy the invariant. State the algorithm before predicting one exact array. Quicksort normally rearranges in the same array but recursive storage can be linear in the worst case.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Data Structure and Algorithms module | PDF page 11 | lines 14-22

> ii. Quick sort: is the fastest known algorithm. It uses divide and conquer strategy and in the worst case its complexity is O (n2). But its expected complexity is O(nlogn).
> Algorithm:
> 1. Choose a pivot value (mostly the first element is taken as the pivot value)
> 2. Position the pivot element and partition the list so that:
> • the left part has items less than or equal to the pivot value
> • the right part has items greater than or equal to the pivot value

> 4. Recursively sort the right part

Question sources

Mock exam 1 · Question 15

Question 111 | Q01578

An owning dynamically allocated linked-list API must provide item search, insertion and removal. Removal unlinks and frees its node before returning; it returns any needed payload by value. Which additional function is unnecessary and would violate the contract if its result were dereferenced?

A. A function that returns a pointer to an already freed node for later dereferencing

B. A function that searches for an item from the list

C. A function that inserts an item in the list

D. A function that removes an item from the list

E. None of the choices is correct

Hint

Compare the required operations, access order and representation metadata with each option.

Answer A: A. A function that returns a pointer to an already freed node for later dereferencing

The API explicitly requires search, insertion and removal, so those operations belong in its interface. Its removal contract frees the node before returning, leaving that node's storage unavailable for later dereference. An additional function promising a usable pointer to the freed node is therefore inappropriate. Returning a copied payload is different and remains allowed; the distinction concerns storage lifetime rather than whether deletion may report a value.

Why each choice is right or wrong

A - Correct: A usable pointer to a freed node violates the stated lifetime contract.

B - Incorrect: Item search is explicitly required by this API.

C - Incorrect: Item insertion is explicitly required by this API.

D - Incorrect: Item removal is explicitly required by this API.

E - Incorrect: A identifies an inappropriate extra function.

Primary note proof

Study-note section DSA03

> A C struct groups named fields, including arrays and pointers. A singly linked node needs payload plus a same-type link. C fields cannot have initializers inside the type declaration; modern C++ permits default member initializers. In C++, match new with delete and new[] with delete[]. Repair links before freeing a node; never dereference it afterwards.

Study-note section DSA09

> Prepend with new.next=head; head=new. To insert after a known predecessor p, set new.next=p.next before p.next=new. Appending with only head requires a tail traversal; maintaining tail avoids it. Delete the head by saving old=head, advancing head=head.next and releasing old in C++.

1. Single Linked lists
It is a self-referential structure (Structures can hold pointers to instances of themselves), that allow
to create a chain of structs/Nodes with related data. Each node in the list contains data items and pointer to next node.
Basic Operations on Single Linked List
I. Creating Linked Lists
Structure definition of a single linked list need to contain both data items declaration and next node
pointer. In addition the first node pointer is essential to keep track of the list to perform various operations on the list. Thus, it is initialized to NULL first as the list is empty before any node added
to the chain.

Data Structure and Algorithms module | PDF page 5 | lines 35-41

IV. Deleting a node from the list
When a node is deleted, the space that it took up should be reclaimed. Otherwise the computer will eventually run out of memory space. This is done with the delete instruction:
delete temp; // Release the memory pointed to by temp
However, we can't just delete the nodes willy-nilly as it would break the chain. We need
to reassign the pointers and then delete the node at the last moment. We can delete nodes
at the start, middle or end of the list. Here let’s see the steps to delete at the end.

Question sources

Mock exam 3 · Question 10

Question 112 | Q01579

Consider a max-heap of n>=3 distinct keys, stored in ordinary level-order array form. Its binary tree is full: every internal node has two children. Which statement is false?

A. The root is the biggest element.

B. The second biggest element is necessarily found at depth 1 (root is at depth 0)

C. The search for the smallest element can be accomplished in O(log n) time (worst case)

D. The last element of the array is necessarily the right most child on the lowest level.

Hint

Compare the required operations, access order and representation metadata with each option.

Answer C: C is false: finding the minimum can require Theta(n) time.

The root contains the maximum key. With distinct keys, the second largest must be one of its children, since a deeper key has a larger ancestor above it. Completeness places the final occupied array slot at the rightmost occupied position of the lowest level. The minimum can occur at any leaf, however, so finding it may require a linear scan rather than logarithmic worst-case time. C is therefore false.

Why each choice is right or wrong

A - Incorrect: The max-heap order makes the root the largest key, so this is true rather than the requested false statement.

B - Incorrect: Distinct keys ensure the second largest is a root child, so this is true.

C - Correct: The minimum may require scanning linearly many leaves; the logarithmic worst-case claim is false.

D - Incorrect: Level-order storage of a complete heap ends at the rightmost occupied position on the lowest level.

Primary note proof

Study-note section DSA23

> A binary max-heap is complete with each parent at least its children; a min-heap reverses this order. Unlike BSTs, heaps do not order entire subtrees. The root is maximum. If all keys are distinct, the second largest is a root child. With duplicate maxima, the second largest distinct value may be deeper: [9,9,9,8,7,6,5] is a valid max-heap and that value is 8 at index 3. The minimum may be any leaf, requiring linear worst-case scanning.

Study-note section DSA18

> Complete means all earlier levels are filled and the last fills from left.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

> iii. Heap Sort
> Heap sort operates by first converting the list in to a heap tree. Heap tree is a binary tree in which
> each node has a value greater than both its children (if any). It uses a process called "adjust to accomplish its task (building a heap tree) whenever a value is larger than its parent. The time complexity of heap sort is O(nlogn).
> Algorithm:
> 1. Construct a binary tree
> • The root node corresponds to Data[0].
> • If we consider the index associated with a particular node to be i, then the left child of this node corresponds to the element with index 2*i+1 and the right child corresponds to the element with index 2*i+2. If any or both of these elements do not exist in the array, then the corresponding child node does not exist either.

2. Construct the heap tree from initial binary tree using "adjust" process.
Sort by swapping the root value with the lowest, right most value and deleting the lowest, right most value and inserting the deleted value in the array in it proper position.

Data Structure and Algorithms module | PDF page 9 | lines 14-19

- Ancestors of a node: parent, grandparent, grand-grandparent, etc of a node.
- Descendants of a node: children, grandchildren, grand-grandchildren etc of a node.
- Depth of a node: number of ancestors or length of the path from the root to the node.
- Height of a tree: depth of the deepest node.
- Subtree: a tree consisting of a node and its descendants.
- Binary tree: a tree in which each node has at most two children called left child and right child.

Question sources

Mock exam 3 · Question 11

Question 113 | Q01580

For ordinary top-down array mergesort on n=8 items with left-first ties and no merge-skipping, which description alone guarantees the maximum possible number of key comparisons across the merges?

A. When the list is initially sorted in the "reverse" order

B. When the list is already sorted in the "right" order

C. When the list contains all similar elements

D. When the list contains all distinct elements

E. None of the choices is correct

Hint

Compare the required operations, access order and representation metadata with each option.

Answer E: E. None of the choices is correct

Maximum merge comparisons depend on the interleaving of the sorted runs, rather than merely on a broad input label. Sorted or reverse-sorted input produces separated runs, and equal keys let left-first merging exhaust a run early. Distinct keys permit a worst interleaving but do not force one; already sorted distinct keys are a counterexample. None of A-D therefore guarantees the requested exact maximum.

Why each choice is right or wrong

A - Incorrect: Reverse order alone does not force worst interleavings.

B - Incorrect: Sorted runs can be merged with an early exhaustion of one side.

C - Incorrect: Left-first equal keys exhaust a run without maximum interleaving.

D - Incorrect: Distinct keys can already be sorted, so distinctness is insufficient.

E - Correct: No preceding description alone guarantees the exact maximum comparison count.

Primary note proof

Study-note section DSA37

> Split into halves, sort them, then merge by advancing the smaller current front. With left-first tie handling, equal keys retain order. Ordinary array merging needs a linear auxiliary buffer. There are logarithmically many levels with linear merge work per level, giving n log n time even on sorted input unless an optimization skips merges.

Study-note section DSA37

> Reverse order alone does not characterize maximum merge comparisons.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Data Structure and Algorithms module | PDF page 11 | lines 38-44

> iv. Merge sort
> Merge sort uses divide and conquer strategy and its time complexity is O(nlogn).
> Algorithm:
> 1. Divide the array in to two halves.
> 2. Recursively sort the first n/2 items.
> 3. Recursively sort the last n/2 items.
> 4. Merge sorted items (using an auxiliary array).

Mock exam 3 · Question 12

Question 114 | Q01618

If a sorted list contains 100 elements, what is the maximum number of comparisons to make to search for an element using binary searching algorithm?

A. None of the choices are correct

B. 100

C. 10

D. 7

E. 50

Hint

Compare the required operations, access order and representation metadata with each option.

Answer D: 7

With one midpoint-key comparison per visited node, the maximum probes are floor(log2 100)+1=7, since 64<=100<128. Equivalently seven binary levels can distinguish up to 127 keys. Evidence: assigned PDF pages 3.

Why each choice is right or wrong

A - Incorrect: Seven is present as D. See assigned PDF 3.

B - Incorrect: 100 is a complete linear scan. See assigned PDF 3.

C - Incorrect: 10 exceeds the needed halving depth. See assigned PDF 3.

D - Correct: Seven midpoint probes suffice in the worst case. See assigned PDF 3.

E - Incorrect: 50 counts only the first halving, not the number of probes. See assigned PDF 3.

Primary note proof

Study-note section DSA29

> Worst probes are floor($\log_2 n$)+1 for n>0: seven for 100 keys, about twenty for one million. Iteration uses constant space; recursion uses logarithmic stack depth. Linked midpoint traversal loses logarithmic total time. Boundary variants retain a candidate rather than stopping at equality.

Question sources

Mock exam 2 · Question 7

Question 115 | Q01619

For ordinary representations without an extra positional index, which listed structure guarantees O(1) worst-case access to an arbitrary valid logical position as its length grows? Use fixed-size elements and unit-cost address arithmetic.

A. Singly linked list

B. Doubly linked list

C. Every listed linked structure guarantees constant-time access to an arbitrary logical position.

D. Circular linked list

E. Array

Hint

Compare the required operations, access order and representation metadata with each option.

Answer E: E. Array

An array computes an element address from its base address, the requested index and the fixed element size, giving constant-time access. Ordinary singly, doubly and circular linked lists instead follow links to reach a logical position; even starting from the nearer endpoint leaves linear worst-case traversal. The replacement aggregate claim is false because those linked structures lack a direct positional index. Array is therefore the unique matching choice.

Why each choice is right or wrong

A - Incorrect: A singly linked list may traverse linearly many successor links.

B - Incorrect: A doubly linked list still has linear worst-case access to middle positions.

C - Incorrect: The listed linked structures do not all have constant-time arbitrary positional lookup.

D - Incorrect: Circularity changes how a chain ends, not how a logical position is located.

E - Correct: An array computes the address directly with fixed-size element arithmetic.

Primary note proof

Study-note section DSA02

> For equal-size elements, address(A[i]) = base + i × element_size under zero-based indexing. This arithmetic gives constant-time positional access in the usual RAM cost model.

Study-note section DSA08

> An array-linked list still follows links unless separately position-indexed.

Study-note section DSA10

> Finding a position is still linear.

Question sources

Mock exam 2 · Question 8

Question 116 | Q01620

Which listed representations guarantee O(log n) worst-case arbitrary-key lookup under these implementations? Use a height-balanced BST for A, an ordinary singly linked list for C, an ordinary binary heap for D, and a sorted random-access array with binary search for E. Select all that apply.

A. Height-balanced BST

B. A and C

C. Singly linked list

D. Heap

E. Sorted random-access array with binary search

Hint

Compare the required operations, access order and representation metadata with each option.

Answer A, E: A. Height-balanced BST; E. Sorted random-access array with binary search

A height-balanced BST has logarithmic height, so following its ordered search path takes logarithmic worst-case time. A sorted random-access array supports logarithmic binary-search probes. An ordinary singly linked list must traverse links, and a heap does not order entire subtrees by arbitrary search keys. Thus the combined A-and-C claim fails because C lacks the guarantee, while A and E independently meet it.

Why each choice is right or wrong

A - Correct: Balance bounds the BST search path logarithmically.

B - Incorrect: C lacks the logarithmic guarantee, so A and C is false.

C - Incorrect: Singly linked lookup may scan all nodes.

D - Incorrect: Heap order privileges the extreme but not arbitrary-key lookup.

E - Correct: Binary search on a sorted random-access array is logarithmic.

Primary note proof

Study-note section DSA19

> Search compares at each node and follows one child until equality or null. Insertion uses that same path to attach a new leaf. Operations cost O(height): logarithmic for balanced trees, linear for a chain. Best-case successful search is Theta(1), a root hit. An optimal BST minimizes expected search cost using access probabilities; constructing it is a different problem from searching it.

Study-note section DSA29

Worst probes are floor($\log_2 n$)+1 for n>0: seven for 100 keys, about twenty for one million. Iteration uses constant space; recursion uses logarithmic stack depth. Linked midpoint traversal loses logarithmic total time. Boundary variants retain a candidate rather than stopping at equality.

Study-note section DSA23

Unlike BSTs, heaps do not order entire subtrees.

Module passages - related reading

Mock exam 2 · Question 9

Question 117 | Q00426B

A queue is a ?

A. FIFO (First In First Out) list

B. LIFO (Last In First Out) list

C. Ordered array

D. Linear tree

Hint

Compare the required operations, access order and representation metadata with each option.

Answer A: FIFO (First In First Out) list

The source expressly calls queues First in First out lists. Evidence: assigned PDF pages 7.

Why each choice is right or wrong

A - Correct: FIFO preserves arrival order. See assigned PDF 7.

B - Incorrect: LIFO names a stack. See assigned PDF 7.

C - Incorrect: An ordered array is one possible storage form, not the abstract queue rule. See assigned PDF 7.

D - Incorrect: Linear tree is not the source queue definition. See assigned PDF 7.

Primary note proof

Study-note section DSA14

> An ordinary queue enqueues at rear, dequeues at front, and peeks at front. This is FIFO or first-come, first-served. A linked implementation with head and tail supports both operations in constant time: append at tail, remove at head. The first insertion sets both pointers; removing the last item clears both. With head alone, insertion must traverse to the tail.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Data Structure and Algorithms module | PDF page 7 | lines 10-16

> “A queue is an ordered list in which all insertions at one end called REAR and deletions are made at another end called FRONT”. Queues are sometimes referred to as First in First out (FIFO) lists.
> The two basic operations are:
> Enqueue - Inserts an item / element at the rear end of the queue. An overflow error occurs if the queue is full.
> Dequeue - Removes an item / element from the front end of the queue, and returns it to the user. An underflow error occurs if the queue is empty.

Question sources

Data Structures & Algorithms practice questions · Question 56

Question 118 | Q00394

What is an internal sorting algorithm?

A. Algorithm that uses tape or disk during the sort

B. Algorithm that uses main memory during the sort

C. Algorithm that involves swapping

D. Algorithm that are considered 'in place'

Hint

Compare the required operations, access order and representation metadata with each option.

Answer B: Sorting whose working dataset fits in main memory.

DSA37 defines internal sorting by fitting the working dataset in memory. Option B expresses that main-memory setting. In contrast, external sorting handles disk-backed runs when data exceeds memory. Swapping is an operation used by some algorithms, and in-place describes auxiliary storage; neither determines whether a sort is internal.

Why each choice is right or wrong

A - Incorrect: Tape or disk working data characterizes external sorting rather than the main-memory internal setting.

B - Correct: Internal sorting keeps its working dataset in main memory, matching the definition in DSA37.

C - Incorrect: Swapping is an implementation operation and does not define the location of the working dataset.

D - Incorrect: In-place concerns auxiliary element storage; an internal sort may still use a separate memory buffer.

Primary note proof

Study-note section DSA37

> Top-down mergesort recurses; bottom-up merges runs of widths 1,2,4,... iteratively. In-place merging variants exist with different tradeoffs; linear merge names an operation, not a universally standardized sort variant. Internal sorting fits the working dataset in memory. External sorting builds sorted runs and merges buffered streams from disk, aiming to reduce I/O. Reverse order alone does not characterize maximum merge comparisons.

Question 119 | SM0008

What is the time complexity order of binary searching algorithm?

A. O(n^3)

B. O(n)

C. O(log n)

D. O(1)

Hint

Compare the required operations, access order and representation metadata with each option.

Answer C: O(log n)

The stated time is proportional to log2 n because each midpoint decision discards half the remaining ordered interval. Evidence: assigned PDF pages 3.

Why each choice is right or wrong

A - Incorrect: Cubic does not match repeated halving. See assigned PDF 3.

B - Incorrect: Linear is the source sequential-search order. See assigned PDF 3.

C - Correct: Logarithmic is the explicit binary-search order. See assigned PDF 3.

D - Incorrect: Constant time occurs for an immediate match, not a general search bound. See assigned PDF 3.

Primary note proof

Study-note section DSA29

Worst probes are floor($\log_2 n$)+1 for n>0: seven for 100 keys, about twenty for one million. Iteration uses constant space; recursion uses logarithmic stack depth. Linked midpoint traversal loses logarithmic total time. Boundary variants retain a candidate rather than stopping at equality.

Question 120 | SM0016

What is the tightest listed worst-case time bound for ordinary quicksort when each partition may choose an extreme pivot?

A. O(n)

B. O(n^2)

C. O(2^n)

D. O(n log n)

Hint

Compare the required operations, access order and representation metadata with each option.

Answer B: B. O(n^2)

An extreme pivot leaves one empty part and one part with only a single element removed. Repeating that pattern makes partition work proportional to n+(n-1)+... rather than distributing it across balanced levels. The sum is quadratic. Balanced partitions explain the n log n alternative, but they are not guaranteed in this worst case. Exponential time is a looser upper bound, not the tightest listed one.

Why each choice is right or wrong

A - Incorrect: Linear time does not cover repeated partition scans.

B - Correct: Repeated extreme pivots produce quadratic total work.

C - Incorrect: Exponential is a much looser upper bound.

D - Incorrect: n log n requires suitably balanced or expected partitions.

Primary note proof

Study-note section DSA36

Choose a pivot, partition, then recursively sort the pieces. Balanced partitions give n log n work; repeated extreme pivots sum n+(n-1)+... to quadratic work. Expected n log n needs an input/random-pivot model. Random and median-of-three choices have different tradeoffs; neither is universally best.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Question 121 | SM0043

Under universal hashing, one random family member is chosen for a table independently of a fixed key set. Which claims are false? Interpret C as an unconditional superiority claim. Select all that apply.

A. In universal hashing a hash function is selected randomly from a set of hash functions for each key

B. In universal hashing a hash function is selected from a set of hash functions independent of keys

C. A single fixed hash function is always better than universal hashing at reducing collisions.

D. Universal hashing controls collision probability without guaranteeing zero collisions.

Hint

Compare the required operations, access order and representation metadata with each option.

Answer A, C: A. In universal hashing a hash function is selected randomly from a set of hash functions for each key; C. A single fixed hash function is always better than universal hashing at reducing collisions.

Universal hashing chooses one random function for the table and then uses it consistently, rather than selecting an unrelated function afresh for each key. Its purpose is to control collision probability for a fixed key set. It does not establish that a single fixed function is always better for avoiding collisions. Thus A and C are false, while independent table-level choice and probability control are the valid principles.

Why each choice is right or wrong

A - Correct: The chosen function is reused for the table rather than chosen afresh per key.

B - Incorrect: Independence from the fixed key set is the stated selection principle.

C - Correct: Unconditional fixed-function superiority does not follow and contradicts the randomized collision-control purpose.

D - Incorrect: Universal choice controls collision probability without promising no collisions.

Primary note proof

Study-note section DSA25

> Determinism means repeated equal keys get the same address for the chosen function. Uniformity means expected keys spread evenly. Universal hashing chooses one function randomly from a suitable family for the table, independently of a fixed key set; it does not choose a fresh unrelated function for each lookup. Random choice controls collision probability, not a promise of zero collisions.

Question 122 | SM0050

In a tree data structure, if a node has no parent node, then the node is _____.

A. Parent node

B. Root node

C. External node

D. Internal node

Hint

Compare the required operations, access order and representation metadata with each option.

Answer B: Root node

The module defines root as a node without a parent, whereas leaves have no child and internal nodes have children. Evidence: assigned PDF pages 9.

Why each choice is right or wrong

A - Incorrect: Parent describes a relation to a child, not the absence of a parent. See assigned PDF 9.

B - Correct: Root is explicitly the parentless node. See assigned PDF 9.

C - Incorrect: External nodes are defined by having no child. See assigned PDF 9.

D - Incorrect: Internal nodes have at least one child, which does not imply parentlessness. See assigned PDF 9.

Primary note proof

Study-note section DSA18

> A rooted tree has one parentless root and one parent per other node. It is connected and acyclic, has n-1 edges, and one path between any pair. Depth counts root-to-node edges; height is maximum depth. A single-node tree therefore has height zero. Leaves have no children.

Question 123 | SM0053

Linked list data structure is _____ type of data structure.

A. Non-linear data structure

B. Fixed size data structure

C. Static data structure

D. Dynamic data structure

Hint

Compare the required operations, access order and representation metadata with each option.

Answer D: Dynamic data structure

Linked nodes are created using new and the module labels linked-list memory dynamic. The size is not fixed by a static array declaration. Evidence: assigned PDF pages 5, 6.

Why each choice is right or wrong

A - Incorrect: The supplied single linked list forms a linear chain. See assigned PDF 5, 6.

B - Incorrect: New nodes can be added at runtime, so size is not intrinsically fixed. See assigned PDF 5, 6.

C - Incorrect: Static describes the source array implementation. See assigned PDF 5, 6.

D - Correct: Dynamic allocation is the linked representation given. See assigned PDF 5, 6.

Primary note proof

Study-note section DSA08

> A singly linked node contains data and next. Head points to the first node; null ends a noncircular chain. Empty means head==null. Nodes allocated as needed grow dynamically, with pointer overhead and no direct index arithmetic.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Data Structure and Algorithms module | PDF page 5 | lines 3-8

> While adding a node to a list, the chain needs to be rearranged properly so that the each nodes are connected to each other. It is possible to add a node anywhere in the chain (at the start, middle or end). Let’s consider adding a node at the end of the list:
> Step 1: First we need to reserve a space for the new node using the keyword new.
> Node *temp = new *Node; // Reserving a space for temporary pointer which points to new node;

Data Structure and Algorithms module | PDF page 6 | lines 43-45

II. Linked list (dynamic memory)
The linked list implementation of stack is adding items at the end of the chain (Push item) and deleting the end node of the list (Pop item).

Question 124 | SM0064

Assume there is a line of patients waiting for service from a clinic. Seriously sick patients should get service first. Which data structure is the most appropriate for this real-world problem?

A. Tree

B. Queue

C. Stack

D. Priority Queue

Hint

Compare the required operations, access order and representation metadata with each option.

Answer D: Priority Queue

Give each patient a key representing medical urgency and serve by that priority. This adapts the module associated-key priority queue to the stated urgency rule. Evidence: assigned PDF pages 8, 7.

Why each choice is right or wrong

A - Incorrect: A tree alone does not define urgency-based service. See assigned PDF 8, 7.

B - Incorrect: A plain FIFO queue serves arrival order rather than illness severity. See assigned PDF 8, 7.

C - Incorrect: A stack gives recent arrivals precedence, regardless of severity. See assigned PDF 8, 7.

D - Correct: Associated priority keys represent how urgently each patient needs service. See assigned PDF 8, 7.

Primary note proof

Study-note section DSA17

A priority queue returns the smallest or largest priority key under its convention. Urgent patients may precede earlier arrivals. Insertions and extractions can interleave. Binary heaps support constant peek and logarithmic insert/extract.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Data Structure and Algorithms module | PDF page 8 | lines 40-45

Priority Queue:- is a queue where each data has an associated key provided at insertion time.
Application of Queue
Queue is goodfor fair (firstcome first served) ordering of actions. Some of queue applications:
• Print server- maintains a queue of print jobs
• Disk Driver- maintains a queue of disk input/output requests
• Task scheduler in multiprocessing system- maintains priority queues of processes

Data Structure and Algorithms module | PDF page 7 | lines 10-16

“A queue is an ordered list in which all insertions at one end called REAR and deletions are made at another end called FRONT”. Queues are sometimes referred to as First in First out (FIFO) lists. The two basic operations are:
Enqueue - Inserts an item / element at the rear end of the queue. An overflow error occurs if the queue is full.
Dequeue - Removes an item / element from the front end of the queue, and returns it to the user. An underflow error occurs if the queue is empty.

Question 125 | SM0076

For an input graph, Depth First Traversal (DFT) algorithm uses _____ data structure to traverse.

A. Priority queue

B. Tree

C. Queue

D. Stack

Hint

Compare the required operations, access order and representation metadata with each option.

Answer D: Stack

DSA42 says DFS recursively explores an unvisited neighbor to completion before returning. The recursive call stack stores return points; an explicit stack can store pending work instead. Both implement latest-pending-work-first order. A queue would change that discipline, while a priority queue or tree alone does not encode the required depth-first frontier behavior.

Why each choice is right or wrong

A - Incorrect: Priority service follows priority keys and does not guarantee finishing the latest active branch first.

B - Incorrect: A tree may represent traversal results, but it does not identify the standard DFS pending-work discipline.

C - Incorrect: FIFO queue order produces breadth-first pending work rather than the required latest-pending-work behavior.

D - Correct: A stack, explicit or supplied by recursion, preserves return points and latest-pending-work-first order.

Primary note proof

Study-note section DSA42

> Mark a vertex, then recursively visit each unmarked neighbour before continuing with later neighbours. An explicit stack can store pending work instead. Both implement latest-pending-work first; a queue would change that discipline. Marking prevents infinite repetition around graph cycles.

Question 126 | SM0082

Which statement is true about the pop() operation of Stack data structures?

A. pop() returns the end/top element but it doesn't delete that element

B. pop() removes the end/top element from the stack

C. pop() inserts a new element at the middle of stack

D. pop() inserts a new element at the beginning/bottom of stack

Hint

Compare the required operations, access order and representation metadata with each option.

Answer B: pop() removes the end/top element from the stack

The pop pseudocode reads the current top and decrements top, so the element is logically removed. Merely inspecting without deletion is peek. Evidence: assigned PDF pages 6.

Why each choice is right or wrong

A - Incorrect: This describes peek, not pop. See assigned PDF 6, 6.

B - Correct: Pop removes the current top by decreasing top. See assigned PDF 6, 6.

C - Incorrect: Pop does not insert, and stack insertion is only at top. See assigned PDF 6, 6.

D - Incorrect: Pop is removal, not bottom insertion. See assigned PDF 6, 6.

Primary note proof

Study-note section DSA11

Stack policy is LIFO, equivalently FILO. Push inserts, pop removes/returns top, and peek only observes. With zero-based occupied slots, top=-1 is empty and top=C-1 is full. Check before A[++top]=x or returning A[top--].

Module passages - related reading

Question 127 | SM0210

A singly linked list of n nodes maintains only its head; there is no tail pointer or index. Appending traverses to the last node before linking a new node. Which listed bounds hold for its worst-case time? Select all that apply.

A. O(n)

B. Theta(1)

C. Theta(n)

D. O(1)

Hint

Compare the required operations, access order and representation metadata with each option.

Answer A, C: A. O(n); C. Theta(n)

The append operation begins at the head and must follow the chain to locate its final node. That requires linear traversal, followed by a constant amount of link work. Its tight worst-case bound is therefore Theta(n), which also implies the upper bound O(n). Neither constant-time choice holds as the list grows. Maintaining a separate tail would change the operation cost, but that representation is explicitly excluded.

Why each choice is right or wrong

A - Correct: O(n) is a valid upper bound on the traversal.

B - Incorrect: The growing traversal prevents a constant tight bound.

C - Correct: Theta(n) is the tight traversal bound.

D - Incorrect: O(1) does not bound arbitrary head-only append traversal.

Primary note proof

Study-note section DSA09

> Prepend with new.next=head; head=new. To insert after a known predecessor p, set new.next=p.next before p.next=new. Appending with only head requires a tail traversal; maintaining tail avoids it. Delete the head by saving old=head, advancing head=head.next and releasing old in C++.

Study-note section DSA06

> For eventually nonnegative functions, f(n)=O(g(n)) means f(n)≤c g(n) for some positive c beyond a threshold k. Omega reverses the inequality; Theta requires both. Little-o means f/g tends to zero; little-omega means it grows without bound. These relations can describe best-case, average-case, worst-case or space functions.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Data Structure and Algorithms module | PDF page 5 | lines 13-24

Step 3: Then add the node at the end of the list. For this we need to check whether the list is empty or not. If list is empty the new node will be the first (Start) node, otherwise navigate forward starting form the first node till last node found and add it next to this node which make the new node the last node.
if (start == NULL) // If list is empty, then new node become start node
start = temp;
else {
temp2 = start; // list not empty! Thus temp2 starts from first node
while (temp2->next!= NULL) { // till the current last node found navigates forward
temp2 = temp2->next; // Move to next link in chain
}
temp2->next = temp; // new node (temp) appended at the end of the list

Data Structure and Algorithms module | PDF page 3 | lines 2-9

I. Big-Oh Notation (O): It's only concerned with what happens for very a large value of n. Big-O expresses an upper bound on the growth rate of a function, for sufficiently large values of n. An upper bound is the best algorithmic solution that has been found for a problem. NB: Each of the following functions is big-O of its successors:
II. Big-Omega Notation (Ω): provides an asymptotic lower bound; f(n)= Ω(g (n)) means that the growth rate of f(n) is greater than or equal to g(n).
III. Theta Notation (Θ): If f(n)= Θ (g(n)), then g(n) is an asymptotically tight bound for f(n) i.e f(n) and g(n) have the same rate of growth.

Computer Science Exit Exam practice collection · Question 138

Question 128 | SM0213

Which ordinary search method requires its input key sequence to be sorted before using comparisons to discard the half that cannot contain a target?

A. Hash search

B. Depth-first search

C. Binary search

D. Linear search

Hint

Compare the required operations, access order and representation metadata with each option.

Answer C: C. Binary search

Binary search compares a target with the midpoint of an ordered interval, then safely discards one half. That elimination depends on sorted order. Linear search can scan unsorted values, hashing selects addresses from keys rather than sorted positions, and depth-first search follows graph adjacency. The revised alternatives therefore have clear operational meanings, and Binary search uniquely matches the stated ordered-half-elimination requirement.

Why each choice is right or wrong

A - Incorrect: Hash lookup uses computed addresses rather than a sorted input interval.

B - Incorrect: Depth-first search follows adjacency, not ordered-array halves.

C - Correct: Binary search needs ordering to safely discard a comparison-selected half.

D - Incorrect: Linear scanning permits unsorted input.

Primary note proof

Study-note section DSA29

> On an ascending random-access sequence, set lo=0, hi=n-1. Compute mid=lo+(hi-lo)//2. Equality finishes; if target<A[mid], set hi=mid-1; otherwise set lo=mid+1.

Study-note section DSA28

> Unsorted data is allowed; sorted data is allowed too.

Study-note section DSA25

> A hash table uses h(key) in 0..m-1 and stores only actual entries plus bucket capacity.

Study-note section DSA42

> Mark a vertex, then recursively visit each unmarked neighbour before continuing with later neighbours.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Data Structure and Algorithms module | PDF page 3 | lines 23-31

> Binary Searching
> • Works on ordered/sorted list
> • Uses divide and conquer method: it locates mid-point and identify which have the target belongs to since the list is sorted. It performs this recursively till the item found or the list is empty(target is not in the list
> • The computational time for this algorithm is proportional to log2 n.

Data Structure and Algorithms module | PDF page 3 | lines 16-22

Linear/Sequential searching
• Works with unsorted List
• Loop through the list starting at the first element
• Time is proportional to the size of input (n) and we call this time complexity O(n).

Computer Science Exit Exam · Sene 2016 · Question 4-3

Computer Science Exit Exam practice collection · Question 139

Question 129 | SM0229

Given a binary search tree, which traversal type would print the values in the nodes in sorted order?

A. Pre-order

B. Pre-order and Post-order

C. In-order

D. Post-order

Hint

Compare the required operations, access order and representation metadata with each option.

Answer C: In-order

All left-subtree keys precede the root, and all right-subtree keys follow it. Recursively visiting left, parent, right therefore emits increasing keys. Evidence: assigned PDF pages 9.

Why each choice is right or wrong

A - Incorrect: Preorder prints root before smaller left keys. See assigned PDF 9, 9.

B - Incorrect: Including preorder cannot guarantee increasing order. See assigned PDF 9, 9.

C - Correct: Inorder matches left keys < root < right keys recursively. See assigned PDF 9, 9.

D - Incorrect: Postorder prints the root after larger right keys. See assigned PDF 9, 9.

Primary note proof

Study-note section DSA19

With distinct keys, every key in a node's left subtree is smaller and every key in its right subtree is larger. Immediate-child comparisons alone are insufficient: root 10, left child 5, and 5's right child 12 violate the root's restriction. Duplicates require a separate count or placement policy.

Study-note section DSA20

Preorder visits node,left,right; inorder left,node,right; postorder left,right,node. Apply recursively; null children do nothing. Inorder returns sorted keys only for a BST. Preorder supports copying, postorder supports deleting children before parents, and level order uses a FIFO queue.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Data Structure and Algorithms module | PDF page 9 | lines 19-25

• Binary tree: a tree in which each node has at most two children called left child and right child.
• Binary search tree (ordered binary tree): a binary tree that may be empty, but if it is not empty it
satisfies the following.
o Every node has a key and no two elements have the same key.
o The keys in the right subtree are larger than the keys in the root.
o The keys in the left subtree are smaller than the keys in the root.
o The left and the right subtrees are also binary search trees.

Data Structure and Algorithms module | PDF page 9 | lines 40-44

III. Tree Traversing:
Binary search tree can be traversed in three ways.
a. Pre order traversal - traversing binary tree in the order of parent, left and right.
b. Inorder traversal - traversing binary tree in the order of left, parent and right.
c. Postorder traversal - traversing binary tree in the order of left, right and parent.

Question 130 | SM0240

If a sequence of operations: push(1), push(2), pop, push(1), push(2), pop, pop, pop, push(2), pop are performed on a stack, the sequence of popped values is:

A. 2,1,2,2,1

B. 2,2,1,1,2

C. 2,1,2,2,2

D. 2,2,1,2,2

Hint

Trace the initial state and update only the fields affected by each permitted operation.

Answer B: 2,2,1,1,2

Trace bottom-to-top: [1], [1,2], pop 2; [1,1], [1,1,2], pop 2; pop 1; pop 1; [2], pop 2. Popped sequence is 2,2,1,1,2. Evidence: assigned PDF pages 6.

Why each choice is right or wrong

A - Incorrect: The second pop is 2, not 1. See assigned PDF 6.

B - Correct: Exactly matches all five top removals. See assigned PDF 6.

C - Incorrect: The second pop is again 2, not 1. See assigned PDF 6.

D - Incorrect: The fourth pop removes the original bottom 1, not 2. See assigned PDF 6.

Primary note proof

Study-note section DSA11

> Stack policy is LIFO, equivalently FILO. Push inserts, pop removes/returns top, and peek only observes. With zero-based occupied slots, top=-1 is empty and top=C-1 is full. Check before A[++top]=x or returning A[top--].

Study-note section DSA12

> Write the stack bottom-to-top after every instruction and record popped values separately. Push 1, push 2, pop emits 2 and leaves [1]. Push 1, push 2, pop, pop, pop then emits 2,1,1; push 2, pop emits 2. The complete output is 2,2,1,1,2.

Question 131 | SM0279

Which of the following is FALSE in Data Structures and Algorithms?

A. A tree contains a cycle

B. Tree is a non-linear data structure

C. A tree is a connected graph

D. A tree with n nodes contains (n-1) edges

Hint

Compare the required operations, access order and representation metadata with each option.

Answer A: A tree contains a cycle

Unique root paths and one parent per nonroot node exclude cycles. The n-1 nonroot nodes each contribute one parent edge, making the rooted tree connected with n-1 edges. Evidence: assigned PDF pages 9, 2.

Why each choice is right or wrong

A - Correct: A cycle contradicts the source unique-path parent hierarchy. See assigned PDF 9, 2.

B - Incorrect: Trees are explicitly classified as nonlinear. See assigned PDF 9, 2.

C - Incorrect: Every node is reachable from the root along a unique path, so the tree is connected. See assigned PDF 9, 2.

D - Incorrect: One parent edge for each nonroot node yields n-1 edges. See assigned PDF 9, 2.

Primary note proof

Study-note section DSA18

> A rooted tree has one parentless root and one parent per other node. It is connected and acyclic, has n-1 edges, and one path between any pair. Depth counts root-to-node edges; height is maximum depth. A single-node tree therefore has height zero. Leaves have no children.

Study-note section DSA01

> An abstract data type (ADT) defines values and operations; representation supplies implementation. Arrays or linked nodes can implement the same LIFO stack. Abstraction keeps relevant details: patient urgency and arrival order matter for service; hair colour does not.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

b. Non-Linear data structures : in which there is order of data items
Example: Trees and Graphs

Question sources

Computer Science Exit Exam · Sene 2016 · Question 26-1

Computer Science Exit Exam practice collection · Question 136

Question 132 | SM0282

A fixed-capacity circular array queue uses front and size indices, modulo slot reuse, and no shifting or resizing. Under unit-cost index arithmetic, what is the tightest listed worst-case pair for enqueue and dequeue, including full/empty checks?

A. O(n), O(1)

B. O(1), O(n)

C. O(1), O(1)

D. O(n), O(n)

Hint

Compare the required operations, access order and representation metadata with each option.

Answer C: C. O(1), O(1)

Enqueue computes a slot from front and size, writes one item and updates the count. Dequeue reads the front slot, advances front modulo capacity and decreases the count. Full or empty checks also inspect only constant-size state. No operation shifts or resizes the array, so each uses constant work in the stated model. The linear alternatives are looser bounds rather than the requested tight pair.

Why each choice is right or wrong

A - Incorrect: Linear enqueue is looser than the constant cost of this implementation.

B - Incorrect: Linear dequeue is looser than its constant index update cost.

C - Correct: Both endpoint operations use constant work.

D - Incorrect: Both linear bounds are looser than the requested tight pair.

Primary note proof

Study-note section DSA15

A simple noncircular array queue may report overflow when rear reaches the final index despite released slots at the front. A circular queue reuses slots with modulo arithmetic. Use a count convention: front points to the next removal, size counts items, and insertion slot is (front+size)%C. Empty means size==0; full means size==C.

Study-note section DSA15

Dequeue reads A[front], sets front=(front+1)%C and decreases size. An alternative reserves one unused slot and uses next(rear)==front for full; its empty test and capacity differ. State the convention before tracing.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Data Structure and Algorithms module | PDF page 7 | lines 18-23

I. Simple Array implementation (static memory).
A simple array structure can be used to implement enqueue & dequeue operations. Thus item will
be added at the end of the array whereas dequeue operation removes items from the front. In simple
array implementation, to add item it checks whether there is room at the rear or not. Therefore, even though there are free released spaces at the front ot the array the queue implementation might
generate overflow message. This is the key drawback to use simple array to implement Queue.

Data Structure and Algorithms module | PDF page 7 | lines 24-26

II. Circular array implementation of Queue Operations
To overcome the above drawback of simple array implementation a circular array can be used, in
which freed spaces are re-used to store data.

Computer Science model exam collection · Question 22

Question 134 | SS149

For this question, an indirect queue application means using FIFO as auxiliary storage inside a graph traversal algorithm, rather than directly modeling a waiting line or scheduling service. Which listed description fits?

A. Operating systems schedule jobs (with equal priority) in the order of arrival (e.g., a print queue).

B. Simulation of real-world queues such as lines at a ticket counter or any other first-come first-served scenario requires a queue.

C. Auxiliary data structure for algorithms

D. Multiprogramming

Hint

Compare the required operations, access order and representation metadata with each option.

Answer C: C. Auxiliary data structure for algorithms

The supplied convention distinguishes an algorithm's internal work storage from a real-world waiting-line model. BFS uses a queue to hold its discovered but not yet explored vertices, so auxiliary algorithm storage is the matching category. Equal-priority job scheduling and ticket-line simulation directly model service waiting. Multiprogramming is a broader operating-system setting and does not specifically name the internal graph-traversal role requested here.

Why each choice is right or wrong

A - Incorrect: Arrival-order print scheduling directly models a service queue.

B - Incorrect: Ticket-line simulation directly models real-world waiting.

C - Correct: An algorithmic frontier queue is auxiliary storage inside graph traversal.

D - Incorrect: Multiprogramming is a broad execution setting, not the specified internal traversal role.

Primary note proof

Study-note section DSA41

Mark the source when enqueuing it. Repeatedly dequeue a vertex, examine its neighbours, and enqueue each unvisited neighbour while marking it. Store predecessor[v] when discovering v if a path must be reconstructed. FIFO ensures vertices at distance d are explored before later distance layers.

Study-note section DSA14

FIFO suits equal-priority printer jobs, shared-resource waiting, asynchronous buffers and level-order exploration. A play sequence can also use a queue. Distinguish airline seat records from waiting requests; an application name alone does not force one representation.

These source passages provide context; the primary note proof is identified separately above.

Data Structure and Algorithms module | PDF page 8 | lines 41-48

Application of Queue
Queue is goodfor fair (firstcome first served) ordering of actions. Some of queue applications:
• Print server- maintains a queue of print jobs
• Disk Driver- maintains a queue of disk input/output requests
• Task scheduler in multiprocessing system- maintains priority queues of processes
• Telephone calls in a busy environment -maintains a queue of telephone calls
• Simulation of waiting line- models real life queues (e.g. supermarkets checkout, customer service line (Bank, custom, airport etc))

Question sources

Computer Science model exam collection · Question 56

Question 135 | SS158

A queue in which the item most recently added is always the first one out refers to:

A. FIFO queue

B. Real time queue

C. Priority queue

D. LIFO queue

Hint

Compare the required operations, access order and representation metadata with each option.

Answer D: LIFO queue

Most recently added first removed is LIFO by definition. The name LIFO queue here describes stack discipline rather than the ordinary FIFO queue. Evidence: assigned PDF pages 6, 7, 8.

Why each choice is right or wrong

A - Incorrect: FIFO removes the earliest insertion. See assigned PDF 6, 7, 8.

B - Incorrect: Real time alone does not specify last-in removal. See assigned PDF 6, 7, 8.

C - Incorrect: Priority depends on keys, not necessarily insertion recency. See assigned PDF 6, 7, 8.

D - Correct: LIFO exactly names last-in-first-out service. See assigned PDF 6, 7, 8.

Primary note proof

Study-note section DSA11

> Stack policy is LIFO, equivalently FILO. Push inserts, pop removes/returns top, and peek only observes. With zero-based occupied slots, top=-1 is empty and top=C-1 is full. Check before A[++top]=x or returning A[top--].

Question 136 | AM0394

Which data structure follows the LIFO (Last-In-First-Out) principle?

A. Stack

B. Queue

C. Linked list

D. Binary tree

Hint

Compare the required operations, access order and representation metadata with each option.

Answer A: Stack

The stack top is both insertion and removal end, so the most recent unremoved insertion leaves first. Evidence: assigned PDF pages 6, 7, 4, 9.

Why each choice is right or wrong

A - Correct: Stack is explicitly LIFO. See assigned PDF 6, 7, 4, 9.

B - Incorrect: Queue is FIFO. See assigned PDF 6, 7, 4, 9.

C - Incorrect: A linked list is a representation with no mandatory service discipline. See assigned PDF 6, 7, 4, 9.

D - Incorrect: A binary tree defines children, not insertion/removal chronology. See assigned PDF 6, 7, 4, 9.

Primary note proof

Study-note section DSA11

> Stack policy is LIFO, equivalently FILO. Push inserts, pop removes/returns top, and peek only observes. With zero-based occupied slots, top=-1 is empty and top=C-1 is full. Check before A[++top]=x or returning A[top--].

“A queue is an ordered list in which all insertions at one end called REAR and deletions are made at another end called FRONT”. Queues are sometimes referred to as First in First out (FIFO) lists.
The two basic operations are:
Enqueue - Inserts an item / element at the rear end of the queue. An overflow error occurs if the queue is full.
Dequeue - Removes an item / element from the front end of the queue, and returns it to the user. An underflow error occurs if the queue is empty.

Data Structure and Algorithms module | PDF page 4 | lines 16-25

1. Single Linked lists
It is a self-referential structure (Structures can hold pointers to instances of themselves), that allow
to create a chain of structs/Nodes with related data. Each node in the list contains data items and pointer to next node.
Basic Operations on Single Linked List
I. Creating Linked Lists
Structure definition of a single linked list need to contain both data items declaration and next node
pointer. In addition the first node pointer is essential to keep track of the list to perform various operations on the list. Thus, it is initialized to NULL first as the list is empty before any node added
to the chain.

Data Structure and Algorithms module | PDF page 9 | lines 19-25

• Binary tree: a tree in which each node has at most two children called left child and right child.
• Binary search tree (ordered binary tree): a binary tree that may be empty, but if it is not empty it
satisfies the following.
o Every node has a key and no two elements have the same key.
o The keys in the right subtree are larger than the keys in the root.
o The keys in the left subtree are smaller than the keys in the root.
o The left and the right subtrees are also binary search trees.

Question 137 | AM0395

Which data structure follows the FIFO (First-In-First-Out) principle?

A. Stack

B. Queue

C. Linked list

D. Binary tree

Hint

Compare the required operations, access order and representation metadata with each option.

Answer B: Queue

FIFO is explicitly the queue policy: enqueue at rear and dequeue at front. Evidence: assigned PDF pages 7, 6.

Why each choice is right or wrong

A - Incorrect: Stack is LIFO. See assigned PDF 7, 6.

B - Correct: Queue preserves insertion order for removal. See assigned PDF 7, 6.

C - Incorrect: A linked list can implement a queue but does not inherently impose FIFO. See assigned PDF 7, 6.

D - Incorrect: Binary-tree structure does not impose FIFO. See assigned PDF 7, 6.

Primary note proof

Study-note section DSA14

> An ordinary queue enqueues at rear, dequeues at front, and peeks at front. This is FIFO or first-come, first-served. A linked implementation with head and tail supports both operations in constant time: append at tail, remove at head. The first insertion sets both pointers; removing the last item clears both. With head alone, insertion must traverse to the tail.

Module passages - related reading

Computer Science MCQ practice collection · Question 395

Computer Science MCQ practice collection · Question 415

Question 138 | AM0396

Which listed representation permits insertion and removal at either endpoint in constant time? Use ordinary stack and FIFO queue interfaces, and interpret C as a doubly linked list maintaining both head and tail.

A. Stack

B. Queue

C. Doubly linked list with head and tail

D. Binary tree

Hint

Compare the required operations, access order and representation metadata with each option.

Answer C: C. Doubly linked list with head and tail

A doubly linked list stores predecessor and successor links, while head and tail provide direct access to both endpoints. Inserting or removing there updates a fixed number of links, including the empty and singleton cases. Ordinary stack and FIFO queue interfaces expose fewer endpoint operations, and a binary tree has no corresponding two-end sequence guarantee. The explicit linked-list variant is essential because singly linked tail deletion needs a predecessor traversal.

Why each choice is right or wrong

A - Incorrect: A stack exposes insertion/removal at one top only.

B - Incorrect: An ordinary FIFO queue does not permit all four endpoint operations.

C - Correct: A doubly linked list with both endpoint pointers supports constant-time operations at each end.

D - Incorrect: A binary tree has no two-end sequence-operation guarantee.

Primary note proof

Study-note section DSA10

> Doubly linked nodes add prev; head and tail enable constant-time operations at both ends. Singly linked tail deletion still needs its predecessor. A circular tail links back to head; stop traversal on returning to the start, handling empty separately.

Study-note section DSA11

> Stack policy is LIFO, equivalently FILO. Push inserts, pop removes/returns top, and peek only observes. With zero-based occupied slots, top=-1 is empty and top=C-1 is full. Check before A[++top]=x or returning A[top--].

Computer Science MCQ practice collection · Question 396

Question 139 | AM0397

Which data structure represents a hierarchical structure with nodes and edges?

A. Stack

B. Queue

C. Linked list

D. Binary tree

Hint

Compare the required operations, access order and representation metadata with each option.

Answer D: Binary tree

A tree is expressly an abstract model of a hierarchical structure, and a binary tree is its at-most-two-children specialization. Evidence: assigned PDF pages 9.

Why each choice is right or wrong

A - Incorrect: Stack is a one-ended linear list. See assigned PDF 9, 9.

B - Incorrect: Queue is a FIFO linear list. See assigned PDF 9, 9.

C - Incorrect: A singly linked list is a chain rather than a branching hierarchy. See assigned PDF 9, 9.

D - Correct: Binary tree matches the hierarchy with nodes and edges. See assigned PDF 9, 9.

Primary note proof

Study-note section DSA18

> A rooted tree has one parentless root and one parent per other node. It is connected and acyclic, has n-1 edges, and one path between any pair. Depth counts root-to-node edges; height is maximum depth. A single-node tree therefore has height zero. Leaves have no children.

Study-note section DSA01

> Trees model hierarchies; graphs model general connections.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Data Structure and Algorithms module | PDF page 9 | lines 3-13

> A tree is a set of nodes and edges that connect pairs of nodes that connect pairs of nodes. It is an abstract model of a hierarchical structure. Rooted tree has the following structure:
> • One node distinguished as root.
> • Every node C except the root is connected from exactly other node P. P is C's parent, and C is one of C's children.
> • There is a unique path from the root to the each node.
> • The number of edges in a path is the length of the path.
> Tree Terminologies:

• Root: a node without a parent.
• Internal node: a node with at least one child.
• External (leaf) node: a node without a child.

Data Structure and Algorithms module | PDF page 9 | lines 19-25

• Binary tree: a tree in which each node has at most two children called left child and right child.
• Binary search tree (ordered binary tree): a binary tree that may be empty, but if it is not empty it
satisfies the following.
o Every node has a key and no two elements have the same key.
o The keys in the right subtree are larger than the keys in the root.
o The keys in the left subtree are smaller than the keys in the root.
o The left and the right subtrees are also binary search trees.

Computer Science MCQ practice collection · Question 397

Question 140 | AM0398

Which data structure is best suited for implementing a backtracking algorithm?

A. Stack

B. Queue

C. Linked list

D. Binary tree

Hint

Compare the required operations, access order and representation metadata with each option.

Answer A: Stack

Backtracking is explicitly listed as a stack application: the latest pending decision can be undone first using pop. Evidence: assigned PDF pages 7, 6.

Why each choice is right or wrong

A - Correct: LIFO naturally returns to the most recent unfinished decision. See assigned PDF 7, 6.

B - Incorrect: FIFO would return to oldest pending work. See assigned PDF 7, 6.

C - Incorrect: A generic linked list does not prescribe backtracking order. See assigned PDF 7, 6.

D - Incorrect: A binary tree can represent choices but does not itself maintain a LIFO return path. See assigned PDF 7, 6.

Primary note proof

Study-note section DSA12

Calls nest on a runtime stack; the latest call returns first. Bracket matching pushes opening brackets and matches each closing bracket against top. Reversal pushes input then pops it. Undo moves the latest action from undo to redo; redo moves it back. A new edit after undo normally clears redo. DFS and backtracking use the same latest-pending-choice discipline.

Computer Science MCQ practice collection · Question 398

Question 141 | AM0399

A dispatcher keeps pending jobs in a sequence. Urgent jobs are added at the front, ordinary jobs at the back; serving removes the front job, and cancellation removes the last job. Which listed representation supports every operation in worst-case constant time as the sequence grows? Use ordinary stack and FIFO queue interfaces, with no additional indexes or auxiliary structures.

A. Stack

B. Queue

C. Doubly linked list with head and tail

D. Binary tree

Hint

Compare the required operations, access order and representation metadata with each option.

Answer C: C. Doubly linked list with head and tail

Urgent arrival inserts at the head, ordinary arrival appends at the tail, service removes the head, and cancellation removes the tail. A doubly linked list with both endpoint pointers updates a fixed number of links for each action; its prev link identifies the predecessor needed for tail removal. A stack exposes only one top, a FIFO queue lacks last-job cancellation and front insertion, and a generic binary tree provides no such endpoint-cost guarantee.

Why each choice is right or wrong

A - Incorrect: One stack top cannot directly supply both service-at-front and cancellation-at-back operations.

B - Incorrect: An ordinary FIFO queue permits rear insertion and front removal, but not urgent front insertion or last-job removal.

C - Correct: Head and tail permit direct endpoint access, and prev links make last-job removal constant time.

D - Incorrect: A generic binary tree has no guarantee for all four ordered-sequence endpoint updates.

Primary note proof

Study-note section DSA10

> Doubly linked nodes add prev; head and tail enable constant-time operations at both ends. Singly linked tail deletion still needs its predecessor. A circular tail links back to head; stop traversal on returning to the start, handling empty separately.

Study-note section DSA14

> An ordinary queue enqueues at rear, dequeues at front, and peeks at front. This is FIFO or first-come, first-served. A linked implementation with head and tail supports both operations in constant time: append at tail, remove at head. The first insertion sets both pointers; removing the last item clears both. With head alone, insertion must traverse to the tail.

Module passages - related reading

> I. Creating Linked Lists
> Structure definition of a single linked list need to contain both data items declaration and next node
> pointer. In addition the first node pointer is essential to keep track of the list to perform various operations on the list. Thus, it is initialized to NULL first as the list is empty before any node

added
to the chain.

Data Structure and Algorithms module | PDF page 5 | lines 13-24

Step 3: Then add the node at the end of the list. For this we need to check whether the list is empty or not. If list is empty the new node will be the first (Start) node, otherwise navigate forward starting form the first node till last node found and add it next to this node which make the new node the last node.
if (start == NULL) // If list is empty, then new node become start node
start = temp;
else {
temp2 = start; // list not empty! Thus temp2 starts from first node
while (temp2->next!= NULL) { // till the current last node found navigates forward
temp2 = temp2->next; // Move to next link in chain
}
temp2->next = temp; // new node (temp) appended at the end of the list

Data Structure and Algorithms module | PDF page 6 | lines 4-13

2. Make temp1 point to whatever the start pointer is pointing to.
3. If the next pointer of what temp1 indicates is NULL, then we've found the last node of the list, so
jump to step 7.
4. Make another pointer, temp2, point to the current node in the list.
5. Make temp1 point to the next item in the list.
6. Go to step 3.
7. If you get this far, then the temporary pointer, temp1, should point to the last item in the list and
the other temporary pointer, temp2, should point to the last-but-one item.
8. Delete the node pointed to by temp1.
9. Mark the next pointer of the node pointed to by temp2 as NULL - it is the new last node.

Data Structure and Algorithms module | PDF page 8 | lines 38-40

Deque (pronounced as Deck): is a Double Ended Queue in which insertion and deletion can occur at either end.
Priority Queue:- is a queue where each data has an associated key provided at insertion time.

Computer Science MCQ practice collection · Question 399

Question 142 | AM0400

Which listed structures admit both array-based and linked-node representations? Links may be array indices or pointers, and binary-tree representations include the complete binary-tree case. Select all that apply.

A. Stack

B. Queue

C. Linked list

D. Binary tree

Hint

Compare the required operations, access order and representation metadata with each option.

Answer A, B, C, D: A. Stack; B. Queue; C. Linked list; D. Binary tree

Stacks and queues have both array and linked-node implementations. A linked list can store its next links as indices into an array or as pointers between allocated nodes. A binary tree can use linked child references, while the complete binary-tree case has the indexed heap representation. The question concerns possible representations, so all four qualify without requiring one universal layout for every instance.

Why each choice is right or wrong

A - Correct: A stack can use an array top or a linked head.

B - Correct: A queue can use circular slots or linked endpoint nodes.

C - Correct: List links may be indices or node references.

D - Correct: Binary trees have linked-node forms and indexed complete-tree forms.

Primary note proof

Study-note section DSA01

> Arrays or linked nodes can implement the same LIFO stack.

Study-note section DSA14

> A linked implementation with head and tail supports both operations in constant time: append at tail, remove at head.

Study-note section DSA15

> A circular queue reuses slots with modulo arithmetic.

Study-note section DSA08

> An array-linked list still follows links unless separately position-indexed.

Study-note section DSA23

> Zero-based array representation: root index 0, left=2i+1, right=2i+2, parent=floor((i-1)/2) for i>0.

Study-note section DSA-S03

A linked binary-tree node stores a payload and two child pointers, one for the left child and one for the right child.

These source passages provide context; the primary note proof is identified separately above.

Data Structure and Algorithms module | PDF page 6 | lines 24-42

I. Array implementation (static memory).
Push(n): Adding item at top
top is the current top of stack and n is its
maximum size
Begin
if (top == n) then stack is full;
else
top := top+1;
stack[top] := item;
end:
Pop(): removing item from stack top
remove top element from the stack and put it in
the item
Begin:
if (top == 0) then stack is empty;
else
item := stack[top];
top := top-1;
end;

Data Structure and Algorithms module | PDF page 6 | lines 43-45

II. Linked list (dynamic memory)
The linked list implementation of stack is adding items at the end of the chain (Push item) and deleting the end node of the list (Pop item).

Data Structure and Algorithms module | PDF page 7 | lines 18-23

I. Simple Array implementation (static memory).
A simple array structure can be used to implement enqueue & dequeue operations. Thus item will
be added at the end of the array whereas dequeue operation removes items from the front. In simple
array implementation, to add item it checks whether there is room at the rear or not. Therefore, even though there are free released spaces at the front ot the array the queue implementation might
generate overflow message. This is the key drawback to use simple array to implement Queue.

Data Structure and Algorithms module | PDF page 8 | lines 35-37

III. Linked list implementation of enqueue and dequeue operations
Enqueue- is inserting a node at the end of a linked list
Dequeue- is deleting the first node in the list

Computer Science MCQ practice collection · Question 400

Computer Science MCQ practice collection · Question 418

Question 143 | AM0401

A character reader supplies a word from left to right. After reading finishes, an output routine must remove one character at a time from a single auxiliary ADT to display the word right to left. It may use only the ADT's standard insertion/removal interface and must preserve the original input. Which ADT directly supplies the needed removal order?

A. Stack

B. Queue

C. Linked list

D. Binary tree

Hint

Compare the required operations, access order and representation metadata with each option.

Answer A: A. Stack

Insert the characters in the order they are read. The required output starts with the last character inserted, then continues toward the earliest one, so a stack's LIFO interface directly supplies the reversal. A queue would preserve the original order. A linked list could represent a stack, but its storage links alone do not prescribe LIFO; a generic tree likewise has no matching removal contract.

Why each choice is right or wrong

A - Correct: Repeated stack removals produce the characters in reverse insertion order.

B - Incorrect: FIFO removal would reproduce the original character order.

C - Incorrect: A list is a possible representation but does not itself prescribe the required removal policy.

D - Incorrect: A generic tree does not define the requested reverse-insertion removal contract.

Primary note proof

Study-note section DSA12

Calls nest on a runtime stack; the latest call returns first. Bracket matching pushes opening brackets and matches each closing bracket against top. Reversal pushes input then pops it. Undo moves the latest action from undo to redo; redo moves it back. A new edit after undo normally clears redo. DFS and backtracking use the same latest-pending-choice discipline.

Study-note section DSA11

Stack policy is LIFO, equivalently FILO.

Study-note section DSA11

Linked stacks achieve constant time by inserting and deleting at the head; using a singly linked tail for pop would require a predecessor traversal.

Study-note section DSA14

An ordinary queue enqueues at rear, dequeues at front, and peeks at front. This is FIFO or first-come, first-served.

Study-note section DSA45

Specify whether a question asks which structure can implement something or which is best under stated costs. ADTs do not force one representation, and serial-access memory is not inherently LIFO.

Question 144 | AM0402

Which data structure is commonly used for implementing function call stacks in programming languages?

A. Stack

B. Queue

C. Linked list

D. Binary tree

Hint

Compare the required operations, access order and representation metadata with each option.

Answer A: Stack

The source explicitly states that a memory stack is used in function calls including recursion, keeping the most recent active call on top. Evidence: assigned PDF pages 6.

Why each choice is right or wrong

A - Correct: Nested calls return in LIFO order through a stack. See assigned PDF 6, 6.

B - Incorrect: Queue FIFO order would not reflect nested returns. See assigned PDF 6, 6.

C - Incorrect: Linked nodes can store frames but the controlling ADT is still a stack. See assigned PDF 6, 6.

D - Incorrect: A binary tree does not provide the specified call-return discipline. See assigned PDF 6, 6.

Primary note proof

Study-note section DSA12

> Calls nest on a runtime stack; the latest call returns first. Bracket matching pushes opening brackets and matches each closing bracket against top. Reversal pushes input then pops it. Undo moves the latest action from undo to redo; redo moves it back. A new edit after undo normally clears redo. DFS and backtracking use the same latest-pending-choice discipline.

Question sources

Computer Science MCQ practice collection · Question 402

Question 145 | AM0403

A message buffer accepts new items at its rear and delivers the oldest waiting item from its front. Which service ADT can maintain this contract using either a circular array or linked head-and-tail nodes? Choose the ADT rather than an underlying storage container.

A. Stack

B. Queue

C. Linked list

D. Binary tree

Hint

Compare the required operations, access order and representation metadata with each option.

Answer B: B. Queue

The oldest waiting message must leave first, while new arrivals join the rear. This is the ordinary queue service contract. The note supplies both a circular-array representation that reuses slots and a linked representation that appends at the tail and removes at the head. A stack serves the newest item first; a generic linked list or tree does not independently specify this FIFO policy.

Why each choice is right or wrong

A - Incorrect: A stack's latest-first removal violates oldest-message-first delivery.

B - Correct: A queue has the stated rear-insertion/front-removal contract and both cited implementations.

C - Incorrect: Linked nodes can store the queue but do not by themselves define its service policy.

D - Incorrect: A binary tree does not inherently define this FIFO message-buffer interface.

Primary note proof

Study-note section DSA15

A simple noncircular array queue may report overflow when rear reaches the final index despite released slots at the front. A circular queue reuses slots with modulo arithmetic. Use a

count convention: front points to the next removal, size counts items, and insertion slot is (front+size)%C. Empty means size==0; full means size==C.

Study-note section DSA14

An ordinary queue enqueues at rear, dequeues at front, and peeks at front. This is FIFO or first-come, first-served. A linked implementation with head and tail supports both operations in constant time: append at tail, remove at head. The first insertion sets both pointers; removing the last item clears both. With head alone, insertion must traverse to the tail.

Question 146 | AM0404

Which data structure has a First-In-First-Out (FIFO) property?

A. Stack

B. Queue

C. Linked list

D. Binary tree

Hint

Compare the required operations, access order and representation metadata with each option.

Answer B: Queue

First-in-first-out is the explicit queue property. Inserting at rear and removing at front preserves the oldest pending element. Evidence: assigned PDF pages 7.

Why each choice is right or wrong

A - Incorrect: Stack is last-in-first-out. See assigned PDF 7.

B - Correct: Queue has FIFO semantics. See assigned PDF 7.

C - Incorrect: A linked-list representation alone imposes no FIFO restriction. See assigned PDF 7.

D - Incorrect: A binary-tree hierarchy is not arrival-order access. See assigned PDF 7.

Primary note proof

Study-note section DSA14

> An ordinary queue enqueues at rear, dequeues at front, and peeks at front. This is FIFO or first-come, first-served. A linked implementation with head and tail supports both operations in constant time: append at tail, remove at head. The first insertion sets both pointers; removing the last item clears both. With head alone, insertion must traverse to the tail.

Question 147 | AM0405

Which data structure is suitable for implementing a breadth-first search algorithm?

A. Stack

B. Queue

C. Linked list

D. Binary tree

Hint

Compare the required operations, access order and representation metadata with each option.

Answer B: Queue

DSA41 enqueues discovered neighbors and dequeues the next pending vertex. This FIFO discipline preserves distance-layer ordering. A linked list can store the queue but does not by itself state the policy. Stack service is latest-first, while a binary tree is not the standard frontier discipline. Queue is therefore the specific suitable ADT among the choices.

Why each choice is right or wrong

A - Incorrect: Stack order selects the latest pending vertex and does not preserve the BFS layer invariant.

B - Correct: Queue FIFO ordering processes earlier distance layers before later discoveries, as BFS requires.

C - Incorrect: A linked list may represent a queue, but linked-list links alone specify no BFS service order.

D - Incorrect: A binary tree does not supply the standard FIFO pending-vertex discipline used by breadth-first search.

Primary note proof

Study-note section DSA41

> Mark the source when enqueuing it. Repeatedly dequeue a vertex, examine its neighbours, and enqueue each unvisited neighbour while marking it. Store predecessor[v] when discovering v if a path must be reconstructed. FIFO ensures vertices at distance d are explored before later distance layers.

Module passages - related reading

Computer Science MCQ practice collection · Question 426

Question 148 | AM0406

Which listed structures can create nodes using dynamic memory allocation in a linked-node implementation? Select all that apply.

A. Stack

B. Queue

C. Linked list

D. Binary tree

Hint

Compare the required operations, access order and representation metadata with each option.

Answer A, B, C, D: A. Stack; B. Queue; C. Linked list; D. Binary tree

Dynamic node allocation is a representation choice rather than a property exclusive to one ADT. A linked stack can allocate a node for each push, a linked queue for each enqueue, and a linked list for insertion. A pointer-based binary tree can allocate a leaf when attaching it. Array implementations also exist, but their existence does not prevent any of these structures from using dynamically allocated nodes.

Why each choice is right or wrong

A - Correct: A linked stack can allocate each new head node.

B - Correct: A linked queue can allocate each new rear node.

C - Correct: A linked list can grow by allocating nodes as needed.

D - Correct: A linked binary tree can allocate an inserted leaf.

Primary note proof

Study-note section DSA-S03

A linked binary-tree node stores a payload and two child pointers, one for the left child and one for the right child. A null child pointer means that child is absent; a root pointer gives access to the whole tree. In a dynamically allocated version, insertion can allocate a node and attach it through the appropriate child link.

Study-note section DSA08

Nodes allocated as needed grow dynamically, with pointer overhead and no direct index arithmetic.

Study-note section DSA11

Linked stacks achieve constant time by inserting and deleting at the head;

Study-note section DSA14

A linked implementation with head and tail supports both operations in constant time: append at tail, remove at head.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Data Structure and Algorithms module | PDF page 5 | lines 3-8

While adding a node to a list, the chain needs to be rearranged properly so that the each nodes are connected to each other. It is possible to add a node anywhere in the chain (at the start, middle or end). Let's consider adding a node at the end of the list:
Step 1: First we need to reserve a space for the new node using the keyword new.
Node *temp = new *Node; // Reserving a space for temporary pointer which points to new node;

Data Structure and Algorithms module | PDF page 6 | lines 43-45

II. Linked list (dynamic memory)
The linked list implementation of stack is adding items at the end of the chain (Push item) and deleting the end node of the list (Pop item).

Data Structure and Algorithms module | PDF page 8 | lines 35-37

III. Linked list implementation of enqueue and dequeue operations
Enqueue- is inserting a node at the end of a linked list
Dequeue- is deleting the first node in the list

Computer Science MCQ practice collection · Question 406

Question 149 | AM0407

Which structures admit an array-based representation? Array slots may contain payloads and integer links; for binary trees include complete trees stored with child-index formulas. Select all that apply.

A. Stack

B. Queue

C. Linked list

D. Binary tree

Hint

Compare the required operations, access order and representation metadata with each option.

Answer A, B, C, D: A. Stack; B. Queue; C. Linked list; D. Binary tree

An array stack uses a top index, while a circular queue uses front and size indices. A linked list can store its links as indices into an array rather than as pointers to separately allocated nodes. Complete binary trees also fit the indexed heap layout. Since the question asks whether representations exist and removes the subjective ease ranking, each of the four listed structures qualifies.

Why each choice is right or wrong

A - Correct: An array top index implements a stack.

B - Correct: Modulo-indexed slots implement a circular queue.

C - Correct: Array indices can encode list links.

D - Correct: Complete binary trees use the indexed heap layout.

Primary note proof

Study-note section DSA11

> With zero-based occupied slots, top=-1 is empty and top=C-1 is full.

Study-note section DSA15

> insertion slot is (front+size)%C.

Study-note section DSA08

> An array-linked list still follows links unless separately position-indexed.

Study-note section DSA23

> Zero-based array representation: root index 0, left=2i+1, right=2i+2, parent=floor((i-1)/2) for i>0. One-based representation uses children 2i,2i+1 and parent floor(i/2). A child exists only if its index is inside the current heap size.

I. Array implementation (static memory).
Push(n): Adding item at top
top is the current top of stack and n is its
maximum size
Begin
if (top == n) then stack is full;
else
top := top+1;
stack[top] := item;
end:
Pop(): removing item from stack top
remove top element from the stack and put it in
the item
Begin:
if (top == 0) then stack is empty;
else
item := stack[top];
top := top-1;
end;

Data Structure and Algorithms module | PDF page 7 | lines 18-23

I. Simple Array implementation (static memory).
A simple array structure can be used to implement enqueue & dequeue operations. Thus item will
be added at the end of the array whereas dequeue operation removes items from the front. In simple
array implementation, to add item it checks whether there is room at the rear or not. Therefore, even though there are free released spaces at the front ot the array the queue implementation might
generate overflow message. This is the key drawback to use simple array to implement Queue.

Data Structure and Algorithms module | PDF page 11 | lines 23-37

iii. Heap Sort
Heap sort operates by first converting the list in to a heap tree. Heap tree is a binary tree in which
each node has a value greater than both its children (if any). It uses a process called "adjust to accomplish its task (building a heap tree) whenever a value is larger than its parent. The time complexity of heap sort is O(nlogn).
Algorithm:
1. Construct a binary tree
• The root node corresponds to Data[0].
• If we consider the index associated with a particular node to be i, then the left child of this node corresponds to the element with index 2*i+1 and the right child corresponds to the element with index 2*i+2. If any or both of these elements do not exist in the array, then the corresponding child node does not exist either.
2. Construct the heap tree from initial binary tree using "adjust" process.

Sort by swapping the root value with the lowest, right most value and deleting the lowest, right most value and inserting the deleted value in the array in it proper position.

Question sources

Computer Science MCQ practice collection · Question 407

Question 150 | AM0408

Which listed representation provides direct next and previous links for walking a linear sequence forward and backward without retracing from its head? Use ordinary stack/queue interfaces and a binary tree without parent or traversal-thread links.

A. Stack

B. Queue

C. Doubly linked list

D. Binary tree

Hint

Compare the required operations, access order and representation metadata with each option.

Answer C: C. Doubly linked list

A doubly linked list retains the forward next link and adds a prev link to each node. Following the corresponding link moves directly to a neighboring node in either direction. Ordinary stack and queue interfaces do not expose this bidirectional traversal contract. A child-linked binary tree without parent or traversal threads also does not provide the specified previous/next linear-sequence links. The concrete list variant makes the guarantee precise.

Why each choice is right or wrong

A - Incorrect: A stack interface exposes its top, not a bidirectional traversal.

B - Incorrect: A queue interface exposes FIFO endpoints, not neighboring prev/next traversal.

C - Correct: Doubly linked nodes provide next and prev links.

D - Incorrect: The specified child-only tree lacks the requested linear previous/next links.

Primary note proof

Study-note section DSA10

Doubly linked nodes add prev; head and tail enable constant-time operations at both ends. Singly linked tail deletion still needs its predecessor. A circular tail links back to head; stop traversal on returning to the start, handling empty separately.

Study-note section DSA08

A singly linked node contains data and next. Head points to the first node; null ends a noncircular chain. Empty means head==null. Nodes allocated as needed grow dynamically, with pointer overhead and no direct index arithmetic.

1. Single Linked lists
It is a self-referential structure (Structures can hold pointers to instances of themselves), that allow
to create a chain of structs/Nodes with related data. Each node in the list contains data items and pointer to next node.
Basic Operations on Single Linked List
I. Creating Linked Lists
Structure definition of a single linked list need to contain both data items declaration and next node
pointer. In addition the first node pointer is essential to keep track of the list to perform various operations on the list. Thus, it is initialized to NULL first as the list is empty before any node added
to the chain.

Question sources

Computer Science MCQ practice collection · Question 408

Question 151 | AM0409

Which specified representations provide direct constant-time inspection of both first and last items in a nonempty sequence? A is a head-only linked stack, B a linked queue with front and rear pointers, C a linked list with head and tail, and D a child-linked binary tree with no cached endpoints. Select all that apply.

A. Head-only linked stack

B. Linked queue with front and rear

C. Linked list with head and tail

D. Child-linked binary tree without endpoint caches

Hint

Compare the algorithmic steps and access policy with the exact resource or ordering requirement in the question.

Answer B, C: B. Linked queue with front and rear; C. Linked list with head and tail

Maintaining references to both endpoints makes their items directly available without traversal. The specified linked queue retains front and rear, and the specified list retains head and tail, so both provide constant-time inspection. A head-only linked stack must follow links to reach its oldest item, and a generic child-linked tree without endpoint caches supplies no direct first/last guarantee. The answer follows the representations, not the generic names alone.

Why each choice is right or wrong

A - Incorrect: A head-only stack lacks a direct reference to its oldest node.

B - Correct: Front and rear pointers directly expose both endpoint items.

C - Correct: Head and tail pointers directly expose both endpoint items.

D - Incorrect: The unaugmented tree has no cached traversal endpoints.

Primary note proof

Study-note section DSA14

> A linked implementation with head and tail supports both operations in constant time: append at tail, remove at head.

Study-note section DSA10

> Doubly linked nodes add prev; head and tail enable constant-time operations at both ends.

Study-note section DSA11

> Linked stacks achieve constant time by inserting and deleting at the head;

Study-note section DSA-S03

> A linked binary-tree node stores a payload and two child pointers, one for the left child and one for the right child.

Question 152 | AM0410

Which data structure can be efficiently used for implementing undo and redo functionality in applications?

A. Stack

B. Queue

C. Linked list

D. Binary tree

Hint

Compare the algorithmic steps and access policy with the exact resource or ordering requirement in the question.

Answer A: Stack

Undo reverses the most recent action first, matching the source stack backtracking/reversal uses. A second stack can retain undone actions and reverse them again for redo. Evidence: assigned PDF pages 7, 6.

Why each choice is right or wrong

A - Correct: Push records actions; pop undoes the most recent; a second LIFO stack supports redo. See assigned PDF 7, 6.

B - Incorrect: FIFO would undo the oldest pending action first. See assigned PDF 7, 6.

C - Incorrect: A generic linked list can implement a stack but supplies no undo discipline by itself. See assigned PDF 7, 6.

D - Incorrect: A binary tree does not directly supply last-action-first reversal. See assigned PDF 7, 6.

Primary note proof

Study-note section DSA12

> Calls nest on a runtime stack; the latest call returns first. Bracket matching pushes opening brackets and matches each closing bracket against top. Reversal pushes input then pops it. Undo moves the latest action from undo to redo; redo moves it back. A new edit after undo normally clears redo. DFS and backtracking use the same latest-pending-choice discipline.

Question sources

Computer Science MCQ practice collection · Question 410

Question 153 | AM0411

A forward-only input sequence must be emitted in reverse order after all input is read, using one auxiliary ADT through its standard insertion/removal interface. Which ADT directly reverses the order without modifying the input links or adding a separate reversal algorithm?

A. Stack

B. Queue

C. Linked list

D. Binary tree

Hint

Compare the algorithmic steps and access policy with the exact resource or ordering requirement in the question.

Answer A: A. Stack

A stack accepts the sequence in arrival order and then removes the most recently inserted item first. Repeated pops therefore emit the complete reverse sequence directly. A FIFO queue preserves the original order. A generic linked list or binary tree does not itself specify the required removal discipline; reversing existing links would be a separate algorithm excluded by this question. The contract identifies the auxiliary reversal ADT.

Why each choice is right or wrong

A - Correct: Push all items and then pop to emit reverse order directly.

B - Incorrect: FIFO removal preserves input order.

C - Incorrect: A generic list has no inherent reverse-removal contract without an added algorithm or stack policy.

D - Incorrect: A generic tree supplies no required reverse-sequence service.

Primary note proof

Study-note section DSA12

> Calls nest on a runtime stack; the latest call returns first. Bracket matching pushes opening brackets and matches each closing bracket against top. Reversal pushes input then pops it. Undo moves the latest action from undo to redo; redo moves it back. A new edit after undo normally clears redo. DFS and backtracking use the same latest-pending-choice discipline.

Study-note section DSA11

> Stack policy is LIFO, equivalently FILO. Push inserts, pop removes/returns top, and peek only observes. With zero-based occupied slots, top=-1 is empty and top=C-1 is full. Check before A[++top]=x or returning A[top--].

Computer Science MCQ practice collection · Question 411

Question 154 | AM0412

Which abstract frontier service policy directly implements the latest-pending-work-first behavior of depth-first search? Choose the ADT, rather than a storage representation that could be given that policy.

A. Stack

B. Queue

C. Linked list

D. Binary tree

Hint

Compare the algorithmic steps and access policy with the exact resource or ordering requirement in the question.

Answer A: A. Stack

DFS finishes the most recently entered unfinished branch before returning to older pending work. A stack directly supplies this latest-pending-work-first rule. A queue would instead remove older pending items first, producing a breadth-first discipline under ordinary graph traversal. A linked list may implement a stack, but its links alone do not prescribe the frontier policy. A binary tree describes possible input relationships rather than the required pending-work ADT.

Why each choice is right or wrong

A - Correct: A stack directly supplies latest-pending-work-first service.

B - Incorrect: A FIFO queue retrieves older pending work first.

C - Incorrect: Linked-list storage alone does not specify a frontier service policy.

D - Incorrect: A binary tree is not the latest-pending-work service ADT.

Primary note proof

Study-note section DSA42

> Mark a vertex, then recursively visit each unmarked neighbour before continuing with later neighbours. An explicit stack can store pending work instead. Both implement latest-pending-work first; a queue would change that discipline. Marking prevents infinite repetition around graph cycles.

Which listed representations can implement a priority queue without retaining an unmodified LIFO or FIFO removal contract? Interpret D as a binary heap and C as an ordered or unordered list using extremum selection. Select all that apply.

A. Stack

B. Queue

C. Linked list

D. Binary tree organized as a binary heap

Hint

Compare the algorithmic steps and access policy with the exact resource or ordering requirement in the question.

Answer C, D: C. Linked list; D. Binary tree organized as a binary heap

A priority queue removes an item with an extreme priority key. An unordered list can scan for that extremum, while an ordered list maintains the relevant order during insertion. A binary heap supplies the same priority contract through heap order and logarithmic insertion/extraction. An unmodified stack or FIFO queue removes according to arrival position rather than priority. Thus the list and heap-shaped binary tree qualify under the stated algorithms.

Why each choice is right or wrong

A - Incorrect: An unmodified stack removes by recency rather than priority.

B - Incorrect: An unmodified FIFO queue removes by arrival order rather than priority.

C - Correct: Ordered or scanned lists can select the extreme priority.

D - Correct: A binary heap implements priority selection through heap order.

Primary note proof

Study-note section DSA17

A priority queue returns the smallest or largest priority key under its convention. Urgent patients may precede earlier arrivals. Insertions and extractions can interleave. Binary heaps support constant peek and logarithmic insert/extract.

Study-note section DSA17

Arrays and lists can also implement priority queues: an unordered sequence gives cheap insertion but linear extremum removal; an ordered sequence reverses that tradeoff. Equal priorities have no inherent FIFO guarantee. If stable service is required, compare (priority, arrival_counter). Choose the priority direction and tie rule before tracing.

These source passages provide context; the primary note proof is identified separately above.

Data Structure and Algorithms module | PDF page 8 | lines 40-45

Priority Queue:- is a queue where each data has an associated key provided at insertion time.
Application of Queue
Queue is goodfor fair (firstcome first served) ordering of actions. Some of queue applications:
• Print server- maintains a queue of print jobs
• Disk Driver- maintains a queue of disk input/output requests
• Task scheduler in multiprocessing system- maintains priority queues of processes

Data Structure and Algorithms module | PDF page 11 | lines 23-37

iii. Heap Sort
Heap sort operates by first converting the list in to a heap tree. Heap tree is a binary tree in which
each node has a value greater than both its children (if any). It uses a process called "adjust to accomplish its task (building a heap tree) whenever a value is larger than its parent. The time complexity of heap sort is O(nlogn).
Algorithm:
1. Construct a binary tree
• The root node corresponds to Data[0].
• If we consider the index associated with a particular node to be i, then the left child of this node corresponds to the element with index 2*i+1 and the right child corresponds to the element with index 2*i+2. If any or both of these elements do not exist in the array, then the corresponding child node does not exist either.
2. Construct the heap tree from initial binary tree using "adjust" process.
Sort by swapping the root value with the lowest, right most value and deleting the lowest, right most value and inserting the deleted value in the array in it proper position.

Computer Science MCQ practice collection · Question 413

Question 156 | AM0416

Which ordinary ADT restricts insertion to the rear and removal or peek to the front, preserving arrival order? Assume standard ADT interfaces rather than additional traversal operations.

A. Stack

B. Queue

C. Linked list

D. Binary tree

Hint

Compare the algorithmic steps and access policy with the exact resource or ordering requirement in the question.

Answer B: B. Queue

The ordinary queue inserts new items at its rear and removes or observes the front item. These restrictions produce FIFO service: earlier arrivals are removed before later arrivals. A stack uses a single top and LIFO order. A general linked list permits operations beyond these restricted endpoints, while a binary tree organizes hierarchical relationships. Specifying the exact operations resolves the original vague use of access.

Why each choice is right or wrong

A - Incorrect: A stack operates at one top using LIFO.

B - Correct: A queue has rear insertion and front removal/peek.

C - Incorrect: A general list does not restrict access to those two operations.

D - Incorrect: A binary tree does not have this FIFO endpoint contract.

Primary note proof

Study-note section DSA14

> An ordinary queue enqueues at rear, dequeues at front, and peeks at front. This is FIFO or first-come, first-served. A linked implementation with head and tail supports both operations in constant time: append at tail, remove at head. The first insertion sets both pointers; removing the last item clears both. With head alone, insertion must traverse to the tail.

Study-note section DSA11

> Stack policy is LIFO, equivalently FILO. Push inserts, pop removes/returns top, and peek only observes. With zero-based occupied slots, top=-1 is empty and top=C-1 is full. Check before A[++top]=x or returning A[top--].

Computer Science MCQ practice collection · Question 416

Question 157 | AM0417

Which structures can use nodes connected by pointers in a linked implementation? Do not require that every implementation use pointers. Select all that apply.

A. Stack

B. Queue

C. Linked list

D. Binary tree

Hint

Compare the algorithmic steps and access policy with the exact resource or ordering requirement in the question.

Answer A, B, C, D: A. Stack; B. Queue; C. Linked list; D. Binary tree

Pointer links can connect the nodes of several structures. A linked list uses next links, a linked stack operates at the chain head, and a linked queue maintains endpoint references around a chain. A pointer-based binary tree instead links child nodes along branches. All four therefore admit a node-and-pointer representation. Their alternative array layouts do not invalidate this existence claim about linked implementations.

Why each choice is right or wrong

A - Correct: A linked stack connects nodes through head-chain links.

B - Correct: A linked queue connects nodes and retains endpoint pointers.

C - Correct: A linked list directly uses node links.

D - Correct: A pointer-based tree links its child nodes.

Primary note proof

Study-note section DSA-S03

A linked binary-tree node stores a payload and two child pointers, one for the left child and one for the right child. A null child pointer means that child is absent; a root pointer gives access to the whole tree. In a dynamically allocated version, insertion can allocate a node and attach it through the appropriate child link.

Study-note section DSA01

Arrays or linked nodes can implement the same LIFO stack.

Study-note section DSA14

A linked implementation with head and tail supports both operations in constant time: append at tail, remove at head.

Study-note section DSA08

A singly linked node contains data and next.

Data Structure and Algorithms module | PDF page 4 | lines 16-25

1. Single Linked lists
It is a self-referential structure (Structures can hold pointers to instances of themselves), that allow
to create a chain of structs/Nodes with related data. Each node in the list contains data items and pointer to next node.
Basic Operations on Single Linked List
I. Creating Linked Lists
Structure definition of a single linked list need to contain both data items declaration and next node
pointer. In addition the first node pointer is essential to keep track of the list to perform various operations on the list. Thus, it is initialized to NULL first as the list is empty before any node added
to the chain.

Data Structure and Algorithms module | PDF page 9 | lines 19-25

• Binary tree: a tree in which each node has at most two children called left child and right child.
• Binary search tree (ordered binary tree): a binary tree that may be empty, but if it is not empty it
satisfies the following.
o Every node has a key and no two elements have the same key.
o The keys in the right subtree are larger than the keys in the root.
o The keys in the left subtree are smaller than the keys in the root.
o The left and the right subtrees are also binary search trees.

Computer Science MCQ practice collection · Question 417

Question 158 | AM0419

Which data structure allows elements to be inserted and removed from both ends?

A. Stack

B. Queue

C. Deque

D. Binary tree

Hint

Compare the algorithmic steps and access policy with the exact resource or ordering requirement in the question.

Answer C: Deque

A double-ended queue permits insertion and deletion at either end by definition. Evidence: assigned PDF pages 8.

Why each choice is right or wrong

A - Incorrect: Stack restricts both operations to one top. See assigned PDF 8.

B - Incorrect: Ordinary queue fixes insertion rear and deletion front. See assigned PDF 8.

C - Correct: Deque is expressly defined by operations at both ends. See assigned PDF 8.

D - Incorrect: A binary tree is a hierarchy, not a double-ended sequence. See assigned PDF 8.

Primary note proof

Study-note section DSA16

> A deque permits both-end insertion/removal without guaranteeing middle access. Endpoint-linked operations are constant but middle indexing is linear. A circular-array deque may support indexed access. Dequeue names removal; deque names the structure.

Computer Science MCQ practice collection · Question 419

Question 159 | AM0420

Which ADTs impose an item-removal order through their ordinary service contract? Use LIFO for stacks, FIFO for queues, and smallest-priority-first with FIFO ties for priority queues. A generic binary tree has no specified traversal. Select all that apply.

A. Stack

B. Queue

C. Priority queue

D. Binary tree

Hint

Compare the algorithmic steps and access policy with the exact resource or ordering requirement in the question.

Answer A, B, C: A. Stack; B. Queue; C. Priority queue

Stacks impose reverse arrival order and queues impose arrival order. A priority queue also imposes an order once the priority direction and tie rule are supplied; this version chooses the smallest priority and serves equal priorities FIFO. A generic binary tree supplies a shape with several possible traversals rather than a single inherent removal order. Consequently the three service ADTs qualify and the unspecified tree does not.

Why each choice is right or wrong

A - Correct: A stack imposes LIFO removal.

B - Correct: A queue imposes FIFO removal.

C - Correct: The stated priority and tie rules define priority-queue removal order.

D - Incorrect: A generic tree without a traversal has no single inherent removal order.

Primary note proof

Study-note section DSA11

> Stack policy is LIFO, equivalently FILO. Push inserts, pop removes/returns top, and peek only observes. With zero-based occupied slots, top=-1 is empty and top=C-1 is full. Check before A[++top]=x or returning A[top--].

Study-note section DSA14

> This is FIFO or first-come, first-served.

> a. Pre order traversal - traversing binary tree in the order of parent, left and right.
> b. Inorder traversal - traversing binary tree in the order of left, parent and right.
> c. Postorder traversal - traversing binary tree in the order of left, right and parent.

Question sources

Computer Science MCQ practice collection · Question 420

Question 160 | AM0421

Which is the most general listed binary-tree family defined by the following distinct-key invariant alone, without an additional balancing discipline: every key in a node's left subtree is smaller, and every key in its right subtree is larger?

A. AVL tree

B. Binary search tree

C. Red-black tree

D. B-tree

Hint

Compare the algorithmic steps and access policy with the exact resource or ordering requirement in the question.

Answer B: B. Binary search tree

The global left-smaller/right-larger invariant defines the binary search tree family. It applies to every descendant in each subtree, not only immediate children. AVL and red-black trees satisfy that ordering but impose additional balancing disciplines, so they are more specialized than the family requested. The binary-tree restriction also excludes a general B-tree. Asking for the most general family prevents those BST subclasses from becoming competing selections.

Why each choice is right or wrong

A - Incorrect: AVL adds balance requirements beyond the stated invariant.

B - Correct: BST is the general family defined by the strict subtree ordering alone.

C - Incorrect: Red-black trees add a balancing discipline beyond the stated invariant.

D - Incorrect: A general B-tree is not the requested binary-tree family.

Primary note proof

Study-note section DSA19

> With distinct keys, every key in a node's left subtree is smaller and every key in its right subtree is larger. Immediate-child comparisons alone are insufficient: root 10, left child 5, and 5's right child 12 violate the root's restriction. Duplicates require a separate count or placement policy.

Study-note section DSA22

> AVL balance factor is height(left)-height(right); every node must have factor -1,0 or 1. After insertion or deletion, update heights upward and rotate where necessary. LL imbalance needs a right rotation; RR needs left; LR rotates the left child left then the node right; RL is symmetric. Rotations preserve inorder key order.

Study-note section DSA-S03

> A B-tree is a balanced multiway search tree. Its allowed branching factor can exceed two, so a general B-tree is not the binary-tree family. Balanced describes a height discipline; it does not by itself restrict every node to two children.

Computer Science MCQ practice collection · Question 421

Question 161 | AM0422

Which data structure represents a hierarchical structure with a set of connected nodes?

A. Stack

B. Queue

C. Linked list

D. Binary tree

Hint

Compare the algorithmic steps and access policy with the exact resource or ordering requirement in the question.

Answer D: Binary tree

The module defines trees as hierarchical structures consisting of nodes and connecting edges. Binary trees specialize that hierarchy to two possible children. Evidence: assigned PDF pages 9.

Why each choice is right or wrong

A - Incorrect: Stack is a linear LIFO list. See assigned PDF 9, 9.

B - Incorrect: Queue is a linear FIFO list. See assigned PDF 9, 9.

C - Incorrect: Single linked list is a sequential chain. See assigned PDF 9, 9.

D - Correct: Binary tree is the hierarchical option. See assigned PDF 9, 9.

Primary note proof

Study-note section DSA18

A rooted tree has one parentless root and one parent per other node. It is connected and acyclic, has n-1 edges, and one path between any pair. Depth counts root-to-node edges; height is maximum depth. A single-node tree therefore has height zero. Leaves have no children.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Data Structure and Algorithms module | PDF page 9 | lines 3-13

A tree is a set of nodes and edges that connect pairs of nodes that connect pairs of nodes. It is an abstract model of a hierarchical structure. Rooted tree has the following structure:
• One node distinguished as root.
• Every node C except the root is connected from exactly other node P. P is C's parent, and C is one of C's children.
• There is a unique path from the root to the each node.
• The number of edges in a path is the length of the path.
Tree Terminologies:
• Root: a node without a parent.
• Internal node: a node with at least one child.
• External (leaf) node: a node without a child.

Data Structure and Algorithms module | PDF page 9 | lines 19-25

• Binary tree: a tree in which each node has at most two children called left child and right child.
• Binary search tree (ordered binary tree): a binary tree that may be empty, but if it is not empty it satisfies the following.
o Every node has a key and no two elements have the same key.
o The keys in the right subtree are larger than the keys in the root.
o The keys in the left subtree are smaller than the keys in the root.

Question 162 | AM0423

Which data structure allows efficient insertion and deletion at both ends?

A. Stack

B. Queue

C. Deque

D. Binary tree

Hint

Compare the algorithmic steps and access policy with the exact resource or ordering requirement in the question.

Answer C: Deque

The source deque definition allows insertion and deletion at either end. With endpoint references these are local operations; no middle search is needed. Evidence: assigned PDF pages 8.

Why each choice is right or wrong

A - Incorrect: Stack offers only the top endpoint. See assigned PDF 8.

B - Incorrect: Queue fixes rear insertion and front deletion, not both operations at both ends. See assigned PDF 8.

C - Correct: Deque supplies the requested two-ended operations. See assigned PDF 8.

D - Incorrect: Binary trees do not define two list ends. See assigned PDF 8.

Primary note proof

Study-note section DSA16

> A deque permits both-end insertion/removal without guaranteeing middle access. Endpoint-linked operations are constant but middle indexing is linear. A circular-array deque may support indexed access. Dequeue names removal; deque names the structure.

Study-note section DSA10

> Doubly linked nodes add prev; head and tail enable constant-time operations at both ends. Singly linked tail deletion still needs its predecessor. A circular tail links back to head; stop traversal on returning to the start, handling empty separately.

Question 163 | AM0425

Which data structure uses the concept of "first in, last out" to handle function calls and recursion?

A. Stack

B. Queue

C. Linked list

D. Binary tree

Hint

Compare the algorithmic steps and access policy with the exact resource or ordering requirement in the question.

Answer A: Stack

FILO is explicitly equivalent to LIFO, and the source names stack memory for calls and recursion. The most recent call returns before the earlier waiting caller. Evidence: assigned PDF pages 6.

Why each choice is right or wrong

A - Correct: Stack supplies FILO nesting for function frames. See assigned PDF 6, 6.

B - Incorrect: Queue is FIFO and would not match nested returns. See assigned PDF 6, 6.

C - Incorrect: A linked list can store frames but does not itself impose call order. See assigned PDF 6, 6.

D - Incorrect: A binary tree does not implement the stated endpoint discipline by its definition. See assigned PDF 6, 6.

Primary note proof

Study-note section DSA12

> Calls nest on a runtime stack; the latest call returns first. Bracket matching pushes opening brackets and matches each closing bracket against top. Reversal pushes input then pops it. Undo moves the latest action from undo to redo; redo moves it back. A new edit after undo normally clears redo. DFS and backtracking use the same latest-pending-choice discipline.

Study-note section DSA11

> Stack policy is LIFO, equivalently FILO.

> • Infix to Postfix Transformation
> • It is useful during the execution of recursive programs

• A Stack is useful for designing the compiler in operating system to store local variables inside a function block.
• A stack (memory stack) can be used in function calls including recursion.

Question sources

Computer Science MCQ practice collection · Question 425

Question 164 | AM0427

Which data structure is suitable for implementing depth-first search (DFS) algorithm?

A. Stack

B. Queue

C. Linked list

D. Binary tree

Hint

Compare the algorithmic steps and access policy with the exact resource or ordering requirement in the question.

Answer A: Stack

DSA42 describes recursively finishing an unvisited neighbor before returning to the parent. Explicit stack storage or the runtime call stack preserves this latest-pending-work-first behavior. A FIFO queue changes the exploration order. Linked lists can store frames but do not themselves define stack order, and a binary tree alone is not a frontier policy.

Why each choice is right or wrong

A - Correct: A stack stores pending frames or vertices so the latest unfinished branch is resumed first.

B - Incorrect: A queue serves the oldest pending work and changes the depth-first exploration discipline.

C - Incorrect: A linked list may store a stack, but its name alone supplies no depth-first service order.

D - Incorrect: A binary tree is not the standard pending-work ADT needed to preserve DFS return points.

Primary note proof

Study-note section DSA42

Mark a vertex, then recursively visit each unmarked neighbour before continuing with later neighbours. An explicit stack can store pending work instead. Both implement latest-pending-work first; a queue would change that discipline. Marking prevents infinite repetition around graph cycles.

Question sources

Computer Science MCQ practice collection · Question 427

Question 165 | AM0428

A capacity-limited cache evicts entries strictly in insertion order; cache hits do not change that order. Which ADT should maintain its eviction order? Ask for the service policy rather than a possible storage implementation.

A. Stack

B. Queue

C. Linked list

D. Binary tree

Hint

Compare the algorithmic steps and access policy with the exact resource or ordering requirement in the question.

Answer B: B. Queue

The earliest inserted resident entry must be evicted first, and hits do not move it. This is FIFO order, which a queue directly maintains through rear insertion and front removal. A linked list could be used to implement that queue but does not independently prescribe the eviction discipline. A stack reverses insertion order, and a generic binary tree provides no FIFO eviction contract.

Why each choice is right or wrong

A - Incorrect: LIFO would evict the most recent insertion rather than the oldest.

B - Correct: FIFO queue service matches insertion-order eviction.

C - Incorrect: A linked list is a possible representation but does not itself prescribe FIFO service.

D - Incorrect: A generic binary tree does not prescribe insertion-order eviction.

Primary note proof

Study-note section DSA27

> A dictionary or compiler symbol table can use hashing for expected constant lookup, or a balanced tree for logarithmic lookup with ordering. A bounded cache also needs eviction rules: FIFO uses a queue; LRU can combine hash lookup with a doubly linked recency list. Move a hit to the recent end and evict the least-recent end when full. No storage structure is universally best without operation and policy requirements.

Question 166 | AM0429

Which data structure is commonly used for implementing undo-redo functionality in text editors?

A. Stack

B. Queue

C. Linked list

D. Binary tree

Hint

Compare the algorithmic steps and access policy with the exact resource or ordering requirement in the question.

Answer A: Stack

Undo applies the inverse of the latest action, a LIFO operation. Keeping undone actions on another stack supports redo in the reverse order of undo. Evidence: assigned PDF pages 7, 6.

Why each choice is right or wrong

A - Correct: Two stacks implement the required action reversal and restoration ordering. See assigned PDF 7, 6.

B - Incorrect: FIFO would undo actions in their original order. See assigned PDF 7, 6.

C - Incorrect: A linked list can store history but needs an added stack discipline. See assigned PDF 7, 6.

D - Incorrect: A binary tree does not intrinsically select the latest action. See assigned PDF 7, 6.

Primary note proof

Study-note section DSA12

Calls nest on a runtime stack; the latest call returns first. Bracket matching pushes opening brackets and matches each closing bracket against top. Reversal pushes input then pops it. Undo moves the latest action from undo to redo; redo moves it back. A new edit after undo normally clears redo. DFS and backtracking use the same latest-pending-choice discipline.

Hint

Compare the algorithmic steps and access policy with the exact resource or ordering requirement in the question.

Answer A: Stack

Easy traversal here is interpreted as repeated access/removal by the defining ADT rule. A stack pops the most recently pushed remaining element first. Evidence: assigned PDF pages 6.

Why each choice is right or wrong

A - Correct: Stack expressly enforces last-in-first-out. See assigned PDF 6.

B - Incorrect: Queue expressly enforces first-in-first-out. See assigned PDF 6.

C - Incorrect: A linked list can emulate LIFO only after choosing an endpoint policy. See assigned PDF 6.

D - Incorrect: A binary tree traversal is determined by child order, not insertion recency. See assigned PDF 6.

Primary note proof

Study-note section DSA11

> Stack policy is LIFO, equivalently FILO. Push inserts, pop removes/returns top, and peek only observes. With zero-based occupied slots, top=-1 is empty and top=C-1 is full. Check before A[++top]=x or returning A[top--].

> “A stack is an ordered list in which all insertions and deletions are made at one end, called the top”. Stacks are sometimes referred to as Last in First out (LIFO) lists. Stacks have some useful terminology associated with them:
> • Push To add an element to the stack
> • Pop To remove an element from the stock
> • Peek To look at elements in the stack without removingthem
> • LIFO Refers to the last in, first out behavior of thestack
> • FILO (First in Last Out) : equivalent to LIFO

Question sources

Computer Science MCQ practice collection · Question 430

Question 168 | AM0431

Which specified representation supports constant-time insertion/deletion at either endpoint and constant-time indexed access to the logical middle item? Assume fixed capacity, no shifting or resizing, spare space for insertion, and a nonempty sequence for access.

A. Stack

B. Queue

C. Fixed-capacity circular-array deque

D. Binary tree

Hint

Compare the algorithmic steps and access policy with the exact resource or ordering requirement in the question.

Answer C: C. Fixed-capacity circular-array deque

A circular-array deque maps logical position k to a slot by adding the front index and reducing modulo capacity. That makes the middle item directly indexable. Endpoint insertions and deletions change only a slot and constant-size indices when no resize or shift occurs. A linked deque would not provide this indexing guarantee, so the array representation is explicit. The other ordinary ADT interfaces lack the combined operation set.

Why each choice is right or wrong

A - Incorrect: A stack does not expose both-end updates and middle indexing.

B - Incorrect: An ordinary queue does not expose all four endpoint operations or arbitrary middle access.

C - Correct: The fixed circular-array deque supplies endpoint updates and indexed middle access.

D - Incorrect: A generic binary tree lacks constant-time access by middle sequence position.

Primary note proof

Study-note section DSA16

> A deque permits both-end insertion/removal without guaranteeing middle access. Endpoint-linked operations are constant but middle indexing is linear. A circular-array deque may support indexed access. Dequeue names removal; deque names the structure.

Study-note section DSA15

> insertion slot is (front+size)%C.

Study-note section DSA02

> This arithmetic gives constant-time positional access in the usual RAM cost model.

Data Structure and Algorithms module | PDF page 8 | lines 38-40

> Deque (pronounced as Deck): is a Double Ended Queue in which insertion and deletion can occur at either end.
> Priority Queue:- is a queue where each data has an associated key provided at insertion time.

Data Structure and Algorithms module | PDF page 4 | lines 16-25

> 1. Single Linked lists
> It is a self-referential structure (Structures can hold pointers to instances of themselves), that allow
> to create a chain of structs/Nodes with related data. Each node in the list contains data items and pointer to next node.
> Basic Operations on Single Linked List
> I. Creating Linked Lists
> Structure definition of a single linked list need to contain both data items declaration and next node

pointer. In addition the first node pointer is essential to keep track of the list to perform various operations on the list. Thus, it is initialized to NULL first as the list is empty before any node added
to the chain.

Data Structure and Algorithms module | PDF page 7 | lines 10-16

“A queue is an ordered list in which all insertions at one end called REAR and deletions are made at another end called FRONT”. Queues are sometimes referred to as First in First out (FIFO) lists. The two basic operations are:
Enqueue - Inserts an item / element at the rear end of the queue. An overflow error occurs if the queue is full.
Dequeue - Removes an item / element from the front end of the queue, and returns it to the user. An underflow error occurs if the queue is empty.

Question sources

Computer Science MCQ practice collection · Question 431

Question 169 | AM0432

Which data structure is commonly used for implementing the undo operation in a text editor?

A. Stack

B. Queue

C. Linked list

D. Binary tree

Hint

Compare the algorithmic steps and access policy with the exact resource or ordering requirement in the question.

Answer A: Stack

The latest action must be reversed first, matching LIFO and the source backtracking application. Pushing action records and popping the latest implements that order. Evidence: assigned PDF pages 6, 7.

Why each choice is right or wrong

A - Correct: Top holds the latest pending action to undo. See assigned PDF 6, 7.

B - Incorrect: FIFO selects the oldest pending action instead. See assigned PDF 6, 7.

C - Incorrect: A generic linked list needs a chosen stack discipline to implement undo. See assigned PDF 6, 7.

D - Incorrect: A binary tree alone does not impose reverse chronology. See assigned PDF 6, 7.

Primary note proof

Study-note section DSA12

Calls nest on a runtime stack; the latest call returns first. Bracket matching pushes opening brackets and matches each closing bracket against top. Reversal pushes input then pops it. Undo moves the latest action from undo to redo; redo moves it back. A new edit after undo normally clears redo. DFS and backtracking use the same latest-pending-choice discipline.

1. Infix notation: A+(B*C) Equivalent Postfix notation ABC*+
2. Infix notation: (A+B)*C Equivalent Postfix notation AB+C*

Question sources

Computer Science MCQ practice collection · Question 432

Question 170 | AM0433

A bounded FIFO buffer must reuse freed array slots by wrapping indices modulo its fixed capacity, without shifting items. New insertions are rejected while full. Which listed term specifically names this storage representation?

A. Stack

B. Queue

C. Linked list

D. Circular buffer

Hint

Compare the algorithmic steps and access policy with the exact resource or ordering requirement in the question.

Answer D: D. Circular buffer

A circular buffer reuses its fixed slots by wrapping indices modulo capacity, so released positions can be used again without moving surviving items. The FIFO order is tracked logically rather than by requiring the front to remain at physical slot zero. Queue names the service ADT and can have other representations; it does not specifically identify this layout. Stack and linked list likewise do not name the stated circular-array representation.

Why each choice is right or wrong

A - Incorrect: A stack names LIFO service rather than the specified FIFO ring storage.

B - Incorrect: Queue names the FIFO ADT but does not specifically identify its storage layout.

C - Incorrect: A linked list does not name modulo-indexed circular array slots.

D - Correct: Circular buffer specifically names the stated fixed-slot wraparound representation.

Primary note proof

Study-note section DSA15

> A simple noncircular array queue may report overflow when rear reaches the final index despite released slots at the front. A circular queue reuses slots with modulo arithmetic. Use a count convention: front points to the next removal, size counts items, and insertion slot is (front+size)%C. Empty means size==0; full means size==C.

Study-note section DSA16

> Merging FIFO queues needs an explicit policy: append one sequence after another or alternate their fronts. Splitting by a predicate preserves each subgroup’s original order if each removed item is appended to its matching output queue. A fixed-capacity buffer also needs a full-policy choice: reject, block or overwrite. Capacity alone does not choose a policy.

> II. Circular array implementation of Queue Operations
> To overcome the above drawback of simple array implementation a circular array can be used, in
> which freed spaces are re-used to store data.

Data Structure and Algorithms module | PDF page 7 | lines 18-23

> I. Simple Array implementation (static memory).
> A simple array structure can be used to implement enqueue & dequeue operations. Thus item will
> be added at the end of the array whereas dequeue operation removes items from the front. In

simple
array implementation, to add item it checks whether there is room at the rear or not. Therefore, even though there are free released spaces at the front ot the array the queue implementation might
generate overflow message. This is the key drawback to use simple array to implement Queue.

Question sources

Computer Science MCQ practice collection · Question 433

Question 171 | AM0434

Which ordinary array sorting algorithms have tight worst-case time Theta(n^2)? Select all that apply. Use buffered mergesort, ordinary quicksort, standard insertion sort and iterative heapsort.

A. Merge sort

B. Quick sort

C. Insertion sort

D. Heap sort

Hint

Compare the algorithmic steps and access policy with the exact resource or ordering requirement in the question.

Answer B, C: B. Quick sort; C. Insertion sort

Repeated extreme partitions make ordinary quicksort accumulate quadratic work. Insertion sort on reverse input similarly accumulates quadratic prefix shifts. Buffered mergesort and iterative heapsort have n log n worst-case bounds instead, so they are not tightly quadratic even though quadratic is a valid looser upper bound. The explicit tight-bound question therefore selects quicksort and insertion alone in this primary option set.

Why each choice is right or wrong

A - Incorrect: Buffered mergesort has n log n worst growth.

B - Correct: Extreme quicksort partitions give tight quadratic worst growth.

C - Correct: Reverse-order insertion gives tight quadratic worst growth.

D - Incorrect: Iterative heapsort has an n log n worst bound.

Primary note proof

Study-note section DSA36

Balanced partitions give n log n work; repeated extreme pivots sum n+(n-1)+... to quadratic work.

Study-note section DSA34

Reverse order causes 1+2+...+(n-1) shifts: quadratic time.

Study-note section DSA37

There are logarithmically many levels with linear merge work per level, giving n log n time even on sorted input unless an optimization skips merges.

Study-note section DSA38

Building with bottom-up sinking is linear; repeated extraction gives O(n log n) worst time.

Data Structure and Algorithms module | PDF page 11 | lines 14-22

ii. Quick sort: is the fastest known algorithm. It uses divide and conquer strategy and in the worst case its complexity is O (n2). But its expected complexity is O(nlogn).
Algorithm:
1. Choose a pivot value (mostly the first element is taken as the pivot value)
2. Position the pivot element and partition the list so that:
• the left part has items less than or equal to the pivot value
• the right part has items greater than or equal to the pivot value
3. Recursively sort the left part
4. Recursively sort the right part

Data Structure and Algorithms module | PDF page 3 | lines 34-43

A. Insertion Sort
The most instinctive type of sorting algorithm; it finds the location for an element and move all others up, and insert the element to its right position. It starts with the left most two items and put
them in order. Then add 3rd
item to the relatively sorted portion and find its correct location
(relative to each other) swapping adjacent elements if they are out of order. In such it sorts all item
in the list.
• How many comparisons? => O(n2
) and How many swaps? => O(n2
)

Data Structure and Algorithms module | PDF page 11 | lines 38-44

iv. Merge sort
Merge sort uses divide and conquer strategy and its time complexity is O(nlogn).
Algorithm:
1. Divide the array in to two halves.
2. Recursively sort the first n/2 items.
3. Recursively sort the last n/2 items.
4. Merge sorted items (using an auxiliary array).

Data Structure and Algorithms module | PDF page 11 | lines 23-37

iii. Heap Sort
Heap sort operates by first converting the list in to a heap tree. Heap tree is a binary tree in which
each node has a value greater than both its children (if any). It uses a process called "adjust to accomplish its task (building a heap tree) whenever a value is larger than its parent. The time complexity of heap sort is O(nlogn).
Algorithm:
1. Construct a binary tree
• The root node corresponds to Data[0].
• If we consider the index associated with a particular node to be i, then the left child of this node corresponds to the element with index 2*i+1 and the right child corresponds to the element with index 2*i+2. If any or both of these elements do not exist in the array, then the corresponding child node does not exist either.
2. Construct the heap tree from initial binary tree using "adjust" process.
Sort by swapping the root value with the lowest, right most value and deleting the lowest, right most value and inserting the deleted value in the array in it proper position.

Data Structure and Algorithms module | PDF page 4 | lines 2-8

C. Bubble Sort
The simplest to implement but slowest algorithm on very large inputs. The algorithm loops through
the array from i=0 to n and swap adjacent elements if they are out of order bubbling or pushing out the smallest or largest element to its proper position.
• How many comparisons? => O(n2
) and How many swaps? => O(n2
)

Variant 1 | Alternative version 1

Which ordinary array sorting algorithms have tight worst-case time Theta(n^2)? Use strict-swap bubble sort, ordinary quicksort, buffered mergesort and standard insertion sort. Select all that apply.

A. Bubble sort

B. Quick sort

C. Merge sort

D. Insertion sort

Answer A, B, D: A. Bubble sort; B. Quick sort; D. Insertion sort

Bubble sort can require quadratically many adjacent comparisons, quicksort can accumulate quadratic work through extreme pivots, and insertion sort can perform quadratic shifts on reversed input. Buffered mergesort has n log n growth instead. The variant has bubble, quick, merge and insertion in its own label order, so its complete tight-quadratic selection is A, B and D.

Why each choice is right or wrong

A - Correct: Adjacent bubble passes can require quadratic work.

B - Correct: Extreme quicksort partitions can require quadratic work.

C - Incorrect: Buffered mergesort has n log n growth.

D - Correct: Reverse input causes quadratic insertion shifts.

Primary note proof

Study-note section DSA36

> Balanced partitions give n log n work; repeated extreme pivots sum n+(n-1)+... to quadratic work.

Study-note section DSA34

> Reverse order causes 1+2+...+(n-1) shifts: quadratic time.

Study-note section DSA32

> Quadratic worst/average work comes from up to n(n-1)/2 pair comparisons.

Study-note section DSA37

> There are logarithmically many levels with linear merge work per level, giving n log n time even on sorted input unless an optimization skips merges.

Computer Science MCQ practice collection · Question 434

Computer Science MCQ practice collection · Question 444

Question 172 | AM0435

Which sorting algorithm uses the divide-and-conquer strategy? Use ordinary array implementations, with radix sorting specifically meaning iterative least-significant-digit passes.

A. Bubble sort

B. Selection sort

C. Merge sort

D. Radix sort

Hint

Compare the algorithmic steps and access policy with the exact resource or ordering requirement in the question.

Answer C: C. Merge sort

Mergesort divides the array into two halves, recursively sorts them and merges their results, so it uses divide and conquer. Ordinary bubble sort uses adjacent passes and selection sort repeatedly selects a suffix minimum. The explicitly specified LSD radix method performs stable digit passes rather than recursive subproblem decomposition. This convention removes the possible confusion with MSD radix grouping while retaining the original primary answer.

Why each choice is right or wrong

A - Incorrect: Ordinary bubble sort uses adjacent passes rather than recursive decomposition.

B - Incorrect: Ordinary selection sort repeatedly places one suffix minimum.

C - Correct: Mergesort recursively solves smaller halves and combines their results.

D - Incorrect: The specified iterative LSD form uses digit passes rather than recursive divide and conquer.

Primary note proof

Study-note section DSA-S04

> Divide and conquer reduces a problem to smaller instances of the same kind, solves the required smaller instances and obtains the original result from them. Mergesort recursively sorts two halves and merges; quicksort partitions and recursively sorts the resulting ranges. This course also classifies binary search as divide and conquer: an ordered comparison selects the only half that can contain the target. This is different from simply repeating adjacent swaps, choosing successive minima, or making stable LSD digit passes.

Study-note section DSA39

> LSD radix sorting handles fixed-width digit keys by stably sorting least-significant digit first, then moving left. Stable intermediate passes preserve the ordering already established by less-significant digits. With d digits and radix r, counting-based passes take O(d(n+r)) time and O(n+r) auxiliary storage.

Study-note section DSA34

> Begin with the first element already sorted. For each remaining item, save its value, shift larger preceding values right, and insert it into the gap.

Variant 1 | Alternative version 1

Which ordinary sorting algorithms use divide and conquer by recursively sorting smaller subproblems? Select all that apply.

A. Bubble sort

B. Quick sort

C. Merge sort

D. Insertion sort

Answer B, C: B. Quick sort; C. Merge sort

Quicksort partitions around a pivot and recursively sorts the smaller ranges. Top-down mergesort recursively sorts halves and merges their results. Both therefore apply divide and conquer. Bubble sort's adjacent passes and ordinary insertion sort's growing sorted prefix do not use this recursive subproblem decomposition. The complete answer is B and C; the question requires multiple selection.

Why each choice is right or wrong

A - Incorrect: Bubble sorting repeatedly swaps adjacent inversions instead of recursively decomposing subinstances.

B - Correct: Quicksort partitions around a pivot and recursively sorts the smaller ranges.

C - Correct: Merge sort recursively sorts halves and combines their sorted results.

D - Incorrect: Ordinary insertion sort extends a sorted prefix instead of applying recursive divide and conquer.

Primary note proof

Study-note section DSA-S04

> Divide and conquer reduces a problem to smaller instances of the same kind, solves the required smaller instances and obtains the original result from them. Mergesort recursively sorts two halves and merges; quicksort partitions and recursively sorts the resulting ranges. This course also classifies binary search as divide and conquer: an ordered comparison selects the only half that can contain the target. This is different from simply repeating adjacent swaps, choosing successive minima, or making stable LSD digit passes.

Study-note section DSA36

> Choose a pivot, partition, then recursively sort the pieces. Balanced partitions give n log n work; repeated extreme pivots sum n+(n-1)+... to quadratic work. Expected n log n needs an input/random-pivot model. Random and median-of-three choices have different tradeoffs; neither is universally best.

Study-note section DSA37

> Split into halves, sort them, then merge by advancing the smaller current front. With left-first tie handling, equal keys retain order. Ordinary array merging needs a linear auxiliary buffer. There are logarithmically many levels with linear merge work per level, giving n log n time even on sorted input unless an optimization skips merges.

Study-note section DSA34

> Begin with the first element already sorted. For each remaining item, save its value, shift larger preceding values right, and insert it into the gap.

Computer Science MCQ practice collection · Question 445

Question 173 | AM0436

Which specified sorting implementations preserve the relative order of equal full keys? Use ordinary in-place quicksort, ordinary heapsort, LSD radix with stable digit passes, and mergesort with left-first ties. Select all that apply.

A. Quick sort

B. Heap sort

C. Radix sort

D. Merge sort

Hint

Compare the algorithmic steps and access policy with the exact resource or ordering requirement in the question.

Answer C, D: C. Radix sort; D. Merge sort

Stable LSD radix passes preserve the ordering already established by less significant digits. Equal full keys remain tied on every pass, so their relative order remains unchanged. Mergesort with left-first ties also preserves equal-key order while combining runs. Ordinary in-place quicksort and heapsort do not guarantee that stability because distant exchanges can reorder equal records. Hence both radix and merge qualify under the specified implementations.

Why each choice is right or wrong

A - Incorrect: Ordinary quicksort does not guarantee equal-key stability.

B - Incorrect: Long heap exchanges can reorder equal records.

C - Correct: Stable digit passes preserve the order of equal full keys.

D - Correct: Left-first merge ties preserve equal-key order.

Primary note proof

Study-note section DSA39

> Stable intermediate passes preserve the ordering already established by less-significant digits.

Study-note section DSA37

> With left-first tie handling, equal keys retain order.

Study-note section DSA38

> The method is generally unstable because long root-to-end exchanges can reorder equal keys.

Study-note section DSA31

stack usually log n average, n worst; unstable

Computer Science MCQ practice collection · Question 437

Question 175 | AM0439

Which searching algorithm is based on comparing the target value with elements at midpoints of the array?

A. Linear search

B. Binary search

C. Interpolation search

D. Depth-first search

Hint

Compare the algorithmic steps and access policy with the exact resource or ordering requirement in the question.

Answer B: Binary search

DSA29 computes the midpoint of the current ordered interval, compares it with the target, and discards the half that cannot contain the target. That is exactly the midpoint-based procedure in the stem. Linear search scans successive elements, interpolation estimates a position from values, and DFS follows graph branches rather than ordered-array midpoints.

Why each choice is right or wrong

A - Incorrect: Linear search compares successive elements rather than repeatedly choosing the midpoint of a shrinking ordered interval.

B - Correct: Binary search explicitly compares the target with the current interval midpoint and keeps one half.

C - Incorrect: Interpolation search estimates a probe from numeric values and their distribution, rather than always using the midpoint.

D - Incorrect: Depth-first search explores graph neighbors and branches, not ordered-array midpoint intervals.

Primary note proof

Study-note section DSA29

> On an ascending random-access sequence, set lo=0, hi=n-1. Compute mid=lo+(hi-lo)//2. Equality finishes; if target<A[mid], set hi=mid-1; otherwise set lo=mid+1. Stop unsuccessfully when lo>hi. Reverse comparisons for descending order. Comparable keys and valid finite bounds matter; fixed allocation before population is not an extra algorithmic requirement.

Study-note section DSA30

> Interpolation search estimates the index from numeric values: lo+(hi-lo)×(key-A[lo])/(A[hi]-A[lo]), rounded to a valid index. Guard equal endpoints and out-of-range targets. On sorted, suitably uniform data its expected probes can be O(log log n); pathological distributions can require linear time. Binary search gives a logarithmic worst bound without that distribution assumption.

• The computational time for this algorithm is proportional to log2 n.

Question sources

Computer Science MCQ practice collection · Question 439

Question 176 | AM0440

Which ordinary array-search algorithms require sorted input? For interpolation search also assume comparable numeric values and appropriate endpoint guards. Select all that apply.

A. Linear search

B. Binary search

C. Interpolation search

D. Depth-first search

Hint

Compare the algorithmic steps and access policy with the exact resource or ordering requirement in the question.

Answer B, C: B. Binary search; C. Interpolation search

Binary search relies on order to discard half the remaining candidate interval after a comparison. Interpolation search also relies on sorted numeric values when estimating a candidate position from endpoint values. Both therefore require sorted input, although their further assumptions differ. Linear search simply scans and permits unsorted data. DFS follows graph adjacency rather than relying on a sorted array-search interval.

Why each choice is right or wrong

A - Incorrect: Linear scanning permits unsorted data.

B - Correct: Binary interval elimination needs sorted order.

C - Correct: Interpolation index estimation also needs sorted input.

D - Incorrect: DFS follows graph connections and has no sorted-array requirement.

Primary note proof

Study-note section DSA29

On an ascending random-access sequence, set lo=0, hi=n-1. Compute mid=lo+(hi-lo)//2. Equality finishes; if target<A[mid], set hi=mid-1; otherwise set lo=mid+1. Stop unsuccessfully when lo>hi. Reverse comparisons for descending order. Comparable keys and valid finite bounds matter; fixed allocation before population is not an extra algorithmic requirement.

Study-note section DSA30

Interpolation search estimates the index from numeric values: lo+(hi-lo)×(key-A[lo])/(A[hi]-A[lo]), rounded to a valid index. Guard equal endpoints and out-of-range targets. On sorted, suitably uniform data its expected probes can be O(log log n); pathological distributions can require linear time. Binary search gives a logarithmic worst bound without that distribution assumption.

Study-note section DSA28

Unsorted data is allowed; sorted data is allowed too.

Question sources

Computer Science MCQ practice collection · Question 440

Question 177 | AM0441

Which searching algorithm works by comparing the target value with elements from the beginning of the array until a match is found?

A. Linear search

B. Binary search

C. Interpolation search

D. Depth-first search

Hint

Compare the algorithmic steps and access policy with the exact resource or ordering requirement in the question.

Answer A: A. Linear search

Linear search starts at the beginning and compares successive elements until a match or exhaustion. Binary search instead chooses a midpoint of an ordered interval, and interpolation search estimates a position from endpoint key values. Depth-first search follows an unvisited graph branch before returning. These positive procedural differences classify the alternatives without any appeal to an old module's omissions, so A remains the definite matching choice.

Why each choice is right or wrong

A - Correct: Linear search compares successive elements from the beginning.

B - Incorrect: Binary search probes a midpoint rather than scanning every successive position.

C - Incorrect: Interpolation search estimates a probe position from endpoint values.

D - Incorrect: DFS follows graph adjacency and unfinished branches rather than a beginning-to-end array scan.

Primary note proof

Study-note section DSA28

> Compare the target with successive elements until equal or exhausted.

Study-note section DSA29

> Compute mid=lo+(hi-lo)//2.

Study-note section DSA30

Question sources

Computer Science MCQ practice collection · Question 441

Question 178 | AM0442

Which searching algorithm is more efficient for uniformly distributed data in a sorted array?

A. Linear search

B. Binary search

C. Interpolation search

D. Depth-first search

Hint

Compare the algorithmic steps and access policy with the exact resource or ordering requirement in the question.

Answer C: Interpolation search under the stated uniform-data model.

DSA30 gives interpolation search expected O(log log n) probes on sorted, suitably uniform numeric data. Binary search has logarithmic worst-case probes without that distribution assumption, while linear search scans. The stem supplies the distribution and sortedness conditions that motivate interpolation. The expected advantage does not promise faster finite runs or logarithmic worst-case behavior on arbitrary distributions.

Why each choice is right or wrong

A - Incorrect: Linear search still examines successive elements and does not exploit uniform numeric distribution for sublinear expected probing.

B - Incorrect: Binary search gives logarithmic worst-case probing, but does not exploit uniform values for the stated expected advantage.

C - Correct: Interpolation estimates positions from uniformly distributed sorted numeric values, supporting the note's expected O(log log n) probes.

D - Incorrect: DFS explores graph or tree branches and is not the distribution-based ordered-array search described here.

Primary note proof

Study-note section DSA30

> Interpolation search estimates the index from numeric values: lo+(hi-lo)×(key-A[lo])/(A[hi]-A[lo]), rounded to a valid index. Guard equal endpoints and out-of-range targets. Question sources

Computer Science MCQ practice collection · Question 442

Question 179 | AM0443

Which named algorithms explore a graph or tree by following adjacency links to unvisited vertices, using branch-first or distance-layer-first traversal? Select all that apply.

A. Linear search

B. Binary search

C. Depth-first search

D. Breadth-first search

Hint

Compare the algorithmic steps and access policy with the exact resource or ordering requirement in the question.

Answer C, D: C. Depth-first search; D. Breadth-first search

DFS explores an unvisited branch before returning to later neighbors, using recursion or a stack. BFS instead processes a FIFO frontier so successive distance layers are explored in order. Both follow adjacency relationships and apply to trees as well as general graphs. Linear sequence scanning and binary interval search are different algorithms and do not implement these two adjacency-frontier traversal disciplines.

Why each choice is right or wrong

A - Incorrect: Linear sequence search does not implement the specified adjacency-frontier traversal.

B - Incorrect: Binary search eliminates ordered interval halves rather than following arbitrary adjacency.

C - Correct: DFS is branch-first adjacency traversal.

D - Correct: BFS is distance-layer-first adjacency traversal.

Primary note proof

Study-note section DSA41

> Mark the source when enqueuing it. Repeatedly dequeue a vertex, examine its neighbours, and enqueue each unvisited neighbour while marking it. Store predecessor[v] when discovering v if a path must be reconstructed. FIFO ensures vertices at distance d are explored before later distance layers.

Study-note section DSA42

> Mark a vertex, then recursively visit each unmarked neighbour before continuing with later neighbours. An explicit stack can store pending work instead. Both implement latest-pending-work first; a queue would change that discipline. Marking prevents infinite repetition around graph cycles.

III. Tree Traversing:
Binary search tree can be traversed in three ways.
a. Pre order traversal - traversing binary tree in the order of parent, left and right.
b. Inorder traversal - traversing binary tree in the order of left, parent and right.
c. Postorder traversal - traversing binary tree in the order of left, right and parent.

Question sources

Computer Science MCQ practice collection · Question 443

Question 180 | AM0446

Under a uniform random permutation of distinct keys, which ordinary sorting algorithms have tight average time Theta(n log n)? Use fixed-position-pivot quicksort, buffered mergesort without merge-skipping, and standard bubble/insertion implementations. Select all that apply.

A. Bubble sort

B. Quick sort

C. Merge sort

D. Insertion sort

Hint

Compare the algorithmic steps and access policy with the exact resource or ordering requirement in the question.

Answer B, C: B. Quick sort; C. Merge sort

The random-order model supplies the average-case assumption needed for ordinary quicksort's expected n log n work. Buffered mergesort performs n log n work across input orders, so its average has the same order. Bubble and insertion have quadratic ordinary average behavior under this random permutation model. Tight bounds and the stated distribution make quicksort and mergesort the complete selection, rather than leaving average cost unspecified. The DSA31 comparison table supplies the average-case entries used in this comparison.

Why each choice is right or wrong

A - Incorrect: Ordinary bubble sorting has quadratic random-order average work.

B - Correct: The stated random-input model gives quicksort expected n log n work.

C - Correct: Buffered mergesort has n log n work in every input order.

D - Incorrect: Ordinary insertion has quadratic random-order average work.

Primary note proof

Study-note section DSA31

n log n / n log n / n^2

Study-note section DSA31

n / n^2 / n^2

Study-note section DSA37

There are logarithmically many levels with linear merge work per level, giving n log n time even on sorted input unless an optimization skips merges.

Data Structure and Algorithms module | PDF page 11 | lines 14-22

ii. Quick sort: is the fastest known algorithm. It uses divide and conquer strategy and in the worst case its complexity is O (n2). But its expected complexity is O(nlogn).
Algorithm:
1. Choose a pivot value (mostly the first element is taken as the pivot value)
2. Position the pivot element and partition the list so that:
• the left part has items less than or equal to the pivot value
• the right part has items greater than or equal to the pivot value
3. Recursively sort the left part
4. Recursively sort the right part

Data Structure and Algorithms module | PDF page 11 | lines 38-44

iv. Merge sort
Merge sort uses divide and conquer strategy and its time complexity is O(nlogn).
Algorithm:
1. Divide the array in to two halves.
2. Recursively sort the first n/2 items.
3. Recursively sort the last n/2 items.
4. Merge sorted items (using an auxiliary array).

Data Structure and Algorithms module | PDF page 4 | lines 2-8

C. Bubble Sort
The simplest to implement but slowest algorithm on very large inputs. The algorithm loops through
the array from i=0 to n and swap adjacent elements if they are out of order bubbling or pushing out the smallest or largest element to its proper position.
• How many comparisons? => O(n2
) and How many swaps? => O(n2
)

Data Structure and Algorithms module | PDF page 3 | lines 34-43

A. Insertion Sort
The most instinctive type of sorting algorithm; it finds the location for an element and move all others up, and insert the element to its right position. It starts with the left most two items and put
them in order. Then add 3rd

item to the relatively sorted portion and find its correct location
(relative to each other) swapping adjacent elements if they are out of order. In such it sorts all item
in the list.
• How many comparisons? => O(n2
) and How many swaps? => O(n2
)

Question sources

Computer Science MCQ practice collection · Question 446

Question 181 | AM0447

Which sorting algorithm works by repeatedly selecting the smallest element from the unsorted portion and placing it at the beginning?

A. Bubble sort

B. Quick sort

C. Selection sort

D. Insertion sort

Hint

Compare the algorithmic steps and access policy with the exact resource or ordering requirement in the question.

Answer C: Selection sort

The source selection sort scans for the smallest remaining element and swaps it with the current first unsorted position. Evidence: assigned PDF pages 3, 4, 11.

Why each choice is right or wrong

A - Incorrect: Bubble pushes elements through adjacent swaps. See assigned PDF 3, 4, 11, 3.

B - Incorrect: Quicksort partitions by a pivot, not necessarily the minimum. See assigned PDF 3, 4, 11, 3.

C - Correct: Exactly the minimum-selection and placement procedure given. See assigned PDF 3, 4, 11, 3.

D - Incorrect: Insertion places the next encountered element into a sorted prefix. See assigned PDF 3, 4, 11, 3.

Primary note proof

Study-note section DSA33

At position i, scan the remaining suffix for its minimum, then exchange it with A[i]. There are n-1 meaningful placements and n(n-1)/2 comparisons regardless of initial order. At most n-1

exchanges of distinct positions are needed. A loop that also swaps the last item with itself can count n swap calls.

Question sources

Computer Science MCQ practice collection · Question 447

Question 182 | AM0448

Which ordinary array sorting algorithms are comparison sorts that use constant extra element storage inside the original array? Count recursive call stacks separately from element storage; use buffered mergesort for C. Select all that apply.

A. Bubble sort

B. Quick sort

C. Merge sort

D. Insertion sort

Hint

Compare the algorithmic steps and access policy with the exact resource or ordering requirement in the question.

Answer A, B, D: A. Bubble sort; B. Quick sort; D. Insertion sort

Bubble sort swaps adjacent keys and insertion sort shifts a prefix while retaining one saved key. Quicksort partitions within the same array using constant extra element storage. Its recursive frames are counted separately under the explicitly stated convention. Buffered mergesort instead allocates a linear merge buffer. Therefore bubble, quick and insertion meet the element-storage definition, while a total-auxiliary-space question would need to account for quicksort's stack as well.

Why each choice is right or wrong

A - Correct: Bubble compares and swaps within the original array.

B - Correct: Quicksort partitions in the array; its recursive stack is separately counted.

C - Incorrect: Buffered mergesort needs linear extra element storage.

D - Correct: Insertion compares and shifts within the original array with one saved key.

Primary note proof

Study-note section DSA32

> For ascending order, compare each adjacent pair and swap only when left>right.

Study-note section DSA34

> For each remaining item, save its value, shift larger preceding values right, and insert it into the gap.

Study-note section DSA36

> Quicksort normally rearranges in the same array but recursive storage can be linear in the worst case.

Study-note section DSA37

Ordinary array merging needs a linear auxiliary buffer.

Question sources

Computer Science MCQ practice collection · Question 448

Question 183 | AM0449

Which searching algorithm requires the input array to be sorted?

A. Linear search

B. Binary search

C. Hash search

D. Depth-first search

Hint

Compare the algorithmic steps and access policy with the exact resource or ordering requirement in the question.

Answer B: Binary search

DSA29 defines binary search over an ascending random-access sequence and reverses comparisons for descending data. Sortedness makes the half-elimination step sound. Linear scanning works without order; hashing needs a built table rather than sorted positions; DFS follows adjacency. Only Binary search among this option set requires a sorted input sequence for its ordinary operation.

Why each choice is right or wrong

A - Incorrect: Linear search explicitly permits unsorted data and compares items one after another.

B - Correct: Binary search relies on ordered values to determine which half can still contain the target.

C - Incorrect: Hash lookup needs a hash-table organization, not values arranged in sorted-array order.

D - Incorrect: Depth-first search follows graph or tree adjacency and does not require a sorted input array.

Primary note proof

Study-note section DSA29

On an ascending random-access sequence, set lo=0, hi=n-1. Compute mid=lo+(hi-lo)//2. Equality finishes; if target<A[mid], set hi=mid-1; otherwise set lo=mid+1. Stop unsuccessfully when lo>hi.

Reverse comparisons for descending order. Comparable keys and valid finite bounds matter; fixed allocation before population is not an extra algorithmic requirement.

Study-note section DSA25

Direct addressing reserves a position for every possible key in a finite universe U, costing Theta(|U|) slots. A hash table uses h(key) in 0..m-1 and stores only actual entries plus bucket capacity. With h(k)=k mod 6, key 36 has home address 0; collisions may move its final storage position.

Question sources

Computer Science MCQ practice collection · Question 449

Question 184 | AM0450

Which searching algorithm has a worst-case time complexity of O(log n)?

A. Linear search

B. Binary search

C. Hash search

D. Depth-first search

Hint

Compare the algorithmic steps and access policy with the exact resource or ordering requirement in the question.

Answer B: Binary search has logarithmic worst-case time.

DSA29 bounds binary-search probes by floor($\log_2 n$)+1 on nonempty random-access input. This supplies logarithmic worst-case time under constant-cost comparisons. Linear search may scan all items; adverse hash collisions may require linear work; DFS can inspect all vertices and edges. Their ordinary worst cases do not share binary search's logarithmic bound.

Why each choice is right or wrong

A - Incorrect: Linear search can inspect every item when the target is absent or last, giving linear worst-case time.

B - Correct: Each comparison discards about half the ordered interval, giving logarithmic worst-case probes.

C - Incorrect: Ordinary hash lookup can degrade to linear time under adverse collisions, despite expected constant-time performance.

D - Incorrect: DFS may visit all graph vertices and edges, rather than guarantee logarithmic worst-case work.

Primary note proof

Study-note section DSA29

> Worst probes are floor($\log_2 n$)+1 for n>0: seven for 100 keys, about twenty for one million. Iteration uses constant space; recursion uses logarithmic stack depth. Linked midpoint traversal loses logarithmic total time. Boundary variants retain a candidate rather than stopping at equality.

Study-note section DSA28

> Compare the target with successive elements until equal or exhausted. Unsorted data is allowed; sorted data is allowed too. A first-element match costs Theta(1). An absent target or last-position match needs n comparisons, giving Theta(n) worst time. Uniformly likely successful positions average (n+1)/2 comparisons, still linear.

Study-note section DSA26

> Separate chaining stores colliding entries in a bucket list. Load alpha=n/m is average chain length; expected operations are O(1+alpha) under suitable distribution assumptions, with O(n) worst cases. Open addressing keeps entries inside the array and probes until a key or an available slot is found.

Question sources

Computer Science MCQ practice collection · Question 450

Question 185 | AM0451

Which search compares a target with consecutive sequence elements at a fixed stride of one, stopping at the first match or after exhausting the sequence? No hashing or other preprocessing is used.

A. Linear search

B. Binary search

C. Hash search

D. Depth-first search

Hint

Compare the algorithmic steps and access policy with the exact resource or ordering requirement in the question.

Answer A: A. Linear search

The stated unit stride means the algorithm inspects successive elements in order. It stops early when a comparison matches or reports failure after the sequence is exhausted, which is linear search. Binary search uses a shrinking midpoint interval rather than consecutive positions. Hash search starts from computed addresses, and DFS follows graph adjacency. Specifying stride one distinguishes ordinary scanning from larger-step jump-search interpretations.

Why each choice is right or wrong

A - Correct: Linear search compares successive elements until a match or exhaustion.

B - Incorrect: Binary search chooses midpoints rather than every consecutive element.

C - Incorrect: Hash search uses computed addresses rather than the stated scan.

D - Incorrect: DFS follows graph adjacency rather than consecutive sequence positions.

Primary note proof

Study-note section DSA28

> Compare the target with successive elements until equal or exhausted. Unsorted data is allowed; sorted data is allowed too. A first-element match costs Theta(1). An absent target or last-position match needs n comparisons, giving Theta(n) worst time. Uniformly likely successful positions average (n+1)/2 comparisons, still linear.

Question sources

Computer Science MCQ practice collection · Question 451

Question 186 | AM0452

Which searching algorithm is suitable for unsorted arrays or lists?

A. Linear search

B. Binary search

C. Hash search

D. Depth-first search

Hint

Compare the algorithmic steps and access policy with the exact resource or ordering requirement in the question.

Answer A: Linear search directly searches an unsorted sequence.

DSA28 explicitly allows unsorted data for linear search: compare successive elements until the target is found or the sequence ends. Binary search requires sortedness. Hash lookup can be useful after building a table, but it does not directly search the supplied ordinary list without that preprocessing. DFS presumes graph or tree adjacency rather than a simple sequence query.

Why each choice is right or wrong

A - Correct: Linear search can inspect an unsorted array or list directly without sorting or building another structure.

B - Incorrect: Binary search needs ordering to safely eliminate half the remaining candidate positions.

C - Incorrect: Hash search needs a constructed hash table; the stem supplies an ordinary unsorted array or list.

D - Incorrect: DFS explores graph or tree adjacency and is not the direct unsorted-sequence scan described here.

Primary note proof

Study-note section DSA28

> Compare the target with successive elements until equal or exhausted. Unsorted data is allowed; sorted data is allowed too. A first-element match costs Theta(1). An absent target or last-position match needs n comparisons, giving Theta(n) worst time. Uniformly likely successful positions average (n+1)/2 comparisons, still linear.

Reverse comparisons for descending order. Comparable keys and valid finite bounds matter; fixed allocation before population is not an extra algorithmic requirement.

Study-note section DSA25

Direct addressing reserves a position for every possible key in a finite universe U, costing Theta(|U|) slots. A hash table uses h(key) in 0..m-1 and stores only actual entries plus bucket capacity. With h(k)=k mod 6, key 36 has home address 0; collisions may move its final storage position.

Question sources

Computer Science MCQ practice collection · Question 452

Question 187 | AM0453

Which searching algorithm is commonly used for traversing graphs or trees?

A. Linear search

B. Binary search

C. Hash search

D. Depth-first search

Hint

Compare the algorithmic steps and access policy with the exact resource or ordering requirement in the question.

Answer D: Depth-first search

DSA42 describes marking a vertex and recursively visiting each unmarked neighbor before resuming later neighbors. That procedure is standard depth-first traversal and applies to graphs and trees. Linear search scans a sequence, binary search uses an ordered interval, and hash search queries table addresses. None of those alternatives names the adjacency-following traversal in this option set.

Why each choice is right or wrong

A - Incorrect: Linear search scans sequence elements and is not the named adjacency-following graph/tree traversal.

B - Incorrect: Binary search reduces an ordered interval rather than visiting arbitrary graph or tree connections.

C - Incorrect: Hash search probes key-derived table addresses rather than traversing graph or tree edges.

D - Correct: DFS follows unvisited neighbors recursively or through an explicit stack, providing a standard traversal.

Primary note proof

Study-note section DSA42

> Mark a vertex, then recursively visit each unmarked neighbour before continuing with later neighbours. An explicit stack can store pending work instead. Both implement latest-pending-work first; a queue would change that discipline. Marking prevents infinite repetition around graph cycles.

> c. Postorder traversal - traversing binary tree in the order of left, right and parent.

Question sources

Computer Science MCQ practice collection · Question 453

Question 188 | AM0455

Which specified sorting implementations are stable? Use strict adjacent swaps for bubble, ordinary in-place quicksort, left-first merge ties, and insertion shifts of strictly larger keys only. Select all that apply.

A. Bubble sort

B. Quick sort

C. Merge sort

D. Insertion sort

Hint

Compare the algorithmic steps and access policy with the exact resource or ordering requirement in the question.

Answer A, C, D: A. Bubble sort; C. Merge sort; D. Insertion sort

Bubble sort's strict adjacent swaps do not exchange equal keys. Mergesort preserves ties by taking an equal key from the left run first. Insertion sort shifts only strictly larger keys, leaving equal earlier keys ahead of the inserted one. Those three mechanisms preserve relative equal-key order. Ordinary in-place quicksort does not guarantee it because partition exchanges can move equal records past one another.

Why each choice is right or wrong

A - Correct: Strict adjacent swaps preserve ties.

B - Incorrect: Ordinary quicksort does not guarantee equal-key order.

C - Correct: Left-first equal-key merging preserves ties.

D - Correct: Shifting only larger keys leaves equal earlier keys in place.

Primary note proof

Study-note section DSA32

> Strict swaps preserve equal-key order.

Study-note section DSA34

> Shift only strictly larger keys for stability.

Study-note section DSA37

> With left-first tie handling, equal keys retain order.

Study-note section DSA31

> stack usually log n average, n worst; unstable

Question sources

Computer Science MCQ practice collection · Question 455

Question 189 | AM0456

Which sorting algorithm is commonly used for small input sizes or partially sorted arrays?

A. Bubble sort

B. Quick sort

C. Merge sort

D. Insertion sort

Hint

Compare the algorithmic steps and access policy with the exact resource or ordering requirement in the question.

Answer D: Insertion sort

DSA34 explicitly favors insertion for small arrays or few inversions. Each inversion corresponds to shifting work, so nearly sorted data requires few shifts; sorted input is linear. This low-setup incremental algorithm is the conventional match among the choices. The other algorithms can sort these inputs, but their mere applicability does not identify the specific use case emphasized in the note.

Why each choice is right or wrong

A - Incorrect: Bubble can exploit early stopping but is not the note's specific small-array/few-inversions recommendation.

B - Incorrect: Quicksort incurs partition and recursive setup and is not the cited small-subarray method.

C - Incorrect: Ordinary merge sorting uses its merge levels and buffer even on nearly sorted input.

D - Correct: Insertion has low setup and few shifts on nearly sorted or small arrays.

Primary note proof

Study-note section DSA34

> Few inversions mean few shifts, favouring insertion for nearly sorted or small arrays. Shift only strictly larger keys for stability. A linked implementation saves array shifts but still must locate each insertion position.

Question sources

Computer Science MCQ practice collection · Question 456

Question 190 | AM0457

Which searching algorithm divides the search space into three parts at each step?

A. Linear search

B. Binary search

C. Ternary search

D. Depth-first search

Hint

Compare the algorithmic steps and access policy with the exact resource or ordering requirement in the question.

Answer C: Ternary search

DSA30 explicitly describes sorted-array ternary search as comparing two split points and retaining the relevant third. The three candidate regions give the technique its name. Binary search uses one midpoint and two regions, linear search scans successively, and DFS explores graph branches. Thus Ternary search uniquely matches the described three-part split.

Why each choice is right or wrong

A - Incorrect: Linear search advances through successive items and does not divide the remaining interval into thirds.

B - Incorrect: Binary search uses one midpoint and retains one of two halves, not one of three regions.

C - Correct: Ternary search uses two split points to divide the ordered search interval into three candidate parts.

D - Incorrect: DFS explores graph or tree branches rather than repeatedly trisecting an ordered search interval.

Primary note proof

Study-note section DSA30

> Sorted-array ternary search compares two split points and keeps the relevant third, still logarithmic. Jump search probes block boundaries then scans within a block. Regular intervals could mean unit-step scanning or larger jumps. Interpolation also needs sortedness, so prerequisite questions can overlap binary search.

Question sources

Computer Science MCQ practice collection · Question 457

Question 191 | AM0458

Which ordinary array sorting implementations use O(1) total auxiliary space in both best and average cases? Count live recursive frames; use recursive quicksort without tail-call elimination and buffered mergesort. Select all that apply.

A. Bubble sort

B. Quick sort

C. Merge sort

D. Insertion sort

Hint

Compare the algorithmic steps and access policy with the exact resource or ordering requirement in the question.

Answer A, D: A. Bubble sort; D. Insertion sort

The DSA31 table gives bubble and insertion constant extra storage across input cases. Their iterative forms retain only a fixed number of indices and temporaries, so total auxiliary space stays constant. The same table gives ordinary recursive quicksort a logarithmic average stack, and buffered mergesort needs a linear auxiliary array. Counting all live frames and buffers therefore leaves exactly bubble and insertion as the qualifying choices.

Why each choice is right or wrong

A - Correct: Bubble uses fixed temporary storage across cases.

B - Incorrect: The recursive quicksort stack is not constant in its ordinary average case.

C - Incorrect: Buffered mergesort uses linear auxiliary storage.

D - Correct: Insertion needs a saved key and fixed-size indices.

Primary note proof

Study-note section DSA32

For ascending order, compare each adjacent pair and swap only when left>right.

Study-note section DSA34

For each remaining item, save its value, shift larger preceding values right, and insert it into the gap.

Study-note section DSA31

stack usually log n average, n worst; unstable

Study-note section DSA37

Ordinary array merging needs a linear auxiliary buffer.

Question sources

Computer Science MCQ practice collection · Question 458

Question 192 | AM0459

Which searching algorithm is based on the principle of divide-and-conquer?

A. Linear search

B. Binary search

C. Hash search

D. Depth-first search

Hint

Compare the algorithmic steps and access policy with the exact resource or ordering requirement in the question.

Answer B: Binary search

DSA29 compares the middle value with the target and continues only in the half that can contain it. This solves a smaller instance of the same ordered-search problem and is the divide-and-conquer reduction intended here. Linear scanning removes one candidate at a time, hashing computes addresses, and DFS follows adjacency without this ordered half-elimination rule.

Why each choice is right or wrong

A - Incorrect: Linear search scans successive candidates rather than repeatedly solving a half-size ordered-search instance.

B - Correct: Binary search divides the ordered interval and continues in the only half that can contain the target.

C - Incorrect: Hash search derives an address and resolves collisions rather than recursively dividing an ordered problem.

D - Incorrect: DFS follows adjacency branches and does not inherently apply the ordered half-elimination strategy described here.

Primary note proof

Study-note section DSA-S04

Divide and conquer reduces a problem to smaller instances of the same kind, solves the required smaller instances and obtains the original result from them. Mergesort recursively sorts two halves and merges; quicksort partitions and recursively sorts the resulting ranges. This course also classifies binary search as divide and conquer: an ordered comparison selects the only half that can contain the target. This is different from simply repeating adjacent swaps, choosing successive minima, or making stable LSD digit passes.

Study-note section DSA29

On an ascending random-access sequence, set lo=0, hi=n-1. Compute mid=lo+(hi-lo)//2. Equality finishes; if target<A[mid], set hi=mid-1; otherwise set lo=mid+1. Stop unsuccessfully when lo>hi. Reverse comparisons for descending order. Comparable keys and valid finite bounds matter; fixed allocation before population is not an extra algorithmic requirement.

Question 193 | AM0460

Which sorting algorithm has the worst-case time complexity of O(n log n)?

A. Bubble sort

B. Quick sort

C. Merge sort

D. Insertion sort

Hint

Compare the algorithmic steps and access policy with the exact resource or ordering requirement in the question.

Answer C: Merge sort

Ordinary merge combines n items over log n levels, giving n log n even in the worst case. The other offered algorithms have quadratic adverse-input work. Evidence: assigned PDF pages 4, 11, 3.

Why each choice is right or wrong

A - Incorrect: Bubble can perform quadratic passes/exchanges. See assigned PDF 4, 11, 11, 3.

B - Incorrect: Quicksort is explicitly quadratic in the worst case. See assigned PDF 4, 11, 11, 3.

C - Correct: Merge is explicitly n log n. See assigned PDF 4, 11, 11, 3.

D - Incorrect: Reverse-order insertion requires quadratic movement. See assigned PDF 4, 11, 11, 3.

Primary note proof

Study-note section DSA37

> There are logarithmically many levels with linear merge work per level, giving n log n time even on sorted input unless an optimization skips merges.

Study-note section DSA36

> Balanced partitions give n log n work; repeated extreme pivots sum n+(n-1)+... to quadratic work.

Study-note section DSA34

> Reverse order causes 1+2+...+(n-1) shifts: quadratic time.

Study-note section DSA32

> Quadratic worst/average work comes from up to n(n-1)/2 pair comparisons.

Question sources

Computer Science MCQ practice collection · Question 460

Question 194 | AM0461

Which sorting algorithm is efficient for sorting data in external memory (hard disks)?

A. Bubble sort

B. Quick sort

C. Merge sort

D. Insertion sort

Hint

Compare the algorithmic steps and access policy with the exact resource or ordering requirement in the question.

Answer C: Merge sort using buffered external runs.

DSA37 describes external sorting by building sorted runs and merging buffered disk streams to reduce I/O. Merge sort naturally supports that strategy even when the whole dataset does not fit RAM. Bubble and insertion sorting repeatedly move local data, while ordinary quicksort assumes partition access rather than the external sequential-run pattern specified here.

Why each choice is right or wrong

A - Incorrect: Bubble sort's repeated adjacent passes do not provide the buffered sorted-run strategy used for efficient external sorting.

B - Incorrect: Ordinary quicksort partitioning is not the sequential buffered-run merging strategy identified for external data here.

C - Correct: Merge sorting combines buffered sorted runs sequentially and is directly suited to disk-backed external sorting.

D - Incorrect: Insertion sort's repeated local insertion work does not provide the note's efficient external-run merging mechanism.

Primary note proof

Study-note section DSA37

> Top-down mergesort recurses; bottom-up merges runs of widths 1,2,4,... iteratively. In-place merging variants exist with different tradeoffs; linear merge names an operation, not a universally standardized sort variant. Internal sorting fits the working dataset in memory. External sorting builds sorted runs and merges buffered streams from disk, aiming to reduce I/O. Reverse order alone does not characterize maximum merge comparisons.

Question sources

Computer Science MCQ practice collection · Question 461

Question 195 | AM0462

A large dataset has an equality-key index implemented by a hash table with suitable key distribution and bounded load. No ordered or range queries are needed. Which listed search uses this index for expected constant-time lookup?

A. Linear search

B. Binary search

C. Hash search

D. Depth-first search

Hint

Compare the algorithmic steps and access policy with the exact resource or ordering requirement in the question.

Answer C: C. Hash search

Hash lookup computes a bucket or probe start from the key and uses the existing index to locate an equality match. With suitable distribution and bounded load, the note gives expected constant lookup. The important assumptions are the index and workload, rather than dataset size alone. Linear scanning ignores the index, binary search needs an ordered interval, and DFS follows graph relationships instead of this equality-key access structure.

Why each choice is right or wrong

A - Incorrect: A scan can inspect linearly many records and does not use the hash index.

B - Incorrect: Binary search uses an ordered interval rather than this index.

C - Correct: Hash search uses the stated index with expected constant lookup.

D - Incorrect: DFS follows graph connections rather than the equality-key index.

Primary note proof

Study-note section DSA26

Separate chaining stores colliding entries in a bucket list. Load alpha=n/m is average chain length; expected operations are O(1+alpha) under suitable distribution assumptions, with O(n) worst cases. Open addressing keeps entries inside the array and probes until a key or an available slot is found.

Study-note section DSA27

A dictionary or compiler symbol table can use hashing for expected constant lookup, or a balanced tree for logarithmic lookup with ordering. A bounded cache also needs eviction rules: FIFO uses a queue; LRU can combine hash lookup with a doubly linked recency list. Move a hit to the recent end and evict the least-recent end when full. No storage structure is universally best without operation and policy requirements.

Computer Science MCQ practice collection · Question 462

Question 196 | AM0463

For a uniform random permutation of distinct keys, which listed ordinary algorithms have the smallest tight average-case growth order? Use fixed-position-pivot quicksort, buffered mergesort without merge-skipping, and standard bubble/insertion. Select all algorithms tied for the smallest order.

A. Bubble sort

B. Quick sort

C. Merge sort

D. Insertion sort

Hint

Compare the algorithmic steps and access policy with the exact resource or ordering requirement in the question.

Answer B, C: B. Quick sort; C. Merge sort

Under the stated random-input model, ordinary quicksort has expected n log n work. Buffered mergesort performs n log n work in every order, so its average shares that order. Bubble and insertion have quadratic average work on random permutations. Quicksort and mergesort therefore tie for the smallest asymptotic average order among these options; the question does not ask for a measured running-time ranking between the tied methods. The DSA31 comparison table supplies the average-case entries used in this comparison.

Why each choice is right or wrong

A - Incorrect: Quadratic average growth is larger than n log n.

B - Correct: Expected n log n ties for the smallest listed average growth.

C - Correct: n log n across orders ties for the smallest listed average growth.

D - Incorrect: Quadratic average growth is larger than n log n.

Primary note proof

Study-note section DSA31

> n log n / n log n / n^2

Study-note section DSA31

> n / n^2 / n^2

Study-note section DSA37

> There are logarithmically many levels with linear merge work per level, giving n log n time even on sorted input unless an optimization skips merges.

Question sources

Computer Science MCQ practice collection · Question 463

Question 197 | AM0464

Which data structure is best suited for implementing a dictionary with fast lookup and insertion?

A. Array

B. Linked list

C. Hash table

D. Stack

Hint

Compare the algorithmic steps and access policy with the exact resource or ordering requirement in the question.

Answer C: Hash table for expected fast dictionary lookup and insertion.

DSA27 explicitly names hashing as a dictionary implementation with expected constant lookup. DSA26 qualifies this by a suitable distribution and controlled load; insertion is likewise expected fast under those conditions. Arrays and linked lists lack the same ordinary key-lookup performance, while a stack specifies LIFO access. This is an expected-performance recommendation, not a universal worst-case guarantee.

Why each choice is right or wrong

A - Incorrect: An ordinary array lacks key-derived lookup and may require scanning or maintaining a sorted order with costly insertions.

B - Incorrect: An ordinary linked list needs traversal to locate an arbitrary dictionary key, giving linear worst-case lookup.

C - Correct: A well-sized hash table offers expected fast key lookup and insertion under suitable hashing and load assumptions.

D - Incorrect: A stack exposes LIFO top operations and does not directly provide efficient arbitrary-key dictionary lookup.

Primary note proof

Study-note section DSA26

> Separate chaining stores colliding entries in a bucket list. Load alpha=n/m is average chain length; expected operations are O(1+alpha) under suitable distribution assumptions, with O(n) worst cases. Open addressing keeps entries inside the array and probes until a key or an available slot is found.

Study-note section DSA27

> A dictionary or compiler symbol table can use hashing for expected constant lookup, or a balanced tree for logarithmic lookup with ordering. A bounded cache also needs eviction rules: FIFO uses a queue; LRU can combine hash lookup with a doubly linked recency list. Move a hit to the recent end and evict the least-recent end when full. No storage structure is universally best without operation and policy requirements.

> 1. Single Linked lists
> It is a self-referential structure (Structures can hold pointers to instances of themselves), that allow
> to create a chain of structs/Nodes with related data. Each node in the list contains data items and pointer to next node.

Basic Operations on Single Linked List
I. Creating Linked Lists
Structure definition of a single linked list need to contain both data items declaration and next node
pointer. In addition the first node pointer is essential to keep track of the list to perform various operations on the list. Thus, it is initialized to NULL first as the list is empty before any node added
to the chain.

Data Structure and Algorithms module | PDF page 6 | lines 15-22

“A stack is an ordered list in which all insertions and deletions are made at one end, called the top”. Stacks are sometimes referred to as Last in First out (LIFO) lists. Stacks have some useful terminology associated with them:
• Push To add an element to the stack
• Pop To remove an element from the stock
• Peek To look at elements in the stack without removingthem
• LIFO Refers to the last in, first out behavior of thestack
• FILO (First in Last Out) : equivalent to LIFO

Question sources

Computer Science MCQ practice collection · Question 464

Question 198 | AM0465

Which listed algorithm guarantees shortest paths from one source to all reachable vertices for arbitrary graphs with nonnegative edge weights that may differ? Compare the standard forms of the listed algorithms.

A. Depth-first search

B. Breadth-first search

C. Dijkstra's algorithm

D. Prim's algorithm

Hint

Compare the algorithmic steps and access policy with the exact resource or ordering requirement in the question.

Answer C: C. Dijkstra's algorithm

Standard Dijkstra repeatedly finalizes the unsettled vertex with the smallest tentative distance and relaxes its outgoing edges. Nonnegative edge weights justify this shortest-path procedure even when different edges have different costs. BFS minimizes edge count and is sufficient when edge costs are equal, which is weaker than the stated guarantee. DFS supplies reachability paths, while Prim minimizes total spanning-tree cost rather than source-to-vertex route lengths.

Why each choice is right or wrong

A - Incorrect: A DFS path need not have minimum total weight.

B - Incorrect: BFS minimizes edge count and does not guarantee minimum weight for arbitrary differing costs.

C - Correct: Dijkstra guarantees source shortest paths under nonnegative weights.

D - Incorrect: Prim solves the spanning-tree objective rather than source shortest paths.

Primary note proof

Study-note section DSA43

> For nonnegative weights, standard Dijkstra initializes source distance zero and others infinity, repeatedly finalizes the unsettled vertex with smallest distance, and relaxes each outgoing edge: dist[v]=min(dist[v],dist[u]+w(u,v)). A min-priority queue supports the next choice. BFS is enough when every edge has equal cost; negative edges require another justified method, such as Bellman-Ford.

Study-note section DSA41

> BFS finds minimum-edge paths in unweighted graphs, not arbitrary minimum-weight paths.

Question sources

Computer Science MCQ practice collection · Question 465

Question 199 | AM0466

Which listed standard representations directly implement stack push/pop at an array top or linked-chain head, without simulating LIFO through another ADT? Select all that apply.

A. Array

B. Linked list

C. Queue

D. Tree

Hint

Compare the algorithmic steps and access policy with the exact resource or ordering requirement in the question.

Answer A, B: A. Array; B. Linked list

The array representation maintains a top index and changes it when pushing or popping. The linked representation inserts and removes at the chain head, so the latest node is also the next one removed. Both directly implement LIFO with ordinary constant endpoint operations. A queue has FIFO service, while a generic tree has no stack-top contract; emulations through those ADTs are outside this representation question.

Why each choice is right or wrong

A - Correct: An array with a top index directly implements stack operations.

B - Correct: A linked chain with head insertion/removal directly implements stack operations.

C - Incorrect: An ordinary FIFO queue is not a direct stack representation.

D - Incorrect: A generic tree does not supply the specified stack-top representation.

Primary note proof

Study-note section DSA11

> Stack policy is LIFO, equivalently FILO. Push inserts, pop removes/returns top, and peek only observes. With zero-based occupied slots, top=-1 is empty and top=C-1 is full. Check before A[++top]=x or returning A[top--].

Study-note section DSA01

> Arrays or linked nodes can implement the same LIFO stack.

> I. Array implementation (static memory).
> Push(n): Adding item at top
> top is the current top of stack and n is its
> maximum size

```
Begin
if (top == n) then stack is full;
else
top := top+1;
stack[top] := item;
end:
Pop(): removing item from stack top
remove top element from the stack and put it in
the item
Begin:
if (top == 0) then stack is empty;
else
item := stack[top];
top := top-1;
end;
```

Data Structure and Algorithms module | PDF page 6 | lines 43-45

II. Linked list (dynamic memory)
The linked list implementation of stack is adding items at the end of the chain (Push item) and deleting the end node of the list (Pop item).

Question sources

Computer Science MCQ practice collection · Question 466

Question 200 | AM0467

Given a consistent comparator on a priority field, which listed comparison sorting algorithms can sort records by that field? No particular extraction mechanism or equal-priority stability is required. Select all that apply.

A. Bubble sort

B. Quick sort

C. Merge sort

D. Heap sort

Hint

Compare the algorithmic steps and access policy with the exact resource or ordering requirement in the question.

Answer A, B, C, D: A. Bubble sort; B. Quick sort; C. Merge sort; D. Heap sort

Priority is a key field that any comparison sort can use through a consistent comparator. Bubble compares neighboring priorities, quicksort partitions by priority, mergesort combines priority-ordered runs, and heapsort repeatedly places a priority extreme. Since no heap-extraction mechanism or tie-stability condition is required, every listed algorithm can produce the requested priority ordering. Priorities alone do not identify one unique sorting method.

Why each choice is right or wrong

A - Correct: Bubble can compare adjacent priority fields.

B - Correct: Quicksort can partition with the priority comparator.

C - Correct: Mergesort can merge runs by the priority field.

D - Correct: Heapsort can extract priority extremes.

Primary note proof

Study-note section DSA38

> It is not uniquely the method for sorting by priorities: any comparison sort can compare a priority field. Heap extraction is its distinctive mechanism.

ii. Quick sort: is the fastest known algorithm. It uses divide and conquer strategy and in the worst case its complexity is O (n2). But its expected complexity is O(nlogn).
Algorithm:
1. Choose a pivot value (mostly the first element is taken as the pivot value)
2. Position the pivot element and partition the list so that:
• the left part has items less than or equal to the pivot value
• the right part has items greater than or equal to the pivot value
3. Recursively sort the left part
4. Recursively sort the right part

Data Structure and Algorithms module | PDF page 11 | lines 38-44

iv. Merge sort
Merge sort uses divide and conquer strategy and its time complexity is O(nlogn).
Algorithm:
1. Divide the array in to two halves.
2. Recursively sort the first n/2 items.
3. Recursively sort the last n/2 items.
4. Merge sorted items (using an auxiliary array).

Data Structure and Algorithms module | PDF page 4 | lines 2-8

C. Bubble Sort
The simplest to implement but slowest algorithm on very large inputs. The algorithm loops through
the array from i=0 to n and swap adjacent elements if they are out of order bubbling or pushing out the smallest or largest element to its proper position.
• How many comparisons? => O(n2
) and How many swaps? => O(n2
)

Question sources

Computer Science MCQ practice collection · Question 467

Question 201 | AM0468

An LRU cache already has hash lookup that returns a reference to the matching entry. Which listed representation should maintain recency order so a known entry can be removed and moved to the recent end in constant time, with eviction at the least-recent end?

A. Array

B. Doubly linked list with head and tail

C. Hash table

D. Queue

Hint

State the representation and cost model, then count the operations or storage demanded by the question.

Answer B: B. Doubly linked list with head and tail

The hash index handles locating an entry, while the recency component must unlink a known entry and reconnect it at the recent end. A doubly linked list supplies both neighboring links for that constant-time removal and maintains endpoints for movement and eviction. An array would generally shift entries, a bare hash table does not supply recency order, and an ordinary FIFO queue cannot remove an arbitrary known interior entry.

Why each choice is right or wrong

A - Incorrect: Maintaining array recency order generally requires shifts.

B - Correct: A doubly linked recency list supports unlinking a known node and endpoint updates.

C - Incorrect: The existing hash index handles lookup but does not itself maintain LRU order.

D - Incorrect: An ordinary queue lacks arbitrary known-interior-node removal.

Primary note proof

Study-note section DSA27

> A dictionary or compiler symbol table can use hashing for expected constant lookup, or a balanced tree for logarithmic lookup with ordering. A bounded cache also needs eviction rules: FIFO uses a queue; LRU can combine hash lookup with a doubly linked recency list. Move a hit to the recent end and evict the least-recent end when full. No storage structure is universally best without operation and policy requirements.

Study-note section DSA10

> Doubly linked nodes add prev; head and tail enable constant-time operations at both ends. Singly linked tail deletion still needs its predecessor. A circular tail links back to head; stop traversal on returning to the start, handling empty separately.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Data Structure and Algorithms module | PDF page 4 | lines 16-25

1. Single Linked lists
It is a self-referential structure (Structures can hold pointers to instances of themselves), that allow
to create a chain of structs/Nodes with related data. Each node in the list contains data items and pointer to next node.
Basic Operations on Single Linked List
I. Creating Linked Lists
Structure definition of a single linked list need to contain both data items declaration and next node
pointer. In addition the first node pointer is essential to keep track of the list to perform various operations on the list. Thus, it is initialized to NULL first as the list is empty before any node added
to the chain.

Data Structure and Algorithms module | PDF page 5 | lines 13-24

Step 3: Then add the node at the end of the list. For this we need to check whether the list is empty or not. If list is empty the new node will be the first (Start) node, otherwise navigate forward starting form the first node till last node found and add it next to this node which make the new node the last node.
if (start == NULL) // If list is empty, then new node become start node
start = temp;
else {
temp2 = start; // list not empty! Thus temp2 starts from first node
while (temp2->next!= NULL) { // till the current last node found navigates forward
temp2 = temp2->next; // Move to next link in chain
}
temp2->next = temp; // new node (temp) appended at the end of the list

Data Structure and Algorithms module | PDF page 5 | lines 35-41

IV. Deleting a node from the list
When a node is deleted, the space that it took up should be reclaimed. Otherwise the computer will eventually run out of memory space. This is done with the delete instruction:
delete temp; // Release the memory pointed to by temp
However, we can't just delete the nodes willy-nilly as it would break the chain. We need
to reassign the pointers and then delete the node at the last moment. We can delete nodes
at the start, middle or end of the list. Here let’s see the steps to delete at the end.

Data Structure and Algorithms module | PDF page 7 | lines 10-16

“A queue is an ordered list in which all insertions at one end called REAR and deletions are made at another end called FRONT”. Queues are sometimes referred to as First in First out (FIFO) lists.
The two basic operations are:
Enqueue - Inserts an item / element at the rear end of the queue. An overflow error occurs
if the queue is full.
Dequeue - Removes an item / element from the front end of the queue, and returns it to
the user. An underflow error occurs if the queue is empty.

Computer Science MCQ practice collection · Question 468

Question 202 | AM0469

Which algorithm is used to find the maximum subarray sum in an array?

A. Binary search

B. Quick sort

C. Merge sort

D. Kadane's algorithm

Hint

Use the cited definitions and invariants to distinguish the requested concept from related operations.

Answer D: Kadane’s algorithm

DSA44 directly identifies Kadane as the contiguous maximum-sum-subarray algorithm. It updates the best sum ending at the current item and the best sum seen overall, using linear time and constant working storage. Binary search does not optimize contiguous sums, and quicksort or merge sort reorder values rather than preserve the original adjacency needed by this problem.

Why each choice is right or wrong

A - Incorrect: Binary search locates targets or ordered boundaries; it does not compute a contiguous maximum-sum subarray.

B - Incorrect: Quicksort reorders values and does not preserve the original adjacency required for maximum subarray sum.

C - Incorrect: Merge sort orders values; the named sorting algorithm is not the maximum-subarray recurrence.

D - Correct: Kadane maintains the best sum ending here and the best anywhere, directly solving the stated problem.

Primary note proof

Study-note section DSA44

> Kadane’s algorithm finds a contiguous maximum-sum subarray. For a required nonempty answer, initialize ending=best=A[0]; update ending=max(x,ending+x), then best=max(best,ending). It is linear time with constant working storage. Initializing best=0 instead silently allows an empty answer and fails the nonempty all-negative case.

Computer Science MCQ practice collection · Question 469

Question 203 | AM0470

Which data structure is commonly used to implement a graph?

A. Array

B. Linked list

C. Hash table

D. Adjacency list

Hint

Use the cited definitions and invariants to distinguish the requested concept from related operations.

Answer D: Adjacency list

DSA40 describes adjacency lists as storing each vertex's neighbors in Θ(V+E) space. This names a complete graph representation among the choices. Arrays, linked lists, or maps may store parts of a representation, but those container names alone do not specify how vertices and their edges are encoded. The answer identifies the graph-specific organization.

Why each choice is right or wrong

A - Incorrect: An array can store a matrix or adjacency containers, but its name alone does not specify a graph representation.

B - Incorrect: A linked list can hold neighbor records, but alone does not describe the vertex-to-neighbor organization.

C - Incorrect: Hash tables may index vertices or neighbors, but do not by themselves name the graph representation supplied here.

D - Correct: An adjacency list explicitly associates vertices with their neighbors and is a standard graph representation.

Primary note proof

Study-note section DSA40

> A matrix uses Theta(V^2) space and constant edge lookup. Adjacency lists use Theta(V+E) space and enumerate neighbours. Dense simple graphs approach quadratic edge counts. Examining every edge costs more on denser graphs; vertex-only operations need not inspect every edge.

Computer Science MCQ practice collection · Question 470

Question 204 | AM0471

Which algorithm is used to find the minimum spanning tree in a graph?

A. Depth-first search

B. Breadth-first search

C. Dijkstra's algorithm

D. Prim's algorithm

Hint

Use the cited definitions and invariants to distinguish the requested concept from related operations.

Answer D: Prim’s algorithm

DSA43 defines an MST as a minimum-total-cost connection of all vertices in a connected undirected weighted graph. Prim repeatedly adds the cheapest edge crossing from its current tree to an outside vertex. Dijkstra minimizes source-path distances instead, while BFS and DFS are traversals without a general minimum-weight spanning-tree guarantee. Thus Prim is the listed MST algorithm.

Why each choice is right or wrong

A - Incorrect: DFS can produce a spanning tree but does not generally minimize total edge weight.

B - Incorrect: BFS produces minimum-edge source layers in unweighted graphs, not a general minimum-weight spanning tree.

C - Incorrect: Dijkstra minimizes source-to-vertex distances, a different objective from total spanning-tree connection cost.

D - Correct: Prim grows a spanning tree by repeatedly choosing a cheapest edge crossing to an outside vertex.

Primary note proof

Study-note section DSA43

An MST minimizes the total cost of connecting all vertices of a connected undirected weighted graph. Prim adds the cheapest edge crossing from its current tree to an outside vertex. Kruskal processes edges by increasing weight and rejects those joining vertices already connected. An MST need not give shortest source-to-vertex routes, and equal weights can permit several MSTs.

Study-note section DSA43

For nonnegative weights, standard Dijkstra initializes source distance zero and others infinity, repeatedly finalizes the unsettled vertex with smallest distance, and relaxes each outgoing edge: dist[v]=min(dist[v],dist[u]+w(u,v)). A min-priority queue supports the next choice. BFS is enough when every edge has equal cost; negative edges require another justified method, such as Bellman-Ford.

Question sources

Computer Science MCQ practice collection · Question 471

Question 205 | AM0472

A priority queue needs O(1) peek and O(log n) worst-case insertion and extraction for an interleaved workload. Compare ordinary sorted/unsorted array and linked-list implementations, a binary heap, and an unmodified FIFO queue; exclude representations with extra search indexes. Which meets all requirements?

A. Array

B. Linked list

C. Binary heap

D. Queue

Hint

Use the cited definitions and invariants to distinguish the requested concept from related operations.

Answer C: C. Binary heap

A binary heap exposes the extreme key at its root, so peek is constant, and insertion or extraction restores order along a logarithmic-height path. Ordinary unordered arrays or lists need a linear search for an extreme, while ordered versions pay linear insertion in the general case. An unmodified FIFO queue follows arrival order rather than priority. The stated operation bounds make the heap the unique matching standard representation.

Why each choice is right or wrong

A - Incorrect: Ordinary ordered/unsorted arrays trade linear insertion against linear extremum selection.

B - Incorrect: Ordinary lists likewise have a linear cost in one required operation.

C - Correct: A binary heap provides constant peek and logarithmic insertion/extraction.

D - Incorrect: An unmodified queue serves FIFO rather than priority order.

Primary note proof

Study-note section DSA17

A priority queue returns the smallest or largest priority key under its convention. Urgent patients may precede earlier arrivals. Insertions and extractions can interleave. Binary heaps support constant peek and logarithmic insert/extract.

Study-note section DSA17

Arrays and lists can also implement priority queues: an unordered sequence gives cheap insertion but linear extremum removal; an ordered sequence reverses that tradeoff. Equal priorities have no inherent FIFO guarantee. If stable service is required, compare (priority, arrival_counter). Choose the priority direction and tie rule before tracing.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Data Structure and Algorithms module | PDF page 11 | lines 23-37

iii. Heap Sort
Heap sort operates by first converting the list in to a heap tree. Heap tree is a binary tree in which
each node has a value greater than both its children (if any). It uses a process called "adjust to accomplish its task (building a heap tree) whenever a value is larger than its parent. The time complexity of heap sort is O(nlogn).
Algorithm:
1. Construct a binary tree
• The root node corresponds to Data[0].
• If we consider the index associated with a particular node to be i, then the left child of this node corresponds to the element with index 2*i+1 and the right child corresponds to the element with index 2*i+2. If any or both of these elements do not exist in the array, then the corresponding child node does not exist either.
2. Construct the heap tree from initial binary tree using "adjust" process.
Sort by swapping the root value with the lowest, right most value and deleting the lowest, right most value and inserting the deleted value in the array in it proper position.

Computer Science MCQ practice collection · Question 472

Question 206 | AM0473

Which algorithm is commonly used for pattern matching in strings?

A. Depth-first search

B. Breadth-first search

C. Dijkstra's algorithm

D. Knuth-Morris-Pratt algorithm

Hint

Use the cited definitions and invariants to distinguish the requested concept from related operations.

Answer D: Knuth-Morris-Pratt

DSA44 explicitly defines KMP as finding a pattern inside text. It preprocesses longest proper prefix/suffix lengths and uses them to avoid restarting comparisons after mismatch, giving linear combined pattern-and-text work. DFS, BFS, and Dijkstra concern graph exploration or paths, rather than this specialized substring-matching mechanism. KMP uniquely matches the question among these choices.

Why each choice is right or wrong

A - Incorrect: DFS explores graph or tree branches; it is not the substring-pattern algorithm identified in DSA44.

B - Incorrect: BFS explores graph distance layers rather than applying prefix/suffix reuse for text matching.

C - Incorrect: Dijkstra computes nonnegative weighted shortest paths, not substring pattern occurrences.

D - Correct: KMP is the pattern-matching algorithm using preprocessed prefix/suffix lengths to avoid repeated text comparisons.

Primary note proof

Study-note section DSA44

> Knuth-Morris-Pratt (KMP) finds a pattern inside text. Preprocess the pattern’s longest proper prefix that is also a suffix. After mismatch, fall back using those prefix lengths rather than restarting comparisons from the beginning; the text pointer need not move backward. Pattern preprocessing plus scanning takes O(pattern length+text length).

Question sources

Computer Science MCQ practice collection · Question 473

Question 207 | CS0122

Assume a very large finite key universe U but only n stored keys, with n much smaller than |U|. A hash table uses capacity proportional to n. Compare allocated storage, rather than unconditional speed. Which statement is false?

A. For n much smaller than |U|, the specified hash table uses less allocated storage than direct addressing.

B. Direct Address table doesn't use hash function to map keys

C. Hash table allocates one separate memory slot for each key in the universe U

D. There is one-to-one correspondence between keys in universe U and memory slots in the Direct Address table

Hint

Use the cited definitions and invariants to distinguish the requested concept from related operations.

Answer C: C. Hash table allocates one separate memory slot for each key in the universe U

Direct addressing reserves a distinct slot for every possible key in the universe, whether present or absent, so its storage is proportional to |U|. The specified hash table stores the actual entries plus capacity proportional to n. For this sparse-universe storage comparison, hashing uses less space. C incorrectly attributes the direct-address allocation rule to hashing, while direct key-to-slot mapping and separate universe slots accurately describe direct addressing.

Why each choice is right or wrong

A - Incorrect: Under the sparse-universe storage assumptions, the hash table uses fewer allocated slots.

B - Incorrect: Direct addressing maps directly to a key’s universe slot without compressive hashing.

C - Correct: One slot for every possible key describes direct addressing, not the specified hash table.

D - Incorrect: Each universe key has a separate direct-address slot.

Primary note proof

Study-note section DSA25

> Direct addressing reserves a position for every possible key in a finite universe U, costing Theta(|U|) slots. A hash table uses h(key) in 0..m-1 and stores only actual entries plus bucket capacity. With h(k)=k mod 6, key 36 has home address 0; collisions may move its final storage position.

Question 208 | CS0131

What is the time complexity order of push() operation of Stack data structure implemented using array?

A. O(n)

B. O(log n)

C. O(n^2)

D. O(1)

Hint

State the representation and cost model, then count the operations or storage demanded by the question.

Answer D: O(1)

The fixed-array push checks fullness, increments top and stores one item. A bounded number of unit-cost operations independent of n gives O(1). Evidence: assigned PDF pages 6.

Why each choice is right or wrong

A - Incorrect: Linear would require scanning or copying that the given push does not do. See assigned PDF 6.

B - Incorrect: Logarithmic would require a search/adjustment absent from push. See assigned PDF 6.

C - Incorrect: Quadratic has no nested work in this code. See assigned PDF 6.

D - Correct: Only a fullness test, index increment and one assignment are performed. See assigned PDF 6.

Primary note proof

Study-note section DSA11

> Stack policy is LIFO, equivalently FILO. Push inserts, pop removes/returns top, and peek only observes. With zero-based occupied slots, top=-1 is empty and top=C-1 is full. Check before A[++top]=x or returning A[top--].

Study-note section DSA11

> A count-based alternative uses size=0 and A[size++]=x. Do not combine its empty/full tests with the top-index convention. Fixed-array push/pop are constant time. Linked stacks achieve constant time by inserting and deleting at the head; using a singly linked tail for pop would require a predecessor traversal.

Use the cited definitions and invariants to distinguish the requested concept from related operations.

Answer D: D. At index 0

The home address is obtained by applying the stated remainder function. Since 36 is exactly divisible by 6, the remainder is zero and the home index is 0. The question stops before collision resolution, so occupied slots cannot change this computed address. Index 1 could be a displaced location under some probing state, but it is not the function's output; indices 6 and 35 are outside the table.

Why each choice is right or wrong

A - Incorrect: 35 is outside the valid zero-based range 0-5.

B - Incorrect: 1 is not the remainder of 36 divided by 6.

C - Incorrect: 6 is outside the valid range and is not a possible remainder modulo 6.

D - Correct: 36%6 equals 0.

Primary note proof

Study-note section DSA25

> Direct addressing reserves a position for every possible key in a finite universe U, costing Theta(|U|) slots. A hash table uses h(key) in 0..m-1 and stores only actual entries plus bucket capacity. With h(k)=k mod 6, key 36 has home address 0; collisions may move its final storage position.

Question sources

Computer Science Exit Exam practice collection · Question 132

Question 210 | CS0133

Which method can resolve collision in hashed files by proceeding from the occupied position specified by the hash address and checking subsequent positions until an empty position is found?

A. Open addressing

B. Multiple hashing

C. Chaining

D. Cluster indexing

Hint

Use the cited definitions and invariants to distinguish the requested concept from related operations.

Answer A: Open addressing, specifically linear probing.

DSA26 defines open addressing as keeping entries within the array and probing until an available slot is found. Checking successive positions is its linear-probing form. Multiple hashing changes probe steps, chaining stores collisions in bucket lists, and cluster indexing is not this insertion procedure. Therefore Open addressing is the matching general method among the options.

Why each choice is right or wrong

A - Correct: Open addressing searches alternative table positions; checking successive positions is its linear-probing form.

B - Incorrect: Multiple or double hashing derives another probe step rather than the stated simple successive-slot scan.

C - Incorrect: Chaining puts colliding entries in a bucket list instead of searching successive array slots.

D - Incorrect: Cluster indexing does not name the collision insertion strategy described by the successive-position probing rule.

Primary note proof

Study-note section DSA26

> Separate chaining stores colliding entries in a bucket list. Load alpha=n/m is average chain length; expected operations are O(1+alpha) under suitable distribution assumptions, with O(n) worst cases. Open addressing keeps entries inside the array and probes until a key or an available slot is found.

Study-note section DSA26

> Linear probing tries (h(k)+j)%m. For size 7 and keys 10,17,24, all home addresses are 3 and occupied positions become 3,4,5. Quadratic probing changes the step; double hashing uses h1(k)+j h2(k), modulo m, with a step relatively prime to m to cover all slots. Neither method guarantees no collisions. Deletion needs tombstones or reinsertion so searches do not stop prematurely.

Question sources

Computer Science Exit Exam practice collection · Question 133

Question 211 | CS0134

Which one of the following is true about tree data structure?

A. Tree is a static data structure

B. Tree is a linear data structure

C. Tree forms a cycle - in other words tree is a cyclic data structure

D. There is only one unique path when we traverse from one node to another node in a tree

Hint

Use the cited definitions and invariants to distinguish the requested concept from related operations.

Answer D: There is only one unique path when we traverse from one node to another node in a tree

A rooted tree gives every nonroot node exactly one parent and a unique root path. Between any two nodes, ascend to their common ancestor and descend; a second distinct path would create a cycle and violate the parent/path hierarchy. Evidence: assigned PDF pages 9, 2.

Why each choice is right or wrong

A - Incorrect: The pointer-based tree representation does not require static size. See assigned PDF 9, 2, 9.

B - Incorrect: The source explicitly classifies trees as nonlinear. See assigned PDF 9, 2, 9.

C - Incorrect: A cycle contradicts the unique-path hierarchy. See assigned PDF 9, 2, 9.

D - Correct: The rooted hierarchy gives one unique connecting path for every node pair. See assigned PDF 9, 2, 9.

Primary note proof

Study-note section DSA18

> A rooted tree has one parentless root and one parent per other node. It is connected and acyclic, has n-1 edges, and one path between any pair. Depth counts root-to-node edges; height is maximum depth. A single-node tree therefore has height zero. Leaves have no children.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Data Structure and Algorithms module | PDF page 9 | lines 3-13

> A tree is a set of nodes and edges that connect pairs of nodes that connect pairs of nodes. It is an abstract model of a hierarchical structure. Rooted tree has the following structure:
> • One node distinguished as root.

• Every node C except the root is connected from exactly other node P. P is C's parent, and C is one of C's children.
• There is a unique path from the root to the each node.
• The number of edges in a path is the length of the path.
Tree Terminologies:
• Root: a node without a parent.
• Internal node: a node with at least one child.
• External (leaf) node: a node without a child.

Data Structure and Algorithms module | PDF page 2 | lines 15-18

a. Linear data structure: data items stores in sequence
Example: Array, stack and Queue,
b. Non-Linear data structures : in which there is order of data items
Example: Trees and Graphs

Data Structure and Algorithms module | PDF page 9 | lines 19-25

• Binary tree: a tree in which each node has at most two children called left child and right child.
• Binary search tree (ordered binary tree): a binary tree that may be empty, but if it is not empty it
satisfies the following.
o Every node has a key and no two elements have the same key.
o The keys in the right subtree are larger than the keys in the root.
o The keys in the left subtree are smaller than the keys in the root.
o The left and the right subtrees are also binary search trees.

Question sources

Computer Science Exit Exam practice collection · Question 134

Question 212 | CS0135

For an unordered heap record file without an ordered index or a maintained sorted copy, which statement is not correct? Ordinary insertion uses available storage rather than maintaining field order.

A. Sorting is required to read records in particular field order

B. Linear search can be used to search a necessary record

C. Record insertion is efficient

D. New records are inserted at the beginning of the file

Hint

Use the cited definitions and invariants to distinguish the requested concept from related operations.

Answer D: D. New records are inserted at the beginning of the file

A heap file does not maintain record order by a chosen field. With no ordered index or sorted copy, ordered output therefore requires sorting; an ordinary scan can locate a record, and insertion can place a record in available storage. Nothing requires new records to be inserted at the beginning of the file. D is the incorrect claim, while the explicit no-index scope makes A's ordering requirement appropriate.

Why each choice is right or wrong

A - Incorrect: Under the specified no-index/no-sorted-copy scope, field-ordered output requires ordering the records.

B - Incorrect: A linear scan can search unordered records.

C - Incorrect: Using available storage avoids maintaining a sorted record sequence during insertion.

D - Correct: Heap-file insertion is not required to place every new record at the beginning.

Primary note proof

Study-note section DSA45

> Specify whether a question asks which structure can implement something or which is best under stated costs. ADTs do not force one representation, and serial-access memory is not inherently LIFO. A heap file is an unordered database record file, unrelated to a binary heap: insertion uses available space, scanning can find records, and ordered output requires sorting or an index. It need not insert at the beginning.

Question sources

Computer Science Exit Exam practice collection · Question 135

Question 213 | NS0298

Which listed structures are linear in the course classification? Select all that apply.

A. Tree

B. Array

C. Queue

D. Linked list

Hint

Use the cited definitions and invariants to distinguish the requested concept from related operations.

Answer B, C, D: B. Array; C. Queue; D. Linked list

A linear structure arranges items along a sequence rather than through hierarchical branching. The note explicitly includes arrays, queues and linked lists in that category, giving three valid selections. A tree instead models a hierarchy and is classified as nonlinear. The select-all instruction allows every listed member of the linear category to be recognized rather than forcing an arbitrary single choice.

Why each choice is right or wrong

A - Incorrect: Trees model hierarchy rather than a linear sequence.

B - Correct: Arrays are classified as linear.

C - Correct: Queues are classified as linear.

D - Correct: Linked lists are classified as linear.

Primary note proof

Study-note section DSA01

> An abstract data type (ADT) defines values and operations; representation supplies implementation. Arrays or linked nodes can implement the same LIFO stack. Abstraction keeps relevant details: patient urgency and arrival order matter for service; hair colour does not.

Question sources

Computer Science Exit Exam · 2018 · Question 15

Question 214 | NS0319

Which abbreviations name the stack service policy? Select all that apply.

A. LIFO

B. FIFO

C. FILO

D. FCFS

Hint

Use the cited definitions and invariants to distinguish the requested concept from related operations.

Answer A, C: A. LIFO; C. FILO

The most recently pushed item is removed first by a stack. This is last in, first out, abbreviated LIFO. Equivalently, the first item inserted remains until later items have been removed, making it first in, last out or FILO. FIFO and FCFS instead preserve arrival order in ordinary queue service. Both A and C therefore name the same stack discipline.

Why each choice is right or wrong

A - Correct: LIFO means last in, first out.

B - Incorrect: FIFO means first in, first out, an ordinary queue policy.

C - Correct: FILO is the equivalent first in, last out view of a stack.

D - Incorrect: FCFS describes arrival-order service rather than stack service.

Primary note proof

Study-note section DSA11

> Stack policy is LIFO, equivalently FILO. Push inserts, pop removes/returns top, and peek only observes. With zero-based occupied slots, top=-1 is empty and top=C-1 is full. Check before A[++top]=x or returning A[top--].

Study-note section DSA14

> An ordinary queue enqueues at rear, dequeues at front, and peeks at front. This is FIFO or first-come, first-served. A linked implementation with head and tail supports both operations in constant time: append at tail, remove at head. The first insertion sets both pointers; removing the last item clears both. With head alone, insertion must traverse to the tail.

Question sources

Computer Science Exit Exam · 2018 · Question 44

Question 215 | NS0337

For ordinary binary search on a sorted random-access array of n elements, what is the tightest listed worst-case time bound? Count each indexed probe as constant work.

A. $O(n (\log n)^2)$

B. $O(n^2)$

C. O(n)

D. O(log n)

Hint

State the representation and cost model, then count the operations or storage demanded by the question.

Answer D: D. O(log n)

Binary search repeatedly removes roughly half of the remaining candidate interval. The note bounds its worst probes by $\text{floor}(\log_2 n)+1$ for nonempty input, giving logarithmic worst-case time under constant-cost indexing. The linear, quadratic and n-times-squared-log options all grow faster and are looser upper bounds. Explicitly asking for the tightest bound selects the logarithmic alternative rather than treating every valid Big-O upper bound as equally responsive.

Why each choice is right or wrong

A - Incorrect: $n(\log n)^2$ is a much looser upper bound.

B - Incorrect: Quadratic is a looser upper bound.

C - Incorrect: Linear is a looser upper bound.

D - Correct: Logarithmic matches the interval-halving probe growth.

Primary note proof

Study-note section DSA29

> Worst probes are $\text{floor}(\log_2 n)+1$ for $n>0$: seven for 100 keys, about twenty for one million. Iteration uses constant space; recursion uses logarithmic stack depth. Linked midpoint traversal loses logarithmic total time. Boundary variants retain a candidate rather than stopping at equality.

Study-note section DSA06

> For eventually nonnegative functions, $f(n)=O(g(n))$ means $f(n) \le c\, g(n)$ for some positive c beyond a threshold k. Omega reverses the inequality; Theta requires both. Little-o means f/g tends to zero; little-omega means it grows without bound. These relations can describe best-case, average-case, worst-case or space functions.

Question sources

Computer Science Exit Exam · 2018 · Question 68

Question 216 | NS0351

Which sorting algorithm compares each pair of adjacent elements from the beginning of an array and, if they are in reversed order, swaps them; if at least one swaps has been done, repeat step 1.

A. Insertion sort

B. Bubble sort

C. Selection sort

D. Shell sort

Hint

Use the cited definitions and invariants to distinguish the requested concept from related operations.

Answer B: Bubble sort with early stopping

DSA32 describes adjacent comparisons, swapping strict inversions, and repeating passes until a pass performs no swaps. That matches every part of the stem, including its stopping condition. Insertion grows a sorted prefix, selection chooses a suffix minimum, and Shell uses separated gap subsequences, so none has this exact adjacent full-pass mechanism.

Why each choice is right or wrong

A - Incorrect: Insertion places each next value into a sorted prefix rather than repeating full adjacent passes.

B - Correct: Adjacent inversion swaps and repetition until no swaps identify optimized bubble sort.

C - Incorrect: Selection finds a suffix minimum and exchanges it with the prefix boundary.

D - Incorrect: Shell sorts gap-separated subsequences before its final gap-one insertion pass.

Primary note proof

Study-note section DSA32

> For ascending order, compare each adjacent pair and swap only when left>right. The largest remaining value moves to the final unsorted position after one left-to-right pass. Shrink the next pass by one position. Quadratic worst/average work comes from up to n(n-1)/2 pair comparisons.

Question sources

Computer Science Exit Exam · 2018 · Question 87

Question 217 | NS0354

Among the following one is NOT the application of queue in the real world.

A. It is used in operating systems for handling interrupts.

B. It is used to maintain the play list in media players in order

C. It is used in Depth First search

D. It is widely used as waiting lists for a single shared resource

Hint

Use the cited definitions and invariants to distinguish the requested concept from related operations.

Answer C: Depth-first search uses stack discipline rather than the ordinary queue.

DSA42 finishes a branch using a stack or recursion and explicitly says a queue changes that discipline. DSA14 gives FIFO waiting, play sequences, and asynchronous buffering as queue uses. Interrupt work can also be buffered pending service. Thus the standard DFS claim is the non-queue application among the offered ordinary examples.

Why each choice is right or wrong

A - Incorrect: Pending interrupts can be buffered for later service; queue use need not imply one universal interrupt priority policy.

B - Incorrect: A FIFO play queue can preserve the order of media items.

C - Correct: Standard DFS uses latest-pending-work-first stack or recursion rather than FIFO queue service.

D - Incorrect: Waiting for one shared resource is a direct FIFO queue application.

Primary note proof

Study-note section DSA42

> Mark a vertex, then recursively visit each unmarked neighbour before continuing with later neighbours. An explicit stack can store pending work instead. Both implement latest-pending-work first; a queue would change that discipline. Marking prevents infinite repetition around graph cycles.

Study-note section DSA14

> FIFO suits equal-priority printer jobs, shared-resource waiting, asynchronous buffers and level-order exploration. A play sequence can also use a queue. Distinguish airline seat records from waiting requests; an application name alone does not force one representation.

Study-note section DSA-S02

> An interrupt service routine may need to record work quickly and defer its completion. Operating systems can queue that deferred work for later processing; Windows deferred procedure calls are one concrete example. This is a queue application, but it does not imply that every interrupt system uses a single FIFO service policy.

Question sources

Computer Science Exit Exam · 2018 · Question 91

Question 218 | NS0519

Which data structure uses LIFO?

A. Queue

B. Array

C. Stack

D. Linked List

Hint

Use the cited definitions and invariants to distinguish the requested concept from related operations.

Answer C: Stack

DSA11 explicitly assigns LIFO to a stack. Arrays and linked lists can represent that stack, but neither storage structure inherently fixes its removal order. A queue instead supplies FIFO. The question asks for the service-policy ADT, so Stack is the specific answer rather than one of the possible underlying representations.

Why each choice is right or wrong

A - Incorrect: A queue follows FIFO, not the latest-in-first-out order requested.

B - Incorrect: An array is a representation and does not inherently impose LIFO service.

C - Correct: A stack is explicitly defined by LIFO, equivalently FILO.

D - Incorrect: A linked list can implement several policies and does not inherently require LIFO.

Primary note proof

Study-note section DSA11

> Stack policy is LIFO, equivalently FILO. Push inserts, pop removes/returns top, and peek only observes. With zero-based occupied slots, top=-1 is empty and top=C-1 is full. Check before A[++top]=x or returning A[top--].

Study-note section DSA01

> An abstract data type (ADT) defines values and operations; representation supplies implementation. Arrays or linked nodes can implement the same LIFO stack. Abstraction keeps relevant details: patient urgency and arrival order matter for service; hair colour does not.

Question sources

Data Structures & Algorithms review questions · Question 1

Question 219 | NS0520

What distinguishes a dynamic data structure from a static one?

Hint

Use the cited definitions and invariants to distinguish the requested concept from related operations.

Answer: Dynamic structures can change size at runtime; static structures have fixed capacity.

DSA02 distinguishes fixed arrays from resizable arrays, and DSA08 allocates linked nodes as needed. Runtime growth or shrinkage is the key distinction; fixed capacity need not mean compile-time allocation.

Primary note proof

Study-note section DSA02

> A fixed array has a chosen capacity; the choice need not occur at compile time. A resizable array allocates a larger block and copies when needed. Inserting in the middle shifts later elements, so it costs linear time. Appending into spare capacity is constant; a resizing append can be linear, though repeated geometric growth gives amortized constant append cost.

Study-note section DSA08

> A singly linked node contains data and next. Head points to the first node; null ends a noncircular chain. Empty means head==null. Nodes allocated as needed grow dynamically, with pointer overhead and no direct index arithmetic.

Question sources

Data Structures & Algorithms review questions · Question 2

Question 220 | NS0521

Which classification includes both Trees and Graphs?

A. Linear

B. Homogeneous

C. Non-linear

D. Static

Hint

Use the cited definitions and invariants to distinguish the requested concept from related operations.

Answer C: Non-linear

DSA01 treats arrays, lists, stacks, and queues as linear sequences, trees as hierarchies, and graphs as general connections. Trees and graphs therefore belong to the nonlinear relationship category. Homogeneity describes element types and static describes storage capacity; neither classifies both by their branching relationship structure. C is the appropriate shared category.

Why each choice is right or wrong

A - Incorrect: Linear describes sequence-like structures rather than branching trees and general graphs.

B - Incorrect: Homogeneous concerns uniform element types and does not identify their relationship structure.

C - Correct: Trees and graphs are nonlinear relationship structures, unlike the listed linear sequences.

D - Incorrect: Static concerns storage or capacity decisions, not whether connections branch.

Primary note proof

Study-note section DSA01

> An abstract data type (ADT) defines values and operations; representation supplies implementation. Arrays or linked nodes can implement the same LIFO stack. Abstraction keeps relevant details: patient urgency and arrival order matter for service; hair colour does not.

Question sources

Data Structures & Algorithms review questions · Question 3

Question 221 | NS0522

In an ADT, what two components are always defined?

Hint

Use the cited definitions and invariants to distinguish the requested concept from related operations.

Answer: An ADT defines its values/data and permitted operations.

DSA01 explicitly defines an abstract data type through values and operations, leaving representation to the implementation. The same LIFO stack can therefore use arrays or linked nodes without changing its contract.

Primary note proof

Study-note section DSA01

> An abstract data type (ADT) defines values and operations; representation supplies implementation. Arrays or linked nodes can implement the same LIFO stack. Abstraction keeps relevant details: patient urgency and arrival order matter for service; hair colour does not.

Question sources

Data Structures & Algorithms review questions · Question 4

Question 222 | NS0523

A structure in C that groups int, char, and float is an example of:

A. Homogeneous

B. Non-homogeneous

C. Linear

D. Static

Hint

Use the cited definitions and invariants to distinguish the requested concept from related operations.

Answer B: Non-homogeneous, or heterogeneous

DSA01 directly identifies a record grouping integer, character, and floating fields as heterogeneous. The different field types distinguish it from an ordinary same-element-type array. Linear describes relationships, and static describes storage behavior, neither of which follows merely from the field types. Thus Non-homogeneous is the requested classification.

Why each choice is right or wrong

A - Incorrect: Homogeneous would mean a uniform element type, contrary to the mixed int, char, and float fields.

B - Correct: The record combines different field types and is therefore heterogeneous or non-homogeneous.

C - Incorrect: Linear concerns relationships or order, not the mixed-type classification asked here.

D - Incorrect: Static concerns allocation or lifetime and is not established merely by these field types.

Primary note proof

Study-note section DSA01

> Arrays, linked lists, stacks and queues are linear. Trees model hierarchies; graphs model general connections. A record grouping integer, character and floating fields is heterogeneous; an ordinary array has one element type.

Question sources

Data Structures & Algorithms review questions · Question 5

Question 223 | NS0524

What does abstraction in algorithms allow programmers to do?

Hint

Use the cited definitions and invariants to distinguish the requested concept from related operations.

Answer: Abstraction preserves relevant behavior and hides irrelevant implementation detail.

DSA01 illustrates abstraction using patient urgency and arrival order while ignoring hair colour. Programmers retain the data and operations needed for the task and separate that contract from representation details. This supports the substantive answer without additional facts.

Primary note proof

Study-note section DSA01

> An abstract data type (ADT) defines values and operations; representation supplies implementation. Arrays or linked nodes can implement the same LIFO stack. Abstraction keeps relevant details: patient urgency and arrival order matter for service; hair colour does not.

Question sources

Data Structures & Algorithms review questions · Question 6

Question 224 | NS0525

Which operation involves combining elements from two sorted sets into one sorted set?

Hint

Use the cited definitions and invariants to distinguish the requested concept from related operations.

Answer: Merging

DSA03 calls combining sequences merging and works through sorted inputs by repeatedly emitting the smaller current front. Advancing only the selected sequence preserves sorted output until the remaining suffix is appended. For mathematical sets, duplicate handling additionally follows the set contract.

Primary note proof

Study-note section DSA03

> Traversal processes every item; searching locates a target; insertion and deletion change membership; updating changes a stored value. Sorting reorders items, while merging combines sequences. To merge sorted [1,4] and [2,3], repeatedly emit the smaller front, producing [1,2,3,4]. Destroying a structure releases owned storage.

Study-note section DSA27

> A set forbids duplicate elements.

Question sources

Data Structures & Algorithms review questions · Question 7

Question 225 | NS0526

What is the term for the operation that releases memory when a data structure is no longer needed?

Hint

Use the cited definitions and invariants to distinguish the requested concept from related operations.

Answer: Destruction or deallocation of owned storage.

DSA03 says destroying a structure releases owned storage. In a linked chain, DSA09 visits and releases each owned node; C++ allocation forms must be matched to their deletion forms, and freed nodes must not be dereferenced.

Primary note proof

Study-note section DSA03

> A C struct groups named fields, including arrays and pointers. A singly linked node needs payload plus a same-type link. C fields cannot have initializers inside the type declaration; modern C++ permits default member initializers. In C++, match new with delete and new[] with delete[]. Repair links before freeing a node; never dereference it afterwards.

Study-note section DSA09

> Deleting the tail of a singly linked list requires its predecessor, even when tail itself is known. Handle empty and single-node lists separately; after removing the only node, set both head and tail to null. To remove a known successor, bypass it before deallocation. Clearing an owned n-node chain visits and releases every node.

Question sources

Data Structures & Algorithms review questions · Question 8

Question 226 | NS0527

Given T(n) = 6n + 4, what is the Big-O complexity?

Hint

State the representation and cost model, then count the operations or storage demanded by the question.

Answer: O(n), tightly Θ(n).

For n≥1, 6n+4≤10n, while 6n+4≥6n. These constant upper and lower multiples establish linear growth by DSA06. O(n) is the natural tightest-order response, though larger upper bounds also exist.

Primary note proof

Study-note section DSA06

> For eventually nonnegative functions, f(n)=O(g(n)) means f(n)≤c g(n) for some positive c beyond a threshold k. Omega reverses the inequality; Theta requires both. Little-o means f/g tends to zero; little-omega means it grows without bound. These relations can describe best-case, average-case, worst-case or space functions.

Question sources

Data Structures & Algorithms review questions · Question 9

Question 227 | NS0528

Show why f(n) = $3n^2 + 4n + 1$ is $O(n^2)$. What are the values of c and k?

Hint

Use the cited definitions and invariants to distinguish the requested concept from related operations.

Answer: One valid witness pair is c=8, k=1.

For every n≥1, $4n \le 4n^2$ and $1 \le n^2$, so $3n^2+4n+1 \le 8n^2$. DSA06 supplies the same inequality, proving the required eventual upper bound with c=8 and k=1. Other larger constants may also work.

Primary note proof

Study-note section DSA06

> For eventually nonnegative functions, f(n)=O(g(n)) means f(n)≤c g(n) for some positive c beyond a threshold k. Omega reverses the inequality; Theta requires both. Little-o means f/g tends to zero; little-omega means it grows without bound. These relations can describe best-case, average-case, worst-case or space functions.

Question sources

Data Structures & Algorithms review questions · Question 10

Question 228 | NS0529

Which property of an algorithm ensures it terminates after a finite number of steps?

Hint

Use the cited definitions and invariants to distinguish the requested concept from related operations.

Answer: Finiteness

DSA04 defines finiteness as terminating after finitely many steps for every valid input. It is distinct from definiteness, executable instructions, or correctness: a terminating procedure can still return a wrong answer. The required concept is directly covered.

Primary note proof

Study-note section DSA04

> Finiteness means termination after finitely many steps for every valid input. Definiteness means each instruction has one interpretation; effectiveness means each step is executable. Correctness means meeting the stated result for every valid input. A finite program can still return the wrong answer.

Question sources

Data Structures & Algorithms review questions · Question 11

Question 229 | NS0530

An algorithm has exactly two independent nested loops. Each executes n iterations, and the innermost body performs constant work. Loop-control operations are constant time, with no early exits or hidden nonconstant operations. What is the tight time complexity as n grows?

Hint

State the representation and cost model, then count the operations or storage demanded by the question.

Answer: Theta(n^2) time.

For each of the n outer iterations, the inner loop executes n times, so the constant-cost body runs $n \times n = n^2$ times. Outer-loop overhead is linear and inner-loop control is also bounded by a constant per body execution. Those contributions do not change the dominant quadratic growth. Under the stated independence, fixed loop count and body-cost assumptions, the tight time complexity is Theta(n^2).

Primary note proof

Study-note section DSA07

> A loop i=1; i<n; i*=2 takes about $\log_2 n$ iterations. Two independent n-iteration loops nested around constant work take Theta(n^2). An n-level ordinary recursion with constant live storage per level needs Theta(n) stack space.

Study-note section DSA05

> Time counts chosen operations; space counts memory, including live recursive frames. Distributed algorithms may also measure communication volume. A single assignment is one unit in the elementary model, not literally one second. Sequential blocks add costs; independent nested loops multiply their iteration counts. Conditional worst-case cost includes the test and the more expensive branch.

Question sources

Data Structures & Algorithms review questions · Question 12

Question 230 | NS0531

Big-Theta (Θ) notation represents:

A. Upper bound only

B. Lower bound only

C. Both upper and lower bound

D. Average case only

Hint

State the representation and cost model, then count the operations or storage demanded by the question.

Answer C: Both upper and lower asymptotic bounds.

DSA06 defines Big-O as an eventual upper bound, Omega as the reverse bound, and Theta as requiring both. Thus Theta expresses a tight growth class up to positive constants. It is independent of choosing best, average, or worst input cases; Average case only confuses the bound relation with an input-distribution choice.

Why each choice is right or wrong

A - Incorrect: An upper bound alone is Big-O and does not supply Theta's lower requirement.

B - Incorrect: A lower bound alone is Omega and does not supply Theta's upper requirement.

C - Correct: Theta requires simultaneous eventual upper and lower constant-factor bounds.

D - Incorrect: Theta can describe any case or resource function, not only an average case.

Primary note proof

Study-note section DSA06

> For eventually nonnegative functions, f(n)=O(g(n)) means f(n)≤c g(n) for some positive c beyond a threshold k. Omega reverses the inequality; Theta requires both. Little-o means f/g tends to zero; little-omega means it grows without bound. These relations can describe best-case, average-case, worst-case or space functions.

Question sources

Data Structures & Algorithms review questions · Question 13

Question 231 | NS0532

Which grows faster asymptotically: O(n log n) or O(n)?

Hint

State the representation and cost model, then count the operations or storage demanded by the question.

Answer: Representative n log n grows faster than n; Big-O classes themselves overlap.

DSA06 orders representative rates with n before n log n. Their ratio is log n, which grows without bound, so the representative n log n rate grows faster. However an O(n) function is also O(n log n), so membership alone does not compare actual runtimes.

Primary note proof

Study-note section DSA06

> For eventually nonnegative functions, f(n)=O(g(n)) means f(n)≤c g(n) for some positive c beyond a threshold k. Omega reverses the inequality; Theta requires both. Little-o means f/g tends to zero; little-omega means it grows without bound. These relations can describe best-case, average-case, worst-case or space functions.

Study-note section DSA06

> Increasing representative rates: 1, log n, n, n log n, n^2, n^3, 2^n, 3^n, n!, n^n. Logarithm bases differ only by a constant factor.

Question sources

Data Structures & Algorithms review questions · Question 14

Question 232 | NS0533

What is the running time contribution of a single assignment statement according to analysis rules?

Hint

State the representation and cost model, then count the operations or storage demanded by the question.

Answer: One constant time unit in the elementary-operation model.

DSA05 explicitly treats a single assignment as one unit in an elementary model, not one physical second. The convention abstracts hardware and requires that evaluating the assigned expression itself be constant cost; complicated expressions need their own accounting.

Primary note proof

Study-note section DSA05

> Time counts chosen operations; space counts memory, including live recursive frames. Distributed algorithms may also measure communication volume. A single assignment is one unit in the elementary model, not literally one second. Sequential blocks add costs; independent nested loops multiply their iteration counts. Conditional worst-case cost includes the test and the more expensive branch.

Question sources

Data Structures & Algorithms review questions · Question 15

Question 233 | NS0534

State the Transitivity theorem of Big-O. Why is it useful?

Hint

State the representation and cost model, then count the operations or storage demanded by the question.

Answer: If f∈O(g) and g∈O(h), then f∈O(h); this composes upper bounds.

DSA06 composes the eventual inequalities f≤c g and g≤d h to obtain f≤cd h beyond both thresholds. Choose the larger threshold and multiply the positive witness constants. This lets a complicated bound pass through a simpler intermediate function.

Primary note proof

Study-note section DSA06

> For n≥1, $3n^2+4n+1 \le 8n^2$: c=8,k=1 witness $O(n^2)$. Constants and lower-order terms disappear from tight polynomial growth. Transitivity multiplies witnesses: f≤c g≤cd h beyond both thresholds.

Question sources

Data Structures & Algorithms review questions · Question 16

Question 234 | NS0535

Rank from slowest to fastest growing: $O(n^2)$, $O(1)$, $O(2^n)$, $O(\log n)$, $O(n)$

Hint

State the representation and cost model, then count the operations or storage demanded by the question.

Answer: Increasing representative growth: 1, log n, n, n², 2^n.

DSA06 gives the standard growth ordering, with constants below logarithms, then linear and quadratic functions, then exponential. The ranking compares representative rates, not disjoint Big-O classes, since loose upper bounds overlap.

Primary note proof

Study-note section DSA06

> Increasing representative rates: 1, log n, n, n log n, n^2, n^3, 2^n, 3^n, n!, n^n. Logarithm bases differ only by a constant factor.

Question sources

Data Structures & Algorithms review questions · Question 17

Question 235 | NS0536

What are the three main resources considered in algorithm analysis?

Hint

State the representation and cost model, then count the operations or storage demanded by the question.

Answer: Time, memory space, and-in distributed settings-communication volume.

DSA05 measures operation counts and live memory, and adds communication volume for distributed algorithms. Thus the third resource is context-dependent rather than a universal resource needed by every local algorithm. These are the three supported categories in the note.

Primary note proof

Study-note section DSA05

> Time counts chosen operations; space counts memory, including live recursive frames. Distributed algorithms may also measure communication volume. A single assignment is one unit in the elementary model, not literally one second. Sequential blocks add costs; independent nested loops multiply their iteration counts. Conditional worst-case cost includes the test and the more expensive branch.

Question sources

Data Structures & Algorithms review questions · Question 18

Question 236 | NS0537

What is the worst-case time complexity of Linear Search and when does it occur?

Hint

State the representation and cost model, then count the operations or storage demanded by the question.

Answer: Θ(n) worst time, when absent or at the last position.

DSA28 scans until equality or exhaustion. An absent target or one in the final position requires all n comparisons, giving linear worst time; a first-position match instead takes constant time. The operation and cases are directly supported.

Primary note proof

Study-note section DSA28

> Compare the target with successive elements until equal or exhausted. Unsorted data is allowed; sorted data is allowed too. A first-element match costs Theta(1). An absent target or last-position match needs n comparisons, giving Theta(n) worst time. Uniformly likely successful positions average (n+1)/2 comparisons, still linear.

Question sources

Data Structures & Algorithms review questions · Question 19

Question 237 | NS0538

Binary Search requires the list to be:

A. Unsorted

B. Sorted

C. Circular

D. Linked

Hint

Use the cited definitions and invariants to distinguish the requested concept from related operations.

Answer B: Sorted

DSA29 eliminates half an ordered interval according to the midpoint comparison. That elimination is valid only when comparable values follow a consistent order; descending input works with reversed comparisons. Circularity and links are representation properties, not substitutes for sortedness. An unsorted sequence gives no safe smaller-half decision. Therefore Sorted is the required prerequisite.

Why each choice is right or wrong

A - Incorrect: Without order, a midpoint comparison cannot safely eliminate either half.

B - Correct: Consistent sorted order supports the midpoint half-elimination invariant.

C - Incorrect: Circular storage does not establish the value ordering needed by binary search.

D - Incorrect: Linked storage does not imply sortedness and also changes midpoint-access costs.

Primary note proof

Study-note section DSA29

> On an ascending random-access sequence, set lo=0, hi=n-1. Compute mid=lo+(hi-lo)//2. Equality finishes; if target<A[mid], set hi=mid-1; otherwise set lo=mid+1. Stop unsuccessfully when lo>hi. Reverse comparisons for descending order. Comparable keys and valid finite bounds matter; fixed allocation before population is not an extra algorithmic requirement.

Question sources

Data Structures & Algorithms review questions · Question 20

Question 238 | NS0539

How many steps does Binary Search take for a list of 1,000,000 elements (approximately)?

Hint

Use the cited definitions and invariants to distinguish the requested concept from related operations.

Answer: About 20 worst-case midpoint probes.

DSA29 gives floor($\log_2 n$)+1 probes for n>0. Since 2^19=524288 and 2^20=1048576, one million lies between them, so the worst probe count is twenty under the ordinary interval algorithm. A root/midpoint hit can finish earlier.

Primary note proof

Study-note section DSA29

> Worst probes are floor($\log_2 n$)+1 for n>0: seven for 100 keys, about twenty for one million. Iteration uses constant space; recursion uses logarithmic stack depth. Linked midpoint traversal loses logarithmic total time. Boundary variants retain a candidate rather than stopping at equality.

Question sources

Data Structures & Algorithms review questions · Question 21

Question 239 | NS0540

What is the time complexity of Bubble Sort and why?

Hint

State the representation and cost model, then count the operations or storage demanded by the question.

Answer: Worst and usual average $\Theta(n^2)$; early-stop best $\Theta(n)$.

DSA32 sums repeated adjacent passes to at most n(n−1)/2 comparisons, yielding quadratic worst and ordinary average work. A no-swap early-stop pass makes sorted input linear, while a fixed pass schedule remains quadratic. The answer needs these implementation and case distinctions.

Primary note proof

Study-note section DSA32

> For ascending order, compare each adjacent pair and swap only when left>right. The largest remaining value moves to the final unsorted position after one left-to-right pass. Shrink the next pass by one position. Quadratic worst/average work comes from up to n(n-1)/2 pair comparisons.

Question sources

Data Structures & Algorithms review questions · Question 22

Question 240 | NS0541

In Selection Sort, what does each pass through the unsorted subarray accomplish?

Hint

Use the cited definitions and invariants to distinguish the requested concept from related operations.

Answer: Select the remaining minimum and put it at the next prefix position.

DSA33 scans the unsorted suffix for its minimum and exchanges it with A[i]. After each meaningful pass, the sorted prefix grows by one and contains the smallest keys placed so far. This differs from inserting the next encountered item into a prefix.

Primary note proof

Study-note section DSA33

> At position i, scan the remaining suffix for its minimum, then exchange it with A[i]. There are n-1 meaningful placements and n(n-1)/2 comparisons regardless of initial order. At most n-1 exchanges of distinct positions are needed. A loop that also swaps the last item with itself can count n swap calls.

Question sources

Data Structures & Algorithms review questions · Question 23

Question 241 | NS0542

How does Insertion Sort differ from Selection Sort conceptually?

Hint

Use the cited definitions and invariants to distinguish the requested concept from related operations.

Answer: Selection finds a suffix minimum; insertion places the next item into a sorted prefix.

DSA33 chooses the globally smallest remaining key for each next output position. DSA34 instead takes the next input item, shifts larger prefix values, and inserts it into their gap. Both grow sorted prefixes, but choose their next item differently.

Primary note proof

Study-note section DSA33

> At position i, scan the remaining suffix for its minimum, then exchange it with A[i]. There are n-1 meaningful placements and n(n-1)/2 comparisons regardless of initial order. At most n-1 exchanges of distinct positions are needed. A loop that also swaps the last item with itself can count n swap calls.

Study-note section DSA34

> Begin with the first element already sorted. For each remaining item, save its value, shift larger preceding values right, and insert it into the gap. That gives n-1 insertion passes. On sorted input each pass needs one ordering check and no shifts: linear time. Reverse order causes 1+2+...+(n-1) shifts: quadratic time.

Question sources

Data Structures & Algorithms review questions · Question 24

Question 242 | NS0543

What is the best-case scenario for Bubble Sort and what is its complexity in that case?

Hint

State the representation and cost model, then count the operations or storage demanded by the question.

Answer: Already sorted input; Θ(n) with no-swap early stopping.

DSA32 performs one pass over an already sorted array, makes no swaps, and stops when early-exit detection is enabled. That is linear best work. A fixed-pass implementation still executes its quadratic comparison schedule even on the same input.

Primary note proof

Study-note section DSA32

> Early stopping makes a sorted input linear: one no-swap pass finishes. A fixed pass schedule stays quadratic. Strict swaps preserve equal-key order. Cocktail sort runs bubble passes in both directions and is stable with strict swaps.

Question sources

Data Structures & Algorithms review questions · Question 25

Question 243 | NS0544

What are the two components of each node in a singly linked list?

Hint

Use the cited definitions and invariants to distinguish the requested concept from related operations.

Answer: Payload/data and a next-node link.

DSA08 defines a singly linked node as data plus next. The head reference points to the first node, and a null next terminates an ordinary noncircular chain. Head is a list-level reference rather than a second payload field inside every node.

Primary note proof

Study-note section DSA08

> A singly linked node contains data and next. Head points to the first node; null ends a noncircular chain. Empty means head==null. Nodes allocated as needed grow dynamically, with pointer overhead and no direct index arithmetic.

Question sources

Data Structures & Algorithms review questions · Question 26

Question 244 | NS0545

How does a circular linked list differ from a singly linked list?

Hint

Use the cited definitions and invariants to distinguish the requested concept from related operations.

Answer: A circular tail links back to head instead of ending at null.

DSA10 defines circularity by the tail-to-head link and stops traversal after returning to the start. This is independent of singly versus doubly linked: a singly linked list can itself be circular. Compared with the ordinary noncircular singly linked chain, termination changes from null to return-to-start.

Primary note proof

Study-note section DSA10

> Doubly linked nodes add prev; head and tail enable constant-time operations at both ends. Singly linked tail deletion still needs its predecessor. A circular tail links back to head; stop traversal on returning to the start, handling empty separately.

Study-note section DSA08

> A singly linked node contains data and next. Head points to the first node; null ends a noncircular chain. Empty means head==null. Nodes allocated as needed grow dynamically, with pointer overhead and no direct index arithmetic.

Question sources

Data Structures & Algorithms review questions · Question 27

Question 245 | NS0546

To delete a node from the front of a singly linked list, what single update is needed?

Hint

Use the cited definitions and invariants to distinguish the requested concept from related operations.

Answer: Advance head to the old head's next link, then reclaim the old node.

DSA09 saves old=head, sets head=head.next, and releases old in an owned C++ chain. The essential link update is advancing head; check empty before dereferencing, and clear tail too if the only node was removed. This answers the operation without hiding ownership work.

Primary note proof

Study-note section DSA09

> Prepend with new.next=head; head=new. To insert after a known predecessor p, set new.next=p.next before p.next=new. Appending with only head requires a tail traversal; maintaining tail avoids it. Delete the head by saving old=head, advancing head=head.next and releasing old in C++.

Study-note section DSA09

> Deleting the tail of a singly linked list requires its predecessor, even when tail itself is known. Handle empty and single-node lists separately; after removing the only node, set both head and tail to null. To remove a known successor, bypass it before deallocation. Clearing an owned n-node chain visits and releases every node.

Question sources

Data Structures & Algorithms review questions · Question 28

Question 246 | NS0547

What extra pointer does each node in a doubly linked list have compared to a singly linked list?

Hint

Use the cited definitions and invariants to distinguish the requested concept from related operations.

Answer: A prev link to the predecessor.

DSA10 says doubly linked nodes add prev alongside next. That extra link permits backward traversal and supports endpoint updates when head and tail are maintained. It does not automatically give constant arbitrary positional access, which may still need traversal.

Primary note proof

Study-note section DSA10

> Doubly linked nodes add prev; head and tail enable constant-time operations at both ends. Singly linked tail deletion still needs its predecessor. A circular tail links back to head; stop traversal on returning to the start, handling empty separately.

Question sources

Data Structures & Algorithms review questions · Question 29

Question 247 | NS0548

Why do linked lists have slower access times than arrays?

Hint

State the representation and cost model, then count the operations or storage demanded by the question.

Answer: Arrays compute addresses directly; linked positional access follows a chain.

DSA02 computes an element address from base, index, and element size in constant time. DSA08's chain lacks direct index arithmetic, so reaching an arbitrary position may traverse linearly many links. This comparison concerns positional access rather than every operation: a known-head update can be constant.

Primary note proof

Study-note section DSA02

> For equal-size elements, address(A[i]) = base + i × element_size under zero-based indexing. This arithmetic gives constant-time positional access in the usual RAM cost model. A row-major rectangular matrix uses base + (row × columns + column) × element_size.

Study-note section DSA08

> A singly linked node contains data and next. Head points to the first node; null ends a noncircular chain. Empty means head==null. Nodes allocated as needed grow dynamically, with pointer overhead and no direct index arithmetic.

Question sources

Data Structures & Algorithms review questions · Question 30

Question 248 | NS0549

Convert the infix expression A + B * C - D / E to postfix.

Hint

Use the cited definitions and invariants to distinguish the requested concept from related operations.

Answer: ABC*+DE/-

DSA13 works the exact expression. Multiplication groups B*C and division groups D/E before addition and subtraction. Emit A, then B C *, then +, then D E /, then −, producing ABC*+DE/-.

Primary note proof

Study-note section DSA13

> Infix places an operator between operands and uses precedence and parentheses. Prefix places it first; postfix places it last. Their fixed operator arity determines grouping. To convert infix to postfix, output operands immediately and hold operators on a stack. Pop higher-precedence operators before pushing a new operator; also pop equal precedence for left-associative operators. Parentheses temporarily override this order.

Study-note section DSA13

> A+B*C-D/E becomes ABC*+DE/-.

Question sources

Data Structures & Algorithms review questions · Question 31

Question 249 | NS0550

What condition causes stack overflow in an array-implemented stack?

Hint

Use the cited definitions and invariants to distinguish the requested concept from related operations.

Answer: Attempting push when the fixed array is full.

DSA11 distinguishes full storage from the overflow attempt. Under zero-based top-as-last-occupied convention, full means top=C−1; a count convention uses size=C. A push must check this before writing beyond capacity.

Primary note proof

Study-note section DSA11

> Stack policy is LIFO, equivalently FILO. Push inserts, pop removes/returns top, and peek only observes. With zero-based occupied slots, top=-1 is empty and top=C-1 is full. Check before A[++top]=x or returning A[top--].

Study-note section DSA11

> Overflow is an attempted insertion into full storage; underflow is an attempted removal from empty storage.

Question sources

Data Structures & Algorithms review questions · Question 32

Question 250 | NS0551

What are the three main operations of a Stack and their time complexities?

Hint

State the representation and cost model, then count the operations or storage demanded by the question.

Answer: Push, pop, and peek are O(1) for fixed-array or head-linked stacks.

DSA11 defines push insertion, pop removal/return, and peek observation at top. Fixed-array indexing and linked-head updates take constant work. A resizing append or singly linked tail-pop implementation can change the cost, so the guarantee needs the stated representations.

Primary note proof

Study-note section DSA11

> Stack policy is LIFO, equivalently FILO. Push inserts, pop removes/returns top, and peek only observes. With zero-based occupied slots, top=-1 is empty and top=C-1 is full. Check before A[++top]=x or returning A[top--].

Study-note section DSA11

> A count-based alternative uses size=0 and A[size++]=x. Do not combine its empty/full tests with the top-index convention. Fixed-array push/pop are constant time. Linked stacks achieve constant time by inserting and deleting at the head; using a singly linked tail for pop would require a predecessor traversal.

Question sources

Data Structures & Algorithms review questions · Question 33

Question 251 | NS0552

In postfix notation, why are parentheses unnecessary?

Hint

Use the cited invariant or operation rule, state its assumptions, and trace a small case to justify the result.

Answer: Operator position and known arity determine grouping.

DSA13 places postfix operators after their operands. During stack evaluation, each binary operator consumes the two latest operand values in right-then-left order and pushes their result. The sequence therefore encodes grouping without precedence parentheses.

Primary note proof

Study-note section DSA13

> Infix places an operator between operands and uses precedence and parentheses. Prefix places it first; postfix places it last. Their fixed operator arity determines grouping. To convert infix to postfix, output operands immediately and hold operators on a stack. Pop higher-precedence operators before pushing a new operator; also pop equal precedence for left-associative operators. Parentheses temporarily override this order.

Study-note section DSA13

> To evaluate postfix, push operands. At a binary operator, pop right operand first, then left, and push left op right. Build an expression tree for either prefix (preorder) or postfix (postorder); a stack is useful but is not the only possible conversion representation.

Question sources

Data Structures & Algorithms review questions · Question 34

Question 252 | NS0553

What is the difference between a simple array queue and a circular queue?

Hint

Use the cited invariant or operation rule, state its assumptions, and trace a small case to justify the result.

Answer: Circular wraparound reuses freed front slots; a simple noncircular queue may not.

DSA15 distinguishes a rear index reaching the array end from circular modulo arithmetic. A circular queue can insert into positions freed at the front, while a simple noncircular version may report overflow despite those gaps. Capacity and empty/full conventions still must be consistent.

Primary note proof

Study-note section DSA15

> A simple noncircular array queue may report overflow when rear reaches the final index despite released slots at the front. A circular queue reuses slots with modulo arithmetic. Use a count convention: front points to the next removal, size counts items, and insertion slot is (front+size)%C. Empty means size==0; full means size==C.

Question sources

Data Structures & Algorithms review questions · Question 35

Question 253 | NS0554

A stable priority queue serves smaller numeric priority keys first and compares equal priorities by an increasing arrival counter, also smallest first. If two tasks have equal priority, in what order are they served?

Hint

Use the cited invariant or operation rule, state its assumptions, and trace a small case to justify the result.

Answer: FIFO among equal priorities: the task that arrived earlier is served first.

The priority comparison ties, so the specified comparator proceeds to the arrival counter. An increasing counter gives the earlier arrival the smaller secondary key, causing it to be removed first. Equal-priority tasks are therefore served FIFO under this stable policy. That result follows from the explicitly chosen tie rule; an ordinary priority queue without a stability or comparator rule would not inherently guarantee arrival-order service.

Primary note proof

Study-note section DSA17

> Arrays and lists can also implement priority queues: an unordered sequence gives cheap insertion but linear extremum removal; an ordered sequence reverses that tradeoff. Equal priorities have no inherent FIFO guarantee. If stable service is required, compare (priority, arrival_counter). Choose the priority direction and tie rule before tracing.

Question sources

Data Structures & Algorithms review questions · Question 36

Question 254 | NS0555

What causes queue underflow and what does it indicate?

Hint

Use the cited invariant or operation rule, state its assumptions, and trace a small case to justify the result.

Answer: Dequeue on an empty queue causes underflow.

DSA11 defines underflow as attempted removal from empty storage; DSA15's count convention detects empty using size==0. This indicates that no item exists to return, not that the array is full or that an ordinary emptiness test itself failed.

Primary note proof

Study-note section DSA11

> Overflow is an attempted insertion into full storage; underflow is an attempted removal from empty storage. Merely checking isEmpty does not underflow.

Study-note section DSA15

> A simple noncircular array queue may report overflow when rear reaches the final index despite released slots at the front. A circular queue reuses slots with modulo arithmetic. Use a count convention: front points to the next removal, size counts items, and insertion slot is (front+size)%C. Empty means size==0; full means size==C.

Question sources

Data Structures & Algorithms review questions · Question 37

Question 255 | NS0556

Name three real-world applications of stacks.

Hint

Use the cited invariant or operation rule, state its assumptions, and trace a small case to justify the result.

Answer: Runtime call frames, undo/redo history, and string or sequence reversal.

DSA12 gives nested calls latest-first returns, moving latest actions between undo and redo stacks, and reversing input by pushing then popping. Each example uses the same latest-pending-item discipline. A new edit after undo normally clears redo history.

Primary note proof

Study-note section DSA12

> Calls nest on a runtime stack; the latest call returns first. Bracket matching pushes opening brackets and matches each closing bracket against top. Reversal pushes input then pops it. Undo moves the latest action from undo to redo; redo moves it back. A new edit after undo normally clears redo. DFS and backtracking use the same latest-pending-choice discipline.

Question sources

Data Structures & Algorithms review questions · Question 38

Question 256 | NS0557

What property must hold at every node of a Binary Search Tree?

Hint

Use the cited invariant or operation rule, state its assumptions, and trace a small case to justify the result.

Answer: Every left-subtree key is smaller and every right-subtree key larger, for distinct keys.

DSA19 imposes this invariant over entire subtrees at every node, not only immediate children. A descendant can satisfy its parent comparison yet violate an ancestor bound. Duplicate keys require an explicit count or placement policy instead of silently weakening the distinct-key rule.

Primary note proof

Study-note section DSA19

> With distinct keys, every key in a node's left subtree is smaller and every key in its right subtree is larger. Immediate-child comparisons alone are insufficient: root 10, left child 5, and 5's right child 12 violate the root's restriction. Duplicates require a separate count or placement policy.

Question sources

Data Structures & Algorithms review questions · Question 39

Question 257 | NS0558

List the order of nodes visited in Inorder traversal of BST: root=4, left subtree has 1,2,3, right has 5,6,7.

Hint

Use the cited invariant or operation rule, state its assumptions, and trace a small case to justify the result.

Answer: 1,2,3,4,5,6,7

DSA20 visits left subtree, node, then right subtree for inorder, and says BST inorder returns sorted keys. The supplied seven distinct keys therefore appear in increasing order even though the internal child shapes are not fully specified. Shape would matter to preorder or postorder.

Primary note proof

Study-note section DSA20

> Preorder visits node,left,right; inorder left,node,right; postorder left,right,node. Apply recursively; null children do nothing. Inorder returns sorted keys only for a BST. Preorder supports copying, postorder supports deleting children before parents, and level order uses a FIFO queue.

Study-note section DSA19

> With distinct keys, every key in a node's left subtree is smaller and every key in its right subtree is larger. Immediate-child comparisons alone are insufficient: root 10, left child 5, and 5's right child 12 violate the root's restriction. Duplicates require a separate count or placement policy.

Question sources

Data Structures & Algorithms review questions · Question 40

Question 258 | NS0559

When deleting a BST node with two children, what are the two valid replacement choices?

Hint

Use the cited invariant or operation rule, state its assumptions, and trace a small case to justify the result.

Answer: Inorder predecessor or inorder successor.

DSA21 identifies the maximum key in the left subtree and minimum key in the right subtree as valid replacement values. Copy one into the deleted node, then remove that value's original node, which has at most one child. These preserve the subtree order invariant.

Primary note proof

Study-note section DSA21

> A leaf can be detached by clearing its parent link. For one child, make the parent bypass the node and point to the child. For two children, copy the inorder predecessor (left-subtree maximum) or successor (right-subtree minimum), then delete that replacement from its original location. That second deletion has at most one child.

Question sources

Data Structures & Algorithms review questions · Question 41

Question 259 | NS0560

What is the time complexity of BST search in the best case vs worst case?

Hint

Use the cited invariant or operation rule, state its assumptions, and trace a small case to justify the result.

Answer: Best successful search Θ(1); arbitrary BST worst Θ(n), balanced worst Θ(log n).

DSA19 gives a constant root hit and O(height) search. A chain has linear height, producing linear worst work; logarithmic height disciplines in DSA22 improve that worst bound. Calling every BST logarithmic would incorrectly assume balance.

Primary note proof

Study-note section DSA19

> Search compares at each node and follows one child until equality or null. Insertion uses that same path to attach a new leaf. Operations cost O(height): logarithmic for balanced trees, linear for a chain. Best-case successful search is Theta(1), a root hit. An optimal BST minimizes expected search cost using access probabilities; constructing it is a different problem from searching it.

Study-note section DSA22

> AVL balance factor is height(left)-height(right); every node must have factor -1,0 or 1. After insertion or deletion, update heights upward and rotate where necessary. LL imbalance needs a right rotation; RR needs left; LR rotates the left child left then the node right; RL is symmetric. Rotations preserve inorder key order.

Question sources

Data Structures & Algorithms review questions · Question 42

Question 260 | NS0561

What is the key difference between BFS and DFS graph traversal?

Hint

Use the cited invariant or operation rule, state its assumptions, and trace a small case to justify the result.

Answer: BFS explores distance layers with FIFO; DFS finishes branches with a stack or recursion.

DSA41 enqueues discoveries in layer order, while DSA42 resumes the latest unfinished branch before later neighbors. Both can traverse all reachable vertices, but their pending-work discipline and visitation order differ. BFS also has the unweighted minimum-edge guarantee.

Primary note proof

Study-note section DSA41

> Mark the source when enqueuing it. Repeatedly dequeue a vertex, examine its neighbours, and enqueue each unvisited neighbour while marking it. Store predecessor[v] when discovering v if a path must be reconstructed. FIFO ensures vertices at distance d are explored before later distance layers.

Study-note section DSA42

> Mark a vertex, then recursively visit each unmarked neighbour before continuing with later neighbours. An explicit stack can store pending work instead. Both implement latest-pending-work first; a queue would change that discipline. Marking prevents infinite repetition around graph cycles.

Question sources

Data Structures & Algorithms review questions · Question 43

Question 261 | NS0562

A directed graph has edges with direction; an undirected graph does not. Give one real-world example of each.

Hint

Use the cited invariant or operation rule, state its assumptions, and trace a small case to justify the result.

Answer: Directed: following accounts; undirected: a mutual friendship relationship.

DSA40 gives following as directed because u following v need not imply v following u. It gives mutual friendship as undirected, representing a symmetric connection. The examples concern relation semantics rather than whether lines happen to be drawn with arrows.

Primary note proof

Study-note section DSA40

> A graph has vertices V and edges E. Directed edges distinguish u→v from v→u; undirected edges represent two-way relationships. Following accounts is directed; a mutual friendship relation is undirected. Weighted edges carry costs; unweighted shortest-path questions count edges. DAG expands to directed acyclic graph. Trees are connected acyclic graphs, although graph data structures may also contain cycles.

Question sources

Data Structures & Algorithms review questions · Question 44

Question 262 | NS0563

Why is a dense graph more computationally expensive to process than a sparse graph?

Hint

Use the cited invariant or operation rule, state its assumptions, and trace a small case to justify the result.

Answer: Edge-processing algorithms do more work when E is larger.

DSA40 says dense simple graphs approach quadratic edge counts and adjacency lists use Θ(V+E) space. Traversals or algorithms inspecting every edge therefore require more work as density increases. This is not universal: a vertex-only operation need not inspect edges.

Primary note proof

Study-note section DSA40

> A matrix uses Theta(V^2) space and constant edge lookup. Adjacency lists use Theta(V+E) space and enumerate neighbours. Dense simple graphs approach quadratic edge counts. Examining every edge costs more on denser graphs; vertex-only operations need not inspect every edge.

Study-note section DSA41

> BFS finds minimum-edge paths in unweighted graphs, not arbitrary minimum-weight paths. With adjacency lists it costs O(V+E); scanning a matrix costs O(V^2). To traverse a disconnected graph, restart from each unvisited vertex. Neighbour order affects tied traversal order but not minimum distances.

Question sources

Data Structures & Algorithms review questions · Question 45

Question 263 | NS0564

In a full binary tree, every node has either 0 or 2 children. How does this differ from a complete binary tree?

Hint

Use the cited invariant or operation rule, state its assumptions, and trace a small case to justify the result.

Answer: Full restricts each node to zero or two children; complete restricts level filling.

DSA18 defines full by each node's child count and complete by filled earlier levels plus left-filled final level. Those are distinct conditions: completeness can allow one child at the boundary, while fullness alone need not keep every level filled.

Primary note proof

Study-note section DSA18

> Binary means at most two children. Full means each node has zero or two children. Complete means all earlier levels are filled and the last fills from left. Perfect means all leaves share a level and every internal node has two children. Balanced means height stays logarithmic under a stated rule; it does not require a perfect shape.

Question sources

Data Structures & Algorithms review questions · Question 46

Question 264 | NS0565

What distinguishes a weighted graph from an unweighted graph, and when would you prefer weighted?

Hint

Use the cited invariant or operation rule, state its assumptions, and trace a small case to justify the result.

Answer: Weighted edges carry differing costs; use them when edge costs matter.

DSA40 assigns costs to weighted edges and says unweighted shortest-path questions count edges. Distances or travel costs can therefore justify weights when fewer edges is not the true objective. DSA43 then distinguishes weighted shortest paths from unweighted BFS.

Primary note proof

Study-note section DSA40

> A graph has vertices V and edges E. Directed edges distinguish u→v from v→u; undirected edges represent two-way relationships. Following accounts is directed; a mutual friendship relation is undirected. Weighted edges carry costs; unweighted shortest-path questions count edges. DAG expands to directed acyclic graph. Trees are connected acyclic graphs, although graph data structures may also contain cycles.

Study-note section DSA43

> For nonnegative weights, standard Dijkstra initializes source distance zero and others infinity, repeatedly finalizes the unsettled vertex with smallest distance, and relaxes each outgoing edge: dist[v]=min(dist[v],dist[u]+w(u,v)). A min-priority queue supports the next choice. BFS is enough when every edge has equal cost; negative edges require another justified method, such as Bellman-Ford.

Question sources

Data Structures & Algorithms review questions · Question 47

Question 265 | NS0566

If a BST receives keys in sorted order (1,2,3,4,5), what shape does the tree take and what is the search complexity?

Hint

Use the cited invariant or operation rule, state its assumptions, and trace a small case to justify the result.

Answer: An ordinary unbalanced insertion forms a right chain; worst search is Θ(n).

DSA19 explicitly traces sorted insertion 1,2,3,4,5 into a right chain. Each new larger key follows right links to the tail, making the height linear. Worst search follows that chain, while a root hit remains constant. Balanced insertion would rotate and is a different assumption.

Primary note proof

Study-note section DSA19

> Search compares at each node and follows one child until equality or null. Insertion uses that same path to attach a new leaf. Operations cost O(height): logarithmic for balanced trees, linear for a chain. Best-case successful search is Theta(1), a root hit. An optimal BST minimizes expected search cost using access probabilities; constructing it is a different problem from searching it.

Study-note section DSA19

> Sorted insertions 1,2,3,4,5 instead form a right chain.

Question sources

Data Structures & Algorithms review questions · Question 48

Question 266 | NS0567

When would you choose a linked list over an array? Give a specific scenario.

Hint

Use the cited invariant or operation rule, state its assumptions, and trace a small case to justify the result.

Answer: Choose links for frequent known-location updates, such as a doubly linked history cursor.

DSA10 gives browser history with a doubly linked cursor as an application. With references to current insertion or removal positions, link changes avoid shifting an array's later elements; arbitrary positional lookup can still be linear. This concrete scenario supports the choice without claiming universal superiority.

Primary note proof

Study-note section DSA10

> Lists suit changing sequences when references to insertion positions are already available. Finding a position is still linear. Lists can hold polynomial terms (coefficient, exponent), directory or block links, child lists in nonbinary trees, and hash chains. Browser history can use a doubly linked cursor. A playlist may be circular; airline seat lookup requires a specified seat-record model, not an automatic linked-list answer.

Study-note section DSA02

> A fixed array has a chosen capacity; the choice need not occur at compile time. A resizable array allocates a larger block and copies when needed. Inserting in the middle shifts later elements, so it costs linear time. Appending into spare capacity is constant; a resizing append can be linear, though repeated geometric growth gives amortized constant append cost.

Question sources

Data Structures & Algorithms review questions · Question 1

Question 267 | NS0568

How does a stack differ from a queue? Give an application for each.

Hint

Use the cited invariant or operation rule, state its assumptions, and trace a small case to justify the result.

Answer: Stack: LIFO for undo; queue: FIFO for equal-priority printer jobs.

DSA11 gives latest-first stack service and DSA12 applies it to undoing the latest edit. DSA14 gives arrival-order queues for equal-priority printing. Both ADTs may use arrays or nodes; their service order, not that representation, is the distinction.

Primary note proof

Study-note section DSA11

> Stack policy is LIFO, equivalently FILO. Push inserts, pop removes/returns top, and peek only observes. With zero-based occupied slots, top=-1 is empty and top=C-1 is full. Check before A[++top]=x or returning A[top--].

Study-note section DSA14

> FIFO suits equal-priority printer jobs, shared-resource waiting, asynchronous buffers and level-order exploration. A play sequence can also use a queue. Distinguish airline seat records from waiting requests; an application name alone does not force one representation.

Study-note section DSA12

> Undo moves the latest action from undo to redo; redo moves it back.

Question sources

Data Structures & Algorithms review questions · Question 2

Question 268 | NS0569

Why is a balanced BST (like AVL) preferred over a regular BST? Explain the worst-case scenario.

Hint

Use the cited invariant or operation rule, state its assumptions, and trace a small case to justify the result.

Answer: Balance prevents linear-height chains and guarantees logarithmic worst search.

DSA22 maintains AVL balance factors through rotations that preserve inorder. DSA19 shows ordinary sorted insertion producing a chain, where a search can traverse all nodes. Maintaining logarithmic height prevents that worst degradation, though root-hit best time remains constant.

Primary note proof

Study-note section DSA22

> AVL balance factor is height(left)-height(right); every node must have factor -1,0 or 1. After insertion or deletion, update heights upward and rotate where necessary. LL imbalance needs a right rotation; RR needs left; LR rotates the left child left then the node right; RL is symmetric. Rotations preserve inorder key order.

Study-note section DSA19

> Search compares at each node and follows one child until equality or null. Insertion uses that same path to attach a new leaf. Operations cost O(height): logarithmic for balanced trees, linear for a chain. Best-case successful search is Theta(1), a root hit. An optimal BST minimizes expected search cost using access probabilities; constructing it is a different problem from searching it.

Question sources

Data Structures & Algorithms review questions · Question 3

Question 269 | NS0570

What is a hash collision? Name two methods to resolve collisions and compare them.

Hint

Use the cited invariant or operation rule, state its assumptions, and trace a small case to justify the result.

Answer: A collision maps different keys to one home address; compare chaining and open addressing.

DSA26 stores colliding entries in bucket lists for chaining, whereas open addressing probes other array slots. Chaining uses link or bucket overhead and expected O(1+α) work; probing keeps entries inside the table and requires careful load and deletion policies. Neither prevents all collisions.

Primary note proof

Study-note section DSA26

> Separate chaining stores colliding entries in a bucket list. Load alpha=n/m is average chain length; expected operations are O(1+alpha) under suitable distribution assumptions, with O(n) worst cases. Open addressing keeps entries inside the array and probes until a key or an available slot is found.

Study-note section DSA26

> Linear probing tries (h(k)+j)%m. For size 7 and keys 10,17,24, all home addresses are 3 and occupied positions become 3,4,5. Quadratic probing changes the step; double hashing uses h1(k)+j h2(k), modulo m, with a step relatively prime to m to cover all slots. Neither method guarantees no collisions. Deletion needs tombstones or reinsertion so searches do not stop prematurely.

Question sources

Data Structures & Algorithms review questions · Question 4

Question 270 | NS0571

What is the difference between BFS and DFS? Which finds the shortest path?

Hint

Use the cited invariant or operation rule, state its assumptions, and trace a small case to justify the result.

Answer: BFS uses FIFO layers and finds shortest unweighted paths; DFS uses branch-first stack order.

DSA41 guarantees minimum-edge paths for BFS on unweighted graphs. DSA42 says DFS paths are reachability witnesses but need not be shortest. Differing edge weights require an appropriate weighted-path algorithm, such as Dijkstra under nonnegative weights.

Primary note proof

Study-note section DSA41

> BFS finds minimum-edge paths in unweighted graphs, not arbitrary minimum-weight paths. With adjacency lists it costs O(V+E); scanning a matrix costs $O(V^2)$. To traverse a disconnected graph, restart from each unvisited vertex. Neighbour order affects tied traversal order but not minimum distances.

Study-note section DSA42

> Using the same graph and alphabetical neighbours, recursive DFS can discover A,B,D,C. Its path is a valid reachability witness but not necessarily shortest. Adjacency-list cost is O(V+E), with O(V) visited state and possible stack depth. DFS supports cycle and connectivity analysis; a directed cycle test distinguishes active recursion vertices from already completed ones.

Study-note section DSA43

> BFS is enough when every edge has equal cost; negative edges require another justified method, such as Bellman-Ford.

Question sources

Data Structures & Algorithms review questions · Question 5

Algorithm Design & Analysis review questions · Question 4

Question 271 | NS0572

A text editor needs to implement multi-level undo. Which data structure is most appropriate and why?

Hint

Use the cited invariant or operation rule, state its assumptions, and trace a small case to justify the result.

Answer: Use an undo stack, with a second redo stack if needed.

DSA12 moves the latest action from undo to redo and reverses that movement for redo. Pushing each new edit and popping for undo naturally matches the most-recent-edit-first requirement. A new edit after undo normally clears redo history.

Primary note proof

Study-note section DSA12

> Calls nest on a runtime stack; the latest call returns first. Bracket matching pushes opening brackets and matches each closing bracket against top. Reversal pushes input then pops it. Undo moves the latest action from undo to redo; redo moves it back. A new edit after undo normally clears redo. DFS and backtracking use the same latest-pending-choice discipline.

Questions & Worked Answers

305 questions + 1 source variants

Question 1 | Q00008

Which symbol is used to write a single line comment in JavaScript?

A. <?

B. <!---------->

C. //

D. &&

Hint

Check exact language syntax, declaration rules and execution context before reasoning about the result.

Answer C: //

A single-line JavaScript comment starts with two forward slashes (p.46); text following it on that line is ignored. Evidence: PDF p. 46.

Why each choice is right or wrong

A - Incorrect: PHP-style opening delimiter, not the stated JS comment form.

B - Incorrect: HTML-style comment delimiters do not match the JS rule.

C - Correct: Exactly the double forward slash specified on p.46.

D - Incorrect: Logical conjunction syntax is not the double-slash comment delimiter.

Primary note proof

Study-note section WEB15

> // comments end at line end; /* */ span a block.

Study-note section WEB23

> Use <?php ...

> 4.3 JavaScript Comments
> As with HTML and CSS, it is possible to write comments into a JavaScript code
> that will be ignored by the browser, and exist to provide instructions to fellow

developers on how the code works. There are two types of JavaScript comments
- A single line comment written after a double forward slash (//)
// I am a single line comment
- A multiline comment is written between the strings (/* */)

Question sources

MOE Computer Science Exit Exam · 2016 · Question 8

Question 2 | Q00018

Which attribute of INPUT tag defines the number of characters that can be displayed in a text box without scrolling?

A. SIZE

B. MAXLENGTH

C. VALUE

D. TYPE

Hint

Separate the control role, displayed content, submitted value and form destination.

Answer A: SIZE controls approximate visible text-input width.

WEB09 distinguishes size from maxlength: size describes the approximate visible width of a text input, while maxlength limits how much text can be entered. That matches the stem's focus on characters displayed without scrolling. VALUE provides initial content and TYPE selects the control kind; neither is the width-setting attribute requested here.

Why each choice is right or wrong

A - Correct: SIZE controls approximate visible width for a text input, matching the display-without-scrolling description.

B - Incorrect: MAXLENGTH limits entered text length rather than determining how wide the input appears.

C - Incorrect: VALUE supplies the control's content, not its visible character-width setting.

D - Incorrect: TYPE selects the input-control kind rather than its approximate visible width.

Primary note proof

Study-note section WEB09

For a text input, size indicates approximate visible width, whereas maxlength limits entered text length.

Study-note section WEB-S02

For a text input, the value attribute supplies its initial text value; it does not specify the control's width.

Module passages - related reading

MOE Computer Science Exit Exam · 2016 · Question 18

Question 3 | Q00020

Which method can be used to divide a browser into smaller sub windows so that each sub window displaying a different HTML document?

A. Using paragraphs

B. Using frames

C. Using images

D. Using tables

Hint

Use the element or attribute meaning and document structure, rather than appearance or a similar-looking name.

Answer B: Using frames

Frames display independent windows/subwindows and each frame may contain a different web page (p.20). This matches dividing the browser into document views. Evidence: PDF p. 20, PDF p. 20, PDF p. 17.

Why each choice is right or wrong

A - Incorrect: Paragraphs structure text (p.15), not separate document views.

B - Correct: Frames explicitly provide the required subwindows.

C - Incorrect: Images embed visual content, not independent HTML documents.

D - Incorrect: Tables structure rows and columns, not separate document views.

Primary note proof

Study-note section WEB10

Legacy frameset/frame divides a window into separate documents; frameset replaced body in old frameset documents.

Study-note section WEB06

<p> marks paragraphs;
 is a line break and <hr> a thematic break.

Study-note section WEB08

<table> contains rows <tr>, header cells <th> and data cells <td>; a td is not the table itself.

MOE Computer Science Exit Exam · 2016 · Question 20

Question 4 | Q00037

Which statement is false about potential benefits of well-designed external style sheets? Treat benefits as possibilities, not guarantees.

A. Style sheets can support accessible presentation

B. Style sheets can create a consistent appearance

C. Style sheets can make HTML pages easier to maintain

D. Style sheets cannot reduce repeated markup or transferred file size

Hint

Identify which elements a rule targets and distinguish selector syntax from declaration syntax.

Answer D: Style sheets cannot reduce repeated markup or transferred file size

External CSS lets several pages reuse presentation rules, making visual changes easier to maintain and helping consistency. Reuse and caching can reduce repeated markup and transfers, although savings depend on the implementation. Accessible presentation is also possible, but CSS alone does not establish accessibility. The false statement is the absolute denial of any size or transfer savings; the other choices describe potential benefits rather than universal promises.

Why each choice is right or wrong

A - Incorrect: Accessible presentation can be supported, though semantic markup and usable controls are still needed.

B - Incorrect: Reused rules can give pages a consistent appearance.

C - Incorrect: Central rules reduce repeated presentation edits across pages.

D - Correct: This absolute denial is false: reuse and caching can reduce repeated markup and transfers.

Primary note proof

Study-note section WEB11

> External CSS promotes reuse, consistent design and caching; it does not guarantee that every page becomes smaller or accessible.

Study-note section WEB07

> Give controls programmatic labels, clear link text and keyboard access; visual styling alone does not establish accessibility.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 28 | lines 27-31

> 3. External style sheets
> An external style sheet is used when the style is applied to many pages. With an
> external style sheet, you can change the look of an entire website by changing one file

(the style sheet). Each page should be linked to the style sheet using the <link> tag inside the head section.

Question sources

MOE Computer Science Exit Exam · 2016 · Question 37

Question 5 | Q00062

What will be the out of the following JavaScript statement? Math.abs(-9)

A. 9

B. -9

C. 1

D. 0

Hint

Track the value and type at each operation, applying the stated conversion, indexing or mathematical rule.

Answer A: 9

WEB18 explicitly evaluates Math.abs(-9) as 9. Absolute value removes the negative sign from a negative numeric argument and leaves its magnitude, so the result is neither the original negative number nor a Boolean-like one or zero. This is an expression result; no rounding or text conversion is involved.

Why each choice is right or wrong

A - Correct: The absolute value of negative nine is its nonnegative magnitude, nine.

B - Incorrect: Negative nine is the input; absolute value does not preserve its negative sign.

C - Incorrect: Math.abs returns numeric magnitude rather than a Boolean-like value of one.

D - Incorrect: The input is nonzero, so its absolute value is not zero.

Primary note proof

Study-note section WEB-S08

For finite numeric arguments, Math.abs(x) gives the nonnegative magnitude, Math.floor(x) gives the greatest integer no larger than x, and Math.sqrt(x) gives the nonnegative square root for nonnegative x.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

<?php
echo abs(-4.2); // 4.2 (double/float)
echo abs(5); // 5 (integer)
echo abs(-5); // 5 (integer)
?>

Question sources

MOE Computer Science Exit Exam · 2016 · Question 62

Question 6 | Q00064

In the legacy browser expression document.bgColor, what is bgColor?

A. bgColor is a method

B. bgColor is the document object

C. bgColor is a property

D. bgColor is an event handler

Hint

Distinguish the browser object or dialog role from the kind of response it collects.

Answer C: bgColor is a property

The expression uses the lowercase document object name and the exact camelCase member bgColor. In this legacy API, bgColor is a property representing background color, rather than a method call or event handler. Asking specifically about the member avoids confusing it with window.document, which is itself a property. Current code normally changes the background through document.body.style.backgroundColor rather than this legacy interface.

Why each choice is right or wrong

A - Incorrect: No function is invoked or named by this legacy color member.

B - Incorrect: document is the object on which the member is accessed, not the bgColor value.

C - Correct: The legacy member stores a background-color setting.

D - Incorrect: The member is a color property, not an event callback.

Primary note proof

Study-note section WEB22

> document.bgColor is a legacy property; Document.bgcolor has wrong object/case.

Study-note section WEB22

> In a normal browser page, window exposes the browsing context and document is its document property.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 53 | lines 2-3

> Example
> element.style.backgroundColor = “red”;

Web Programming module | PDF page 56 | lines 17-25

> All global JavaScript objects, functions, and variables automatically become
> members of the window object.
> Global variables are properties of the window object
> Global functions are methods of the window object.
> Even the document object (of the HTML DOM) is a property of the window
> object:
> window.document.getElementById("header");
> is the same as:
> document.getElementById("header");

Question sources

MOE Computer Science Exit Exam · 2016 · Question 64

Question 7 | Q00069

Look at the following valid PHP array:
$list = array("outside" => "red", "inside" => "brown", "top" => "black", "under" => "blue");
Which exact string key indexes the value "black"?

A. brown

B. outside

C. under

D. top

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer D: top

PHP associative arrays map explicit keys to values. In each pair, the text before the contiguous => operator is the key and the text after it is the value. The pair containing black therefore uses the key top. String-key case matters, so the lowercase spelling is retained in the corrected choices. The other offered strings either identify another entry or are themselves a value rather than the requested key.

Why each choice is right or wrong

A - Incorrect: brown is the value associated with inside, not the key of black.

B - Incorrect: outside identifies red.

C - Incorrect: under identifies blue.

D - Correct: top is the exact key paired with black.

Primary note proof

Study-note section WEB26

> PHP arrays map integer/string keys to values.

Study-note section WEB26

> Associative syntax uses a contiguous => operator: ["top"=>"black"] stores black under key"top".

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 69 | lines 4-22

> Syntax
> An array can be created using the array() language construct. It takes any number
> of comma-separated key => value pairs as arguments.
> array(
> key => value,
> key2 => value2,
> key3 => value3,
> ...
>)
> E.g.
> <?php
> $array1 = array("Item 1", "Item 2", "Item 3", "Item 4");
> $array2 = array('item1' => "Item 1",
> 'item2' => "Item 2",
> 'item3' => "Item 3",
> 'item4' => "Item 4");
> ?>
> The use of => is similar to the regular = assignment operator, except that you are
> assigning a value to an index and not to a variable.

Question sources

MOE Computer Science Exit Exam · 2016 · Question 69

Question 8 | Q00075

Which statement is false about modern JavaScript running in a browser sandbox?

A. The language cannot support sophisticated applications

B. Scripts can access selected client devices through permission-based APIs

C. Scripts have restricted access to arbitrary client files and hardware

D. Script source can be supplied as text and executed by the browser

Hint

Check exact language syntax, declaration rules and execution context before reasoning about the result.

Answer A: The language cannot support sophisticated applications

Browser JavaScript supports sophisticated applications; its sandbox is a restriction on access to resources, not proof of an inherently weak language. Selected file or device access can be exposed through permission-based APIs, while arbitrary hardware access remains restricted. JavaScript source can be included in pages or loaded from a script file. Thus the language-capability claim is false, while the qualified environment and source-delivery claims are compatible.

Why each choice is right or wrong

A - Correct: The note explicitly allows sophisticated applications, so this denial is false.

B - Incorrect: Permission-based APIs allow selected device access.

C - Incorrect: Sandbox restrictions limit arbitrary resource access.

D - Incorrect: Script inclusion supplies source for browser execution.

Primary note proof

Study-note section WEB01

> Browser scripts are sandboxed, but may access selected files/devices through permission-based APIs.

Study-note section WEB01

> They are not inherently limited to trivial programs, nor can they freely access arbitrary client hardware.

Study-note section WEB15

> Use <script src="app.js"></script> for an external .js file; script content has no HTML closing-tag syntax inside its JavaScript source.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 44 | lines 3-7

> 4.1 Introduction to JavaScript
> JavaScript (JS) is a lightweight, interpreted or compiled programming language. It is a single threaded, dynamic language, supporting object oriented, functional programming styles. Do not confuse JavaScript with the Java Programming language. The two-programming language have very different syntax, semantics, and use.

Web Programming module | PDF page 44 | lines 21-28

> We can use JavaScript in coordination with Application programming interfaces (APIs). APIs provide us extra information. They are ready made code building blocks that are used to simplify programming in JavaScript. There are two types of APIs
> - Third party API → are not built into the browser. We have to grab the code from the web. Examples: Twitter API, Google maps API etc.
> - Browser API → are built into the browser. Examples DOM (Document object model) which is covered later in this chapter, Geolocation API, Canvas and WebGL, Audio and Video elements

Question sources

MOE Computer Science Exit Exam · 2016 · Question 75

Question 9 | Q00155

Which one of the following is false?

A. A web browser is a software that runs on a server

B. A user agent renders resources for a user to view

C. A website is a collection of resources in various forms

D. A web page is the basic unit of information storage on the www

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer A: A web browser is a software that runs on a server

The module places web pages on servers and says web clients view them using a browser (p.9). Thus A reverses the browser role in the ordinary client/server description. Web pages hold web information (p.8); B and C describe the compatible rendering/resource roles, though they are not verbatim definitions. Evidence: PDF p. 9, PDF p. 8, PDF p. 9.

Why each choice is right or wrong

A - Correct: Client-side browser role contradicts this server-role claim in the teaching model.

B - Incorrect: A browser views pages, consistent with rendering resources.

C - Incorrect: Website files are hosted together (p.9), consistent with this collection description.

D - Incorrect: Page 8 explicitly says web information is stored in Web pages.

Primary note proof

Study-note section WEB01

> A browser/user agent requests resources and renders HTML/CSS, then runs permitted JavaScript.

Study-note section WEB01

> A web/HTTP server receives requests and returns representations, sometimes invoking application code.

Study-note section WEB02

> A website groups resources; a page is one document/resource.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 9 | lines 2-4

> • Web pages are files stored on computers called Web servers.
> • Computers reading the Web pages are called Web clients.
> • Web clients view the pages with a program called a Web browser.

Web Programming module | PDF page 8 | lines 29-34

> • The World Wide Web (WWW) is most often called the Web.
> • The Web is a network of computers all over the world.
> • All the computers in the Web can communicate with each other.
> • All the computers use a communication standard called HTTP.
> How does the WWW work?
> • Web information is stored in documents called Web pages.

Web Programming module | PDF page 9 | lines 13-21

> Web hosting is the place where all the files of your website live. Web hosting is a service that allows organizations and individuals to post a website or a web page onto the Internet. A web host, or web hosting service provider, is a business that provides the technologies and services needed for the website or webpage to be viewed in the Internet. Websites are hosted, or stored, on special computers called servers. When Internet users want to view your website, all they need to do is type your website address or domain (the domain name for the site has to be registered) into their browser. Their computer will then connect to your server and your webpages will be delivered to them through the browser.

Question sources

Addis Ababa University mock exam · Question 57

Question 10 | Q00157

Which one of the following is the correct syntax for document type declaration in HTML5?

A. </doctype html>

B. <!doctype! Html>

C. <doctype! Html>

D. <!doctype html>

Hint

Use the element or attribute meaning and document structure, rather than appearance or a similar-looking name.

Answer D: <!doctype html>

The module examples begin <!DOCTYPE html> (p.21 and p.30). D has that declaration form, with lowercase keyword; the other choices change its punctuation. Evidence: PDF p. 21, PDF p. 30.

Why each choice is right or wrong

A - Incorrect: A closing-tag slash is not the demonstrated declaration.

B - Incorrect: Extra exclamation after doctype is absent from the example.

C - Incorrect: Missing exclamation immediately after <.

D - Correct: Matches the module declaration structure.

Primary note proof

Study-note section WEB06

> <!DOCTYPE html> selects modern standards mode; <html> is the document root, <head> holds metadata, and <body> contains document content.

Addis Ababa University mock exam · Question 59

Computer Science Exit Exam · Sene 2016 · Question 16-1

Computer Science Exit Exam practice collection · Question 38

Question 11 | Q00158

In HTML, how do we create a link to another site?

A. click here

B. click here

C. click here

D. <a "http://www.somedomain.com">click here

Hint

Use the element or attribute meaning and document structure, rather than appearance or a similar-looking name.

Answer A: click here

Page 14 requires an anchor with an href containing the web address. A supplies that attribute and encloses link text between a and /a. Evidence: PDF p. 14.

Why each choice is right or wrong

A - Correct: Exactly the anchor/href pattern on p.14.

B - Incorrect: url does not substitute for the stated href attribute.

C - Incorrect: link does not substitute for href.

D - Incorrect: A bare quoted URL omits the required href attribute.

Primary note proof

Study-note section WEB07

> Use Read for a link; href is the destination, not url/link.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 14 | lines 5-9

> In HTML, a link is created by wrapping the text or other content inside an <a> tag (anchor tag) and using the href attribute, also known as Hypertext reference, or target that contains the web address.
> Here is an example of a link to the google website
> Google.

Question sources

Addis Ababa University mock exam · Question 60

Question 12 | Q00159

Which one of the following form attribute is used to assign the server-side script file that processes the form data?

A. Action

B. Autocomplete

C. Method

D. Target

Hint

Separate the control role, displayed content, submitted value and form destination.

Answer A: Action

The form attribute action points to the backend script processing collected data. Method instead specifies upload method; target controls the result window.

Why each choice is right or wrong

A - Correct: Backend processing script is precisely action.

B - Incorrect: Autocomplete is not assigned the processing-script role.

C - Incorrect: Method determines the submission method, not script filename.

D - Incorrect: Target determines window/frame for the result.

Primary note proof

Study-note section WEB09

> A form’s action identifies its processing URL, method its submission method, and enctype its encoding.

Study-note section WEB-S02

> A form’s target identifies the window or frame in which the submitted result is displayed.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 21 | lines 23-31

> Form attributes:
> - action → Backend script ready to process the data collected
> - method → method used to upload Data. The most frequently used
> - target → Specify the target window or frame where the result of the script will be displayed. It takes values like _blank, _self, _parent etc.
> - enctype → tells how the browser encodes data. Possible values
> 1. application/x-www-form-urlencoded → most common and used from simple scenarios
> 2. mutlipart/form-data → used to upload binary data

Computer Science Exit Exam · Sene 2016 · Question 31-4

Computer Science Exit Exam practice collection · Question 39

Question 13 | Q00160

What does this JavaScript print in an ordinary browser page?
<script>
let x = 4 + "4";
document.write(x);
</script>

A. 44

B. 8

C. 4

D. The code contains an error

Hint

Track the value and type at each operation, applying the stated conversion, indexing or mathematical rule.

Answer A: 44

The addition expression is complete and ends with a semicolon. Because one operand is a string, + performs concatenation here: the numeric operand contributes its text and the result is the string 44. document.write then emits those two digits.

Why each choice is right or wrong

A - Correct: The string operand makes the two digit representations concatenate.

B - Incorrect: Numeric addition would require numeric operands rather than the given string.

C - Incorrect: The right operand contributes another digit to the output.

D - Incorrect: The expression is syntactically valid.

Primary note proof

Study-note section WEB16

> + can concatenate when a string is involved; arithmetic / converts ordinary numeric strings.

Study-note section WEB22

> document.write is a method/function property; writing after document load can replace the document.

Module passages - related reading

Addis Ababa University mock exam · Question 62

Question 14 | Q00161

What does the following valid PHP code output?

```
<?php
$color = "maroon";
$var = $color[2];
echo "$var";
?>
```

A. a

B. Error

C. var

D. r

Hint

Trace the bindings and operations in order; preserve the exact string characters and distinguish returned values from emitted output.

Answer D: r

PHP string offsets start at zero. The characters of maroon at offsets zero, one and two are m, a and r, so the selected character is r. The variable is interpolated by the double-quoted echo string and no extra spacing is added.

Why each choice is right or wrong

A - Incorrect: a is at offset one.

B - Incorrect: The PHP delimiter and string access are valid.

C - Incorrect: Interpolation emits the value of $var, not its name.

D - Correct: r occupies offset two of maroon.

Primary note proof

Study-note section WEB24

> String offsets start at zero: "maroon"[2] is r when the surrounding PHP is valid.

Study-note section WEB24

> Double-quoted strings interpolate variables and escapes such as \n; single quotes normally preserve dollar names literally.

Study-note section WEB23

> Use <?php ...

Web Programming module | PDF page 63 | lines 27-33

> 5.4 Data Types and Variables in PHP
> PHP is a very loosely typed language. This means that variables do not have to be declared before they are used, and that PHP always converts variables to the type required by their context when they are accessed. Variables can store data of different types, and different data types can do different things. PHP supports the following data types: String, Integer, Float (floating point numbers - also called double), Boolean, Array, Object, NULL and Resource

Web Programming module | PDF page 70 | lines 2-8

> We can also create arrays by adding the index of the item in between the square brackets. This will enable us to add items in unorderly fashion
> <?php
> $sample[0] = "sample 1";
> $sample[1] = "sample 2";

```
$sample[2] = "sample 3";
$sample[3] = "sample 4";
```

Question sources

Addis Ababa University mock exam · Question 63

Question 15 | Q00162

In PHP, which function initiates a session?

A. start()

B. s_start()

C. session_start()

D. session_str()

Hint

Follow the identifier and server-side state through the stated lifecycle or access check; distinguish client-controlled claims from server decisions.

Answer C: session_start()

The Starting a PHP Session example explicitly calls session_start() before storing information (p.76). Evidence: PDF p. 76.

Why each choice is right or wrong

A - Incorrect: Not the session initializer named by the module.

B - Incorrect: Not the documented name.

C - Correct: Exact documented initializer.

D - Incorrect: Not the documented name.

Primary note proof

Study-note section WEB29

session_start() starts/resumes PHP session handling and makes $_SESSION available.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 76 | lines 6-16

Starting a PHP Session
Before you can store user information in your PHP session, you must first start up the session.
<?php session_start(); ?>
<html>

<body>.....
</body>
</html>
The code above will register the user's session with the
server, allow you to start saving user information, and assign a UID for that user's
session.

Question sources

Addis Ababa University mock exam · Question 64

Question 16 | Q00163

Which single option gives the complete selection of the listed PHP superglobals?

A. $_GET

B. $_POST

C. $_SERVER

D. All of the above

Hint

Identify the data source or security responsibility precisely, and check whether a combined source or a different control could also qualify.

Answer D: All of the above

The names $_GET, $_POST and $_SERVER are all PHP superglobals, representing query values, supported form POST data and request/environment details respectively. The question asks for the complete selection in one option, so All of the above is the best response. Each individual array is genuinely a superglobal, but selecting just one would omit the other two valid entries.

Why each choice is right or wrong

A - Incorrect: True individually, but incomplete because POST and SERVER are also superglobals.

B - Incorrect: True individually, but incomplete because GET and SERVER are also superglobals.

C - Incorrect: True individually, but incomplete because GET and POST are also superglobals.

D - Correct: This aggregate includes all three valid superglobals.

Primary note proof

Study-note section WEB27

$_GET contains query parameters; $_POST contains supported form POST data; $_FILES upload metadata; $_SERVER request/environment details; $_COOKIE cookie values; $_SESSION session data after startup.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 62 | lines 12-26

> PHP provides a large number of predefined variables to any script which it runs.
> PHP provides an additional set of predefined arrays containing variables from the web server the environment, and user input. These new arrays are called superglobals –
> All the following variables are automatically available in every scope.
> - $GLOBALS → Contains a reference to every variable which is currently available within the global scope of the script. The keys of this array are the names of the global variables.
> - $_SERVER → This is an array containing information such as headers, paths, and script locations. The entries in this array are created by the web server. There is no guarantee that every web server will provide any of these. See next section for a complete list of all the SERVER variables.
> - $_GET → An associative array of variables passed to the current script via the HTTP GET method.
> - $_POST → An associative array of variables passed to the current script via the HTTP POST method.

Addis Ababa University mock exam · Question 65

Question 17 | Q00265

Which of the following is the correct syntax to link an external style sheet in the HTML file?

A. <link rel="stylesheet" src="style.css" />

B. <link rel="stylesheet" href="style.css" />

C. <style rel="stylesheet" src="style.css" />

D. <style rel="stylesheet" link="style.css" />

Hint

Identify which elements a rule targets and distinguish selector syntax from declaration syntax.

Answer B: <link rel="stylesheet" href="style.css" />

The external CSS example uses <link rel="stylesheet" href="style.css"> (p.29). B matches the element, relationship and URL attribute. Evidence: PDF p. 29, PDF p. 28.

Why each choice is right or wrong

A - Incorrect: src is not the demonstrated stylesheet URL attribute.

B - Correct: Matches the complete link/rel/href pattern.

C - Incorrect: style is used for embedded rules, and src is wrong here.

D - Incorrect: style with link does not implement the module external-link syntax.

Primary note proof

Study-note section WEB11

> An external sheet uses <link rel="stylesheet" href="styles.css"> in head; an internal sheet uses style; an inline declaration uses an element’s style attribute.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 29 | lines 2-6

> E.g.
> <link rel="stylesheet" href="style.css">
> The rel attributes names the relationship of the linked document to the current document. The href attribute specifies the URL of the linked document. The URL can be relative or absolute

Web Programming module | PDF page 28 | lines 12-14

> 2. Embedded stylesheet
> This type of stylesheet should be used when a single document has a unique style. You define internal styles in the head section by using the <style> tag.

Mock exam 4 · Question 67

Question 18 | Q00266

Which of the following is used for concatenation in PHP?

A. *(Asterisk)

B. . (dot)

C. append()

D. + (plus)

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer B: . (dot)

PHP examples concatenate labels, variables and HTML strings with dot, for example echo "name:".$name."
" (p.72). Evidence: PDF p. 72, PDF p. 64.

Why each choice is right or wrong

A - Incorrect: Asterisk is arithmetic, not the joining operator in the example.

B - Correct: Dot joins the strings and variables in the PHP example.

C - Incorrect: No append() string operation is established.

D - Incorrect: Plus performs numeric addition in the p.64 example, not the demonstrated string joining.

Primary note proof

Study-note section WEB24

> Dot concatenates; + is arithmetic.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

```
$first=6;
$second=5;
$result=$first+$second;
Echo $result;
```

Question sources

Mock exam 4 · Question 68

Question 19 | Q00268

Which one of the following is not used to generate dynamic web pages?

A. JSP

B. PHP

C. CSS

D. ASP.NET

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer C: CSS controls presentation rather than generating server-side pages.

WEB01 assigns CSS presentation and identifies PHP, JSP/Java, and ASP.NET applications as generating server responses. In this role distinction, CSS is the exclusion: it styles a representation rather than executing the server page-generation logic. CSS can affect displayed appearance, but that does not make it a server-side dynamic-page generator like the other offered technologies.

Why each choice is right or wrong

A - Incorrect: JSP/Java applications are identified in WEB01 as server-side response generators.

B - Incorrect: PHP applications can generate server responses and access databases, fitting dynamic-page generation.

C - Correct: CSS supplies presentation rules rather than the server logic that generates dynamic page representations.

D - Incorrect: ASP.NET applications are identified as server-side response generators, so they are not the exclusion.

Primary note proof

Study-note section WEB01

> HTML supplies structure/meaning; CSS controls presentation; JavaScript supplies programmable interactivity.

Study-note section WEB01

> PHP, Python, JSP/Java and ASP.NET applications generate server responses and access databases; C# is commonly used with ASP.NET.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 26 | lines 4-10

> In the previous chapter we have seen how to structure a web page using HTML.
> Now it is time to add presentation to our sites, to do that we will be using a technology
> called CSS. CSS (Cascading Style Sheets) is the code that styles web content. Using
> CSS you can apply styles to make web pages look exactly how you want. This works
> because CSS is connected to the DOM(Document Object Model). CSS is not a
> programming language. It's not a markup language either. CSS is a style sheet
> language. CSS is what you use to selectively style HTML elements.

Web Programming module | PDF page 60 | lines 4-10

> PHP is a server-side scripting language, which can be embedded in HTML or used as
> a standalone binary (although the former use is much more common). PHP stands for
> Hypertext Preprocessor. The product was originally named Personal Home Page Tools,

Question sources

Mock exam 4 · Question 70

Question 20 | Q00314

In PHP MySQLi, after mysqli_init() and mysqli_ssl_set(...) have configured the required TLS and certificate-verification settings, which function initiates the database connection?

A. mysqli_real_connect(...)

B. pdo_connect_ssl()

C. mysql_ssl_connect()

D. secure_connect()

Hint

Identify the API and operation first, then distinguish connection setup, statement execution and result processing.

Answer A: mysqli_real_connect(...)

MySQLi separates initialization and TLS configuration from opening the connection. Under the stated setup, mysqli_real_connect performs the connection step using the configured handle and required options. The other names are not standard connection functions in the supplied note. Choosing the actual API does not mean that any call automatically verifies certificates; that protection depends on the verification configuration explicitly included in the question.

Why each choice is right or wrong

A - Correct: This is the connection step in the documented MySQLi TLS sequence.

B - Incorrect: This is not the documented PDO or MySQLi connection API.

C - Incorrect: The note rejects this invented SSL connection function.

D - Incorrect: The note rejects this generic invented function name.

Primary note proof

Study-note section WEB31

> Configure MySQLi TLS options through mysqli_init(), mysqli_ssl_set(...) and mysqli_real_connect(...) with the required verification configuration.

Study-note section WEB31

> mysqli_ssl_connect(), pdo_connect_ssl(), mysql_ssl_connect() and secure_connect() are not substitutes for the MySQLi TLS configuration sequence above.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 79 | lines 9-16

5.13.2 Creating Database Connection in PHP
1. Connecting to MySQL
The basic command to initiate a MySQL connection is
$link=mysql_connect($hostname, $user, $password); if you‘re using variables, or
$link=mysql_connect(„localhost“, „root“, „sesame“); if you‘re using literal strings. Here
$Hostname - the ip address or hostname of the MySQL server. If the MySQL server
and the php server are on the same machine use localhost or 127.0.0.1, else use the ip
address of the database server.

University of Gondar model exam · Question 45

Question 21 | Q00315

Which JavaScript function is used to display a dialog box with an alert message?

A. console.log()

B. confirm()

C. alert()

D. prompt()

Hint

Distinguish the browser object or dialog role from the kind of response it collects.

Answer C: alert()

Alert shows a browser popup containing its argument (p.47). Prompt requests input, confirm returns a Boolean choice, and console.log writes to the console (p.46). Evidence: PDF p. 47, PDF p. 46.

Why each choice is right or wrong

A - Incorrect: Console output is not an alert dialog.

B - Incorrect: Confirmation presents OK/Cancel and returns a Boolean.

C - Correct: Exactly the documented alert popup.

D - Incorrect: Prompt additionally requests text input.

Primary note proof

Study-note section WEB22

alert displays information, confirm returns a Boolean, and prompt requests text or returns null on cancellation.

Study-note section WEB22

console.log logs diagnostics.

Study-note section WEB-S03

Alert is a notification; confirm additionally asks for an OK/Cancel decision, while prompt additionally offers a text field.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 47 | lines 2-9

2. Alert: shows a browser pop up with the information inside the parenthesis
3. The write() method
- The write() method writes HTML expressions or JavaScript code to a document.
- The write() method is mostly used for testing: If it is used after an HTML document is fully loaded, it will delete all existing HTML.
Usage:
document.write(expr)

Web Programming module | PDF page 46 | lines 16-27

Accepting user input in JavaScript actually is not a difficult task. JavaScript has a function called prompt, which is used to accept input from the user. But for the result to be useful for us, it has to be stored in a variable. Here is a simple example
var name = prompt("Enter your name: ");
alert("Hello " + name);
➢ Prompt will show a modal windows with a text message, an input field for the visitor, and the buttons OK/Cancel
➢ We can also use confirm to get information from a user:- the function confirm shows a modal window with a question and two buttons: OK and Cancel
The result is true if OK is pressed and false otherwise
Generating an output in JavaScript can be done in different ways.
1. Console.log: outputs a string to the browser console.

Computer Science model exam · Question 46

University of Gondar model exam · Question 46

Question 22 | Q00316

Which JavaScript method is used to select an HTML element by its ID?

A. getElementById()

B. getElementByTag()

C. getElementByName()

D. getElementByClass()

Hint

Track which node is selected or created, and distinguish changing content from attaching a node.

Answer A: getElementById()

The DOM methods list says getElementById(id) returns the element with that specific ID (p.52). Evidence: PDF p. 52.

Why each choice is right or wrong

A - Correct: Exact ID lookup method.

B - Incorrect: Not the documented getElementsByTagName; also tag selection differs.

C - Incorrect: No getElementByName is defined here; not ID lookup.

D - Incorrect: Not the documented class lookup and not ID lookup.

Primary note proof

Study-note section WEB20

> document.getElementById("x") returns the matching element or null; querySelector(".item") returns the first match, and querySelectorAll returns a static NodeList.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 52 | lines 10-19

> 4.10.1 Accessing HTML elements in JavaScript
> In the DOM Api, there are different methods to get access to HTML elements. We will list the available methods here, but only the most recent methods are covered here.
> - getElementById(id) returns an element with that specific ID
> - getElmentsByClassName(class) returns elements with that specific class
> getElementsByTagName(tag) returns elements with the given tag name
> - querySelector(selector) → The Document method querySelector() returns the first Element within the document that matches the specified selector, or group of selectors. If no matches are found, null is returned.

University of Gondar model exam · Question 47

Question 23 | Q00317

Which language is used to add interactivity and dynamic behavior to a web page?

A. HTML

B. PHP

C. CSS

D. JavaScript

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer D: JavaScript

The module divides roles: HTML structure, CSS presentation, JavaScript functionality and interactive content updates (p.44). Evidence: PDF p. 44, PDF p. 60.

Why each choice is right or wrong

A - Incorrect: HTML supplies structure.

B - Incorrect: PHP generates server output, whereas this stem targets page interactivity.

C - Incorrect: CSS supplies presentation.

D - Correct: JavaScript supplies interactive browser behavior.

Primary note proof

Study-note section WEB01

> HTML supplies structure/meaning; CSS controls presentation; JavaScript supplies programmable interactivity.

Study-note section WEB01

> PHP, Python, JSP/Java and ASP.NET applications generate server responses and access databases; C# is commonly used with ASP.NET.

Computer Science model exam · Question 48

University of Gondar model exam · Question 48

Question 24 | Q00318

Which of the following languages is primarily responsible for defining the structure and content of a web page?

A. HTML

B. JavaScript

C. PHP

D. CSS

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer A: HTML

HTML defines the meaning and structure of web content; CSS handles presentation and JavaScript behavior (p.10). Evidence: PDF p. 10, PDF p. 60.

Why each choice is right or wrong

A - Correct: Precisely the module HTML role.

B - Incorrect: Behavior rather than primary structure.

C - Incorrect: Server-generated dynamic output, not the markup language defining structure.

D - Incorrect: Presentation rather than primary content structure.

Primary note proof

Study-note section WEB01

> HTML supplies structure/meaning; CSS controls presentation; JavaScript supplies programmable interactivity.

Study-note section WEB01

> PHP, Python, JSP/Java and ASP.NET applications generate server responses and access databases; C# is commonly used with ASP.NET.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 10 | lines 9-16

> HTML (HyperText Markup Language) is the most basic building block of the Web.
> HTML is not a programming language rather it is a markup language that tells web browsers how to structure the web page. HTML consists of a series of elements, which you use to enclose, wrap or markup different parts of content to make it appear or act in a certain way.
> HTML defines the meaning and structure of web content. Other technologies besides HTML are generally used to describe a web page's appearance/presentation (CSS) or functionality/ behavior (JavaScript).

Web Programming module | PDF page 60 | lines 4-10

> PHP is a server-side scripting language, which can be embedded in HTML or used as a standalone binary (although the former use is much more common). PHP stands for Hypertext Preprocessor. The product was originally named Personal Home Page Tools, and many people still think that is what the acronym stands for. Question sources

Computer Science model exam · Question 49

University of Gondar model exam · Question 49

Question 25 | Q00319

Which PHP function is used to check if a file or directory exists?

A. file_exists()

B. file_exists_check()

C. is_file()

D. file_check()

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer A: file_exists()

WEB30 directly distinguishes file_exists, which tests files or directories, from is_file, which narrows the test to regular files. The question explicitly includes either a file or directory, so file_exists matches. The other two named checks are not the provided APIs, while is_file is too restrictive for the requested test.

Why each choice is right or wrong

A - Correct: file_exists() checks existence for files or directories, exactly the two entry kinds in the stem.

B - Incorrect: file_exists_check() is not the filesystem existence API identified by the complete note.

C - Incorrect: is_file() tests regular files and would not report an existing directory as a regular file.

D - Incorrect: file_check() is not the filesystem existence API given in WEB30.

Primary note proof

Study-note section WEB30

> file_exists tests files or directories; is_file narrows to regular files.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

University of Gondar model exam · Question 50

Question 26 | Q00320

Using the procedural MySQLi API with connection $conn, which function reports rows changed, inserted or deleted by the last successful data-changing statement?

A. mysqli_num_rows($result)

B. $stmt->rowCount()

C. get_affected_rows($conn)

D. mysqli_affected_rows($conn)

Hint

Identify the API and operation first, then distinguish connection setup, statement execution and result processing.

Answer D: mysqli_affected_rows($conn)

The procedural MySQLi affected-row function takes a connection and reports the effect of a successful data-changing statement under the connection's options. Counting rows in a SELECT result is a different operation, and a PDO statement method belongs to a different API. The question specifies both the API and the kind of row count, making the procedural call uniquely appropriate without assuming all PHP database interfaces share identical function names.

Why each choice is right or wrong

A - Incorrect: This counts rows in a result set, not the last data-changing statement's effect.

B - Incorrect: This is a PDO statement method rather than the requested procedural MySQLi call.

C - Incorrect: This is not the documented procedural function.

D - Correct: This is the documented affected-row function for the connection.

Primary note proof

Study-note section WEB32

> mysqli_num_rows counts a result's rows; mysqli_affected_rows($conn) counts changed/inserted/deleted rows under its options; mysqli_insert_id($conn) reports a generated AUTO_INCREMENT value from the connection.

Study-note section WEB-S04

> PDOStatement::rowCount() is a method on a PDO statement object that reports affected rows for its DELETE, INSERT or UPDATE statement.

Web Programming module | PDF page 80 | lines 16-23

> 5.13.4 Processing Query Result.
> 4. Fetching data sets
> The result of a query returned by the mysql_query() function is an interger showing the

success or failure of the function not the desired data. So you have to use one of the mysql_fetch_..() functions to get the actual result. There are many functions to do so, but the most commonly used ones are- Mysql_fetch_row($result) - this function takes the result of the mysql_query() function as an argument and returns the data as an enumerated array.

Computer Science model exam · Question 51

University of Gondar model exam · Question 51

Question 27 | Q00321

Which PHP superglobal array is used to retrieve information about the server and execution environment?

A. $_POST

B. $_SESSION

C. $_GET

D. $_SERVER

Hint

Identify the data source or security responsibility precisely, and check whether a combined source or a different control could also qualify.

Answer D: $_SERVER

$_SERVER is the predefined array for server-created headers, paths and script locations (p.62). Evidence: PDF p. 62, PDF p. 76.

Why each choice is right or wrong

A - Incorrect: POST contains form/request variables.

B - Incorrect: SESSION stores per-user application state (p.76).

C - Incorrect: GET contains GET request variables.

D - Correct: Matches server/execution information.

Primary note proof

Study-note section WEB27

$_GET contains query parameters; $_POST contains supported form POST data; $_FILES upload metadata; $_SERVER request/environment details; $_COOKIE cookie values; $_SESSION session data after startup.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 62 | lines 19-26

- $_SERVER → This is an array containing information such as headers, paths, and script locations. The entries in this array are created by the web server. There is no guarantee that every web server will provide any of these. See next section for a complete list of all the SERVER variables.
- $_GET → An associative array of variables passed to the current script via the HTTP GET method.
- $_POST → An associative array of variables passed to the current script via the HTTP POST method.

Web Programming module | PDF page 76 | lines 17-23

Storing a Session Variable
The correct way to store and retrieve session variables is to use the PHP $_SESSION variable:

```
<?php
session_start();
// store session data
$_SESSION['views']=1;
```

Computer Science model exam · Question 52

University of Gondar model exam · Question 52

Question 28 | Q00322

Which PHP superglobal is the dedicated source for supported form fields submitted using HTTP POST, rather than a configurable combination of request sources?

A. $_REQUEST

B. $_GET

C. $_POST

D. $_SERVER

Hint

Identify the data source or security responsibility precisely, and check whether a combined source or a different control could also qualify.

Answer C: $_POST

$_POST is the dedicated array for supported form POST data. $_REQUEST may also contain POST values, but combines sources according to configuration and is therefore not the dedicated source requested. $_GET contains query parameters, while $_SERVER contains request and environment details. The distinction is the origin-specific array, not whether a value could appear in more than one superglobal.

Why each choice is right or wrong

A - Incorrect: $_REQUEST can include POST values, but combines configured request sources rather than identifying only POST form data.

B - Incorrect: $_GET contains URL query parameters rather than the dedicated POST form map.

C - Correct: $_POST is specifically the supported form POST-data source.

D - Incorrect: $_SERVER holds request/environment information, not the submitted POST field map.

Primary note proof

Study-note section WEB27

> $_GET contains query parameters; $_POST contains supported form POST data; $_FILES upload metadata; $_SERVER request/environment details; $_COOKIE cookie values; $_SESSION session data after startup.

Study-note section WEB27

> $_REQUEST may combine GET/POST/cookie data according to configuration; it is not a database interface and has ambiguous precedence, so prefer the intended source.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Science model exam · Question 53

University of Gondar model exam · Question 53

Question 29 | Q00357

Which names describe a server that receives webpage requests through HTTP/HTTPS and returns representations? Select all that apply.

A. Http Server

B. Web Server

C. FTP server

D. DNS Server

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer A, B: Http Server; Web Server

A web server is also called an HTTP server in this context. It receives requests and returns resource representations, possibly invoking application code to construct them. The two labels describe the same serving role and must both be selected. FTP serves a distinct transfer purpose, while DNS supplies name-to-record resolution. The question now explicitly permits the synonymous correct names instead of forcing an arbitrary choice between them.

Why each choice is right or wrong

A - Correct: HTTP server names the request-and-response role described.

B - Correct: Web server is the equivalent name in this context.

C - Incorrect: FTP is not the stated HTTP webpage-serving role.

D - Incorrect: DNS resolves names rather than returning webpage representations through HTTP.

Primary note proof

Study-note section WEB01

> A web/HTTP server receives requests and returns representations, sometimes invoking application code.

Study-note section WEB02

> Hosting supplies an environment where a site is served; domain registration reserves a name, and DNS maps names to network records.

Study-note section WEB-S14

> HTTP defines web application requests, response status codes and representations.

Study-note section WEB-S14

> An HTTP exchange can use underlying TCP connections and IP addresses; naming that network stack does not identify the application-level method or status semantics.

Study-note section WEB-S14

FTP is a file-transfer application protocol.

Study-note section WEB-S14

SMTP transports electronic mail.

University of Gondar model exam · Question 87

Question 30 | Q00722

The attribute used in the body tag to change the default font color for the page is _____.

A. Bgcolor attribute

B. text attribute

C. color attribute

D. link tag

Hint

Identify the requested presentation effect and layout context before matching the property or rule.

Answer B: text attribute

The body attribute list explicitly gives text="text color" separately from bgcolor and link (p.12). Evidence: PDF p. 12.

Why each choice is right or wrong

A - Incorrect: bgcolor sets background color.

B - Correct: text is explicitly paired with text color.

C - Incorrect: color is not the listed body default-text attribute.

D - Incorrect: link is paired with link color, not all text.

Primary note proof

Study-note section WEB13

> In historical markup, the body text attribute controlled default text color, while bgcolor controlled background.

Question sources

Computer Science model exam 2 · Question 63

Question 31 | Q00723

For a basic static website with no client scripts that change its displayed content, which single option gives the complete set of true statements about its stored-page delivery model?

A. Changing the stored page representation requires changing the stored file

B. The server returns stored files rather than constructing a response from application logic

C. The page representation is delivered as stored

D. Viewers requesting the same unchanged file receive the same stored representation

E. All of the above.

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer E: All of the above.

A basic static server returns stored files rather than dynamically constructing representations from application logic. The question restricts content to the stored representation and excludes scripts that could change the rendered view. Under those assumptions, A through D describe compatible aspects of the same model. All of the above is the complete single selection; each individual statement is true but would cover only part of the requested set.

Why each choice is right or wrong

A - Incorrect: True but incomplete: it states only how the stored representation changes.

B - Incorrect: True but incomplete: it states the serving model alone.

C - Incorrect: True but incomplete: it omits the other delivery properties.

D - Incorrect: True but incomplete: it states sameness for the same unchanged resource only.

E - Correct: This aggregate contains every true statement under the specified model.

Primary note proof

Study-note section WEB02

> A basic static server returns stored files; dynamic processing constructs a representation from logic, requests or data.

Study-note section WEB02

> Static pages can still run interactive browser scripts, and dynamic generation need not change visible text every time.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 8 | lines 3-6

1.1 Course overview
This chapter deals with the Overview of Internet, website, webpage, types of websites (Static vs dynamic), webpage design tools, Web World Wide Web, Web Hosting and Domain Name Registration. To deliver these contents active learning methods such as

scope, a new and more appropriate name was selected by community vote. PHP is the language that you use to make the server generate dynamic output-output that is potentially different each time a browser re-quests a page.

Question sources

Computer Science model exam 2 · Question 64

Question 32 | Q00724

Which single option gives the complete selection of technologies that can generate server-side web responses?

A. PHP

B. ASP.NET

C. Python

D. All of the above

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer D: All of the above

PHP, Python and ASP.NET applications can generate server responses and access databases. The question deliberately asks about technologies rather than calling every entry a programming language, since ASP.NET is an application technology. All three listed entries satisfy that broader but precise role, so the aggregate is the complete single answer. Selecting an individual entry would state a true example while omitting the other two supported server-side technologies.

Why each choice is right or wrong

A - Incorrect: PHP fits, but this single entry omits the other valid technologies.

B - Incorrect: ASP.NET applications fit, but the selection is incomplete.

C - Incorrect: Python applications fit, but the selection is incomplete.

D - Correct: All three entries support server response generation.

Primary note proof

Study-note section WEB01

PHP, Python, JSP/Java and ASP.NET applications generate server responses and access databases; C# is commonly used with ASP.NET.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 60 | lines 3-10

5.1 Introduction to PHP
PHP is a server-side scripting language, which can be embedded in HTML or used as a standalone binary (although the former use is much more common). PHP stands for Hypertext Preprocessor. The product was originally named Personal Home Page Tools, and many people still think that is what the acronym stands for. But as it expanded in scope, a new and more appropriate name was selected by community vote. PHP is the language that you use to make the server generate dynamic output-output that is potentially different each time a browser re-quests a page.

Question sources

Computer Science model exam 2 · Question 65

Question 33 | Q00725

Which option gives the complete set of listed JavaScript dialogs that can display a supplied message, whether or not they also collect a response?

A. Prompt

B. Alert

C. Confirm

D. All of the above

Hint

Distinguish the browser object or dialog role from the kind of response it collects.

Answer D: All of the above

Alert, confirm and prompt all present a supplied message. Alert provides a notification, confirm additionally requests an OK/Cancel decision, and prompt additionally offers a text field. The question asks for the complete set of qualifying dialogs, so All of the above is the complete selection. Each individual dialog is a true example but omits the other two qualifying dialogs.

Why each choice is right or wrong

A - Incorrect: Prompt displays a message while requesting text, so it qualifies; selecting it alone omits alert and confirm and is incomplete.

B - Incorrect: Alert displays a notification, so it qualifies; selecting it alone omits prompt and confirm and is incomplete.

C - Incorrect: Confirm displays a message while requesting an OK/Cancel decision, so it qualifies; selecting it alone omits prompt and alert and is incomplete.

D - Correct: All three listed dialogs can display a supplied message, so this is the complete qualifying set.

Primary note proof

Study-note section WEB-S03

> alert(message), confirm(message) and prompt(message) all present a supplied message.

Study-note section WEB22

> alert displays information, confirm returns a Boolean, and prompt requests text or returns null on cancellation.

Module passages - related reading

> 2. Alert: shows a browser pop up with the information inside the parenthesis
> 3. The write() method
> - The write() method writes HTML expressions or JavaScript code to a document.

Web Programming module | PDF page 46 | lines 16-25

> Accepting user input in JavaScript actually is not a difficult task. JavaScript has a function called prompt, which is used to accept input from the user. But for the result to be useful for us, it has to be stored in a variable. Here is a simple example
> var name = prompt("Enter your name: ");
> alert("Hello " + name);
> ➢ Prompt will show a modal windows with a text message, an input field for the visitor, and the buttons OK/Cancel
> ➢ We can also use confirm to get information from a user:- the function confirm shows a modal window with a question and two buttons: OK and Cancel
> The result is true if OK is pressed and false otherwise

Question sources

Computer Science model exam 2 · Question 66

Question 34 | Q00726

What does these code possibly refers to<link rel="stylesheet" href="styles.css"> ?

A. Defines a new CSS by the name styles

B. Calls an internal style sheet called styles

C. Calls an external style sheet called styles

D. Defines an inline CSS by the name styles

Hint

Identify which elements a rule targets and distinguish selector syntax from declaration syntax.

Answer C: Calls an external style sheet called styles

The link tag identifies a separate stylesheet URL (p.29); p.28 explains that this links an external stylesheet shared by pages. Evidence: PDF p. 29, PDF p. 28.

Why each choice is right or wrong

A - Incorrect: It references an existing file, not a CSS definition.

B - Incorrect: Internal CSS instead uses a style block.

C - Correct: It links the external styles.css file.

D - Incorrect: Inline CSS instead uses an element style attribute.

Primary note proof

Study-note section WEB11

> An external sheet uses <link rel="stylesheet" href="styles.css"> in head; an internal sheet uses style; an inline declaration uses an element’s style attribute.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Science model exam 2 · Question 67

Question 35 | Q00727

Which valid HTML snippet uses CSS to set the body background color to yellow?

A. <body background="yellow">

B. <background>yellow</background>

C. <body style="background-color: yellow">

D. <background color="yellow">text<background>

Hint

Identify which elements a rule targets and distinguish selector syntax from declaration syntax.

Answer C: <body style="background-color: yellow">

The CSS property background-color controls an element's background. An inline declaration belongs in the opening element's style attribute, so the body tag applies the requested color. The other snippets either use a background attribute instead of the specified CSS property or invent markup that does not express this body style.

Why each choice is right or wrong

A - Incorrect: This uses an attribute rather than the requested background-color declaration.

B - Incorrect: This invents a background element instead of styling body.

C - Correct: The valid body start tag contains the appropriate CSS declaration.

D - Incorrect: This markup does not supply a valid body style declaration.

Primary note proof

Study-note section WEB13

> color sets text color; background-color sets background; font-size size, font-family face, font-style italic, font-weight weight, text-align inline-content alignment, and text-decoration effects such as underline.

Study-note section WEB11

> An external sheet uses <link rel="stylesheet" href="styles.css"> in head; an internal sheet uses style; an inline declaration uses an element's style attribute.

Some of the common attributes used in the body element
✓ bgcolor="color"
✓ background="img url"
✓ text="text color"

Question sources

Computer Science model exam 2 · Question 68

Question 36 | Q00728

What is the method used to get the result from the form data sent with both GET and POST?

A. $_REQUEST

B. $_POST

C. $_GET

D. A & B

Hint

Identify the data source or security responsibility precisely, and check whether a combined source or a different control could also qualify.

Answer A: $_REQUEST can combine GET and POST input according to configuration.

WEB27 states that $_GET contains query parameters and $_POST supported form POST data, while $_REQUEST may combine GET, POST, and cookie data according to configuration. Therefore $_REQUEST is the offered combined-source mechanism. It is an array rather than a method, and its configuration-dependent precedence is a reason to prefer an explicit source in real code.

Why each choice is right or wrong

A - Correct: $_REQUEST can combine GET and POST values according to PHP configuration, matching the combined-source question.

B - Incorrect: $_POST holds supported form POST data and does not generally combine query GET values.

C - Incorrect: $_GET holds URL query parameters rather than combining both query and form POST sources.

D - Incorrect: Adding $_POST to the already combined $_REQUEST is redundant and is not the single combined mechanism requested.

Primary note proof

Study-note section WEB27

> $_GET contains query parameters; $_POST contains supported form POST data; $_FILES upload metadata; $_SERVER request/environment details; $_COOKIE cookie values; $_SESSION session data after startup.

Study-note section WEB27

> $_REQUEST may combine GET/POST/cookie data according to configuration; it is not a database interface and has ambiguous precedence, so prefer the intended source.

Module passages - related reading

Web Programming module | PDF page 73 | lines 11-18

> • $_GET[]: It is used the retrieve the information from the form control through the parameters sent in the URL. It takes the attribute given in the url as the parameter.
> • $_POST[]: It is used the retrieve the information from the form control through the HTTP POST method. IT takes name attribute of corresponding form control as the parameter.
> • $_REQUEST[]: It is used to retrieve an information while using a database.

Question sources

Computer Science model exam 2 · Question 69

Question 37 | Q00729

When using mysqli_connect(), which argument selects the default database and may be deferred until after connecting?

A. Host

B. Database

C. Username

D. Password

Hint

Identify the API and operation first, then distinguish connection setup, statement execution and result processing.

Answer B: Database

The mysqli_connect signature separates host, user, password and database, followed by port and socket. Selecting a database can be deferred even though several arguments also have defaults. The revised question asks which argument performs that particular selection, rather than incorrectly implying only one argument is optional. The database argument names the initial database; the remaining listed arguments identify the server or provide authentication credentials.

Why each choice is right or wrong

A - Incorrect: The host identifies the server, not the default database.

B - Correct: This selects the initial database and can be deferred.

C - Incorrect: The username supplies an authentication identity.

D - Incorrect: The password supplies a credential, not the database selection.

Primary note proof

Study-note section WEB31

> mysqli_connect(host,user,password,database,port,socket) opens a connection; selecting a database can be deferred, and defaults make several arguments technically optional.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 79 | lines 9-29

> 5.13.2 Creating Database Connection in PHP
> 1. Connecting to MySQL
> The basic command to initiate a MySQL connection is
> $link=mysql_connect($hostname, $user, $password); if you‘re using variables, or
> $link=mysql_connect(„localhost“, „root“, „sesame“); if you‘re using literal strings. Here
> $Hostname - the ip address or hostname of the MySQL server. If the MySQL server and the php server are on the same machine use localhost or 127.0.0.1, else use the ip address of the database server.
> $User - the user name of the database if specified by one of the grant commands. If username and password is not given to the database (which is not recommended) use root as your username which is the default.
> $Password - the password of the database if specified by one of the grant commands. The default password for any MySQL database is empty, so if password is not granted leave it null. $link - is a variable and is called the link identifier. You will use this variable later.
> 2. Selecting the database
> After creating the connection identifier, the next thing, you will do is select a database among the databases you have created. To do this you will use the mysql_select_db() method.
> Syntax:
> $db=mysql_select_db(„dbname“,[link identifier]);

Question sources

Computer Science model exam 2 · Question 70

Question 38 | Q00888

Consider the CSS reset:
nav ul {
list-style-type: none;
margin: 0;
padding: 0;
}
What does this rule itself accomplish for a navigation list?

A. Aligns the navigation bar to the right

B. Adds hover effects to list items

C. Removes list bullets and default margin and padding

D. Converts the list into a dropdown menu

Hint

Identify which elements a rule targets and distinguish selector syntax from declaration syntax.

Answer C: Removes list bullets and default margin and padding

The rule selects unordered lists inside nav elements. list-style-type removes list markers, while margin and padding reset the relevant spacing to zero. Nothing in the rule chooses a horizontal or right-aligned layout, installs a hover state or implements dropdown behavior.

Why each choice is right or wrong

A - Incorrect: No alignment property is supplied.

B - Incorrect: No hover selector or interaction rule is supplied.

C - Correct: These are exactly the marker and spacing effects of the three declarations.

D - Incorrect: A dropdown needs additional layout and interaction rules.

Primary note proof

Study-note section WEB08

> Resetting nav ul with list-style-type:none; margin:0; padding:0 removes bullets and default spacing only; it does not itself arrange links horizontally or create a dropdown.

Study-note section WEB11

> Type p selects paragraph elements, .notice selects a class, #logo an ID, h1,h2 groups selectors, nav ul selects descendants and nav>ul direct children.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 39 | lines 2-10

tag. Lists by default have a list-style-type, margin and padding properties set by the user agent style sheet. Since we don't want the default styling lets reset it
Here is the code to do that
ul {
list-style-type: none;
margin: 0;
padding: 0;
}
Next set the display property of ul to flex. This will align the list items

Question sources

Computer Science Exit Exam · 2018 · Question 1

Question 39 | Q00919

Which PHP superglobal is dedicated specifically to retrieving URL query parameters, rather than a configurable mixture of request sources?

A. $_REQUEST

B. $_POST

C. $_GET

D. isset()

Hint

Identify the data source or security responsibility precisely, and check whether a combined source or a different control could also qualify.

Answer C: $_GET

URL query values belong to $_GET. $_REQUEST can also include query data under some configurations, but it combines sources and therefore is not the dedicated query array requested here. $_POST represents supported form POST data, and isset tests whether an entry exists and is non-null rather than retrieving the entry's value. The question asks for the dedicated query array, making $_GET the unique selection.

Why each choice is right or wrong

A - Incorrect: This can mix query, POST and cookie sources according to configuration.

B - Incorrect: This represents form POST data rather than the dedicated URL query source.

C - Correct: This is the dedicated query-parameter superglobal.

D - Incorrect: This tests existence and non-null; it is not a request-data array.

Primary note proof

Study-note section WEB27

$_GET contains query parameters; $_POST contains supported form POST data; $_FILES upload metadata; $_SERVER request/environment details; $_COOKIE cookie values; $_SESSION session data after startup.

Study-note section WEB27

$_REQUEST may combine GET/POST/cookie data according to configuration; it is not a database interface and has ambiguous precedence, so prefer the intended source.

Study-note section WEB27

isset tests existence and non-null, not truth or valid syntax.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 73 | lines 9-18

• isset(): This function is used to determine whether the variable or a form control is having a value or not.
• $_GET[]: It is used the retrieve the information from the form control through the parameters sent in the URL. It takes the attribute given in the url as the parameter.
• $_POST[]: It is used the retrieve the information from the form control through the HTTP POST method. IT takes name attribute of corresponding form control as the parameter.
• $_REQUEST[]: It is used to retrieve an information while using a database.

Computer Science Exit Exam · 2018 · Question 32

Question 40 | Q00926

In CSS, which property is used to change the text color of an element?

A. text-color

B. font-color

C. color

D. Foreground

Hint

Identify the requested presentation effect and layout context before matching the property or rule.

Answer C: color

The color property sets foreground content color (p.34), and p.31 illustrates p { color: red; }. Evidence: PDF p. 34, PDF p. 31.

Why each choice is right or wrong

A - Incorrect: Not the documented CSS name.

B - Incorrect: Not the documented CSS name.

C - Correct: Exact property used for text/foreground color.

D - Incorrect: A description of the effect, not the CSS property spelling.

Primary note proof

Study-note section WEB13

> color sets text color; background-color sets background; font-size size, font-family face, font-style italic, font-weight weight, text-align inline-content alignment, and text-decoration effects such as underline.

```

Question sources

Computer Science Exit Exam · 2018 · Question 39

Question 41 | Q00946

is a service that allows organizations and individuals to post a website or a

web page onto the Internet.

A. Web hosting

B. Internet service provider

C. .

Web client

D. Domain name registration

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer A: Web hosting

The module defines web hosting as the service allowing organizations/individuals to post a website or web page onto the Internet (p.9). Evidence: PDF p. 9.

Why each choice is right or wrong

A - Correct: Exact definition.

B - Incorrect: An ISP access service is not the hosting definition here.

C - Incorrect: A web client reads pages rather than hosting them.

D - Incorrect: Registration reserves a name, not the hosting service.

Primary note proof

Study-note section WEB02

> Hosting supplies an environment where a site is served; domain registration reserves a name, and DNS maps names to network records.

Study-note section WEB02

> An ISP provides connectivity.

Study-note section WEB01

> A browser/user agent requests resources and renders HTML/CSS, then runs permitted JavaScript.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 9 | lines 12-24

> What is web hosting?
> Web hosting is the place where all the files of your website live. Web hosting is a service that allows organizations and individuals to post a website or a web page onto the Internet. A web host, or web hosting service provider, is a business that provides the technologies and services needed for the website or webpage to be viewed in the Internet. Websites are hosted, or stored, on special computers called servers. When Internet users want to view your website, all they need to do is type your website address or domain (the domain name for the site has to be registered) into their browser. Their computer will then connect to your server and your webpages will be delivered to them through the browser.
> Domain Name Registration
> Domain name registration is the act of reserving a name on the Internet for a certain period. To get the address of a new website you have to register the domain name with

Question 42 | Q00958

Which protocol is mostly used for communication between client and server in a web application?

A. FTP

B. SMTP

C. .
HTTP

D. SSH

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer C: .
HTTP

The WWW discussion explicitly says web computers use the HTTP communication standard (p.8). Evidence: PDF p. 8.

Why each choice is right or wrong

A - Incorrect: Not the module web communication standard.

B - Incorrect: Not the module web communication standard.

C - Correct: HTTP is expressly named.

D - Incorrect: Not the module web communication standard.

Primary note proof

Study-note section WEB01

> The Internet connects networks; the Web is a resource system commonly using HTTP.

Study-note section WEB-S14

> HTTP defines web application requests, response status codes and representations.

Study-note section WEB-S14

> An HTTP exchange can use underlying TCP connections and IP addresses; naming that network stack does not identify the application-level method or status semantics.

Study-note section WEB-S14

> FTP is a file-transfer application protocol.

Study-note section WEB-S14

> SMTP transports electronic mail.

Module passages - related reading

Web Programming module | PDF page 8 | lines 29-34

• The World Wide Web (WWW) is most often called the Web.
• The Web is a network of computers all over the world.
• All the computers in the Web can communicate with each other.
• All the computers use a communication standard called HTTP.
How does the WWW work?
• Web information is stored in documents called Web pages.

Question sources

Computer Science Exit Exam · 2018 · Question 71

Question 43 | Q00960

What is the extension of JavaScript file?

A. javaS

B. JS

C. ¢.
java

D. CSS

Hint

Identify which elements a rule targets and distinguish selector syntax from declaration syntax.

Answer B: JS

The external script example uses script.js, establishing the .js extension (p.45). B represents JS, ignoring case of the descriptive option. Evidence: PDF p. 45, PDF p. 44.

Why each choice is right or wrong

A - Incorrect: javaS is not the demonstrated extension.

B - Correct: JS corresponds to the demonstrated .js extension.

C - Incorrect: java is not the demonstrated extension; Java is a different language.

D - Incorrect: CSS is for stylesheets, not JavaScript.

Primary note proof

Study-note section WEB15

Use <script src="app.js"></script> for an external .js file; script content has no HTML closing-tag syntax inside its JavaScript source.

Study-note section WEB15

JavaScript originated at Netscape; it is distinct from Java and supports sophisticated applications through prototype-based objects and first-class functions.

Study-note section WEB11

An external sheet uses <link rel="stylesheet" href="styles.css"> in head; an internal sheet uses style; an inline declaration uses an element's style attribute.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 45 | lines 12-14

- We can also include JavaScript as an external file. We can use a similar syntax
like the internal and add the src attribute. Here is how
<script src="script.js" defer></script>

Web Programming module | PDF page 44 | lines 4-7

JavaScript (JS) is a lightweight, interpreted or compiled programming language. It is a single threaded, dynamic language, supporting object oriented, functional programming styles. Do not confuse JavaScript with the Java Programming language. The two-programming language have very different syntax, semantics, and use.

Question sources

Computer Science Exit Exam · 2018 · Question 73

Question 44 | Q00980

A developer stores $_SESSION["user_id"] server-side and an editable logged_in cookie client-side. A protected endpoint grants access solely when logged_in=1 and never validates the server-side session. An unauthenticated attacker sets that cookie. Which statement is most accurate?

A. The endpoint is vulnerable: trusting the cookie alone bypasses the required server-session authorization

B. The endpoint is secure because server-side session data exists

C. The endpoint is vulnerable only if the genuine session ID is exposed

D. The endpoint is secure if HTTPS is used

Hint

Follow the identifier and server-side state through the stated lifecycle or access check; distinguish client-controlled claims from server decisions.

Answer A: The endpoint is vulnerable: trusting the cookie alone bypasses the required server-session authorization

The protected endpoint trusts an attacker-controlled value rather than checking authenticated server-side state. Setting the flag is therefore sufficient to gain the access that should require session authorization. Merely storing a user ID elsewhere does not help when that state is never consulted. No genuine session identifier must be stolen for this bypass, and HTTPS protects transmission rather than proving that a client-generated authorization claim is true.

Why each choice is right or wrong

A - Correct: The stated cookie-only authorization path allows the attacker to bypass the required session check.

B - Incorrect: Unused server-side state does not protect this endpoint.

C - Incorrect: No genuine session ID is needed when the endpoint trusts only the flag.

D - Incorrect: Transport protection does not make a forged client flag trustworthy.

Primary note proof

Study-note section WEB29

> A client cookie logged_in=1 is attacker-controlled.

Study-note section WEB29

> If the server trusts it alone, authorization can be bypassed.

Study-note section WEB29

> HTTPS does not make client-generated claims trustworthy.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 59 | lines 4-7

> Create a Cookie with JavaScript
> JavaScript can create, read, and delete cookies with the document.cookie property.
> With JavaScript, a cookie can be created like this:
> document.cookie = "username=John Doe";

Web Programming module | PDF page 76 | lines 2-5

> in one application. A PHP session allows you to store user information on the server for later use (i.e., username, shopping items, etc.). However, session information is temporary and will be deleted after the user has left the website. If you need a permanent storage you may want to store the data in a database.

Web Programming module | PDF page 76 | lines 17-23

> Storing a Session Variable
> The correct way to store and retrieve session variables is to use the PHP $_SESSION variable:

```
<?php
session_start();
// store session data
$_SESSION['views']=1;
```

Question sources

Computer Science Exit Exam · 2018 · Question 93

Question 45 | Q00985

Which one of the following is not feature of dynamic web page?

A. Contents can be generated on-the-fly

B. Changing content or lively

C. Contain the same prebuilt content each time the page is loaded

D. Ability to connect to a database

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer C: Always serving the same prebuilt content is the static-generation description.

WEB02 contrasts a basic static server returning stored files with dynamic processing constructing a representation from logic, requests, or data. C describes the prebuilt static delivery model rather than the distinctive feature of dynamic generation. Dynamic pages may still happen to display identical text across loads; the exclusion concerns same prebuilt content as a model, not a requirement that every dynamic response visibly change.

Why each choice is right or wrong

A - Incorrect: Generating content on demand is directly consistent with dynamic processing from logic, requests, or data.

B - Incorrect: Dynamic content can change with inputs or application data, although visible changes are not mandatory on every load.

C - Correct: Always returning the same prebuilt content describes the static delivery model rather than dynamic response generation.

D - Incorrect: Server-side applications can access databases while constructing dynamic responses, as described in WEB01.

Primary note proof

Study-note section WEB02

> A basic static server returns stored files; dynamic processing constructs a representation from logic, requests or data.

Study-note section WEB02

> Static pages can still run interactive browser scripts, and dynamic generation need not change visible text every time.

Study-note section WEB01

> PHP, Python, JSP/Java and ASP.NET applications generate server responses and access databases; C# is commonly used with ASP.NET.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 60 | lines 8-16

> scope, a new and more appropriate name was selected by community vote. PHP is the language that you use to make the server generate dynamic output-output that is potentially different each time a browser re-quests a page.
> Client-side scripting is the glamorous, eye-catching part of Web development. In contrast, server-side scripting is invisible to the user. Server-side Web scripting is mostly about connecting Web sites to back-end servers, such as databases. This enables the following types of two-way communication:
> ➢ Server to client: Web pages can be assembled from back end-server output.
> ➢ Client to server: Customer-entered information can be acted upon.

Question sources

Computer Science Exit Exam · 2018 · Question 98

Question 46 | Q00986

Why should form <input> elements include an associated <label> with the for attribute?

A. It enables offline form storage

B. It encrypts user data

C. .
It increases form submission speed

D. It improves accessibility: screen readers announce the label when the input is focused

Hint

Separate the control role, displayed content, submitted value and form destination.

Answer D: An associated label gives the input an accessible name.

WEB09 connects a label's for value to the control's id. WEB07 requires programmatic labels for accessibility. Together these support an input label that assistive technology can announce when the control is focused. That association does not store the form offline, encrypt data, or increase submission speed; its purpose here is accessible identification of the control.

Why each choice is right or wrong

A - Incorrect: Label association identifies a control and does not create offline form storage.

B - Incorrect: A label does not encrypt values or change transport security; encryption needs a separate mechanism.

C - Incorrect: Linking a label to an input does not increase network or form-submission speed.

D - Correct: The associated label provides accessible control identification that screen readers can announce on focus.

Primary note proof

Study-note section WEB09

> A label's for matches the control's id; name identifies its submitted field.

Study-note section WEB07

> Give controls programmatic labels, clear link text and keyboard access; visual styling alone does not establish accessibility.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 21 | lines 13-22

> 2.2.10 HTML Form and Form Controls
> The <form> HTML element represents a document section containing interactive controls for submitting information. An HTML form is a section of a document containing normal content, markup, special elements called controls (checkboxes, radio buttons, menus, etc.) and labels on those controls. HTML Forms are required, when we want to collect data from a user. Using forms, we can build a website with user registration. We take the information collected from the user and then post it to the backend application such as php.
> Users interact with forms through named controls. There are various from controls available like text fields, text area, check box, drop-down menus etc.

Question sources

Computer Science Exit Exam · 2018 · Question 99

Question 47 | Q00992

Which HTML tag is used for program listing?

A. <p>

B. <pre>

C. <head>

D. <sub>

Hint

Use the element or attribute meaning and document structure, rather than appearance or a similar-looking name.

Answer B: <pre> preserves program-listing whitespace.

WEB06 says <pre> preserves source whitespace, which is needed for displaying an indented program listing. <code> can additionally mark code semantics, but it is not offered here. A paragraph does not preserve the listing's whitespace by itself, head is metadata, and sub marks a subscript. Therefore <pre> is the matching listed tag.

Why each choice is right or wrong

A - Incorrect: A paragraph marks prose structure and does not by itself preserve a program listing's indentation and line breaks.

B - Correct: The preformatted element preserves source whitespace, making it suitable for an indented program listing.

C - Incorrect: The head holds metadata rather than visible program-listing content.

D - Incorrect: The sub element marks subscript text and does not provide preformatted listing whitespace.

Primary note proof

Study-note section WEB06

> <pre> preserves source whitespace; <code> marks code.

Study-note section WEB06

> <!DOCTYPE html> selects modern standards mode; <html> is the document root, <head> holds metadata, and <body> contains document content.

Study-note section WEB06

> <sub>/<sup> mark sub/superscripts.

National Exit Exam practice questions · Question 6

Computer Science Exit Exam practice collection · Question 30

Question 48 | Q00996

Which attribute of a text input limits the number of characters the user may enter, rather than its visible width?

A. MAXLENGTH

B. TYPE

C. ACTION

D. STYLE

Hint

Identify which elements a rule targets and distinguish selector syntax from declaration syntax.

Answer A: MAXLENGTH

For a text input, maxlength limits entered text length, while size controls approximate visible width. The revised question removes the scrolling and new-line language because those are display concerns rather than the entered-character bound. TYPE chooses the control kind, ACTION identifies a form-processing destination and STYLE supplies presentation declarations. Browser length limits improve input behavior but must still be checked server-side when enforcing a security requirement.

Why each choice is right or wrong

A - Correct: MAXLENGTH supplies the entered-text length limit.

B - Incorrect: TYPE selects the input kind rather than a maximum length.

C - Incorrect: ACTION belongs to form destination configuration.

D - Incorrect: STYLE controls presentation rather than this input-length attribute.

Primary note proof

Study-note section WEB09

> For a text input, size indicates approximate visible width, whereas maxlength limits entered text length.

Study-note section WEB09

> A form’s action identifies its processing URL, method its submission method, and enctype its encoding.

Study-note section WEB11

> An external sheet uses <link rel="stylesheet" href="styles.css"> in head; an internal sheet uses style; an inline declaration uses an element’s style attribute.

Module passages - related reading

National Exit Exam practice questions · Question 10

Computer Science Exit Exam practice collection · Question 31

Question 49 | Q01068

Which of the following is not JavaScript Data Types?

A. Undefined

B. Number

C. Boolean

D. Float

Hint

Track the value and type at each operation, applying the stated conversion, indexing or mathematical rule.

Answer D: Float is not a separate JavaScript primitive type.

WEB16 lists undefined, null, Boolean, Number, BigInt, String, and Symbol as primitives and explicitly states that Float is not a separate Number primitive type. Floating-point numeric values belong to Number. Undefined, Number, and Boolean are therefore valid type names in the offered set, leaving Float as the exclusion.

Why each choice is right or wrong

A - Incorrect: Undefined is explicitly listed as a JavaScript primitive type in WEB16.

B - Incorrect: Number is the JavaScript numeric primitive type that includes ordinary floating-point numeric values.

C - Incorrect: Boolean is explicitly listed as the primitive type for true and false values.

D - Correct: Float is not a separate JavaScript primitive type; ordinary floating-point values use Number.

Primary note proof

Study-note section WEB16

> JavaScript primitives are undefined, null, Boolean, Number, BigInt, String and Symbol; objects include arrays, functions and dates.

Study-note section WEB16

> Float is not a separate Number primitive type.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 47 | lines 18-33

> 4.5.1 JavaScript Data types
> A value in JavaScript is always of a certain type. In JavaScript, a variable can take one type at one moment and then another. This is called dynamic typing.
> - Number → represents integers and floating points. There are many operations we can perform on a number multiplication *, division /,

addition +, subtraction - and so on
- String → a string in JavaScript must be surrounded by quotes. We have three different quotes
1. Single quotes --- ‘single’
2. Double quotes --- ‘double’
3. Backticks -- `hello`. In a standard US keyboard, you can find the backticks above the tab key before the number 1 key.
Backticks allows to embed variables and expressions into a string by wrapping them with ${}
alert(`the result is ${1 + 2}`);
- Boolean → a boolean has two values true or false

Web Programming module | PDF page 48 | lines 2-5

- Objects → are used to store a key/value pair property. Objects are created using curly braces {}
- Arrays → are regular objects and used to store indexed values. Arrays are created by using square brackets []

Question sources

Web Programming practice questions · Question 1

Question 50 | Q01069

Which company developed JavaScript?

A. Netscape

B. Bell Labs

C. Sun Microsystems

D. IBM

Hint

Check exact language syntax, declaration rules and execution context before reasoning about the result.

Answer A: Netscape

WEB15 explicitly states that JavaScript originated at Netscape and distinguishes it from Java. Netscape is therefore the company named by the supplied note. None of Bell Labs, Sun Microsystems, or IBM is the origin identified for JavaScript. The Java distinction is especially relevant because the similar language names can encourage a wrong company association.

Why each choice is right or wrong

A - Correct: Netscape is explicitly identified in WEB15 as the company where JavaScript originated.

B - Incorrect: Bell Labs is not the JavaScript origin given in the complete study note.

C - Incorrect: The note distinguishes JavaScript from Java and identifies Netscape, not Sun Microsystems, as its origin.

D - Incorrect: IBM is not the company identified as JavaScript's origin in WEB15.

Primary note proof

Study-note section WEB15

> JavaScript originated at Netscape; it is distinct from Java and supports sophisticated applications through prototype-based objects and first-class functions.

Question 51 | Q01070

Inside which HTML element do we put the JavaScript?

A. <script>

B. <head>

C. <meta>

D. <style>

Hint

Identify which elements a rule targets and distinguish selector syntax from declaration syntax.

Answer A: <script>

Page 44 says JavaScript uses the script tag, and p.45 shows the enclosed script block. Evidence: PDF p. 44, PDF p. 45, PDF p. 28.

Why each choice is right or wrong

A - Correct: Actual code-containing element.

B - Incorrect: A possible surrounding document section, not the script element.

C - Incorrect: Metadata element, not code container.

D - Incorrect: Embedded stylesheet element, not JavaScript container.

Primary note proof

Study-note section WEB15

> Use <script src="app.js"></script> for an external .js file; script content has no HTML closing-tag syntax inside its JavaScript source.

Study-note section WEB06

> <!DOCTYPE html> selects modern standards mode; <html> is the document root, <head> holds metadata, and <body> contains document content.

Study-note section WEB11

> An external sheet uses <link rel="stylesheet" href="styles.css"> in head; an internal sheet uses style; an inline declaration uses an element's style attribute.

> 4.2.1 JavaScript Syntax
> JavaScript is added to an HTML document in a similar fashion as that of CSS. The main difference is we use <script> tag instead of <link> tag.
> Here is the basic JavaScript syntax

Web Programming module | PDF page 45 | lines 2-8

> <script>
> // JavaScript code goes here
> </script>
> - Internal JavaScript is one way of including JavaScript using the script tag inside our HTML document. We can use the above syntax to include it anywhere in our document. The best place to include a JavaScript file is before the end of body tag </body>.

Web Programming module | PDF page 28 | lines 12-14

> 2. Embedded stylesheet
> This type of stylesheet should be used when a single document has a unique style. You define internal styles in the head section by using the <style> tag.

Question sources

Web Programming practice questions · Question 3

Question 52 | Q01071

Which of the following is correct about features of JavaScript?

A. It can not Handling dates and time.

B. JavaScript is a object-based scripting language.

C. JavaScript is not interpreter based scripting language.

D. All of the above

Hint

Track the value and type at each operation, applying the stated conversion, indexing or mathematical rule.

Answer B: JavaScript supports prototype-based objects.

WEB15 says JavaScript supports sophisticated applications through prototype-based objects and first-class functions, directly supporting B. WEB16 also includes dates among objects, refuting the claimed inability to handle dates and time. The broad denial of interpreted scripting is not a supported language definition. Since at least A is false, All cannot hold; B is the supported positive feature.

Why each choice is right or wrong

A - Incorrect: The note includes Date objects, so the claim that JavaScript cannot handle dates and time is false.

B - Correct: Prototype-based objects support the description of JavaScript as an object-based scripting language.

C - Incorrect: This blanket denial is not a supported feature definition; browser JavaScript runs as scripts through its runtime.

D - Incorrect: All fails because the date/time incapability claim is false, while the object-based feature is supported.

Primary note proof

Study-note section WEB15

> JavaScript originated at Netscape; it is distinct from Java and supports sophisticated applications through prototype-based objects and first-class functions.

Study-note section WEB16

> JavaScript primitives are undefined, null, Boolean, Number, BigInt, String and Symbol; objects include arrays, functions and dates.

Study-note section WEB-S05

> JavaScript implementations may interpret or compile source; interpretation and compilation are execution strategies rather than competing language identities.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

> 4.1 Introduction to JavaScript
> JavaScript (JS) is a lightweight, interpreted or compiled programming language. It is a single threaded, dynamic language, supporting object oriented, functional programming styles. Do not confuse JavaScript with the Java Programming language. The two-programming language have very different syntax, semantics, and use.

Question sources

Web Programming practice questions · Question 4

Question 53 | Q01072

Choose the correct JavaScript syntax to change the content of the following HTML code.

A. document.getElement ("letsfindcourse").innerHTML = "I am a letsfindcourse";

B. document.getElementById ("letsfindcourse").innerHTML = "I am a letsfindcourse";

C. document.getId ("letsfindcourse") = "I am a letsfindcourse";

D. document.getElementById ("letsfindcourse").innerHTML = I am a letsfindcourse;

Hint

Track which node is selected or created, and distinguish changing content from attaching a node.

Answer B: Use document.getElementById(...).innerHTML with a quoted string.

WEB20 identifies document.getElementById as the ID lookup and innerHTML as a descendant-markup replacement property. B combines the correct method spelling with a quoted string value. A and C invent lookup names; D lacks string quotes and cannot parse as the intended assignment. Execution still requires that the element exist, which should be checked in real code.

Why each choice is right or wrong

A - Incorrect: document.getElement is not the ID lookup method defined in WEB20.

B - Correct: The exact ID lookup and quoted innerHTML assignment are valid, assuming that the requested element exists.

C - Incorrect: document.getId is not the DOM method, and assigning directly to that call does not set element content.

D - Incorrect: The intended replacement text is unquoted, so the JavaScript assignment is syntactically invalid.

Primary note proof

Study-note section WEB20

document.getElementById("x") returns the matching element or null; querySelector(".item") returns the first match, and querySelectorAll returns a static NodeList.

Study-note section WEB20

innerHTML parses/replaces descendants, so += reparses/replaces the prior descendant content too and can destroy listeners/state.

Study-note section WEB16

Strings use either quote style, with appropriate escaping.

Question sources

Web Programming practice questions · Question 5

Question 54 | Q01073

which of the following are advantages of JavaScript?

A. Less server interaction

B. Increased interactivity

C. Richer interfaces

D. All of the above

Hint

Separate event dispatch, handler registration and cancellation of the browser default action.

Answer D: All three are possible JavaScript benefits.

WEB01 assigns JavaScript programmable interactivity, and WEB21 describes browser checks that give immediate feedback. Such client work can avoid some server round trips, support richer controls, and increase interactivity. Each preceding option names a possible benefit rather than a guarantee of good implementation. The combined All choice therefore captures the full supported set.

Why each choice is right or wrong

A - Incorrect: Local client computation can avoid some requests, but this option states only one of the listed benefits.

B - Incorrect: JavaScript supplies programmable interactivity, but this is only part of the full supported set.

C - Incorrect: Programmable controls can provide richer interfaces, alongside the other possible benefits.

D - Correct: Reduced requests for local work, interactivity, and richer interfaces are all possible benefits of browser JavaScript.

Primary note proof

Study-note section WEB01

> HTML supplies structure/meaning; CSS controls presentation; JavaScript supplies programmable interactivity.

Study-note section WEB21

> Browser checks improve feedback; repeat validation and authorization on the server.

Web Programming practice questions · Question 6

Question 55 | Q01074

Which statement is true about modern JavaScript and browser capabilities?

A. Browser scripts cannot freely read or write arbitrary client files without an appropriate API and permission

B. JavaScript cannot be used for networking applications

C. JavaScript doesn't have any multi-threading or multiprocessor capabilities

D. All of the above

Hint

Identify the execution side and communication pattern, keeping runtime, transport, data format and callback roles distinct.

Answer A: Browser scripts cannot freely read or write arbitrary client files without an appropriate API and permission

Modern JavaScript can make network requests and can use workers for concurrent computation. Browser scripts may also access selected files or devices through permission-based APIs, so their restriction is on unrestricted access, not all file interaction. The first choice states that boundary precisely. The two remaining capability denials are false, which also makes All of the above false. The answer distinguishes host permissions from the expressive power of the language.

Why each choice is right or wrong

A - Correct: The sandbox does not allow arbitrary unrestricted file access.

B - Incorrect: Browser network APIs and server runtimes refute this denial.

C - Incorrect: Workers provide concurrent computation, refuting this absolute denial.

D - Incorrect: The networking and concurrency denials are false.

Primary note proof

Study-note section WEB01

> Browser scripts are sandboxed, but may access selected files/devices through permission-based APIs.

Study-note section WEB22

> Browser workers support concurrent computation, but DOM access normally remains on the page’s main thread.

Study-note section WEB34

> With fetch, await fetch(url) obtains a response, then check response.ok and parse await response.json().

Question sources

Web Programming practice questions · Question 7

Question 56 | Q01075

Microsoft has developed a popular HTML editor called?

A. Dreamweaver

B. FrontPage

C. HomeSite

D. Macromedia

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer B: FrontPage

WEB02 explicitly identifies Microsoft FrontPage and Macromedia HomeSite5 as historical editors. Therefore FrontPage is the Microsoft editor requested. HomeSite belongs to the other attribution given in the note; Macromedia is a company name rather than the Microsoft product. This is historical product recognition, not a current editor recommendation.

Why each choice is right or wrong

A - Incorrect: Dreamweaver is not the Microsoft editor identified in the supplied historical attribution.

B - Correct: WEB02 explicitly identifies FrontPage as the historical Microsoft editor.

C - Incorrect: HomeSite5 is attributed to Macromedia rather than Microsoft in the note.

D - Incorrect: Macromedia is the company in the HomeSite attribution, not the requested Microsoft editor name.

Primary note proof

Study-note section WEB02

> Historical editor-name items refer to Microsoft FrontPage and Macromedia HomeSite5, not languages or required modern tools.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

> HTML is composed of several tags. HTML Document:-
> - A text document containing markup tags
> - The tags tell the browser how to display the document
> - Should have an .htm or .html file name extension
> - Can be created using a simple text editor

Question sources

Web Programming practice questions · Question 8

Question 57 | Q01076

HomeSite 5 is a well-liked HTML and JavaScript editor from Macromedia.

A. True

B. False

C. Can be true or false

D. Cannot say

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer A: True as a historical product attribution.

WEB02 explicitly identifies Macromedia HomeSite5 as a historical editor. That supports the product-and-company attribution in the statement. Well-liked is an informal popularity description, not a measurable language or browser property supplied here. On the factual historical attribution being tested, True is the supported choice; the note does not recommend the product as a current required editor.

Why each choice is right or wrong

A - Correct: The historical attribution to Macromedia HomeSite5 is explicitly supported by WEB02.

B - Incorrect: False contradicts the product-and-company attribution given in the complete note.

C - Incorrect: The historical attribution is settled in the note rather than varying between true and false.

D - Incorrect: The note supplies the historical attribution needed to answer the factual part of the statement.

Primary note proof

Study-note section WEB02

> Historical editor-name items refer to Microsoft FrontPage and Macromedia HomeSite5, not languages or required modern tools.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

> - Can be created using a simple text editor

Question sources

Web Programming practice questions · Question 9

Question 58 | Q01077

Outside strings and comments, in a context where token boundaries are preserved and line breaks cannot trigger different parsing or automatic semicolon insertion, which single option gives the complete selection of whitespace that can be ignored?

A. spaces

B. tabs

C. newlines

D. All of the above

Hint

Check exact language syntax, declaration rules and execution context before reasoning about the result.

Answer D: All of the above

JavaScript normally uses whitespace to separate tokens. In the explicitly restricted context, extra spaces, tabs and newlines can all be removed without changing the program's meaning. The exclusions matter: whitespace inside strings is data, and line breaks can change parsing in other contexts. All of the above is therefore the complete single choice here; each individual whitespace kind is eligible but would be an incomplete selection.

Why each choice is right or wrong

A - Incorrect: Spaces qualify here, but this choice omits the other qualifying whitespace.

B - Incorrect: Tabs qualify here, but this choice is incomplete.

C - Incorrect: Newlines qualify under the explicit parsing restriction, but this choice is incomplete.

D - Correct: This includes all three qualifying whitespace kinds in the stated context.

Primary note proof

Study-note section WEB15

> Whitespace usually separates tokens but newlines can affect parsing, especially after return.

Web Programming practice questions · Question 10

Question 59 | Q01078

JavaScript is designed for following purpose -

A. to style HTML pages

B. to execute Queries related to databases on a server

C. to add interactivity to html pages

D. All of the above

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer C: to add interactivity to html pages

The module assigns JavaScript interactive features/functionality, HTML structure and CSS presentation (p.44). Evidence: PDF p. 44, PDF p. 60.

Why each choice is right or wrong

A - Incorrect: Styling is principally CSS in this division.

B - Incorrect: Server database query execution is not the stated browser JavaScript purpose.

C - Correct: Matches interactive feature role.

D - Incorrect: The module role distinction prevents all three being its stated primary design purpose.

Primary note proof

Study-note section WEB01

> HTML supplies structure/meaning; CSS controls presentation; JavaScript supplies programmable interactivity.

Study-note section WEB01

> PHP, Python, JSP/Java and ASP.NET applications generate server responses and access databases; C# is commonly used with ASP.NET.

> Client-side scripting is the glamorous, eye-catching part of Web development. In contrast, server-side scripting is invisible to the user. Server-side Web scripting is mostly about connecting Web sites to back-end servers, such as databases. This enables the following types of two-way communication:
> ➢ Server to client: Web pages can be assembled from back end-server output.
> ➢ Client to server: Customer-entered information can be acted upon.

Question sources

Web Programming practice questions · Question 11

Question 60 | Q01079

What will be the output of the following JavaScript code?
var string1 = "Letsfindcourse"; var intvalue = 30; alert (string1 + intvalue);

A. Letsfindcourse 30

B. 30

C. Letsfindcourse30

D. Exception

Hint

Track the value and type at each operation, applying the stated conversion, indexing or mathematical rule.

Answer C: Letsfindcourse30

WEB16 states that + can concatenate when a string is involved. Here string1 is Letsfindcourse and intvalue is number 30, so the numeric operand is represented as text and appended to the string. Neither operand contains a trailing or leading space. The alert therefore displays Letsfindcourse30, not the spaced version.

Why each choice is right or wrong

A - Incorrect: The code contains no separator space between the string and number, so this adds an unwritten character.

B - Incorrect: The original string is retained by concatenation rather than discarded.

C - Correct: The string operand triggers concatenation, appending 30 directly with no extra space.

D - Incorrect: String-plus-number concatenation is valid JavaScript and does not throw merely because the operand types differ.

Primary note proof

Study-note section WEB16

> + can concatenate when a string is involved; arithmetic / converts ordinary numeric strings.

Study-note section WEB22

> alert displays information, confirm returns a Boolean, and prompt requests text or returns null on cancellation.

Question 61 | Q01080

Among the following, which one is a ternary operator in JavaScript?

A. #

B. ::

C. &:

D. ?:

Hint

Track the value and type at each operation, applying the stated conversion, indexing or mathematical rule.

Answer D: ?:

The module explicitly gives condition ? value1 : value2 as the ternary operator syntax (p.50). Evidence: PDF p. 50.

Why each choice is right or wrong

A - Incorrect: Not the shown syntax.

B - Incorrect: Double colon is not the shown syntax.

C - Incorrect: Ampersand-colon is not the shown syntax.

D - Correct: Question mark and colon match the shown conditional expression.

Primary note proof

Study-note section WEB17

> A condition ? x : y chooses one branch.

Web Programming practice questions · Question 13

Question 62 | Q01081

Which option names the three clauses of the general JavaScript for-loop form, regardless of how the loop variable changes?

A. the initialization, the Incrementation, and update

B. the initialization, the test, and the update

C. the initialization, the test, and Incrementation

D. All of the above

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer B: the initialization, the test, and the update

The general form is for(initialization; test; update). Initialization runs once, the test decides whether another iteration starts, and the update follows each completed body. An update can increment, decrement or perform another expression. Therefore an increment-only description is narrower than the general clause name. The first alternative also omits the test, so the aggregate alternative is incorrect.

Why each choice is right or wrong

A - Incorrect: Incrementation and update overlap, and the condition/test clause is missing.

B - Correct: These are the three general clause names, independent of the particular update expression.

C - Incorrect: Incrementing is one possible update; it is not the general name for a clause that may instead decrement or do something else.

D - Incorrect: The first alternative omits the test, and the increment-only alternative is not the general form.

Primary note proof

Study-note section WEB19

> for(initialization;test;update) initializes once, checks before each iteration, then updates after each body.

> }

Question sources

Web Programming practice questions · Question 14

Question 63 | Q01082

Which JavaScript operators compare equality and inequality without type coercion, while == and != remain available for coercive comparison?

A. It uses bitwise checking

B. === and !==

C. It uses equals() and notequals() instead

D. It uses equalto()

Hint

Track the value and type at each operation, applying the stated conversion, indexing or mathematical rule.

Answer B: === and !==

JavaScript supports both loose and strict equality operators. == and != can coerce types, while === and !== compare without that coercion. The strict operators are alternatives with different comparison rules rather than replacements that remove the loose operators from the language. Bitwise checking and the invented equality function names do not identify these language operators, so the corrected question has a single supported answer.

Why each choice is right or wrong

A - Incorrect: Bitwise operations are different from strict equality comparisons.

B - Correct: These are the strict equality and inequality operators.

C - Incorrect: These function names are not the language's strict comparison operators.

D - Incorrect: This is not the language's strict equality operator.

Primary note proof

Study-note section WEB17

> JavaScript has ==/!= with coercion and ===/!== without coercion; strict operators do not replace or remove the loose ones.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 49 | lines 2-8

> 4.6 Arithmetic and Logical Operators in JavaScript
> Arithmetic operators are used to perform mathematical operations between numeric operands. We can perform different operations on numbers, like addition, subtraction multiplication. Here is the list of arithmetic operators we can use on numbers

Logical Operators:
In JavaScript, the logical operators are used to combine two or more conditions.
JavaScript provides the following logical operators.

Question 64 | Q01083

What should appear at the very end of your JavaScript?The <script language="javascript"> tag

A. <script>

B. </script>

C. </script language="javascript">

D. All of the above

Hint

Check exact language syntax, declaration rules and execution context before reasoning about the result.

Answer B: </script>

The script block shown on p.45 ends with </script>; attributes belong in the opening tag.
Evidence: PDF p. 45.

Why each choice is right or wrong

A - Incorrect: Opening tag does not close the block.

B - Correct: Exact closing delimiter.

C - Incorrect: The demonstrated closing tag has no attributes.

D - Incorrect: Only B matches the actual closing delimiter.

Primary note proof

Study-note section WEB15

> Use <script src="app.js"></script> for an external .js file; script content has no HTML closing-tag syntax inside its JavaScript source.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

```
<script>
// JavaScript code goes here
</script>
```

Question sources

Web Programming practice questions · Question 16

Question 65 | Q01084

Which listed item is a directive string rather than a JavaScript keyword that introduces a statement form? Treat with as its legacy non-strict form.

A. if

B. with

C. debugger

D. use strict

Hint

Check exact language syntax, declaration rules and execution context before reasoning about the result.

Answer D: use strict

A quoted "use strict" in a directive prologue selects strict semantics. It is not a reserved keyword introducing a special statement form, although the quoted text is syntactically an expression statement. By contrast, if introduces a conditional statement, with names a legacy scope-lookup statement forbidden in strict mode, and debugger names a statement that can invoke a debugger facility.

Why each choice is right or wrong

A - Incorrect: if names the conditional statement form, so it is not the requested non-keyword directive.

B - Incorrect: with names a statement form, even though strict mode restricts its use.

C - Incorrect: debugger names a JavaScript statement form rather than a directive string.

D - Correct: "use strict" is a directive string, not a reserved statement keyword; technically its quoted form is an expression statement.

Primary note proof

Study-note section WEB15

> “use strict” is a directive string, not a reserved statement keyword.

Study-note section WEB-S05

> An if statement conditionally executes code.

Study-note section WEB-S05

> The legacy with statement temporarily extends name lookup and is forbidden in strict mode.

Study-note section WEB-S05

> A debugger statement may invoke an active debugging facility.

Module passages - related reading

Question sources

Web Programming practice questions · Question 17

Question 66 | Q01086

Which symbol is used for comments in JavaScript?

A. \\

B. //

C. * *\

D. * */

Hint

Check exact language syntax, declaration rules and execution context before reasoning about the result.

Answer B: //

The comment rule explicitly uses // for a single line and /* */ for multiline (p.46). All alternatives except B reverse slash direction. Evidence: PDF p. 46.

Why each choice is right or wrong

A - Incorrect: Backslashes are not the rule.

B - Correct: Exact single-line delimiter.

C - Incorrect: Backslash-star is not forward-slash-star.

D - Incorrect: Incorrect opening backslash, even though closing portion resembles a block end.

Primary note proof

Study-note section WEB15

> // comments end at line end; /* */ span a block.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 46 | lines 4-14

4.3 JavaScript Comments
As with HTML and CSS, it is possible to write comments into a JavaScript code that will be ignored by the browser, and exist to provide instructions to fellow developers on how the code works. There are two types of JavaScript comments
- A single line comment written after a double forward slash (//)
// I am a single line comment
- A multiline comment is written between the strings (/* */)
/*
I am
a multi line comment
*/

Question sources

Web Programming practice questions · Question 19

Question 67 | Q01087

Which of them is not the looping structures in JavaScript?

A. for

B. while

C. forwhich

D. dowhile

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer C: forwhich is not a JavaScript loop form.

WEB19 defines for, while, and do...while loops. The option dowhile names that last construct informally; its actual source spelling is do ... while. forwhich is not one of the language's loop forms. Thus C is the intended non-loop name without treating informal collapsed words as executable source tokens.

Why each choice is right or wrong

A - Incorrect: for is explicitly a JavaScript loop form with initialization, test, and update clauses.

B - Incorrect: while is explicitly a loop that tests before its body.

C - Correct: forwhich is not a defined JavaScript loop form in the note.

D - Incorrect: Read as the loop name do...while, this is the supported at-least-once construct, not a literal token.

Primary note proof

Study-note section WEB19

for(initialization;test;update) initializes once, checks before each iteration, then updates after each body.

Study-note section WEB19

while checks before its body; do...while executes at least once.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 50 | lines 19-33

Loops
Loops are a way to repeat the same code multiple times.
- While loop → while loop has the following syntax
while (condition) {
//"loop body"
}
- Do-while loop → do while loops are very similar to that of while loops, but
in do while even if the condition is false there is always on execution
do{
//"loop body"
} while (condition);
- For loop → syntax
for (begin; condition; step) {
// ... loop body ...
}

Question sources

Web Programming practice questions · Question 20

Question 68 | Q01088

Which operations evaluate to undefined in ordinary JavaScript? A variable read means a direct expression read, not typeof. Select all that apply.

A. Directly reading an undeclared variable

B. Reading a declared var variable before it has been assigned a value

C. Reading a missing property of an ordinary object

D. All of the above

Hint

Track the value and type at each operation, applying the stated conversion, indexing or mathematical rule.

Answer B, C: Reading a declared var variable before it has been assigned a value; Reading a missing property of an ordinary object

An unassigned declared var variable has the value undefined, and an absent ordinary object property also evaluates to undefined. A direct read of an undeclared variable instead normally throws ReferenceError. The question excludes typeof and uses var to avoid a block-scoped temporal-dead-zone case. Both B and C must be selected; All of the above is false because it would include the undeclared-variable read.

Why each choice is right or wrong

A - Incorrect: A direct undeclared-variable read throws ReferenceError.

B - Correct: An unassigned var binding evaluates to undefined.

C - Correct: An absent ordinary object property evaluates to undefined.

D - Incorrect: This includes A, which throws instead of producing undefined.

Primary note proof

Study-note section WEB16

> An unassigned declared variable or missing ordinary object property evaluates to undefined; directly reading an undeclared variable usually throws ReferenceError.

Study-note section WEB15

> var has function/global scope; let/const are block-scoped.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 48 | lines 6-21

> 4.5.2 Variable declaration in JavaScript
> Variables are used to store this information. A variable is a “named storage” for data. We can use variables to store goodies, visitors, and other data. We have three ways of creating variables in JavaScript
> - Using the let keyword → the following statement declares a variable
> let message;
> now we can put values using the assignment operator (=)
> - Using var keyword → we can also declare variable using the var keyword in a similar fashion as let. There is a subtle difference between declaring a variable using var and let. Variables declared with var are hoisted where as those declared with let are not. The other difference between var and let is variables declared with let has a block level scope unlike that of var. Variables declared with var have function level scope
> - Using const keyword → to declare a constant variable we can use const instead of var and let. Variables declared with const can not be changed once they are declared.

Question sources

Web Programming practice questions · Question 21

Question 69 | Q01089

What are the types of Pop up boxes available in JavaScript?

A. Alert

B. Prompt

C. Confirm

D. All of the above

Hint

Distinguish the browser object or dialog role from the kind of response it collects.

Answer D: All of the above

Prompt shows an input modal, confirm a choice modal (p.46), and alert an informational popup (p.47). Thus all three listed dialog forms are covered. Evidence: PDF p. 46, PDF p. 47.

Why each choice is right or wrong

A - Incorrect: A covered popup, but not the full list.

B - Incorrect: A covered input popup.

C - Incorrect: A covered confirmation popup.

D - Correct: Combines the three documented forms.

Primary note proof

Study-note section WEB-S03

> alert(message), confirm(message) and prompt(message) all present a supplied message.

Study-note section WEB22

> alert displays information, confirm returns a Boolean, and prompt requests text or returns null on cancellation.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 46 | lines 16-25

> Accepting user input in JavaScript actually is not a difficult task. JavaScript has a function called prompt, which is used to accept input from the user. But for the result to be useful for us, it has to be stored in a variable. Here is a simple example
> var name = prompt("Enter your name: ");
> alert("Hello " + name);
> ➢ Prompt will show a modal windows with a text message, an input field for the

visitor, and the buttons OK/Cancel
➢ We can also use confirm to get information from a user:- the function confirm shows a modal window with a question and two buttons: OK and Cancel
The result is true if OK is pressed and false otherwise

Web Programming module | PDF page 47 | lines 2-2

2. Alert: shows a browser pop up with the information inside the parenthesis

Question sources

Web Programming practice questions · Question 22

Question 70 | Q01090

what is the disadvantage of using innerHTML in JavaScript?

A. Content cannot be replaced everywhere

B. We can use like "appending to innerHTML"

C. Even if you use +=like "innerHTML = innerHTML + 'html'" still the old content is replaced by html

D. The entire innerHTML content is not re-parsed and build into elements, therefore its not slower

Hint

Track which node is selected or created, and distinguish changing content from attaching a node.

Answer C: Even innerHTML += reparses and replaces descendant nodes.

WEB20 says innerHTML parses and replaces descendants. The += form reads the old markup string, concatenates new markup, and assigns the entire result, so prior descendants are recreated rather than preserved. Existing node listeners or state can be lost. C captures that disadvantage; D explicitly denies the reparsing behavior and is false.

Why each choice is right or wrong

A - Incorrect: This vague restriction is not the specific innerHTML drawback established here.

B - Incorrect: Using apparent append syntax is possible; the disadvantage is that it still replaces and reparses existing descendants.

C - Correct: The += assignment reparses and replaces prior descendant content, potentially losing node listeners and state.

D - Incorrect: The note says the entire assigned markup is reparsed; this option incorrectly denies that mechanism.

Primary note proof

Study-note section WEB20

innerHTML parses/replaces descendants, so += reparses/replaces the prior descendant content too and can destroy listeners/state.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 52 | lines 3-9

4.10 JavaScript DOM (Document object Model)
The Document Object Model (DOM) is the data representation of the objects that comprise the structure and content of a document on the web. The Document Object Model (DOM) is a programming interface for web documents. It represents the page so that programs can change the document structure, style, and content. The DOM represents the document as nodes and objects; that way, programming languages can interact with the page.

Question sources

Web Programming practice questions · Question 23

Question 71 | Q01091

What are the two basic groups of dataypes in JavaScript?

A. Primitive

B. Reference types.

C. All of the above

D. None of the above

Hint

Track the value and type at each operation, applying the stated conversion, indexing or mathematical rule.

Answer C: Both primitive and object/reference groups.

WEB16 lists primitive values and contrasts them with objects such as arrays, functions, and dates. In the informal two-group teaching model, those object values are often called reference types. A and B each name only one group; All combines the two categories requested. This does not make Array a separate primitive or replace the detailed primitive-type list.

Why each choice is right or wrong

A - Incorrect: Primitive names one of the two requested groups but omits the object/reference group.

B - Incorrect: Reference types informally names the object group but omits the primitive group.

C - Correct: All combines primitives and the informal object/reference group, supplying both categories requested.

D - Incorrect: The note explicitly distinguishes primitives from objects, so the two-group classification is available.

Primary note proof

Study-note section WEB16

> JavaScript primitives are undefined, null, Boolean, Number, BigInt, String and Symbol; objects include arrays, functions and dates.

Study-note section WEB16

> Arrays are objects, even though informal texts call them an array data type.

Web Programming practice questions · Question 24

Question 72 | Q01092

Which of the following are the errors in JavaScript?

A. Load time errors

B. Run time errors:

C. Logical Errors:

D. All of the above

Hint

Check exact language syntax, declaration rules and execution context before reasoning about the result.

Answer D: All three broad error categories.

WEB19 distinguishes parse-time syntax errors, runtime thrown errors, and logical errors. Interpreting load time errors as the question's broad label for parse/load failures, all three listed categories are valid. They differ in when and how failure appears: parsing may prevent execution, runtime errors occur during execution, and logical errors can produce incorrect results without throwing.

Why each choice is right or wrong

A - Incorrect: Parse or load failures are a valid broad error category, but this option omits the other listed categories.

B - Incorrect: Thrown execution errors are runtime errors, but they are only one of the listed categories.

C - Incorrect: Logical errors can produce wrong results without throwing, but they are not the only error category.

D - Correct: All covers the broad parse/load, runtime, and logical-error categories distinguished in the note.

Primary note proof

Study-note section WEB-S05

> A syntax error prevents source from being parsed successfully.

Study-note section WEB-S05

> A runtime error arises while executing a program.

Study-note section WEB-S05

> A logical error is a defect in the algorithm or expression that can produce an incorrect result without throwing an exception.

4.10.4 Handling Exception in JavaScript
There's a syntax construct try...catch that allows us to "catch" errors so the script can, instead of dying, do something more reasonable.
The "try...catch" syntax
The try...catch construct has two main blocks: try, and then catch:

```
try {
// code...
} catch (err) {
// error handling
}
```

Web Programming practice questions · Question 25

Question 73 | Q01093

Which JavaScript function capability is illustrated by storing a function in a variable and passing it as an argument?

A. First-class functions

B. Functions restricted to class-member calls

C. Functions restricted to one fixed call site

D. All of the above

Hint

Check exact language syntax, declaration rules and execution context before reasoning about the result.

Answer A: First-class functions

JavaScript functions can be stored and passed as values. This is the first-class-function capability: a function can be assigned to a variable and supplied as an argument. Functions are not restricted to class-member invocation or one fixed call site. Those restrictions conflict with the stated ability to pass a function value, so the aggregate alternative is also false.

Why each choice is right or wrong

A - Correct: Storing and passing a function as a value is the first-class-function capability.

B - Incorrect: A function value can be stored and passed outside a class-member call; JavaScript does not impose this restriction.

C - Incorrect: Passing a function value allows its use at other call sites, contradicting the proposed fixed-site restriction.

D - Incorrect: The restrictions in the other two alternatives conflict with first-class function values, so the aggregate is false.

Primary note proof

Study-note section WEB19

function f(x){return x*2;} has a parameter and returns a value; functions can be passed/stored like other values.

Study-note section WEB15

JavaScript originated at Netscape; it is distinct from Java and supports sophisticated applications through prototype-based objects and first-class functions.

Module passages - related reading

Web Programming module | PDF page 44 | lines 4-7

JavaScript (JS) is a lightweight, interpreted or compiled programming language. It is a single threaded, dynamic language, supporting object oriented, functional programming styles. Do not confuse JavaScript with the Java Programming language. The two-programming language have very different syntax, semantics, and use.

Web Programming module | PDF page 51 | lines 18-30

4.9 JavaScript Functions
Functions are the main “building blocks” of the program. They allow the code to be called many times without repetition. To create a function, we can use a function declaration.
function showCSMessage() {
alert('Hello CS Students!');
}
To create a function, first we use the function keyword then the function name.
There are times when we remove the function name. This type Functions without a function name are called anonyms functions.
After the function name we optionally put parameters in between the parenthesis, if we don’t have parameters, we always have to put the empty parenthesis and then finally the block of code to be executed.

Question 74 | Q01094

Which exact name is not a standard screen property in a normal browser page?

A. availHeight

B. colorsDepth

C. availWidth

D. colorDepth

Hint

Distinguish the browser object or dialog role from the kind of response it collects.

Answer B: colorsDepth

JavaScript property names are case-sensitive. The standard names are availHeight, availWidth and colorDepth, all with the shown camelCase spelling. The distractor colorsDepth has an extra s and is not the standard color-depth property. The valid names use their exact case-sensitive spelling.

Why each choice is right or wrong

A - Incorrect: This is the exact available-height property name.

B - Correct: The extra s makes this different from colorDepth.

C - Incorrect: This is the exact available-width property name.

D - Incorrect: This is the exact color-depth property name.

Primary note proof

Study-note section WEB22

> screen.availHeight, screen.availWidth and screen.colorDepth have exact camelCase spelling; ColorsDepth is not the property.

Question 75 | Q01095

JavaScript string using double quotes is exactly the same as a string using single quotes?

A. True

B. False

Hint

Track the value and type at each operation, applying the stated conversion, indexing or mathematical rule.

Answer A: True

The module lists single and double quotes as two valid ways to surround strings (p.47). For identical content requiring no different escaping, they represent the same string value. Evidence: PDF p. 47.

Why each choice is right or wrong

A - Correct: Correct for the same content under the stated assumption.

B - Incorrect: No difference in value solely from the quote choice is described.

Primary note proof

Study-note section WEB16

> Strings use either quote style, with appropriate escaping.

Question sources

Web Programming practice questions · Question 28

Question 76 | Q01096

What does this JavaScript output?
var a = "20";
var b = a = 30;
document.write(a + b);

A. Error in Script

B. '20'30

C. 2030

D. 60

Hint

Track the value and type at each operation, applying the stated conversion, indexing or mathematical rule.

Answer D: 60

Assignment first stores the Number 30 in a, replacing its previous string value, and then assigns that same Number to b. At the addition, both operands are therefore numeric thirty. Their sum is sixty, which document.write emits. The choice supplies the computed result rather than preserving the incorrect fifty. String concatenation does not occur because the original string no longer remains in either operand.

Why each choice is right or wrong

A - Incorrect: The assignments and addition are valid JavaScript.

B - Incorrect: The original string has been replaced and quotes are not emitted.

C - Incorrect: Neither operand is the string twenty when addition occurs.

D - Correct: Both operands are Number 30, giving the supplied numeric sum.

Primary note proof

Study-note section WEB17

> var a="20"; var b=a=30; assigns Number 30 to both, so a+b is 60, not 50.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

3. The write() method
- The write() method writes HTML expressions or JavaScript code to a document.
- The write() method is mostly used for testing: If it is used after an HTML document is fully loaded, it will delete all existing HTML.
Usage:
document.write(expr)

Question sources

Web Programming practice questions · Question 29

Question 77 | Q01097

What is divide by 0 in JavaScript?
var a = 10;var b = 0;document.write(a/b);

A. Nothing is printed

B. 0 is printed

C. Infinity is printed

D. Some Garbage Value

Hint

Track the value and type at each operation, applying the stated conversion, indexing or mathematical rule.

Answer C: Infinity is printed.

WEB16 states that a nonzero Number divided by zero produces signed Infinity. Here a is positive 10 and b is positive zero, so a/b yields positive Infinity. document.write converts that value to its displayed text. This is not the 0/0 case, which produces NaN, and ordinary Number division does not yield an arbitrary garbage value.

Why each choice is right or wrong

A - Incorrect: The expression evaluates to Infinity and document.write displays its text, so output is not empty.

B - Incorrect: Dividing positive ten by zero does not produce zero under JavaScript Number arithmetic.

C - Correct: A positive nonzero Number divided by positive zero yields Infinity, which is printed.

D - Incorrect: JavaScript defines this result as Infinity rather than an unspecified garbage value.

Primary note proof

Study-note section WEB16

> "abc"/"def" produces NaN; nonzero Number divided by zero produces signed Infinity, while 0/0 produces NaN.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming practice questions · Question 30

Question 78 | Q01098

Which of the following function of Array object applies a function simultaneously against two values of the array (from right-to-left) as to reduce it to a single value?

A. pop()

B. reduce()

C. push()

D. reduceRight()

Hint

Track the value and type at each operation, applying the stated conversion, indexing or mathematical rule.

Answer D: reduceRight(), applied sequentially from right to left.

WEB18 distinguishes reduce from reduceRight by traversal direction. reduceRight combines an accumulator with each element from right to left, giving the single accumulated result described. The stem's simultaneously is inaccurate: callbacks are sequential, not parallel. Pop and push change the array's end, while reduce processes left to right. D uniquely matches the intended directional reduction.

Why each choice is right or wrong

A - Incorrect: pop removes the last item and does not repeatedly combine items into an accumulated result.

B - Incorrect: reduce combines left to right, contrary to the direction specified in the question.

C - Incorrect: push appends items at the array end rather than reducing existing items to one accumulated value.

D - Correct: reduceRight performs the requested right-to-left reduction, but sequentially rather than literally simultaneously.

Primary note proof

Study-note section WEB18

> reduce combines sequentially from left to right; reduceRight combines sequentially from right to left with an accumulator, not simultaneous parallel execution.

Study-note section WEB18

> Array push/pop add/remove at the end; unshift/shift act at the beginning.

Web Programming practice questions · Question 31

Question 79 | Q01099

What is the output of following Javascript?var a = 'letsfind';var b = 'course';var c = a/b;document.write(c);

A. letsfindcourse

B. letsfind/course

C. NaN

D. None of the above

Hint

Track the value and type at each operation, applying the stated conversion, indexing or mathematical rule.

Answer C: NaN

WEB16 says arithmetic division converts ordinary numeric strings and gives NaN when nonnumeric strings are divided. Neither letsfind nor course is a numeric string, so a/b cannot produce a meaningful Number and evaluates to NaN. Division does not concatenate strings or insert a slash into displayed text. document.write therefore prints NaN.

Why each choice is right or wrong

A - Incorrect: Concatenation would use + with strings; the source instead applies arithmetic division.

B - Incorrect: The slash is an operator, not a literal character appended between the two strings.

C - Correct: Both operands are nonnumeric strings, so numeric division evaluates to NaN and that text is written.

D - Incorrect: NaN is explicitly offered and matches the defined conversion result.

Primary note proof

Study-note section WEB16

> + can concatenate when a string is involved; arithmetic / converts ordinary numeric strings.

Study-note section WEB16

> "abc"/"def" produces NaN; nonzero Number divided by zero produces signed Infinity, while 0/0 produces NaN.

Question 80 | Q01100

What does the following JavaScript code write? var a = 1; document.write(a--); document.write(a);

A. 00

B. 01

C. 11

D. 10

Hint

Track the value and type at each operation, applying the stated conversion, indexing or mathematical rule.

Answer D: 10

The source uses a-- despite the introductory mention of ++. Starting with a=1, postfix decrement yields the old value 1 to the first write and then changes a to 0. The second write outputs 0. No separator is written between calls, so the displayed result is 10, exactly as WEB17 explains.

Why each choice is right or wrong

A - Incorrect: Postfix decrement yields the original one for the first write, so the first digit cannot be zero.

B - Incorrect: This reverses the old-value and updated-value order of the two writes.

C - Incorrect: The decrement changes a to zero before the second write, so the second digit is not one.

D - Correct: The first write gets old value one, then the second gets updated zero, yielding adjacent text 10.

Primary note proof

Study-note section WEB17

> With a=1, printing a-- then a prints10.

Study-note section WEB17

> Postfix a++ yields the old value and then increments a.

Module passages - related reading

Question sources

Web Programming practice questions · Question 33

Question 81 | Q01101

Find output of below JavaScript addition codedocument.write("1 plus 1 is " + 1 + 1);

A. 2

B. 1 plus 1 is 2

C. 1 plus 1 is 11

D. 1 plus 1 is 1 + 1

Hint

Track the value and type at each operation, applying the stated conversion, indexing or mathematical rule.

Answer C: 1 plus 1 is 11

WEB17 explicitly traces this expression. Starting with a string makes the first + concatenate the first numeric 1, producing a longer string. The next + then concatenates the second 1 rather than adding numbers. The original literal supplies the words and spaces, while the two appended digits have no extra separator. The result is 1 plus 1 is 11.

Why each choice is right or wrong

A - Incorrect: The initial string is retained, and the two numbers are not added together first.

B - Incorrect: This would require grouping the numeric addition before concatenating it with the initial string.

C - Correct: Left-to-right evaluation concatenates each one to the existing string, producing the final digits 11.

D - Incorrect: The plus signs are operators rather than literal characters in the output string.

Primary note proof

Study-note section WEB17

"1 plus 1 is "+1+1 concatenates left to right to "1 plus 1 is 11".

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

4.5.3 Data Type Conversion
Type conversations are a very common occurrence in JavaScript. Operators and functions converts the values given to them to the right type. Mathematical operations convert value to numbers.
- String conversion → we can use String(value) function to convert a value to string
- Numeric Conversion → happens automatically in mathematical operations and expression. We can use the Number(value) function to explicitly convert a value to a number:
let str = "123";
let num = Number(str);

Question sources

Web Programming practice questions · Question 34

Question 82 | Q01102

In JavaScript, Arrays are data type. State True or False

A. True

B. False

Hint

Track the value and type at each operation, applying the stated conversion, indexing or mathematical rule.

Answer A: True

The data-type discussion explicitly includes arrays and defines them as regular objects storing indexed values. True fits the broad teaching use of data type; this does not mean arrays are a separate primitive type. Evidence: PDF p. 48.

Why each choice is right or wrong

A - Correct: Arrays are included in the type discussion as objects.

B - Incorrect: False would require the narrower unspoken meaning of separate primitive type.

Primary note proof

Study-note section WEB16

> Arrays are objects, even though informal texts call them an array data type.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Question sources

Web Programming practice questions · Question 35

Question 83 | Q01103

Does JavaScript allow exception handling?

A. Yes, it provides try, catch as well as throw key word for exception handling

B. Yes, but it provides only try block

C. Yes, but it provides only Try catch block, but does not allow throw exception

D. No

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer A: Yes: try, catch, and throw are supported.

WEB19 explicitly states that try/catch handles thrown errors during execution and throw signals an error. Thus A includes both handling and signaling mechanisms. The alternatives claiming only try, denying throw, or denying exception handling contradict that rule. This concerns runtime exception handling; it does not imply that every parse-time or logical error is caught automatically.

Why each choice is right or wrong

A - Correct: JavaScript provides try/catch to handle thrown errors and throw to signal them, as WEB19 states.

B - Incorrect: The language provides catch and throw as well as try, so this restriction is false.

C - Incorrect: WEB19 explicitly includes throw; the language does not prohibit explicitly signaling an exception.

D - Incorrect: JavaScript does support exception handling through the mechanisms described in the complete note.

Primary note proof

Study-note section WEB19

> try/catch handles thrown errors during execution; throw signals one; finally runs cleanup.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Question sources

Web Programming practice questions · Question 36

Question 84 | Q01104

Which of the following method checks if its argument is not a number?

A. isNaN()

B. nonNaN()

C. NaN()

D. None of the above

Hint

Track the value and type at each operation, applying the stated conversion, indexing or mathematical rule.

Answer A: isNaN(), with coercion caveats.

WEB16 distinguishes global isNaN, which converts its argument first, from Number.isNaN, which does not. Of the offered names, isNaN is the actual check for a NaN result after coercion. It is not a universal test for whether the original argument's type is Number. Neither nonNaN nor calling NaN as a function supplies the described API.

Why each choice is right or wrong

A - Correct: Global isNaN exists and tests for NaN after numeric conversion; it is not a pure original-type test.

B - Incorrect: nonNaN() is not the check named in the supplied JavaScript API rule.

C - Incorrect: NaN is the special numeric value, not the callable checking function offered here.

D - Incorrect: isNaN is offered and matches the intended check, subject to the note's coercion caveat.

Primary note proof

Study-note section WEB-S08

> Global isNaN(value) tests whether conversion to Number produces NaN.

Study-note section WEB-S08

> NaN is itself a special numeric value, not a callable checking function.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming practice questions · Question 37

Question 85 | Q01105

What does parseInt("12.8", 10) return in JavaScript?

A. Throws Error

B. It returns the decimal values in string form

C. The Number value 12

D. None of the listed option

Hint

Track the value and type at each operation, applying the stated conversion, indexing or mathematical rule.

Answer C: The Number value 12

parseInt reads digits in the supplied radix until it reaches a character that cannot continue that integer representation. Here it consumes the digits before the decimal point and stops at the point, returning Number 12. It does not round the decimal value, return a string or throw merely because a decimal point appears. The concrete string avoids claiming that every decimal-looking input has a usable leading integer prefix.

Why each choice is right or wrong

A - Incorrect: A decimal point after an initial digit sequence does not require an exception.

B - Incorrect: The return value is a Number, not a string containing the decimal.

C - Correct: The radix-ten digit prefix yields Number 12.

D - Incorrect: A listed choice gives the actual result.

Primary note proof

Study-note section WEB16

parseInt("12.8",10) reads12, stopping at the dot; this is parsing, not rounding.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming practice questions · Question 38

Question 86 | Q01106

What is the output of below JavaScript code?alert (type of new Date());

A. Throws Error

B. object

C. Displays Nothing

D. Current Date

Hint

Track the value and type at each operation, applying the stated conversion, indexing or mathematical rule.

Answer A: Syntax error: the source says type of rather than typeof.

type of new Date() is invalid JavaScript syntax; the operator is typeof, written as one word. Therefore the shown program errors before displaying an ordinary value. typeof new Date() would evaluate to "object", but that is a different expression from the code shown.

Why each choice is right or wrong

A - Correct: The spaced text type of is not the typeof operator, causing a syntax error in the literal source.

B - Incorrect: object is the result after repairing type of to typeof, which the task has not authorized.

C - Incorrect: The primary result is a syntax error, not successful execution with an intentionally empty display.

D - Incorrect: A valid typeof expression reports a type, rather than the current date value.

Primary note proof

Study-note section WEB19

A literal type of expression is not the typeof operator.

Study-note section WEB41

x=4+"4"5 is a syntax error because an operator is missing; bool ans=true and type of new Date() are syntax errors too.

Study-note section WEB16

typeof new Date() is "object"; typeof null is historically "object".

D. 11

Hint

Track the value and type at each operation, applying the stated conversion, indexing or mathematical rule.

Answer D: 11

WEB17 traces this exact JavaScript pattern. The left operand reads 10; postfix a++ yields old 10 and then sets a to 11. Equality therefore compares 10 with 10 and is true. The body runs after the increment and writes the updated value 11. These JavaScript evaluation rules should not be replaced with C/C++ assumptions.

Why each choice is right or wrong

A - Incorrect: The expression is valid JavaScript; its specified evaluation order does not produce the supposed error.

B - Incorrect: The comparison uses old ten on both sides and is true, so the body does execute.

C - Incorrect: Ten is the compared old value, but the increment has completed before document.write reads a.

D - Correct: The equality succeeds using old values, then the body prints the updated value eleven.

Primary note proof

Study-note section WEB17

> Postfix a++ yields the old value and then increments a.

Study-note section WEB17

> If a=10, a==a++ compares10 with10, then the body sees11.

Question sources

Web Programming practice questions · Question 40

Question 88 | Q01108

An inline onkeydown handler returns false for a cancelable keydown event whose default action is text insertion. Which statement correctly describes the cancellation?

A. The default text-insertion action associated with the handled keydown is canceled

B. A later keypress handler retroactively cancels the earlier keydown event

C. The keyup event is necessarily prevented from being dispatched

D. Every later keyboard event is necessarily canceled

Hint

Separate event dispatch, handler registration and cancellation of the browser default action.

Answer A: The default text-insertion action associated with the handled keydown is canceled

An appropriate inline event handler can use a false return value to cancel the handled event's default action. With the cancelable text-insertion action specified here, that default action is stopped. This does not erase an earlier event or guarantee that later keyboard events disappear. The distinction is between canceling a default behavior and suppressing an entire sequence of event dispatches; addEventListener would require preventDefault instead.

Why each choice is right or wrong

A - Correct: The inline handler convention consumes false to cancel the specified default action.

B - Incorrect: A later handler cannot undo the dispatch of an earlier event.

C - Incorrect: Canceling a default action does not guarantee suppression of keyup dispatch.

D - Incorrect: The cancellation concerns the handled default action, not every later event.

Primary note proof

Study-note section WEB21

> Returning false from an addEventListener callback does not cancel it; return false works in an appropriate inline/onsubmit property handler whose caller uses that return.

Study-note section WEB21

> For cancelable keyboard defaults, call preventDefault rather than assuming a different key event itself disappears.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 53 | lines 4-18

> 4.10.3 Events in JavaScript
> An event is a signal that something has happened. All DOM nodes generate such signals (but events are not limited to DOM).
> Here's a list of the most useful DOM events, just to take a look at:
> - click - when the mouse clicks on an element (touchscreen devices generate it

on a tap).
- contextmenu - when the mouse right-clicks on an element.
- mouseover / mouseout - when the mouse cursor comes over / leaves an element.
- mousedown / mouseup - when the mouse button is pressed / released over an element.
- mousemove - when the mouse is moved.
Event Handlers
To react on events we can assign a handler - a function that runs in case of an event.
Handlers are a way to run JavaScript code in case of user actions.

Web Programming module | PDF page 54 | lines 6-7

- passive: if true, then the handler will not call preventDefault(), we'll explain that later in Browser default actions.

Web Programming practice questions · Question 41

Question 89 | Q01109

The _____ method of an Array object adds and/or removes elements from an array.

A. Reverse

B. Shift

C. Slice

D. Splice

Hint

Track the value and type at each operation, applying the stated conversion, indexing or mathematical rule.

Answer D: splice()

WEB18 defines splice(start,deleteCount,...items) as mutating an array by removing and inserting elements. That is the combined operation in the stem. The options capitalize method names as terms; the actual JavaScript call is lowercase splice(). reverse changes order, shift removes only the first item, and slice produces a shallow copy rather than that mutation.

Why each choice is right or wrong

A - Incorrect: reverse() changes element order in place rather than adding or removing the requested entries.

B - Incorrect: shift() removes one first element; it is not the general combined insertion/removal method.

C - Incorrect: slice() returns a shallow copy of a selected range rather than mutating through insertion or removal.

D - Correct: The actual lowercase splice() method removes and optionally inserts entries in the original array.

Primary note proof

Study-note section WEB18

> slice returns a selected shallow copy; splice(start,deleteCount,...items) mutates by removal/insertion.

Study-note section WEB18

> reverse reverses in place.

Study-note section WEB18

> Array push/pop add/remove at the end; unshift/shift act at the beginning.

Question 90 | Q01110

The term PHP is an acronym for PHP:_____.

A. Hypertext Preprocessor

B. Hypertext multiprocessor

C. Hypertext markup Preprocessor

D. Hypertune Preprocessor

Hint

Check exact language syntax, declaration rules and execution context before reasoning about the result.

Answer A: Hypertext Preprocessor

Page 60 explicitly expands PHP as Hypertext Preprocessor. No extra markup, multi-, or Hypertune term occurs in that expansion. Evidence: PDF p. 60.

Why each choice is right or wrong

A - Correct: Exact expansion.

B - Incorrect: Changes Preprocessor to multiprocessor.

C - Incorrect: Adds markup to the expansion.

D - Incorrect: Changes Hypertext to Hypertune.

Primary note proof

Study-note section WEB23

> PHP means PHP: Hypertext Preprocessor.

But as it expanded in scope, a new and more appropriate name was selected by community vote. PHP is the

Question sources

Web Programming practice questions · Question 43

Question 91 | Q01111

PHP is a _____ language?

A. user-side scripting

B. client-side scripting

C. server-side scripting

D. Both B and C

Hint

Check exact language syntax, declaration rules and execution context before reasoning about the result.

Answer C: server-side scripting

In the web execution model used here, PHP runs on the server, generates responses and can access databases. The browser receives its output rather than executing the PHP source as its client-side script. Client-side interactivity is supplied by languages such as JavaScript. Thus server-side scripting is the matching category, and the combined alternative incorrectly adds client-side execution.

Why each choice is right or wrong

A - Incorrect: User-side is not the server-execution category described for PHP.

B - Incorrect: Client-side scripting runs in the browser, whereas the described PHP processing runs on the server.

C - Correct: PHP is the server-side scripting language in this web application model.

D - Incorrect: This combines the correct server role with a client-side role that does not apply to PHP source in the described model.

Primary note proof

Study-note section WEB01

> PHP, Python, JSP/Java and ASP.NET applications generate server responses and access databases; C# is commonly used with ASP.NET.

Study-note section WEB23

> It can emit ordinary text and HTML.

Question sources

Web Programming practice questions · Question 46

Question 94 | Q01114

Which of the below statements is equivalent to $sub -= $sub?

A. $sub = $sub

B. $sub = $sub -$sub

C. $sub = $sub - 1

D. $sub = $sub - $sub - 1

Hint

Trace the bindings and operations in order; preserve the exact string characters and distinguish returned values from emitted output.

Answer B: $sub = $sub - $sub

WEB26 explicitly expands $sub-=$sub into $sub=$sub-$sub. Compound subtraction uses the existing left-side value minus the stated right-side value and stores the result back. Here both references name the same value; no constant one is subtracted. The expression is therefore not decrement and does not preserve the old value by simple reassignment.

Why each choice is right or wrong

A - Incorrect: Simple self-assignment leaves the value unchanged rather than subtracting the right-hand operand.

B - Correct: This is the exact expansion of compound subtraction with $sub on both sides.

C - Incorrect: Subtracting one is decrement; the actual right-hand operand is $sub rather than the constant one.

D - Incorrect: The extra subtraction of one is absent from the compound assignment and changes its meaning.

Primary note proof

Study-note section WEB26

> $sub-=$sub is $sub=$sub-$sub, not decrement.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 64 | lines 10-12

> ➢ The value of a variable is the value of its most recent assignment.
> ➢ Variables are assigned with the = operator, with the variable on the left-hand side and the expression to be evaluated on the right.

Web Programming module | PDF page 65 | lines 8-12

> Arithmetic Operators:
> Arithmetic operators do what you would expect. They are used to perform mathematics. You can use them for the main four operations (plus, minus, multiply, and

divide) as well as to find a modulus (the remainder after a division) and to increment or decrement a value.

Question sources

Web Programming practice questions · Question 47

Question 95 | Q01115

Which PHP statement reliably outputs the literal characters $lfc, regardless of the variable's current value?

A. echo "$lfc";

B. echo "$$lfc";

C. echo '$lfc';

D. echo "$lfc;";

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer C: echo '$lfc';

Double-quoted PHP strings interpolate variable names, so the unescaped occurrences of $lfc depend on the variable's value. A single-quoted string normally preserves the dollar name literally and therefore emits the requested characters. Extra dollar signs or quoted semicolons do not turn the remaining double-quoted choices into reliable literal output. The option changes the quoting rather than assuming a convenient variable value.

Why each choice is right or wrong

A - Incorrect: Double quotes interpolate the variable's value.

B - Incorrect: The extra dollar sign does not prevent interpolation of $lfc.

C - Correct: Single quotes preserve the dollar name as literal text.

D - Incorrect: The variable is interpolated and the semicolon inside the string is also output.

Primary note proof

Study-note section WEB24

Double-quoted strings interpolate variables and escapes such as \n; single quotes normally preserve dollar names literally.

Study-note section WEB24

To emit literal $lfc use echo '$lfc'; or escape the dollar in double quotes.

5.3 PHP Output Statements
The two most basic constructs for printing to output are echo and print. Their language status is somewhat confusing, because they are basic constructs of the PHP language, rather than being functions. As a result, they can be used either with parentheses or without them.
Echo
The simplest use of echo is to print a string as argument.
For example:
echo “This will print in the user’s browser window.”;
Or equivalently:
echo(“This will print in the user’s browser window.”);
You can also give multiple arguments to the unparenthesized version of echo, separated by commas, as in:
echo “This will print in the “, “user‟s browser window.”;

Question sources

Web Programming practice questions · Question 48

Question 96 | Q01116

Which of the below symbol is a newline character?

A. \r

B. \n

C. /r

D. /n

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer B: \n

WEB24 identifies \n among escapes interpreted in PHP double-quoted strings. That sequence represents a newline; a forward slash does not introduce the escape. \r denotes a different line-control character rather than the newline sequence requested. Interpretation depends on string context, since single-quoted strings generally preserve such escapes rather than processing them the same way.

Why each choice is right or wrong

A - Incorrect: \r is the carriage-return escape, a different line-control character from the newline sequence requested.

B - Correct: \n is the newline escape sequence recognized in the note's double-quoted string context.

C - Incorrect: A forward slash does not introduce the newline escape, so /r is ordinary text here.

D - Incorrect: The newline escape uses a backslash; /n with a forward slash is ordinary text.

Primary note proof

Study-note section WEB-S06

> In double-quoted PHP strings, backslash-n represents a line feed and backslash-r represents a carriage return.

Study-note section WEB-S06

> The written sequences are \n and \r; forward-slash sequences such as /n are ordinary text.

Question 97 | Q01117

PHP files can contain _____ code.

A. text

B. HTML

C. python

D. Both A and B

Hint

Check exact language syntax, declaration rules and execution context before reasoning about the result.

Answer D: Both A and B

PHP can be embedded within ordinary HTML (p.60); the output examples contain text strings (p.63). Thus text and HTML can coexist in a PHP document. Evidence: PDF p. 60, PDF p. 63.

Why each choice is right or wrong

A - Incorrect: Text can occur, but A alone omits HTML.

B - Incorrect: HTML can occur, but B alone omits text.

C - Incorrect: The module does not define Python embedding or execution.

D - Correct: Combines the supported text and HTML forms.

Primary note proof

Study-note section WEB23

> It can emit ordinary text and HTML.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Question 98 | Q01118

What will be the output of the following PHP code?
<?php
$x = 8;
$y = 8.0;
echo ($x === $y);
?>

A. 8 === 8

B. No Output

C. 1

D. 0

Hint

Trace the bindings and operations in order; preserve the exact string characters and distinguish returned values from emitted output.

Answer B: No output characters.

In PHP, 8===8.0 is false because int and float differ, despite equal numeric values. echo false emits an empty string. Consequently the shown code produces no output characters, rather than printing zero. The comparison expression itself is evaluated and is not emitted as source text.

Why each choice is right or wrong

A - Incorrect: echo evaluates the comparison instead of printing its source expression.

B - Correct: Strict identity fails for int versus float, and echo false emits no characters.

C - Incorrect: One is the echo representation of true; the strict identity comparison here is false.

D - Incorrect: Although the comparison is false, echo false emits an empty string rather than the digit zero.

Primary note proof

Study-note section WEB24

PHP 8==8.0 is true, but 8===8.0 is false because types differ; echo false emits an empty string, echo true emits1.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 63 | lines 27-33

> 5.4 Data Types and Variables in PHP
> PHP is a very loosely typed language. This means that variables do not have to be declared before they are used, and that PHP always converts variables to the type required by their context when they are accessed. Variables can store data of different types, and different data types can do different things. PHP supports the following data types: String, Integer, Float (floating point numbers - also called double), Boolean, Array, Object, NULL and Resource

Question 99 | Q01119

The script that executes at the browser side is called _____

A. Client-side scripting

B. Server-side scripting

C. Both A and B

D. None of the above

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer A: Client-side scripting

The module distinguishes client/browser behavior from server-side PHP. Code executing in the browser is client-side scripting in this model. Evidence: PDF p. 9, PDF p. 60, PDF p. 56.

Why each choice is right or wrong

A - Correct: Browser-side matches client-side.

B - Incorrect: PHP server processing happens on the server.

C - Incorrect: The stated execution site is the client, not both.

D - Incorrect: A matches the documented client/server distinction.

Primary note proof

Study-note section WEB01

> A browser/user agent requests resources and renders HTML/CSS, then runs permitted JavaScript.

Study-note section WEB01

> PHP, Python, JSP/Java and ASP.NET applications generate server responses and access databases; C# is commonly used with ASP.NET.

Question sources

Web Programming practice questions · Question 52

Question 100 | Q01120

How many basic PHP output language constructs are counted when callable output functions such as printf and print_r are excluded?

A. 1

B. 2

C. 3

D. 4

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer B: 2

The note identifies echo and print as two basic output constructs. This count is about that language-construct category, rather than every way a PHP program can produce output. Functions such as printf and print_r provide additional output mechanisms but do not increase the specified count of constructs. The revised category therefore supports one numeric choice without implying that PHP has only two output mechanisms altogether.

Why each choice is right or wrong

A - Incorrect: Both echo and print belong to the specified category, so one is too few.

B - Correct: The category contains the two named basic constructs.

C - Incorrect: This would count an additional mechanism outside the specified construct category.

D - Incorrect: This would mix other output mechanisms into the restricted category.

Primary note proof

Study-note section WEB24

> They are two basic output constructs, not the only output mechanisms; printf, print_r and others exist.

Module passages - related reading

Question 101 | Q01122

How many return value does echo statement has?

A. 1

B. 2

C. 3

D. 0

Hint

Trace the bindings and operations in order; preserve the exact string characters and distinguish returned values from emitted output.

Answer D: 0

Page 63 contrasts print, which returns a value, with echo, which does not. Thus echo has zero return values; zero here counts return values rather than describing a returned numeric zero. Evidence: PDF p. 63.

Why each choice is right or wrong

A - Incorrect: Would give echo the return behavior assigned to print.

B - Incorrect: No two return values are described.

C - Incorrect: No three return values are described.

D - Correct: No return value, expressed as count zero.

Primary note proof

Study-note section WEB24

> echo is a language construct with no return value and can emit comma-separated expressions.

Study-note section WEB24

> print takes one expression and returns1.

Web Programming module | PDF page 63 | lines 21-26

> Print
> The command print is very similar to echo, with two important differences:
> ✦ unlike echo, print can accept only one argument.
> ✦ unlike echo, print returns a value, which represents whether the print statement succeeded. The value returned by print will be 1 if the printing was successful and 0 if unsuccessful.

Question sources

Web Programming practice questions · Question 55

Question 102 | Q01123

What exact raw response text does this PHP emit, before any browser HTML rendering?
<?php
echo "Hello world </br> I am learning PHP at letsfindcourse";
?>

A. Hello world

B. Hello world </br> I am learning PHP at letsfindcourse

C. Hello worldI am learning PHP at letsfindcourse

D. Error

Hint

Trace the bindings and operations in order; preserve the exact string characters and distinguish returned values from emitted output.

Answer B: Hello world </br> I am learning PHP at letsfindcourse

echo emits the characters of its string without automatically adding or removing spaces. Because the question asks for raw response text, the break-like markup remains present exactly as written; browser error recovery is irrelevant to this output. Both phrases and the spaces around the markup are preserved. The HTML fragment's unusual closing form does not make the surrounding PHP string syntactically invalid.

Why each choice is right or wrong

A - Incorrect: This omits the markup and the second phrase.

B - Correct: This preserves every character in the emitted string.

C - Incorrect: This omits the intervening spaces, markup and separation.

D - Incorrect: The markup is inside a valid PHP string and causes no PHP parse error.

Primary note proof

Study-note section WEB24

> PHP sends markup as response characters; a browser then interprets it.

Study-note section WEB24

> Neither automatically inserts spaces/newlines.

Question 103 | Q01124

What will be the output of the following PHP code?
<?php
$five = 5;
print($five);
print $five;
?>

A. 05

B. 55

C. 50

D. Error

Hint

Trace the bindings and operations in order; preserve the exact string characters and distinguish returned values from emitted output.

Answer B: 55

print accepts one argument and may be written with or without parentheses (p.63). Both statements print the assigned 5, with no intervening separator, giving 55. Evidence: PDF p. 63, PDF p. 63, PDF p. 64.

Why each choice is right or wrong

A - Incorrect: First output is 5, not zero.

B - Correct: Two successive prints of 5 concatenate in output.

C - Incorrect: Second output is also 5.

D - Incorrect: Both print forms are explicitly permitted.

Primary note proof

Study-note section WEB24

Two prints of5 emit55; "I"."am" emitsIam.

Study-note section WEB-S06

The basic print and echo constructs can be written with or without parentheses when their syntax permits it.

5.3 PHP Output Statements
The two most basic constructs for printing to output are echo and print. Their language status is somewhat confusing, because they are basic constructs of the PHP language, rather than being functions. As a result, they can be used either with parentheses or without them.

Web Programming module | PDF page 63 | lines 21-26

Print
The command print is very similar to echo, with two important differences:
✦ unlike echo, print can accept only one argument.
✦ unlike echo, print returns a value, which represents whether the print statement succeeded. The value returned by print will be 1 if the printing was successful and 0 if unsuccessful.

Web Programming module | PDF page 64 | lines 10-12

➢ The value of a variable is the value of its most recent assignment.
➢ Variables are assigned with the = operator, with the variable on the left-hand side and the expression to be evaluated on the right.

Question sources

Web Programming practice questions · Question 57

Question 104 | Q01125

What will be the output of the following PHP code?
<?php
print("I"."am"."learning"."php");
?>

A. Iamlearningphp

B. I am learning php

C. Nothing

D. error

Hint

Trace the bindings and operations in order; preserve the exact string characters and distinguish returned values from emitted output.

Answer A: Iamlearningphp

The PHP examples join strings and variables using dot (p.72). Joining I, am, learning and php inserts no spaces, so the resulting single argument is Iamlearningphp and print emits it. Evidence: PDF p. 72, PDF p. 63.

Why each choice is right or wrong

A - Correct: Preserves all characters with no added spaces.

B - Incorrect: No operand contains a space.

C - Incorrect: print produces output, not silence.

D - Incorrect: Single joined argument fits print.

Primary note proof

Study-note section WEB24

> Dot concatenates; + is arithmetic.

Study-note section WEB24

> Neither automatically inserts spaces/newlines.

Web Programming practice questions · Question 58

Question 105 | Q01126

which of the following is correct echo statement?

A. echo "<h2>PHP is Fun!</h2>";

B. echo "PHP is Fun!
";

C. echo "PHP ", "is ", "Fun!";

D. All of the above

Hint

Trace the bindings and operations in order; preserve the exact string characters and distinguish returned values from emitted output.

Answer D: All of the above

Echo accepts quoted strings, including HTML in generated output, and multiple comma-separated arguments when unparenthesized (p.63). All three snippets meet those forms. Evidence: PDF p. 63, PDF p. 60.

Why each choice is right or wrong

A - Incorrect: Valid string containing heading markup.

B - Incorrect: Valid string containing a line-break tag.

C - Incorrect: Valid unparenthesized multiple-argument echo.

D - Correct: All A-C are valid under the cited echo rules.

Primary note proof

Study-note section WEB24

> echo is a language construct with no return value and can emit comma-separated expressions.

Study-note section WEB24

> PHP sends markup as response characters; a browser then interprets it.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 63 | lines 11-20

> The simplest use of echo is to print a string as argument.
> For example:
> echo “This will print in the user’s browser window.”;
> Or equivalently:
> echo(“This will print in the user’s browser window.”);
> You can also give multiple arguments to the unparenthesized version of echo,
> separated by commas, as in:
> echo “This will print in the “, “user‟s browser window.”;

The parenthesized version, however, will not accept multiple arguments:
echo (“This will produce a “, “PARSE ERROR!”);

Web Programming module | PDF page 60 | lines 20-22

By default, PHP documents end with the extension .php. When a web server encounters this extension in a requested file, it automatically passes it to the PHP processor. At its very simplest, a PHP document will output only HTML.

Question sources

Web Programming practice questions · Question 59

Question 106 | Q01127

What will be the output of the following PHP code?
<?php
echo "This is Letsfindcourse";
?>

A. This is Letsfindcourse

B. This is Letsfindcourse(Letsfindcourse in italic)

C. This is

D. Error

Hint

Trace the bindings and operations in order; preserve the exact string characters and distinguish returned values from emitted output.

Answer B: This is Letsfindcourse(Letsfindcourse in italic)

Echo emits the quoted HTML string (p.63); the i element renders its content in italics (p.15). Consequently the full text is displayed with Letsfindcourse italicized. Evidence: PDF p. 63, PDF p. 15.

Why each choice is right or wrong

A - Incorrect: Text is present but this omits the requested formatting distinction.

B - Correct: States both the text and italic formatting.

C - Incorrect: Incorrectly drops the i element content.

D - Incorrect: The quoted string and i tags fit the documented forms.

Primary note proof

Study-note section WEB24

PHP sends markup as response characters; a browser then interprets it.

Study-note section WEB-S07

In the browser’s default presentation, an i element typically displays its text in italics.

Web Programming practice questions · Question 60

Question 107 | Q01128

Any variables declared in PHP must begin with a _____?

A. .

B. #

C. &

D. $

Hint

Check exact language syntax, declaration rules and execution context before reasoning about the result.

Answer D: $

All PHP variables have a leading dollar sign according to p.64. Evidence: PDF p. 64.

Why each choice is right or wrong

A - Incorrect: Dot is not the variable prefix.

B - Incorrect: Hash is not the variable prefix.

C - Incorrect: Ampersand is not the variable prefix.

D - Correct: Exact mandatory leading symbol.

Primary note proof

Study-note section WEB23

> Variables begin with $, then a letter/underscore and subsequent letters/digits/underscores; $AGE18 works but $18AGE does not.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 64 | lines 6-9

> All variables in PHP are denoted with a leading dollar sign ($).
> All variables in PHP start with a leading $ sign. After the initial $, variable names must be composed of letters (uppercase or lowercase), digits (0-9), and underscore characters (_). Furthermore, the first character after the $ may not be a number.

Question sources

Web Programming practice questions · Question 61

Question 108 | Q01129

A variable can have _____?

A. long descriptive names

B. short names

C. Both A and B

D. None of the above

Hint

Check exact language syntax, declaration rules and execution context before reasoning about the result.

Answer C: Both A and B

After $, identifiers may contain letters, digits and underscores, with no stated fixed short length; both short and descriptive names fit this rule. Names must still satisfy the first-character restriction. Evidence: PDF p. 64.

Why each choice is right or wrong

A - Incorrect: Allowed but not the only allowed length style.

B - Incorrect: Allowed but not the only allowed length style.

C - Correct: Both comply when characters are valid.

D - Incorrect: The naming rule permits both examples of name length.

Primary note proof

Study-note section WEB23

> Variables begin with $, then a letter/underscore and subsequent letters/digits/underscores; $AGE18 works but $18AGE does not.

Question sources

Web Programming practice questions · Question 62

Question 109 | Q01131

Which characters may start a PHP variable identifier immediately after its mandatory $ sign? Select all that apply.

A. letter

B. underscore

C. A digit

D. A space

Hint

Check exact language syntax, declaration rules and execution context before reasoning about the result.

Answer A, B: letter; underscore

A PHP variable begins with a dollar sign followed by a letter or underscore. Digits may occur later in the identifier but may not be the first character after the sigil. A space cannot form that initial identifier character either. The question specifies the position being tested and replaces the vague no-numbers and aggregate wording with concrete candidate characters, allowing both valid initial-character classes to be selected.

Why each choice is right or wrong

A - Correct: A letter is allowed immediately after the dollar sign.

B - Correct: An underscore is also allowed immediately after the dollar sign.

C - Incorrect: A digit may appear later, but cannot start the identifier.

D - Incorrect: A space is not an allowed initial identifier character.

Primary note proof

Study-note section WEB23

> Variables begin with $, then a letter/underscore and subsequent letters/digits/underscores; $AGE18 works but $18AGE does not.

Question sources

Web Programming practice questions · Question 64

Question 110 | Q01132

PHP variables are case-sensitive?

A. True

B. False

C. Only the variable named sum is case-sensitive

D. None of the above

Hint

Check exact language syntax, declaration rules and execution context before reasoning about the result.

Answer A: True

PHP variable names are case-sensitive generally. Two names that differ in letter case can identify different variables, regardless of whether the name is sum or something else. True therefore gives the general rule. False contradicts it, and the sum-only restriction is false because case sensitivity is not limited to that name. None is incorrect because the true general statement is offered.

Why each choice is right or wrong

A - Correct: PHP variable names are case-sensitive as a general rule, exactly as WEB23 states.

B - Incorrect: False contradicts the explicit case-sensitivity rule for PHP variable names.

C - Incorrect: Case sensitivity applies to PHP variable names generally, not only to sum.

D - Incorrect: True is offered and matches the note, so None is not applicable.

Primary note proof

Study-note section WEB23

> Names are case-sensitive.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Question sources

Web Programming practice questions · Question 65

Question 111 | Q01133

In the common PHP teaching taxonomy that counts persistent function-local storage as an additional category alongside visibility categories, how many variable categories are counted?

A. 2

B. 3

C. 1

D. 4

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer B: 3

The stated teaching taxonomy counts local, global and static as three categories. Global and local distinguish visibility, while a static local describes persistence across calls within the execution lifecycle. The question makes this mixed teaching convention explicit rather than treating static storage as an independent visibility scope. Counting only visibility would answer a different question, which is why the narrower numeric choice is now justified.

Why each choice is right or wrong

A - Incorrect: Two counts local/global visibility alone and omits the stated static category.

B - Correct: The specified teaching taxonomy counts local, global and static.

C - Incorrect: One omits the distinctions explicitly included in the taxonomy.

D - Incorrect: No fourth category is included in the stated convention.

Primary note proof

Study-note section WEB25

> Common “three scopes” teaching counts local, global and static, but state the taxonomy.

Study-note section WEB25

> A static local retains its value across calls during the execution lifecycle; static storage is not simply another visibility scope.

Question 112 | Q01134

choose the incorrect variable name in php?

A. $_AGE

B. $18AGE

C. $AGE18

D. $_AGE18

Hint

Check exact language syntax, declaration rules and execution context before reasoning about the result.

Answer B: $18AGE

PHP variable names may include underscores, letters and digits, but the first character after $ cannot be numeric (p.64). Only $18AGE violates that rule. Evidence: PDF p. 64.

Why each choice is right or wrong

A - Incorrect: Underscore then letters is permitted.

B - Correct: Starts with digit 1 after $, expressly forbidden.

C - Incorrect: Letter start and later digits are permitted.

D - Incorrect: Underscore start and later digits are permitted.

Primary note proof

Study-note section WEB23

> Variables begin with $, then a letter/underscore and subsequent letters/digits/underscores; $AGE18 works but $18AGE does not.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Question sources

Web Programming practice questions · Question 67

Question 113 | Q01135

A variable declared _____ has a GLOBAL SCOPE?

A. outside program

B. inside function

C. outside function

D. None of the Above

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer C: Outside a function

WEB25 directly states that a variable outside a function has global scope. A function's own locals and by-value parameters are separate bindings; functions must explicitly refer to globals through global or $GLOBALS when needed. Outside program is not a declaration location, and inside function describes the ordinary local-binding setting rather than the requested global one.

Why each choice is right or wrong

A - Incorrect: Outside program is not a meaningful place for a declaration within the executing PHP source.

B - Incorrect: Ordinary variables declared inside a function are local to that function, not automatically global.

C - Correct: A declaration outside a function creates a global binding under the rule given in WEB25.

D - Incorrect: Outside function is explicitly offered and matches the global-scope rule.

Primary note proof

Study-note section WEB25

> A variable outside a function has global scope.

Study-note section WEB25

> A function's locals and by-value parameters are separate bindings; use global $x or $GLOBALS["x"] to refer to a global explicitly.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 62 | lines 15-18

> All the following variables are automatically available in every scope.
> - $GLOBALS → Contains a reference to every variable which is currently available within the global scope of the script. The keys of this array are the names of the global variables.

Question sources

Web Programming practice questions · Question 68

Question 114 | Q01136

Which of the following will be output of the following code?

```
<?php
function myTest() {
static $x;
echo $x;
}
myTest();
?>
```

A. 0

B. 1

C. No Output

D. Error

Hint

Trace the bindings and operations in order; preserve the exact string characters and distinguish returned values from emitted output.

Answer C: No output

WEB25 states that an uninitialized static local begins as null and echo emits no characters for it. The function declares static $x but never assigns or increments it, then echoes that null value on its only call. The source is valid, so neither an error nor an assumed numeric initialization is the supported result.

Why each choice is right or wrong

A - Incorrect: The uninitialized static local begins as null; echo does not print an assumed numeric zero.

B - Incorrect: No assignment or increment produces one anywhere in the function.

C - Correct: Echoing the initial null static local emits no output characters.

D - Incorrect: Declaring an uninitialized static local is valid PHP and does not itself produce an error.

Primary note proof

Study-note section WEB25

> An uninitialized static local begins as null, so echo emits no characters.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 64 | lines 13-17

> ➢ Variables can, but do not need, to be declared before assignment.
> ➢ Variables have no intrinsic type other than the type of their current value.
> In PHP, because types are associated with values rather than variables, no such declaration is necessary-the first step in using a variable is to assign it a value.
> ✓ Variables used before they are assigned have default values.

Question sources

Web Programming practice questions · Question 70

Question 115 | Q01137

Which of the following is NOT a super global variable ?

A. $_SERVER

B. $_GLOBAL

C. $_GET

D. $_POST

Hint

Identify the data source or security responsibility precisely, and check whether a combined source or a different control could also qualify.

Answer B: $_GLOBAL

The predefined list includes $_SERVER, $_GET and $_POST, while the global map is $GLOBALS, not $_GLOBAL. B confuses its spelling and is not the listed superglobal. Evidence: PDF p. 62.

Why each choice is right or wrong

A - Incorrect: Explicitly listed.

B - Correct: Wrong spelling for $GLOBALS; not the module superglobal.

C - Incorrect: Explicitly listed.

D - Incorrect: Explicitly listed.

Primary note proof

Study-note section WEB27

> $GLOBALS is the actual global-symbol array; $_GLOBAL is not the built-in name.

Study-note section WEB27

> $_GET contains query parameters; $_POST contains supported form POST data; $_FILES upload metadata; $_SERVER request/environment details; $_COOKIE cookie values; $_SESSION session data after startup.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 62 | lines 12-26

PHP provides a large number of predefined variables to any script which it runs.
PHP provides an additional set of predefined arrays containing variables from the web server the environment, and user input. These new arrays are called superglobals –
All the following variables are automatically available in every scope.
- $GLOBALS → Contains a reference to every variable which is currently available within the global scope of the script. The keys of this array are the names of the global variables.
- $_SERVER → This is an array containing information such as headers, paths, and script locations. The entries in this array are created by the web server. There is no guarantee that every web server will provide any of these. See next section for a complete list of all the SERVER variables.
- $_GET → An associative array of variables passed to the current script via the HTTP GET method.
- $_POST → An associative array of variables passed to the current script via the HTTP POST method.

Question sources

Web Programming practice questions · Question 71

Question 116 | Q01138

Predict the output of the following code snippet :

```
<?php
$i=10;
function sample($i)
{
$i++;
echo $i.",";
}
echo $i.",";
GLOBAL $i;
sample($i);
echo $i;
?>
```

A. 11,11,11

B. 10,11,11

C. 10,11,10

D. 10,10,10

Hint

Trace the bindings and operations in order; preserve the exact string characters and distinguish returned values from emitted output.

Answer C: 10,11,10

WEB25 traces this exact pattern: the initial global print emits 10, the function increments its local by-value parameter to 11, and the caller remains 10 afterward. The source writes commas after the first two values. A top-level GLOBAL statement does not turn the function's parameter into a reference, so the final output is 10,11,10.

Why each choice is right or wrong

A - Incorrect: The first print occurs before any increment and therefore emits ten rather than eleven.

B - Incorrect: The function increments a by-value local parameter, so the final caller value remains ten.

C - Correct: The caller prints ten, the local parameter prints eleven, and the unchanged caller prints ten.

D - Incorrect: The function does increment its local parameter, so the middle output is eleven rather than ten.

Primary note proof

Study-note section WEB25

> If global $i=10 and sample($i) increments/prints its by-value parameter, the caller's $i stays10.

Study-note section WEB25

> A global statement outside the function does not turn its value parameter into a reference.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 72 | lines 7-22

> Function definitions have the following form:
> function function_name([parameter [, ...]])
> {
> // Statements
> }
> That is, function definitions have four parts:
> - A definition starts with the word function.
> - A name follows, which must start with a letter or underscore, followed by
> any number of letters, numbers, or underscores.
> - The parentheses are required.
> - One or more parameters, separated by commas, are optional
> Example:
> function info($name,$age,$salary){

```
echo “name:”.$name.”<br>”;
echo “age:”.$age.”<br>”;
echo “salary:”.$salary.”<br>”; }
```

Web Programming module | PDF page 62 | lines 15-18

All the following variables are automatically available in every scope.
- $GLOBALS → Contains a reference to every variable which is currently available within the global scope of the script. The keys of this array are the names of the global variables.

Web Programming module | PDF page 65 | lines 8-12

Arithmetic Operators:
Arithmetic operators do what you would expect. They are used to perform mathematics. You can use them for the main four operations (plus, minus, multiply, and divide) as well as to find a modulus (the remainder after a division) and to increment or decrement a value.

Question sources

Web Programming practice questions · Question 72

Question 117 | Q01139

Can we change the value of constant during the execution of the script.

A. can

B. can not

C. depends on data type

D. depends on variable

Hint

Check exact language syntax, declaration rules and execution context before reasoning about the result.

Answer B: Cannot redefine the constant during ordinary script execution.

WEB23 says constants cannot normally be redefined during execution. That immutability is the property being tested, rather than whether a variable can receive another value. The offered data-type and variable-dependent alternatives do not override the constant binding rule. Therefore can not is the appropriate general answer in the note’s PHP context.

Why each choice is right or wrong

A - Incorrect: Ordinary constant bindings cannot be reassigned as variables can during script execution.

B - Correct: The note explicitly says constants cannot normally be redefined during execution.

C - Incorrect: The redefinition restriction is a binding rule rather than a choice determined by the constant's data type.

D - Incorrect: A constant's ordinary redefinition rule does not depend on the value of some variable.

Primary note proof

Study-note section WEB23

> Constants cannot normally be redefined during execution.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

B. &copy

C. &reg

D. &lt

Hint

Use the element or attribute meaning and document structure, rather than appearance or a similar-looking name.

Answer B: ©

WEB06 explicitly includes © among HTML entities. Thus the choice stem &copy identifies the copyright reference; the complete unambiguous spelling includes its semicolon. The other option names refer to different character references rather than copyright. This answer identifies the entity name, not a permission or copyright-policy assertion.

Why each choice is right or wrong

A - Incorrect: The times entity name does not identify the copyright symbol requested in the stem.

B - Correct: The copy entity name identifies copyright; write the full reference as © including the semicolon.

C - Incorrect: The reg entity name is not the copyright reference explicitly identified in WEB06.

D - Incorrect: The lt entity is the less-than reference, not the copyright reference.

Primary note proof

Study-note section WEB06

> Entities include ©, <, > and &.

Question 122 | Q01171

In which HTML tag allows you to supply all kinds of information about your web page.

A. a | <head> x

B. i? <meta> v

C. /@| <title> x

D. | <body> x

Hint

Use the element or attribute meaning and document structure, rather than appearance or a similar-looking name.

Answer B: i? <meta> v

The meta section defines meta elements as structured metadata about a web page. head contains metadata elements but is the broader container; title supplies only a title, body the visible content. Evidence: PDF p. 13, PDF p. 12.

Why each choice is right or wrong

A - Incorrect: Broader container, not the metadata element requested.

B - Correct: Exact metadata element.

C - Incorrect: Only supplies page title.

D - Incorrect: Contains visible page content.

Primary note proof

Study-note section WEB06

> Meta charset declares encoding; description summarizes the page; viewport controls mobile viewport behavior.

Study-note section WEB06

> <!DOCTYPE html> selects modern standards mode; <html> is the document root, <head> holds metadata, and <body> contains document content.

Study-note section WEB06

> <title> supplies the page/tab title.

Module passages - related reading

Web Programming module | PDF page 13 | lines 4-10

> 2.2.2 Meta tag
> Meta elements are tags used in HTML document to provide structured metadata about a web page. This element represents metadata that cannot be represented by

other HTML meta-related elements, like <base>, <link>, <script>, <style> or <title>. Meta elements are part of a web pages head section. There can be more than one meta element with different attributes on the same web page. In general, meta elements convey hidden information about the document.

Web Programming module | PDF page 12 | lines 6-20

<head>...</head>
- Contains information which is not displayed in the browser display area and may contain other tags in it
- Both the start and end tags may be omitted and inferred from child elements (HTML5)
- The head element may contain other elements such as base, link, meta, style, script, title
<title></title>
- Web browsers usually display it in a window's title bar when the window is open, and (where applicable) in the task bar when the window is minimized.
- Sets the title of the web page to be displayed in the browser's title bar and is found within the <head> tag.
<body></body>
-The body tag contains the visible part of the web page and is displayed in the

Computer Science Exit Exam practice questions · Question 32

Question 123 | Q01180

Which of the following is used to add styles and formatting to a webpage in CSS?

A. Functions

B. Variables

C. Selectors

D. Arrays

Hint

Identify which elements a rule targets and distinguish selector syntax from declaration syntax.

Answer C: Selectors

A selector identifies the elements to be styled and its declaration block supplies the styles (p.29). C is the listed mechanism for attaching styling rules to webpage elements. Evidence: PDF p. 29.

Why each choice is right or wrong

A - Incorrect: Functions are not the ruleset component selecting elements.

B - Incorrect: Variables are not the selecting component described.

C - Correct: Selectors identify the targets of CSS rules.

D - Incorrect: Arrays are not a CSS rule component here.

Primary note proof

Study-note section WEB11

> A rule is selector { property: value; }.

Study-note section WEB11

> A selector chooses where declarations apply; it is not itself the property that sets a color.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 29 | lines 8-15

> A selector group and an associated declarations block, together, are called a ruleset, or often a rule. A Cascading Style Sheet (CSS) rule is a statement that defines the style of one or more elements in your web page. These rules follow a specific structure.
> The whole structure is called a ruleset. Note the names of the individual parts:
> Selector -
> This is the HTML element name at the start of the ruleset. It defines the element(s) to be styled.

Question sources

Computer Science model exam 2 · Question 1

Question 124 | Q01200

Using PHP8 standard database extensions, which snippet can issue the shown SELECT against MySQL? Assume $pdo is an initialized PDO connection using the MySQL driver, $conn is an initialized MySQLi connection, and the users table exists.

A. $result = mysql_query("SELECT * FROM users WHERE id = 1");

B. $result=mysqliquery(conn, "SELECT * FROM users WHERE id = 1");

C. $result = $pdo->query("SELECT * FROM users WHERE id = 1");

D. $result = pg_query("SELECT * FROM users WHERE id = 1");

Hint

Identify the API and operation first, then distinguish connection setup, statement execution and result processing.

Answer C: $result = $pdo->query("SELECT * FROM users WHERE id = 1");

With the stated MySQL PDO connection, $pdo->query executes the SELECT and returns its statement object, so C is valid. The old mysql_* extension is removed in PHP8. B misspells mysqli_query and omits the dollar prefix on its connection variable. pg_query belongs to the PostgreSQL extension and does not execute through either stated MySQL connection.

Why each choice is right or wrong

A - Incorrect: mysql_query belongs to the removed mysql_* extension and is not a PHP8 standard MySQL call.

B - Incorrect: The procedural spelling is mysqli_query($conn, ...); the offered name and bare conn do not form that call.

C - Correct: The initialized MySQL-driver PDO connection can execute this SELECT through its query method.

D - Incorrect: pg_query belongs to the PostgreSQL extension rather than the stated MySQL connections.

Primary note proof

Study-note section WEB31

> PHP8 uses MySQLi or PDO; the old mysql_* extension was removed, so migrate older snippets to a supported API.

Study-note section WEB-S04

> With an initialized PDO connection, $pdo->query($sql) executes an SQL statement without placeholders and returns a PDOStatement for processing its results.

Study-note section WEB-S04

> The procedural MySQLi query form is mysqli_query($conn, $sql), using a MySQLi connection and the correctly spelled function name.

Study-note section WEB-S04

> The pg_query function belongs to PHP's PostgreSQL extension; it is not a MySQL connection API.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 80 | lines 2-15

> 5.13.3 Sending Query to MySQL Database using PHP
> A database query from PHP is basically a MySQL command wrapped up in a tiny
> PHP function called mysql_query(). This is where you use the basic SQL workhorses
> of SELECT,
> INSERT, UPDATE, and DELETE, CREATE or DROP a table (but not those to create
> or drop an entire database) can be used with this PHP function.
> Syntax:
> [$resultvar=] mysql_query("query",[link identifier]);

$resultvar - is an optional result variable. This is used when the query is a select statement.
Query - is any valid insert, delete, update, select, create table or drop table statement enclosed by quotes. It is a good habit to hold the query in a separate variable to add flexibility to your code.
Link identifier-is an optional link identifier

Web Programming module | PDF page 80 | lines 16-23

5.13.4 Processing Query Result.
4. Fetching data sets
The result of a query returned by the mysql_query() function is an interger showing the success or failure of the function not the desired data. So you have to use one of the mysql_fetch_..() functions to get the actual result. There are many functions to do so, but the most commonly used ones are- Mysql_fetch_row($result) - this function takes the result of the mysql_query() function as an argument and returns the data as an enumerated array.

Question sources

Computer Science model exam 2 · Question 21

Question 125 | Q01201

Assume document.body exists and element is a newly created, detached div. Which snippet inserts that element into the document body?

A. element.appendChild(document.createTextNode("Hello, world!"));

B. var element = document.createElement("div");

C. document.body.appendChild(element);

D. document.getElementByld("container").appendChild(element);

Hint

Track which node is selected or created, and distinguish changing content from attaching a node.

Answer C: document.body.appendChild(element);

Creating a DOM element and inserting it are separate steps. The question supplies the already-created detached div, so appendChild on document.body performs the required insertion. Creating another div would leave it detached, and appending a text node changes the contents of an existing element rather than inserting that element into the body. The final choice retains the incorrect lookup spelling, which fails instead of providing the required insertion.

Why each choice is right or wrong

A - Incorrect: This adds a text node inside element, leaving element detached.

B - Incorrect: This creates another detached div rather than inserting it.

C - Correct: This attaches the supplied div to the existing document body.

D - Incorrect: getElementByld is misspelled and is not the documented lookup method.

Primary note proof

Study-note section WEB20

> Creation alone does not insert it.

Study-note section WEB20

> createTextNode makes text; appendChild attaches an existing node.

Study-note section WEB20

> getElementByld with a lowercase l replacing I is a different, nonexistent method.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 52 | lines 3-20

> 4.10 JavaScript DOM (Document object Model)
> The Document Object Model (DOM) is the data representation of the objects that comprise the structure and content of a document on the web. The Document Object Model (DOM) is a programming interface for web documents. It represents the page so that programs can change the document structure, style, and content. The DOM represents the document as nodes and objects; that way, programming languages can interact with the page.
> 4.10.1 Accessing HTML elements in JavaScript
> In the DOM Api, there are different methods to get access to HTML elements. We will list the available methods here, but only the most recent methods are covered here.
> - getElementById(id) returns an element with that specific ID
> - getElmentsByClassName(class) returns elements with that specific class
> getElementsByTagName(tag) returns elements with the given tag name
> - querySelector(selector) → The Document method querySelector() returns the first Element within the document that matches the specified selector, or group of selectors. If no matches are found, null is returned.
> element = document.querySelector(selectors);

Question sources

Computer Science model exam 2 · Question 22

Question 126 | Q01221

Which of the following is used to include an external JavaScript file in an HTML document?

A. <script href="file.js"></script>

B. <link rel="stylesheet" href="file.js">

C. <script type="text/javascript" src="file.js"></script>

D. <link rel="stylesheet" type="text/javascript" href="file.js">

Hint

Identify which elements a rule targets and distinguish selector syntax from declaration syntax.

Answer C: <script type="text/javascript" src="file.js"></script>

The module external-file syntax uses a script element with src pointing to script.js. C uses this structure; stylesheet link elements do not load executable script in that example. Evidence: PDF p. 45, PDF p. 29.

Why each choice is right or wrong

A - Incorrect: href is not the script source attribute shown.

B - Incorrect: Links as stylesheet instead of script.

C - Correct: Uses script and src as required.

D - Incorrect: Still links as a stylesheet rather than script.

Primary note proof

Study-note section WEB15

> Use <script src="app.js"></script> for an external .js file; script content has no HTML closing-tag syntax inside its JavaScript source.

Study-note section WEB11

> An external sheet uses <link rel="stylesheet" href="styles.css"> in head; an internal sheet uses style; an inline declaration uses an element’s style attribute.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 45 | lines 12-14

> - We can also include JavaScript as an external file. We can use a similar syntax
> like the internal and add the src attribute. Here is how
> <script src="script.js" defer></script>

Web Programming module | PDF page 29 | lines 2-6

> E.g.
> <link rel="stylesheet" href="style.css">

The rel attributes names the relationship of the linked document to the current document. The href attribute specifies the URL of the linked document. The URL can be relative or absolute

Question sources

Computer Science model exam 2 · Question 42

Question 127 | Q01224

Which of the following is used to define the structure of a webpage in HTML?

A. Tags

B. Classes

C. IDs

D. Styles

Hint

Identify which elements a rule targets and distinguish selector syntax from declaration syntax.

Answer A: Tags

HTML tags delimit elements that establish content structure (pp.10-11). Classes and IDs identify elements, while styles concern presentation. Evidence: PDF p. 10, PDF p. 11.

Why each choice is right or wrong

A - Correct: Tags form structural elements.

B - Incorrect: Identifiers do not replace structural tags.

C - Incorrect: Unique identifiers do not replace structural tags.

D - Incorrect: Presentation rather than the HTML structural mechanism.

Primary note proof

Study-note section WEB06

Tags mark boundaries; an element includes content and attributes, or is a void element such as img.

Study-note section WEB11

Type p selects paragraph elements, .notice selects a class, #logo an ID, h1,h2 groups selectors, nav ul selects descendants and nav>ul direct children.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 10 | lines 9-16

HTML (HyperText Markup Language) is the most basic building block of the Web. HTML is not a programming language rather it is a markup language that tells web browsers how to structure the web page. HTML consists of a series of elements, which you use to enclose, wrap or markup different parts of content to make it appear or act in a certain way.
HTML defines the meaning and structure of web content. Other technologies besides HTML are generally used to describe a web page's appearance/presentation (CSS) or functionality/ behavior (JavaScript).

Web Programming module | PDF page 11 | lines 11-17

2.2 HTML Tags
In HTML, a tag is used for creating an element. Tags are used to delimit the start and end of elements in the markup. Normal html elements have a start tag to indicate where they begin, and an end tag to indicate where they end. The start and end tags of certain normal elements can be omitted. An HTML tag is composed of the name of the element, surrounded by angle brackets (<>). An end tag also has a slash after the opening angle bracket, to distinguish it from the start tag.

Question sources

Computer Science model exam 2 · Question 45

Question 128 | Q01235

Which PHP mechanisms can participate in generating dynamic content and server-side processing? Select all that apply.

A. Functions

B. Variables

C. Classes

D. Objects

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer A, B, C, D: Functions; Variables; Classes; Objects

Dynamic PHP responses can combine values, reusable behavior and object-based structures. Variables hold incoming or computed data; functions carry out processing; classes define application state and behavior; objects are instances used by that logic. None of these mechanisms alone defines dynamic PHP, but each can participate in it. The revised wording therefore asks for all contributors rather than forcing one exclusive mechanism from four compatible choices.

Why each choice is right or wrong

A - Correct: Functions can process inputs and return values or produce output.

B - Correct: Variables hold request data and computed values used in a response.

C - Correct: Classes define state and behavior for server application logic.

D - Correct: Objects instantiate classes and can participate in generating responses.

Primary note proof

Study-note section WEB26

A function can receive arguments, return a value, or produce output; classes/objects/variables also support server processing, so no single one of these mechanisms alone defines “dynamic PHP.” Use braces to make nesting explicit.

Study-note section WEB33

A class defines properties/methods; new creates an object, $obj->field accesses a property, and $obj->method() calls a method.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 60 | lines 4-16

PHP is a server-side scripting language, which can be embedded in HTML or used as a standalone binary (although the former use is much more common). PHP stands for Hypertext Preprocessor. The product was originally named Personal Home Page Tools, and many people still think that is what the acronym stands for. But as it expanded in scope, a new and more appropriate name was selected by community vote. PHP is the language that you use to make the server generate dynamic output-output that is potentially different each time a browser re-quests a page.
Client-side scripting is the glamorous, eye-catching part of Web development. In contrast, server-side scripting is invisible to the user. Server-side Web scripting is mostly about connecting Web sites to back-end servers, such as databases. This enables the following types of two-way communication:
➢ Server to client: Web pages can be assembled from back end-server output.
➢ Client to server: Customer-entered information can be acted upon.

Web Programming module | PDF page 71 | lines 23-30

5.9 PHP Functions
A function is a set of statements that performs a particular function and-optionally-returns a value. Functions have many advantages
- Involve less typing
- Reduce syntax and other programming errors
- Decrease the loading time of program files
PHP comes with hundreds of ready-made functions. You have seen some of them like print, echo, count, sizeof

Web Programming module | PDF page 85 | lines 13-18

Object-oriented programming (OOP) opens the door to cleaner designs, easier maintenance, and greater code reuse. In php OOP we use the term class, which refers

to a template for building objects. And an object is an instance of a class. The data associated with an object are called its properties. The functions associated with an object are called its methods. When you define a class, you define the names of its properties and give the code for its methods.

Web Programming module | PDF page 62 | lines 3-10

Variables are used to store data, like string of text, numbers, etc. Variable values can change over the course of a script. Here're some important things to know about variables:
- In PHP, a variable does not need to be declared before adding a value to it. PHP automatically converts the variable to the correct data type, depending on its value.
- After declaring a variable, it can be reused throughout the code.
- The assignment operator (=) used to assign value to a variable.

Question sources

Computer Science model exam 2 · Question 56

Question 129 | Q01236

Which of these JavaScript libraries, frameworks or platforms can contribute to interactive web interfaces when combined with suitable responsive layout and styling? Select all that apply.

A. jQuery

B. React

C. Angular

D. Vue.js

Hint

Match the stated application requirement to the capabilities and category of each technology.

Answer A, B, C, D: jQuery; React; Angular; Vue.js

jQuery supports DOM operations, React builds component interfaces, and Angular and Vue also support interactive interfaces. Their categories differ, but the revised question includes libraries, frameworks and platforms rather than treating those terms as exclusive. Responsive behavior additionally requires appropriate layout and styling; it is not guaranteed by choosing one name. Each listed technology can contribute under that condition, so all four choices are valid.

Why each choice is right or wrong

A - Correct: jQuery can provide DOM interaction while layout rules handle responsive presentation.

B - Correct: React components can implement interactive interfaces with responsive styles.

C - Correct: Angular supplies component-based application capabilities.

D - Correct: Vue can build interactive interfaces and use responsive layout styles.

Primary note proof

Study-note section WEB38

> jQuery simplifies DOM operations; React builds component interfaces; Angular is a component platform, distinct from older AngularJS; Vue also builds interactive interfaces.

Study-note section WEB38

> Each can contribute to a responsive interface, so those generic descriptions do not identify one unique framework.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 94 | lines 14-17

> d. React.js
> React.js is an open-source front-end JavaScript library for building user interfaces based on UI components. React builds encapsulated component that manage their own state, then compose them to complex UIs. To build for the web, developers use

Question sources

Computer Science model exam 2 · Question 57

Question 130 | Q01239

Which snippet applies a one-column card layout only when the viewport is at most 600 CSS pixels wide?

A. @media (max-width: 600px) { .cards { grid-template-columns: 1fr; } }

B. .container { display: flex; }

C. box { transform: rotate(45deg); }

D. .menu { background-color: #f00; }

Hint

Identify the requested presentation effect and layout context before matching the property or rule.

Answer A: @media (max-width: 600px) { .cards { grid-template-columns: 1fr; } }

The required behavior depends on viewport width, so the rule must contain the appropriate media condition and a concrete layout declaration. max-width:600px applies at or below that width, and the single 1fr track makes the card grid one column. A plain flex declaration does not express this breakpoint or column requirement. Rotation and background color affect appearance without implementing the requested conditional layout.

Why each choice is right or wrong

A - Correct: The media condition and one-track declaration implement the stated breakpoint behavior.

B - Incorrect: This does not specify the requested viewport condition or card-grid track count.

C - Incorrect: Rotation does not create the conditional one-column layout.

D - Incorrect: A background color does not alter the grid at the required breakpoint.

Primary note proof

Study-note section WEB14

> Responsive design combines flexible layout, images, viewport metadata and media queries, for example @media(max-width:600px){.cards{grid-template-columns:1fr}}.

Study-note section WEB14

> Grid organizes rows and columns with explicit tracks, such as grid-template-columns:1fr 2fr.

> The background shorthand CSS property sets all background style properties at once, such as color, image, origin and size, or repeat method. You have also specific background properties that you can apply like background-color, background-image etc.
> To set the background-color of an element and provide the value of the color in different form.
> 1. Keyword values -> red, blue

Question sources

Computer Science model exam 2 · Question 60

Question 131 | Q01244

Which of the following is used to store user data on the server-side in web applications?

A. Cookies

B. Sessions

C. Local storage

D. IndexedDB

Hint

Follow the identifier and server-side state through the stated lifecycle or access check; distinguish client-controlled claims from server decisions.

Answer B: Sessions

In conventional server-backed sessions, the browser normally keeps an opaque identifier and the user’s session data resides in server-controlled storage. Cookies, localStorage and IndexedDB instead retain data on the client side. Client storage may participate in an application design, but it is not the server-side session-data store requested. Sessions therefore match the stated location.

Why each choice is right or wrong

A - Incorrect: Cookies hold browser-side values; a session cookie normally carries an identifier rather than the server’s session-data store.

B - Correct: A server-backed session keeps the user's session data in server-controlled storage.

C - Incorrect: localStorage retains origin-specific strings in browser storage rather than storing the server's session data.

D - Incorrect: IndexedDB is structured local browser storage rather than the server's session-data store.

Primary note proof

Study-note section WEB29

> Normally the browser holds an opaque session identifier while data resides in server-controlled storage.

Study-note section WEB28

> Cookies are browser-held name/value data automatically attached to matching requests subject to domain, path, expiry, Secure and SameSite rules.

Study-note section WEB28

> localStorage persists origin-specific string values across sessions until removed/cleared; sessionStorage is scoped to a page session/tab.

Study-note section WEB28

> IndexedDB supplies structured local storage.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 76 | lines 2-5

> in one application. A PHP session allows you to store user information on the server for later use (i.e., username, shopping items, etc.). However, session information is temporary and will be deleted after the user has left the website. If you need a permanent storage you may want to store the data in a database.

Web Programming module | PDF page 58 | lines 12-19

> Cookies let you store user information in web pages.
> What are Cookies?
> Cookies are data, stored in small text files, on your computer.
> When a web server has sent a web page to a browser, the connection is shut down, and the server forgets everything about the user. Cookies were invented to solve the problem "how to remember information about the user":
> When a user visits a web page, his/her name can be stored in a cookie.
> Next time the user visits the page, the cookie "remembers" his/her name.

Question sources

Computer Science model exam 2 · Question 65

Question 132 | Q01515

Identify the function in JavaScript which is used to send messages to users requesting for text input?

A. getInput()

B. alert()

C. prompt ()

D. display()

Hint

Distinguish the browser object or dialog role from the kind of response it collects.

Answer C: prompt ()

Prompt displays a modal asking for text input; alert is an informational popup. C names the documented text-input operation. Evidence: PDF p. 46, PDF p. 47.

Why each choice is right or wrong

A - Incorrect: Not the documented input function.

B - Incorrect: Informational popup, not text entry.

C - Correct: Exact text-input function.

D - Incorrect: Not the documented input function.

Primary note proof

Study-note section WEB22

> alert displays information, confirm returns a Boolean, and prompt requests text or returns null on cancellation.

Study-note section WEB-S03

> Alert is a notification; confirm additionally asks for an OK/Cancel decision, while prompt additionally offers a text field.

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 46 | lines 16-20

> Accepting user input in JavaScript actually is not a difficult task. JavaScript has a function called prompt, which is used to accept input from the user. But for the result to be useful for us, it has to be stored in a variable. Here is a simple example
> var name = prompt("Enter your name: ");
> alert("Hello " + name);

Web Programming module | PDF page 47 | lines 2-2

> 2. Alert: shows a browser pop up with the information inside the parenthesis

Question sources

Mock exam 1 · Question 31

Question 133 | Q01516

In HTML, which attribute is used to create a link that opens in a new window tab?

A. src="_blank"

B. target="_self"

C. target="_blank"

D. src="_self"

Hint

Use the element or attribute meaning and document structure, rather than appearance or a similar-looking name.

Answer C: target="_blank"

WEB07 says _blank targets a new browsing context, while _self uses the current one. Therefore target="_blank" is the offered attribute-value pair for a new tab or window. Browser preferences determine whether the new context appears as a tab or window, so the markup does not force that UI distinction. src does not select a link target context.

Why each choice is right or wrong

A - Incorrect: src does not select the browsing context where an anchor link is opened.

B - Incorrect: The _self target uses the current context rather than requesting a new one.

C - Correct: The _blank target requests a new context; browser preferences decide whether that is a tab or window.

D - Incorrect: src is not the target attribute, and _self would indicate the current context anyway.

Primary note proof

Study-note section WEB07

> target="_self" uses the current context, _blank a new context, _parent its parent and _top the top-level context.

Study-note section WEB07

> Browser preferences determine tab versus window.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 14 | lines 5-9

> In HTML, a link is created by wrapping the text or other content inside an <a> tag (anchor tag) and using the href attribute, also known as Hypertext reference, or target

that contains the web address.
Here is an example of a link to the google website
Google.

1. application/x-www-form-urlencoded → most common and used from simple scenarios
2. mutlipart/form-data → used to upload binary data

Question sources

Mock exam 1 · Question 32

Question 134 | Q01517

In which HTML element, we put the JavaScript code using?

A. <javascript>...</javascript>

B. <script>...</script>

C. <js>...</js>

D. <css>...</css>

Hint

Check exact language syntax, declaration rules and execution context before reasoning about the result.

Answer B: <script>...</script>

Page 45 encloses JavaScript between script and /script. None of the invented javascript, js or css element names matches that example. Evidence: PDF p. 45.

Why each choice is right or wrong

A - Incorrect: Not the shown element.

B - Correct: Exact enclosing element.

C - Incorrect: Not the shown element.

D - Incorrect: CSS is presentation and this is not the script element.

Primary note proof

Study-note section WEB15

> Use <script src="app.js"></script> for an external .js file; script content has no HTML closing-tag syntax inside its JavaScript source.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 45 | lines 2-8

> <script>
> // JavaScript code goes here
> </script>
> - Internal JavaScript is one way of including JavaScript using the script tag inside our HTML document. We can use the above syntax to include it anywhere in our document. The best place to include a JavaScript file is before the end of body tag </body>.

Question sources

Mock exam 1 · Question 33

Question 135 | Q01609

Which of the following CSS style property is used to specify an italic text?

A. font-weight

B. font-family

C. font-size

D. font-style

Hint

Identify the requested presentation effect and layout context before matching the property or rule.

Answer D: font-style

The font property list distinguishes font-style, font-weight, font-family and font-size; its example uses italic (pp.34-35). The style component corresponds to italic, rather than weight, family or size. Evidence: PDF p. 34, PDF p. 35.

Why each choice is right or wrong

A - Incorrect: Weight concerns heaviness, not the style component named in the list.

B - Incorrect: Family names the typeface, not italic style.

C - Incorrect: Size sets dimensions rather than italic style.

D - Correct: Style is the named italic-related font component.

Primary note proof

Study-note section WEB13

> color sets text color; background-color sets background; font-size size, font-family face, font-style italic, font-weight weight, text-align inline-content alignment, and text-decoration effects such as underline.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 34 | lines 21-31

> 3.3.2 Font and Text Properties
> The font CSS shorthand property sets all the different properties of an element's font. Alternatively, it sets an element's font to a system font. The property is a shorthand for the following properties
> - font-family
> - font-size
> - font-stretch
> - font-style
> - font-variant

- font-weight
- line-height

Web Programming module | PDF page 35 | lines 2-2

font: italic 1.2em "Fira Sans", serif;

Question sources

Mock exam 3 · Question 41

Question 136 | Q01610

Which of the following function is used to create a session?

A. isset()

B. $_SESSION()

C. session_destroy()

D. session_start()

Hint

Follow the identifier and server-side state through the stated lifecycle or access check; distinguish client-controlled claims from server decisions.

Answer D: session_start()

The Starting a PHP Session example calls session_start() before storing data. $_SESSION stores data; session_destroy removes it; isset tests presence. Evidence: PDF p. 76, PDF p. 77, PDF p. 73.

Why each choice is right or wrong

A - Incorrect: Presence test, not startup.

B - Incorrect: SESSION is the storage array, not initializer function.

C - Incorrect: Destroys instead of starting.

D - Correct: Exact session startup function.

Primary note proof

Study-note section WEB29

session_start() starts/resumes PHP session handling and makes $_SESSION available.

Study-note section WEB-S09

session_destroy() removes the data associated with the current PHP session.

Study-note section WEB27

isset tests existence and non-null, not truth or valid syntax.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 76 | lines 6-23

Starting a PHP Session
Before you can store user information in your PHP session, you must first start up the session.
<?php session_start(); ?>
<html>
<body>.....
</body>
</html>
The code above will register the user's session with the server, allow you to start saving user information, and assign a UID for that user's session.
Storing a Session Variable
The correct way to store and retrieve session variables is to use the PHP $_SESSION variable:
<?php
session_start();
// store session data
$_SESSION['views']=1;

Web Programming module | PDF page 77 | lines 5-16

Destroying a Session
If you wish to delete some session data, you can use the unset() or the session_destroy() function. The unset() function is used to free the specified session variable:
<?php
unset($_SESSION['views']);
?>
You can also completely destroy the session by calling the session_destroy() function:
<?php
session_destroy();
?>
session_destroy() will reset your session and you will lose all your stored session data.

Web Programming module | PDF page 73 | lines 9-10

• isset(): This function is used to determine whether the variable or a form control is having a value or not.

Question sources

Mock exam 3 · Question 42

Question 137 | Q01611

Which of the following is the correct output for the following JavaScript code:
function check(option) {
return(option ? "true" : "false");
}
bool ans=true;
console.log(check(ans));

A. false

B. Runtime Error

C. true

D. Compilation Error

Hint

Track the value and type at each operation, applying the stated conversion, indexing or mathematical rule.

Answer D: Parse-time syntax error, described by the option as Compilation Error.

WEB19 explicitly states that bool ans=true is not a JavaScript declaration. Parsing fails before check(ans) is called, so neither string result is logged. Replacing bool with let would make the conditional return "true", but that is a different program. D is the closest offered category for the source's parse-time failure rather than a runtime exception.

Why each choice is right or wrong

A - Incorrect: The conditional function is never executed because the declaration prevents successful parsing.

B - Incorrect: The failure occurs during parsing, before a running program could raise a runtime error.

C - Incorrect: true would follow only after repairing bool to a valid JavaScript declaration keyword.

D - Correct: Compilation Error is the offered label closest to the actual parse-time SyntaxError.

Primary note proof

Study-note section WEB19

> bool ans=true is not JavaScript declaration syntax; use let ans=true.

Study-note section WEB-S05

> A syntax error prevents source from being parsed successfully.

Study-note section WEB17

> A condition ? x : y chooses one branch.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 48 | lines 6-22

4.5.2 Variable declaration in JavaScript
Variables are used to store this information. A variable is a “named storage” for data. We can use variables to store goodies, visitors, and other data. We have three ways of creating variables in JavaScript
- Using the let keyword → the following statement declares a variable
let message;
now we can put values using the assignment operator (=)
- Using var keyword → we can also declare variable using the var keyword in a similar fashion as let. There is a subtle difference between declaring a variable using var and let. Variables declared with var are hoisted where as those declared with let are not. The other difference between var and let is variables declared with let has a block level scope unlike that of var. Variables declared with var have function level scope
- Using const keyword → to declare a constant variable we can use const instead of var and let. Variables declared with const can not be changed once they are declared.
const PI = 3.14;

Web Programming module | PDF page 50 | lines 15-18

Ternary Operators:
Ternary operator is represented by a question mark “?”. We can use ternary operator to perform conditional operations like if-else statement
let result = condition ? value1 : value2;

Question sources

Mock exam 3 · Question 43

Question 138 | Q01651

What makes AJAX unique?

A. It works the same with all web browsers

B. It works as a stand-alone web-development tool

C. It uses C++ as its programming language

D. It makes data requests asynchronously

Hint

Identify the execution side and communication pattern, keeping runtime, transport, data format and callback roles distinct.

Answer D: It makes data requests asynchronously

AJAX is expressly asynchronous and exchanges data with the server without refreshing the page. It combines XML, HTML, CSS and JavaScript rather than being a standalone language/tool. Evidence: PDF p. 89.

Why each choice is right or wrong

A - Incorrect: All-browser identity is not the stated distinguishing feature.

B - Incorrect: Contradicts use of several cooperating technologies.

C - Incorrect: The documented scripting language is JavaScript, not C++.

D - Correct: Exact asynchronous-request distinction.

Primary note proof

Study-note section WEB34

> AJAX means Asynchronous JavaScript and XML, but responses can be JSON, text, HTML or XML.

Study-note section WEB34

> It is a technique, not a language, standalone framework or mandatory XML protocol.

Study-note section WEB02

> Open standards do not guarantee identical support for every feature in every browser.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 89 | lines 4-13

> AJAX is a web development technique for creating interactive web applications.
> AJAX stands for Asynchronous JavaScript and XML. It can send and receive information in various formats, including JSON, XML, HTML, and text files. AJAX is a new technique for creating better, faster, and more interactive web applications with the help of XML, HTML, CSS, and Java Script. AJAX's most appealing characteristic is its "asynchronous" nature, which means it can communicate with the server, exchange data, and update the page without having to refresh the page.
> The two major features of AJAX allow you to do the following:
> - Make requests to the server without reloading the page
> - Receive and work with data from the server

Question sources

Mock exam 2 · Question 40

Question 139 | Q01652

Which of the following attribute is used for merging two or more adjacent columns?

A. COLSPAN

B. CELLPADDING

C. CELLSPACING

D. ROWSPAN

Hint

Use the element or attribute meaning and document structure, rather than appearance or a similar-looking name.

Answer A: COLSPAN

Page 18 says colspan and rowspan span columns and rows respectively. Merging adjacent columns requires colspan. Evidence: PDF p. 18.

Why each choice is right or wrong

A - Correct: Columns are explicitly the colspan role.

B - Incorrect: Not the merging attribute identified.

C - Incorrect: Not the merging attribute identified.

D - Incorrect: Spans rows instead of columns.

Primary note proof

Study-note section WEB08

> colspan spans columns; rowspan spans rows.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 18 | lines 15-19

> If you have a reason to merge columns or rows or the website you are building needs this functionality you can use the colspan and rowspan attribute to do so. These attributes are used to span two or more columns or rows respectively. Both colspan and rowspan takes unitless numbers that specifies the number of columns and rows you want to span

Question sources

Mock exam 2 · Question 41

Question 140 | Q01653

Which of the following CSS selector is used to specify a rule to bind a particular unique element?

A. Class

B. Tag

C. Id

D. Name

Hint

Identify which elements a rule targets and distinguish selector syntax from declaration syntax.

Answer C: Id

The module ID selector example targets a specific element, whereas type and class selectors can target groups. C matches the unique identifier requirement. Evidence: PDF p. 31.

Why each choice is right or wrong

A - Incorrect: Class selection can group elements.

B - Incorrect: Type selection applies to all elements of that type.

C - Correct: ID selects the particular identified element.

D - Incorrect: Name is not the unique ID selector described.

Primary note proof

Study-note section WEB11

> Type p selects paragraph elements, .notice selects a class, #logo an ID, h1,h2 groups selectors, nav ul selects descendants and nav>ul direct children.

Study-note section WEB07

> Attributes belong in opening tags, with unique IDs when used for document identification.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 31 | lines 5-24

> 2. Class selector -> The element(s) on the page with the specified class. Multiple
> instances of the same class can appear on a page. We use
> the . (dot) symbol and the name of the class to use it as a
> selector in css
> 3. Id selector -> The element on the page with the specified ID. On a given
> HTML page, each id value should be unique. We use # (hashtag
>) symbol and the name of the id as a selector
> 4. Attribute Selector -> The element(s) on the page with the specified
> attribute.
> 5. Pseudo-class selector -> The specified element(s), but only when in the

specified state. (For example, when a cursor hovers over
a link.)
Q. Read in detail the above ways of selectors it's definition, advantage, syntax and examples for each?
3.2.1 Style Inheritance
In CSS, inheritance controls what happens when no value is specified for a property on an element. CSS uses the document tree for inheritance, in which an element applied to an element is inherited by its descendants.
CSS properties can be categorized in two types:
- Inherited properties - which by default are set to the computed value of

Question sources

Mock exam 2 · Question 42

Question 141 | SM0005

Which statement about ordinary JavaScript functions and identifiers is true?

A. Function names can contain spaces

B. Function names are not case-sensitive

C. Functions can be passed to and stored by other code like other values

D. Function names can begin with digits

Hint

Check exact language syntax, declaration rules and execution context before reasoning about the result.

Answer C: Functions can be passed to and stored by other code like other values

JavaScript functions are values that can be passed as arguments or stored for later use. Identifier rules still apply to ordinary function names: names are case-sensitive, cannot contain spaces and cannot begin with a digit. The true choice tests a supported function property instead of making an unrestricted claim about the number of parameters. Runtime argument limits therefore do not affect the correctness of this version.

Why each choice is right or wrong

A - Incorrect: Spaces are not permitted inside an ordinary function identifier.

B - Incorrect: Identifier names are case-sensitive.

C - Correct: Functions can be stored and passed as values.

D - Incorrect: An ordinary function identifier cannot start with a digit.

Primary note proof

Study-note section WEB15

Identifiers are case-sensitive and may start with letters, underscore or $, not digits or spaces.

Study-note section WEB19

function f(x){return x*2;} has a parameter and returns a value; functions can be passed/stored like other values.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 51 | lines 18-35

4.9 JavaScript Functions
Functions are the main “building blocks” of the program. They allow the code to be called many times without repetition. To create a function, we can use a function declaration.
function showCSMessage() {
alert('Hello CS Students!');
}
To create a function, first we use the function keyword then the function name.
There are times when we remove the function name. This type Functions without a function name are called anonyms functions.
After the function name we optionally put parameters in between the parenthesis, if we don’t have parameters, we always have to put the empty parenthesis and then finally the block of code to be executed.
An arrow function expression is a compact alternative to a traditional function expression, but is limited and can't be used in all situations.
Syntax:
param => expression
Multiple params require parentheses.

Computer Science Exit Exam practice collection · Question 20

Question 142 | SM0014

Look at the following PHP line: $list = array(20, 12, 23, 19, 18); What is the index of data value 19?

A. 2

B. 0

C. 3

D. 1

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer C: 3

PHP numeric array examples start at index zero. In the ordered list, 20 is index 0, 12 is 1, 23 is 2, 19 is 3 and 18 is 4. Evidence: PDF p. 69, PDF p. 70.

Why each choice is right or wrong

A - Incorrect: Index 2 holds 23.

B - Incorrect: Index 0 holds 20.

C - Correct: Index 3 holds 19.

D - Incorrect: Index 1 holds 12.

Primary note proof

Study-note section WEB26

> Numeric arrays start at index0 unless keys are supplied: [20,12,23,19,18] has19 at index3.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 69 | lines 14-15

```
<?php
$array1 = array("Item 1", "Item 2", "Item 3", "Item 4");
```

Web Programming module | PDF page 70 | lines 2-8

```
We can also create arrays by adding the index of the item in between the square
brackets. This will enable us to add items in unorderly fashion
<?php
$sample[0] = "sample 1";
$sample[1] = "sample 2";
$sample[2] = "sample 3";
$sample[3] = "sample 4";
```

National Computer Science Exit Exam · Question 18

National Computer Science Exit Exam

Computer Science Exit Exam practice collection · Question 21

Question 143 | SM0039

Which option is a complete, valid PHP variable-assignment statement inside an open PHP block? No closing PHP tag follows the option to supply an implicit terminator.

A. $test = 9.5

B. $test = "This is 'Computer science'";

C. $test = "Computer;

D. test = 5;

Hint

Check exact language syntax, declaration rules and execution context before reasoning about the result.

Answer B: $test = "This is 'Computer science'";

The balanced double-quoted assignment is complete: it has a dollar-prefixed variable, a matching closing quote and a semicolon. Single quotes inside double quotes are ordinary string characters. The numeric assignment lacks its required semicolon in the stated context, another option has an unterminated string, and the bare test name is not a PHP variable.

Why each choice is right or wrong

A - Incorrect: This is an assignment expression but lacks the semicolon required for a complete statement in the stated context.

B - Correct: The variable name, balanced double quotes and terminating semicolon make a complete assignment.

C - Incorrect: The opening double quote has no matching closing delimiter.

D - Incorrect: A PHP variable must have its dollar prefix; bare test does not name that variable.

Primary note proof

Study-note section WEB23

> Variables begin with $, then a letter/underscore and subsequent letters/digits/underscores; $AGE18 works but $18AGE does not.

Study-note section WEB-S06

> A complete ordinary PHP assignment statement ends with a semicolon.

Study-note section WEB-S06

A string’s closing delimiter must match its opening delimiter; a single quote can appear inside a double-quoted string without ending it.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 62 | lines 27-33

In PHP user defined variable can be declared as:
$var_name = value;
Example
<?php
// Declaring variables
$txt = "Hello World!";
$number = 10;

Web Programming module | PDF page 64 | lines 6-12

All variables in PHP are denoted with a leading dollar sign ($).
All variables in PHP start with a leading $ sign. After the initial $, variable names must be composed of letters (uppercase or lowercase), digits (0-9), and underscore characters (_). Furthermore, the first character after the $ may not be a number.
➢ The value of a variable is the value of its most recent assignment.
➢ Variables are assigned with the = operator, with the variable on the left-hand side and the expression to be evaluated on the right.

Web Programming module | PDF page 61 | lines 28-29

echo "Hello World!";
?>

Question 144 | SM0068

Which one of the following is the smallest heading tag?

A. <H6>

B. <H3>

C. <H4>

D. <H1>

Hint

Use the element or attribute meaning and document structure, rather than appearance or a similar-looking name.

Answer A: <H6>

The module explicitly calls h1 largest and h6 smallest among the default heading formats. A therefore identifies the smallest default heading. Evidence: PDF p. 15.

Why each choice is right or wrong

A - Correct: h6 is explicitly smallest.

B - Incorrect: h3 is not the smallest.

C - Incorrect: h4 is not the smallest.

D - Incorrect: h1 is explicitly largest.

Primary note proof

Study-note section WEB06

> Heading levels h1-h6 express hierarchy, with h6 conventionally smallest in default styling, not a mandatory CSS size.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 15 | lines 5-10

> Headings -
> Headings are predefined formats for text presentation and there are six heading formats defined in HTML:
> <h1> up to <h6>
> <h1> the largest font size

Question 145 | SM0070

In PHP 8 with short_open_tag enabled, which shown delimiters do NOT open and close PHP code? Select all that apply.

A. <? ..... ?>

B. <caption> ..... </caption>

C. <script language="PHP"> ..... </script>

D. <?php ..... ?>

Hint

Check exact language syntax, declaration rules and execution context before reasoning about the result.

Answer B, C: <caption> ..... </caption>; <script language="PHP"> ..... </script>

The full <?php form is valid, and the stated configuration also permits the short <? form. A caption element is HTML markup rather than a PHP delimiter. The historical script-language form is no longer accepted in PHP 8, so it is another non-delimiter under this version. Specifying both version and short-tag configuration makes B and C definite selections rather than relying on an unstated historical environment.

Why each choice is right or wrong

A - Incorrect: The explicitly enabled short-tag configuration makes this PHP delimiter valid.

B - Correct: caption is HTML markup, not a PHP code delimiter.

C - Correct: PHP 8 does not accept this historical script-language delimiter.

D - Incorrect: The full PHP opening and closing form is valid.

Primary note proof

Study-note section WEB23

> Use <?php ...

Study-note section WEB23

> PHP8 no longer accepts historical <script language="PHP"> delimiters; short <? depends on configuration, so use the full form.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 61 | lines 5-14

> Short-open (SGML-style) tags
> Short or short-open tags look like this:
> <?
> //php script
> ?>

Those who escape into and out of HTML frequently in each script will be attracted by the prospect of fewer keystrokes; however, the price of shorter tags is pretty high. Additional adjustment in the php.ini file is required to enable PHP to recognize the tags. PHP code written with short-open tags is less portable because you can‘t be sure another machine will have enabled them in the php.ini file.

Web Programming module | PDF page 60 | lines 23-27

5.2 Basic PHP Syntax
The most universally effective PHP syntax is:
<?php
//php script
?>

Question 146 | SM0077

Which statements about Java and JavaScript are true? Select all that apply.

A. Both are object oriented languages

B. JavaScript and Java are the same programming language

C. Javascript can be used in extremely sophisticated applications

D. JavaScript function identifiers are not case-sensitive

Hint

Check exact language syntax, declaration rules and execution context before reasoning about the result.

Answer A, C: Both are object oriented languages; Javascript can be used in extremely sophisticated applications

Java supports class-based object-oriented programming, while JavaScript supports prototype-based objects; both therefore support object-oriented programming. The Java classification is supplied by the supplementary Oracle tutorial, while the note supplies JavaScript's object model, its distinction from Java and its ability to support sophisticated applications. The languages are not identical, and JavaScript identifiers remain case-sensitive. Thus both the object-oriented statement and the sophisticated-application capability are true.

Why each choice is right or wrong

A - Correct: Both support object-oriented programming, with different object models.

B - Incorrect: The note explicitly distinguishes JavaScript from Java.

C - Correct: The note explicitly supports sophisticated JavaScript applications.

D - Incorrect: JavaScript identifiers are case-sensitive.

Primary note proof

Study-note section WEB-S01

> Java organizes object-oriented programs using classes, objects, inheritance and interfaces.

Study-note section WEB15

> JavaScript originated at Netscape; it is distinct from Java and supports sophisticated applications through prototype-based objects and first-class functions.

Study-note section WEB15

> Identifiers are case-sensitive and may start with letters, underscore or $, not digits or spaces.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 44 | lines 4-19

> JavaScript (JS) is a lightweight, interpreted or compiled programming language. It is a single threaded, dynamic language, supporting object oriented, functional programming styles. Do not confuse JavaScript with the Java Programming language. The two-programming language have very different syntax, semantics, and use.
> 4.2 JavaScript Basic
> JavaScript is a scripting or programming language that allows us to implement complex features on web pages. JavaScript will enable us to display timely content updates, interactive maps, 2D/3D animated graphics etc. JavaScript is one of the three layers of web technologies which lets to add functionality to a web page. The three layers of web technologies are stacked together nicely, HTML will let's structure the webpage, CSS deals with the presentation of the web page and JavaScript the functionality.'
> What can JavaScript really do? It can
> - Stores values inside variables

- Perform operations on pieces of texts
- Run a code in response to events

Question 147 | SM0080

Which one of the following is true about frames in HTML?

A. Every frame must display the same HTML document

B. A legacy frameset document uses body in place of frameset

C. All browsers support frames

D. Frames allow parts of the page to remain stationary while other parts scroll

Hint

Use the element or attribute meaning and document structure, rather than appearance or a similar-looking name.

Answer D: Frames allow parts of the page to remain stationary while other parts scroll

A legacy frameset divides a window into separate documents, and individual frame views can scroll independently. One frame can therefore remain stationary while another scrolls. The documents need not be identical, and the old frameset document used frameset in place of body. The noframes fallback addresses browsers without frame support, so support cannot be asserted for all browsers.

Why each choice is right or wrong

A - Incorrect: Separate frames can display different documents; identical content is not required.

B - Incorrect: The old frameset document replaced body with frameset, the reverse of this claim.

C - Incorrect: The noframes fallback exists for browsers without frame support, so universal support is false.

D - Correct: Independent scrolling lets one frame remain visible while another view scrolls.

Primary note proof

Study-note section WEB10

Legacy frameset/frame divides a window into separate documents; frameset replaced body in old frameset documents.

Study-note section WEB10

Named targets controlled which frame changed; independent scrolling could leave other frames stationary.

Study-note section WEB-S07

A legacy frameset document could include noframes content for user agents that did not support frames or were configured not to display them.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 20 | lines 4-15

2.2.9 HTML Frames
HTML frames allows us to present documents in multiple views, which may be independent windows or sub-windows. Multiple views offer designers a way to keep certain information visible, while other views are scrolled or replaced.
An HTML document that describes frame layout has a different markup than HTML document without frames. A standard document has one HEAD section and one BODY. A frameset document has a HEAD and a FRAMESET in place of BODY.
2.2.9.1 Frame Set
The FRAMESET section of a document specifies the layout of views in the main user agent window. In addition, the FRAMESET section can contain a NOFRAMES element to provide alternate content for user agents that do not support frames or are configured not to display frames.

What will be the output of the following JavaScript statement? Math.floor(5.9)

A. 9

B. 11.8

C. 6

D. 5

Hint

Track the value and type at each operation, applying the stated conversion, indexing or mathematical rule.

Answer D: 5

WEB18 directly evaluates Math.floor(5.9)=5. The floor operation gives the greatest integer not exceeding the input, rather than rounding to the nearest integer or multiplying the input. Thus the fractional part does not push the result up to six; the expression value is five. No string or DOM behavior changes this math result.

Why each choice is right or wrong

A - Incorrect: Nine is not the integer floor of 5.9; it is merely a digit appearing in the input.

B - Incorrect: 11.8 doubles the input and is unrelated to the floor operation.

C - Incorrect: Six would be upward or nearest-integer rounding here, not floor.

D - Correct: Five is the greatest integer no larger than 5.9, matching the explicit note example.

Primary note proof

Study-note section WEB-S08

> For finite numeric arguments, Math.abs(x) gives the nonnegative magnitude, Math.floor(x) gives the greatest integer no larger than x, and Math.sqrt(x) gives the nonnegative square root for nonnegative x.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Question 149 | SM0099

What will be the output of the following JavaScript statement? Math.sqrt(36)

A. 6

B. 30

C. 1

D. 36

Hint

Track the value and type at each operation, applying the stated conversion, indexing or mathematical rule.

Answer A: 6

WEB18 explicitly states Math.sqrt(36)=6. Six squared gives thirty-six, and this function returns the nonnegative square root rather than the original operand or an arithmetic difference. The expression is already a valid numeric function call and needs no parsing repair or context-dependent type coercion to obtain the stated result.

Why each choice is right or wrong

A - Correct: Six is the nonnegative square root of thirty-six, exactly as WEB18 evaluates it.

B - Incorrect: Thirty is not a square root of thirty-six and does not match the defined function.

C - Incorrect: One squared is one, not thirty-six, so it cannot be the result.

D - Incorrect: Thirty-six is the input; sqrt does not simply return it unchanged.

Primary note proof

Study-note section WEB-S08

> For finite numeric arguments, Math.abs(x) gives the nonnegative magnitude, Math.floor(x) gives the greatest integer no larger than x, and Math.sqrt(x) gives the nonnegative square root for nonnegative x.

Question 150 | SM0215

How are the objects organized in the HTML DOM?

A. Hierarchy

B. Queue

C. Stack

D. Class-wise

Hint

Track which node is selected or created, and distinguish changing content from attaching a node.

Answer A: Hierarchy

The module describes a document tree with parent elements and descendants (p.31), and DOM nodes/objects representing document structure (p.52). These relations form a hierarchy rather than a queue, stack or class grouping. Evidence: PDF p. 31, PDF p. 52.

Why each choice is right or wrong

A - Correct: Tree parent/descendant structure is hierarchical.

B - Incorrect: No FIFO sequence is stated as the document organization.

C - Incorrect: No LIFO sequence is stated as the document organization.

D - Incorrect: Class selectors group matches, not the document parent/child structure.

Primary note proof

Study-note section WEB20

> The DOM is a hierarchy of nodes representing the document.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 31 | lines 19-22

> 3.2.1 Style Inheritance
> In CSS, inheritance controls what happens when no value is specified for a

property on an element. CSS uses the document tree for inheritance, in which an element applied to an element is inherited by its descendants.

Web Programming module | PDF page 52 | lines 3-9

4.10 JavaScript DOM (Document object Model)
The Document Object Model (DOM) is the data representation of the objects that comprise the structure and content of a document on the web. The Document Object Model (DOM) is a programming interface for web documents. It represents the page so that programs can change the document structure, style, and content. The DOM represents the document as nodes and objects; that way, programming languages can interact with the page.

Computer Science Exit Exam · Sene 2016 · Question 5-2

Computer Science Exit Exam practice collection · Question 40

Question 151 | SM0232

Which of the following methods can be used to refresh a webpage?

A. location.relocate

B. window.relocate

C. window.refresh

D. location.reload

Hint

Distinguish the browser object or dialog role from the kind of response it collects.

Answer D: location.reload()

WEB22 explicitly says location.reload() reloads the current page. D names that method; it must be called with parentheses to perform the reload. The other alternatives invent relocate or refresh names not identified as the standard method in the note. This operation acts on the current browsing location rather than creating a new page context.

Why each choice is right or wrong

A - Incorrect: location.relocate is not the reload method identified in the browser API rule.

B - Incorrect: window.relocate is not the reload method given in WEB22.

C - Incorrect: window.refresh is not the standard reload method described by the supplied note.

D - Correct: Calling location.reload() reloads the current page; the option names that method.

Primary note proof

Study-note section WEB22

location.reload() reloads the current page.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 58 | lines 2-10

The window.location object can be written without the window prefix.
Some examples:
window.location.href returns the href (URL) of the current page
window.location.hostname returns the domain name of the web host
window.location.pathname returns the path and filename of the current page
window.location.protocol returns the web protocol used (http: or https:)
window.location.assign() loads a new document
Window Location Href
The window.location.href property returns the URL of the current page.

Computer Science Exit Exam · Sene 2016 · Question 10-3

Computer Science Exit Exam practice collection · Question 41

Question 152 | SM0255

Which one of the following is a false statement?

A. Aweb browser is software that runs on a server

B. Awebsite is a collection of resources in various forms

C. Aweb page is the basic unit of information storage on the www

D. Auser agent renders resources for a user to view

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer A: Aweb browser is software that runs on a server

The module places page storage on servers and page viewing with browsers on clients (p.9). A reverses that teaching role. B is consistent with hosted website files; C is explicit web-information storage; D matches the viewing role. Evidence: PDF p. 9, PDF p. 9, PDF p. 8.

Why each choice is right or wrong

A - Correct: False in the module client/server model.

B - Incorrect: Consistent with the collection of hosted website files.

C - Incorrect: Explicitly web information resides in pages.

D - Incorrect: Consistent with browser viewing/rendering resources.

Primary note proof

Study-note section WEB01

A browser/user agent requests resources and renders HTML/CSS, then runs permitted JavaScript.

Study-note section WEB01

A web/HTTP server receives requests and returns representations, sometimes invoking application code.

Study-note section WEB02

A website groups resources; a page is one document/resource.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 9 | lines 2-4

• Web pages are files stored on computers called Web servers.
• Computers reading the Web pages are called Web clients.
• Web clients view the pages with a program called a Web browser.

Web Programming module | PDF page 9 | lines 13-21

Web hosting is the place where all the files of your website live. Web hosting is a service that allows organizations and individuals to post a website or a web page onto the Internet. A web host, or web hosting service provider, is a business that provides the technologies and services needed for the website or webpage to be viewed in the Internet. Websites are hosted, or stored, on special computers called servers. When Internet users want to view your website, all they need to do is type your website address or domain (the domain name for the site has to be registered) into their browser. Their computer will then connect to your server and your webpages will be delivered to them through the browser.

Web Programming module | PDF page 8 | lines 34-34

• Web information is stored in documents called Web pages.

Question sources

Computer Science Exit Exam · Sene 2016 · Question 18-1

Question 153 | SM0267

Which one of the following terms refers to the machine on which the requested resource is stored?

A. Port

B. Query

C. Host

D. Protocol

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer C: Host

The web hosting section says website files reside on a host/server; the location examples identify hostname as the web-host domain. Host therefore names the resource-storing machine role. Evidence: PDF p. 9, PDF p. 58, PDF p. 8.

Why each choice is right or wrong

A - Incorrect: Not the hosting computer role defined.

B - Incorrect: A database/request operation does not name the hosting machine.

C - Correct: Host matches the storage/serving machine role.

D - Incorrect: HTTP is a communication standard rather than a storage machine.

Primary note proof

Study-note section WEB02

> A URL identifies scheme, host, optional port, path, query and fragment; the host identifies the machine/service name, while a fragment selects a local document location.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 9 | lines 13-21

Question 154 | SM0281

Which attribute of the <img> tag is used to display text in place of an image when the image is not displayed?

A. rep

B. pla

C. alt

D. im

Hint

Use the element or attribute meaning and document structure, rather than appearance or a similar-looking name.

Answer C: alt

The img alt value is explicitly a textual description shown when the image cannot be seen or takes too long to render. Evidence: PDF p. 16.

Why each choice is right or wrong

A - Incorrect: Not the named fallback attribute.

B - Incorrect: Not the named fallback attribute.

C - Correct: Exact documented fallback attribute.

D - Incorrect: Not the named fallback attribute.

Primary note proof

Study-note section WEB07

> <img src="photo.jpg" alt="Students in a lab"> supplies source and alternative text.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 16 | lines 27-29

> Another attribute we frequently see in an img tag is alt. Its value is textual description of the image, which is displayed in a situation where the image cannot be seen or takes a long time to render.

Question sources

Computer Science Exit Exam · Sene 2016 · Question 26-3

Computer Science Exit Exam practice collection · Question 36

Question 155 | SM0284

Which of the following is the top-level object in web browsers?

A. Root object

B. Document object

C. JavaScript object

D. Window object

Hint

Distinguish the browser object or dialog role from the kind of response it collects.

Answer D: Window object

The BOM discussion states that global JavaScript objects/functions/variables belong to window and even document is its property. Thus window is the top-level browser object in this teaching model. Evidence: PDF p. 56.

Why each choice is right or wrong

A - Incorrect: Generic root label is not the documented browser object name.

B - Incorrect: Document is a property within window.

C - Incorrect: Generic JavaScript object is not the named top-level object.

D - Correct: Window contains the global members and document.

Primary note proof

Study-note section WEB22

> In a normal browser page, window exposes the browsing context and document is its document property.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 56 | lines 15-25

> The window object is supported by all browsers. It represents the browser's window.
> All global JavaScript objects, functions, and variables automatically become members of the window object.
> Global variables are properties of the window object
> Global functions are methods of the window object.
> Even the document object (of the HTML DOM) is a property of the window object:
> window.document.getElementById("header");
> is the same as:
> document.getElementById("header");

Question sources

Computer Science Exit Exam · Sene 2016 · Question 27-3

Computer Science Exit Exam practice collection · Question 37

Question 156 | SS095

Which CSS selector selects elements whose class list contains notice?

A. p

B. #notice

C. [type="email"]

D. .notice

Hint

Identify which elements a rule targets and distinguish selector syntax from declaration syntax.

Answer D: .notice

A class selector uses a dot followed by the class name, so .notice matches elements that have notice among their classes. An ID selector uses a hash and tests a different attribute. The remaining choices are a type selector and an attribute selector, each meaningful but aimed at another condition. The damaged options are replaced with explicit selector forms rather than claiming to recover an uncertain source-letter mapping.

Why each choice is right or wrong

A - Incorrect: This selects paragraph elements by tag name.

B - Incorrect: This selects the notice ID, not the class token.

C - Incorrect: This tests the type attribute rather than the class list.

D - Correct: This is the class selector for the notice token.

Primary note proof

Study-note section WEB11

> Type p selects paragraph elements, .notice selects a class, #logo an ID, h1,h2 groups selectors, nav ul selects descendants and nav>ul direct children.

Study-note section WEB11

> Attribute selectors match properties such as [type="email"], pseudo-classes states such as :hover/:focus, and pseudo-elements parts such as ::before.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 31 | lines 5-11

2. Class selector -> The element(s) on the page with the specified class. Multiple instances of the same class can appear on a page. We use the . (dot) symbol and the name of the class to use it as a selector in css
3. Id selector -> The element on the page with the specified ID. On a given HTML page, each id value should be unique. We use # (hashtag) symbol and the name of the id as a selector

Question sources

Computer Science model exam collection · Question 2

Question 157 | SS101

Which option identifies components present in an HTTP/1.1 request even when it has no message body?

A. Header fields only

B. Header fields and a mandatory body

C. A response status line, header fields and a mandatory body

D. A request line and header fields

Hint

Identify the protocol layer and the intended request, response or channel semantics.

Answer D: A request line and header fields

HTTP/1.1 requests start with a request line, then contain header fields and a terminating blank line. A body is optional, so neither option that requires one describes every request. A status line begins a response, not a request. The version qualifier matters because HTTP/2 and HTTP/3 encode messages differently; the selected components refer specifically to the textual HTTP/1.1 structure, not every HTTP wire format.

Why each choice is right or wrong

A - Incorrect: This omits the request line.

B - Incorrect: The body is optional, so making it mandatory is wrong.

C - Incorrect: A status line belongs to a response, and a request body is optional.

D - Correct: These components are present before any optional body.

Primary note proof

Study-note section WEB03

An HTTP/1.1 request begins with method, request-target and version, followed by header fields, a blank line, and an optional body.

Study-note section WEB03

A response begins with version, status code and optional reason phrase, then headers, blank line and permitted content.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 89 | lines 20-31

6.3 Sending Request to PHP server
XMLHttpRequest (XHR) is an API that can be used by JavaScript and other web browser scripting languages to transfer and manipulate XML data to and from a webserver using HTTP, establishing an independent connection channel between a webpage's Client-Side and Server-Side.
In order to make an HTTP request to the server with JavaScript, you need an instance of an XMLHttpRequest Object. We make a request to the sever, by calling the open() and send() methods of the HTTP request object, like this:
httpRequest.open('GET', 'http://www.example.org/some.file', true);
httpRequest.send();
open() takes three parameters, the first is the HTTP request method and the second is the URL. The optional third parameter sets whether the request is asynchronous.

Question sources

Computer Science model exam collection · Question 8

Question 158 | SS131

What will be the output of the following code snippet?
<script type="text/javascript" language= 'javascript' >
var a = "exitexam";
var result = a.substring(2, 6);
document.write(result);
</script>

A. xitex

B. texam

C. itex

D. xite

Hint

Track the value and type at each operation, applying the stated conversion, indexing or mathematical rule.

Answer C: itex

substring(2,6) uses a zero-based start and excludes the end index. In exitexam, indices 2, 3, 4 and 5 contain i, t, e and x. document.write therefore emits itex. Starting at index 1 or continuing beyond index 5 produces a different interval, which rules out the other strings.

Why each choice is right or wrong

A - Incorrect: xitex starts at index one and contains five characters, rather than the requested four-character interval.

B - Incorrect: texam starts too late and extends beyond the exclusive end index six.

C - Correct: Indices two through five contain i, t, e, x, producing itex.

D - Incorrect: xite begins at index one rather than the specified zero-based start index two.

Primary note proof

Study-note section WEB18

> A JS string’s substring(start,end) includes start and excludes end: "exitexam".substring(2,6) is "itex".

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 44 | lines 16-19

> What can JavaScript really do? It can

> 1. Single quotes --- ‘single’
> 2. Double quotes --- ‘double’
> 3. Backticks -- `hello`. In a standard US keyboard, you can find the backticks above the tab key before the number 1 key.
> Backticks allows to embed variables and expressions into a string by wrapping them with ${}

Question sources

Computer Science model exam collection · Question 38

Question 159 | SS181

Default method while submitting a form is

A. Get method

B. Set method

C. Post method

D. Put method

Hint

Separate the control role, displayed content, submitted value and form destination.

Answer A: GET

WEB09 explicitly says a form's default method is GET. Therefore omitting the method attribute does not select POST or PUT. WEB04 further distinguishes GET query parameters from POST form bodies, but that difference does not change the default. Set is not the relevant form submission method named in the note.

Why each choice is right or wrong

A - Correct: GET is the default method for an HTML form when its method attribute is omitted.

B - Incorrect: Set is not the default HTML form submission method defined here.

C - Incorrect: POST must be requested explicitly; it is not the form's omitted-method default.

D - Incorrect: PUT is not the default method selected by an ordinary HTML form.

Primary note proof

Study-note section WEB09

> The default method is GET.

Study-note section WEB04

> GET forms usually put name/value pairs in the URL query; POST forms put them in the body.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 21 | lines 23-31

> Form attributes:
> - action → Backend script ready to process the data collected

Question sources

Computer Science model exam collection · Question 88

Question 160 | Q01135_LOCAL69

A variable declared _____ has a LOCAL SCOPE?

A. outside program

B. inside function

C. outside function

D. None of the Above

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer B: Inside a function

WEB25 states that a function's locals and by-value parameters are separate bindings from variables outside it. Thus a variable declared inside a function has ordinary local scope, unless a special explicit global binding is introduced. Outside function is the global-scope location, while outside program is not a meaningful declaration location in the script.

Why each choice is right or wrong

A - Incorrect: Outside program does not describe a declaration location within the executing PHP script.

B - Correct: An ordinary declaration inside a function creates a local binding for that function.

C - Incorrect: Variables declared outside functions have global scope under WEB25.

D - Incorrect: Inside function is offered and matches the ordinary local-binding rule.

Primary note proof

Study-note section WEB25

> A function's locals and by-value parameters are separate bindings; use global $x or $GLOBALS["x"] to refer to a global explicitly.

Study-note section WEB25

> A variable outside a function has global scope.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 62 | lines 15-18

> All the following variables are automatically available in every scope.
> - $GLOBALS → Contains a reference to every variable which is currently available within the global scope of the script. The keys of this array are the names of the global variables.

Web Programming module | PDF page 72 | lines 7-17

Function definitions have the following form:
function function_name([parameter [, ...]])
{
// Statements
}
That is, function definitions have four parts:
- A definition starts with the word function.
- A name follows, which must start with a letter or underscore, followed by any number of letters, numbers, or underscores.
- The parentheses are required.
- One or more parameters, separated by commas, are optional

Web Programming practice questions · Question 69

Question 161 | AM0051

What is the primary markup language used for structuring content on the web?

A. HTML

B. CSS

C. JavaScript

D. PHP

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer A: HTML

HTML is explicitly a markup language telling browsers how to structure pages, while CSS handles appearance and JavaScript behavior. Evidence: PDF p. 10, PDF p. 60.

Why each choice is right or wrong

A - Correct: Exact markup/structure role.

B - Incorrect: Stylesheet/presentation role.

C - Incorrect: Programming/behavior role.

D - Incorrect: Server-side scripting role.

Primary note proof

Study-note section WEB01

HTML supplies structure/meaning; CSS controls presentation; JavaScript supplies programmable interactivity.

Study-note section WEB01

PHP, Python, JSP/Java and ASP.NET applications generate server responses and access databases; C# is commonly used with ASP.NET.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 10 | lines 9-16

HTML (HyperText Markup Language) is the most basic building block of the Web.
HTML is not a programming language rather it is a markup language that tells web browsers how to structure the web page. HTML consists of a series of elements, which you use to enclose, wrap or markup different parts of content to make it appear or act in a certain way.
HTML defines the meaning and structure of web content. Other technologies besides HTML are generally used to describe a web page's appearance/presentation (CSS) or functionality/ behavior (JavaScript).

Web Programming module | PDF page 60 | lines 4-10

PHP is a server-side scripting language, which can be embedded in HTML or used as a standalone binary (although the former use is much more common). PHP stands for Hypertext Preprocessor. The product was originally named Personal Home Page Tools, and many people still think that is what the acronym stands for. But as it expanded in scope, a new and more appropriate name was selected by community vote. PHP is the language that you use to make the server generate dynamic output-output that is potentially different each time a browser re-quests a page.

Question sources

Computer Science MCQ practice collection · Question 51

Question 162 | AM0052

What is the purpose of CSS in web development?

A. To define the semantic document structure using HTML elements

B. To add interactivity and dynamic behavior to web pages

C. To control the visual appearance of web pages

D. To handle server-side processing and database interactions

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer C: To control the visual appearance of web pages

CSS controls visual presentation, including colors, typography and layout. HTML supplies document structure and meaning; JavaScript supplies programmable browser interaction. Server technologies such as PHP generate responses and interact with databases. With the structural distractor confined to semantic elements, the presentation alternative is the unique description of CSS's role.

Why each choice is right or wrong

A - Incorrect: Semantic document elements and structure are HTML's role rather than CSS's presentation role.

B - Incorrect: Programmable interaction is the JavaScript role, distinct from CSS styling.

C - Correct: Visual presentation is the central CSS role.

D - Incorrect: Server processing and database access belong to server application code.

Primary note proof

Study-note section WEB01

> HTML supplies structure/meaning; CSS controls presentation; JavaScript supplies programmable interactivity.

Study-note section WEB01

> PHP, Python, JSP/Java and ASP.NET applications generate server responses and access databases; C# is commonly used with ASP.NET.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 26 | lines 4-16

> In the previous chapter we have seen how to structure a web page using HTML.
> Now it is time to add presentation to our sites, to do that we will be using a technology called CSS. CSS (Cascading Style Sheets) is the code that styles web content. Using CSS you can apply styles to make web pages look exactly how you want. This works because CSS is connected to the DOM(Document Object Model). CSS is not a programming language. It's not a markup language either. CSS is a style sheet language. CSS is what you use to selectively style HTML elements.
> p {
> color: red;
> }
> 3.1.1 Introduction to CSS
> CSS stands for Cascading Style Sheet. It is a stylesheet language used to describe the presentation of a document written in HTML. Styles define how to display HTML

Web Programming module | PDF page 10 | lines 14-16

> HTML defines the meaning and structure of web content. Other technologies besides HTML are generally used to describe a web page's appearance/presentation (CSS) or functionality/ behavior (JavaScript).

Web Programming module | PDF page 60 | lines 11-16

> Client-side scripting is the glamorous, eye-catching part of Web development. In contrast, server-side scripting is invisible to the user. Server-side Web scripting is mostly about connecting Web sites to back-end servers, such as databases. This enables the following types of two-way communication:
> ➢ Server to client: Web pages can be assembled from back end-server output.
> ➢ Client to server: Customer-entered information can be acted upon.

Question sources

Computer Science MCQ practice collection · Question 52

Question 163 | AM0053

Which programming language is primarily used for client-side scripting in web development?

A. HTML

B. CSS

C. JavaScript

D. PHP

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer C: JavaScript

The client-side scripting chapter identifies JavaScript as the language adding browser behavior; HTML structures, CSS presents, PHP executes server-side. Evidence: PDF p. 44, PDF p. 60.

Why each choice is right or wrong

A - Incorrect: Markup structure, not the scripting language.

B - Incorrect: Stylesheet presentation, not scripting.

C - Correct: Exact browser scripting language.

D - Incorrect: Server-side language in p.60.

Primary note proof

Study-note section WEB01

> HTML supplies structure/meaning; CSS controls presentation; JavaScript supplies programmable interactivity.

Study-note section WEB01

PHP, Python, JSP/Java and ASP.NET applications generate server responses and access databases; C# is commonly used with ASP.NET.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 44 | lines 2-15

Chapter 4: Client-Side Scripting (JavaScript)
4.1 Introduction to JavaScript
JavaScript (JS) is a lightweight, interpreted or compiled programming language. It is a single threaded, dynamic language, supporting object oriented, functional programming styles. Do not confuse JavaScript with the Java Programming language. The two-programming language have very different syntax, semantics, and use.
4.2 JavaScript Basic
JavaScript is a scripting or programming language that allows us to implement complex features on web pages. JavaScript will enable us to display timely content updates, interactive maps, 2D/3D animated graphics etc. JavaScript is one of the three layers of web technologies which lets to add functionality to a web page. The three layers of web technologies are stacked together nicely, HTML will let's structure the webpage, CSS deals with the presentation of the web page and JavaScript the functionality.'

Web Programming module | PDF page 60 | lines 4-10

PHP is a server-side scripting language, which can be embedded in HTML or used as a standalone binary (although the former use is much more common). PHP stands for Hypertext Preprocessor. The product was originally named Personal Home Page Tools, and many people still think that is what the acronym stands for. But as it expanded in scope, a new and more appropriate name was selected by community vote. PHP is the language that you use to make the server generate dynamic output-output that is potentially different each time a browser re-quests a page.

Question sources

Computer Science MCQ practice collection · Question 53

Question 164 | AM0054

Which application-layer protocol defines the requests and responses used to retrieve web resources?

A. HTTP

B. FTP

C. TCP/IP

D. SMTP

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer A: HTTP

HTTP defines the application-level exchange for web resource requests and responses. TCP/IP supplies underlying communication facilities, so naming the application layer distinguishes the required role. FTP and SMTP concern other application services rather than the web resource exchange described. HTTPS adds TLS protection to HTTP; the question asks for the underlying web application protocol.

Why each choice is right or wrong

A - Correct: HTTP defines the web resource request/response exchange.

B - Incorrect: FTP is a file-transfer protocol, not the application protocol defining the stated web resource exchange.

C - Incorrect: TCP/IP names underlying network/transport facilities, not this application-layer request/response protocol.

D - Incorrect: SMTP concerns mail transfer rather than the web resource request/response exchange.

Primary note proof

Study-note section WEB01

> The Internet connects networks; the Web is a resource system commonly using HTTP.

Study-note section WEB-S14

> HTTP defines web application requests, response status codes and representations.

Study-note section WEB-S14

> An HTTP exchange can use underlying TCP connections and IP addresses; naming that network stack does not identify the application-level method or status semantics.

Study-note section WEB-S14

> FTP is a file-transfer application protocol.

Study-note section WEB-S14

> SMTP transports electronic mail.

> • The World Wide Web (WWW) is most often called the Web.
> • The Web is a network of computers all over the world.
> • All the computers in the Web can communicate with each other.

• All the computers use a communication standard called HTTP.
How does the WWW work?
• Web information is stored in documents called Web pages.

Question sources

Computer Science MCQ practice collection · Question 54

Question 165 | AM0055

What is the purpose of a web server in web development?

A. To store and manage website files

B. To handle client-side scripting

C. To control the visual appearance of web pages

D. To ensure secure data transmission over the web

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer A: To store and manage website files

Web servers store the files comprising websites and deliver pages to requesting browsers (p.9). Client interactivity and visual styling have separate JavaScript/CSS roles. Evidence: PDF p. 9, PDF p. 44.

Why each choice is right or wrong

A - Correct: Direct storage/hosting role.

B - Incorrect: Client-side behavior is assigned to JavaScript.

C - Incorrect: Presentation is assigned to CSS.

D - Incorrect: Secure transport is not the general server definition supplied.

Primary note proof

Study-note section WEB01

HTML supplies structure/meaning; CSS controls presentation; JavaScript supplies programmable interactivity.

Study-note section WEB01

PHP, Python, JSP/Java and ASP.NET applications generate server responses and access databases; C# is commonly used with ASP.NET.

Question sources

Computer Science MCQ practice collection · Question 55

Question 166 | AM0056

Which listed DBMS is the open-source relational SQL server used by the course's PHP database examples, including its MySQLi connection and query operations?

A. MySQL

B. Oracle

C. SQL Server

D. MongoDB

Hint

Identify the API and operation first, then distinguish connection setup, statement execution and result processing.

Answer A: MySQL

The note identifies MySQL as an open-source SQL DBMS and uses it as the database server for the PHP MySQLi examples. The question asks for that specific course example, so MySQL is the matching system. Oracle, SQL Server and MongoDB are different named systems; this selection does not depend on an unsupported popularity ranking or a claim that no other database has open-source editions.

Why each choice is right or wrong

A - Correct: MySQL is the open-source SQL DBMS used as the server in the course's MySQLi examples.

B - Incorrect: Oracle is a different named database system, not the MySQL server used by these examples.

C - Incorrect: SQL Server is a different named database system from the server used by the course's MySQLi examples.

D - Incorrect: MongoDB is not the named SQL server used by the course's MySQLi examples.

Primary note proof

Study-note section WEB-S04

> MySQL is an open-source SQL database management system.

Study-note section WEB31

> MySQL is a relational DBMS; a database persists structured application data and supports concurrent clients.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 78 | lines 22-31

> 5.13 Database Programming using PHP
> 5.13.1 PHP File Overview on MySQL database
> MySQL, the most popular Open Source SQL database management system, is developed, distributed, and supported by Oracle Corporation. It is a separate application that stores a collection of data. Each database has one or more distinct APIs for creating, accessing, managing, searching and replicating the data it holds.
> - MySQL is a database management system.
> A database is a structured collection of data. It may be anything from a simple shopping list to a picture gallery or the vast amounts of information in a corporate network.

Computer Science MCQ practice collection · Question 56

Question 167 | AM0057

what is the purpose of a cookie in web development?

A. To store and retrieve user preferences and session information

B. To control the visual appearance of web pages

C. To handle client-side scripting

D. To ensure secure data transmission over the web

Hint

Follow the identifier and server-side state through the stated lifecycle or access check; distinguish client-controlled claims from server decisions.

Answer A: To store and retrieve user preferences and session information

Cookies remember user information across requests and are stored as name/value pairs (p.58). A matches retaining preferences/session information rather than styling, executing scripts or guaranteeing transport security. Evidence: PDF p. 58, PDF p. 59.

Why each choice is right or wrong

A - Correct: Matches remembering user information.

B - Incorrect: Presentation is CSS, not cookie storage.

C - Incorrect: Cookies store data, not the client scripting language itself.

D - Incorrect: The cookie definition supplies no secure-transport guarantee.

Primary note proof

Study-note section WEB28

> Cookies are browser-held name/value data automatically attached to matching requests subject to domain, path, expiry, Secure and SameSite rules.

Study-note section WEB29

> Normally the browser holds an opaque session identifier while data resides in server-controlled storage.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 58 | lines 12-23

> Cookies let you store user information in web pages.
> What are Cookies?
> Cookies are data, stored in small text files, on your computer.
> When a web server has sent a web page to a browser, the connection is shut down, and the server forgets everything about the user. Cookies were invented to solve the problem "how to remember information about the user":
> When a user visits a web page, his/her name can be stored in a cookie.
> Next time the user visits the page, the cookie "remembers" his/her name.
> Cookies are saved in name-value pairs like:
> When a browser requests a web page from a server, cookies belonging to the page are added to the request. This way the server gets the necessary data to "remember" information about users.

Web Programming module | PDF page 59 | lines 4-7

> Create a Cookie with JavaScript
> JavaScript can create, read, and delete cookies with the document.cookie property.
> With JavaScript, a cookie can be created like this:
> document.cookie = "username=John Doe";

Computer Science MCQ practice collection · Question 57

Question 168 | AM0058

Which listed programming languages can execute server-side web application code? Select all that apply.

A. HTML

B. CSS

C. JavaScript

D. PHP

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer C, D: JavaScript; PHP

PHP is a server-response language, and JavaScript can execute on the server through runtimes such as Node.js. JavaScript is therefore not excluded merely because it also runs in browsers. HTML supplies document structure and CSS supplies presentation rules rather than the requested server application scripting role. Both supported programming-language choices must be selected under the revised multiple-selection wording.

Why each choice is right or wrong

A - Incorrect: HTML supplies document structure and meaning rather than server application scripting.

B - Incorrect: CSS supplies presentation rules rather than server application scripting.

C - Correct: JavaScript can run server-side, including through Node.js.

D - Correct: PHP can generate server responses and access application data.

Primary note proof

Study-note section WEB01

> HTML supplies structure/meaning; CSS controls presentation; JavaScript supplies programmable interactivity.

Study-note section WEB01

> PHP, Python, JSP/Java and ASP.NET applications generate server responses and access databases; C# is commonly used with ASP.NET.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 60 | lines 4-10

> PHP is a server-side scripting language, which can be embedded in HTML or used as a standalone binary (although the former use is much more common). PHP stands for Hypertext Preprocessor. The product was originally named Personal Home Page Tools, and many people still think that is what the acronym stands for. But as it expanded in scope, a new and more appropriate name was selected by community vote. PHP is the language that you use to make the server generate dynamic output-output that is potentially different each time a browser re-quests a page.

Computer Science MCQ practice collection · Question 58

Question 169 | AM0059

What is the purpose of a framework in web development?

A. To ensure secure data transmission over the web

B. To control the visual appearance of web pages

C. To provide a foundation and structure for developing web applications

D. To handle client-side scripting

Hint

Match the stated application requirement to the capabilities and category of each technology.

Answer C: To provide a foundation and structure for developing web applications

The framework chapter describes integrated components, libraries and developer tools for building applications. This provides the reusable foundation in C; particular frameworks may also style or script pages, but those are narrower uses. Evidence: PDF p. 93, PDF p. 91.

Why each choice is right or wrong

A - Incorrect: Secure transport is not the general framework purpose given.

B - Incorrect: Styling is a subset of Bootstrap functionality, not the general foundation role.

C - Correct: Matches integrated application-building structure/tools.

D - Incorrect: Client scripting is only one part of the framework examples.

Primary note proof

Study-note section WEB38

> A framework supplies conventions and reusable structure; a library supplies callable capabilities.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 93 | lines 12-19

> c. Angular.js
> Angular is a development platform, built on TypeScript. As a platform, Angular includes:
> 1. A component-based framework for building scalable web applications
> 2. A collection of well-integrated libraries that cover a wide variety of features, including routing, forms management, client-server communication, and more
> 3. A suite of developer tools to help you develop, build, test, and update your code

Web Programming module | PDF page 91 | lines 10-15

> Bootstrap is a free front end framework for faster and easier web development.
> It is s an open-source tool collection for creating responsive websites and web applications. It is the most popular HTML, CSS, and JavaScript framework for developing responsive, mobile-first websites.
> Bootstrap solves many problems that we face when using HTML,CSS and vanilla JavaScript.

Question sources

Computer Science MCQ practice collection · Question 59

Question 170 | AM0060

Which programming language is often used for building scalable and high-performance web applications?

A. HTML

B. CSS

C. JavaScript

D. Node.js

Hint

Identify the execution side and communication pattern, keeping runtime, transport, data format and callback roles distinct.

Answer C: JavaScript is the language; Node.js is a runtime.

WEB01 explicitly distinguishes Node.js from the language it runs. JavaScript is therefore the offered programming-language answer for Node-based server applications. HTML and CSS supply structure and presentation. Scalability and performance depend on workload and architecture, as WEB36 explains, so the answer identifies the language without promising that its use alone guarantees high performance.

Why each choice is right or wrong

A - Incorrect: HTML is structural markup rather than the server application language requested.

B - Incorrect: CSS supplies presentation rather than programmable server application logic.

C - Correct: JavaScript is the programming language used by Node applications.

D - Incorrect: Node.js is a JavaScript runtime, not a separate programming language.

Primary note proof

Study-note section WEB01

> Node.js is a JavaScript runtime, not a separate language.

Study-note section WEB36

> One event-loop thread can handle many waiting requests, but long CPU loops or synchronous I/O block its callbacks.

Module passages - related reading

browsers how to structure the web page. HTML consists of a series of elements, which you use to enclose, wrap or markup different parts of content to make it appear or act in a certain way.
HTML defines the meaning and structure of web content. Other technologies besides HTML are generally used to describe a web page's appearance/presentation (CSS) or functionality/ behavior (JavaScript).

Question sources

Computer Science MCQ practice collection · Question 60

Question 171 | AM0061

What is the purpose of AJAX in web development?

A. To control the visual appearance of web pages

B. To handle client-side scripting

C. To ensure secure data transmission over the web

D. To enable asynchronous communication between the client and server

Hint

Identify the execution side and communication pattern, keeping runtime, transport, data format and callback roles distinct.

Answer D: To enable asynchronous communication between the client and server

AJAX asynchronously communicates with the server, exchanges data and updates pages without refresh (p.89). D is the precise purpose; client-side scripting is the broader environment, not the distinguishing function. Evidence: PDF p. 89.

Why each choice is right or wrong

A - Incorrect: Visual styling is a cooperating CSS role.

B - Incorrect: Broad surrounding activity, not the specific AJAX purpose.

C - Incorrect: No secure-transport guarantee is given.

D - Correct: Exact asynchronous client/server exchange purpose.

Primary note proof

Study-note section WEB34

AJAX means Asynchronous JavaScript and XML, but responses can be JSON, text, HTML or XML.

Study-note section WEB34

It is a technique, not a language, standalone framework or mandatory XML protocol.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 89 | lines 4-13

> AJAX is a web development technique for creating interactive web applications.
> AJAX stands for Asynchronous JavaScript and XML. It can send and receive information in various formats, including JSON, XML, HTML, and text files. AJAX is a new technique for creating better, faster, and more interactive web applications with the help of XML, HTML, CSS, and Java Script. AJAX's most appealing characteristic is its "asynchronous" nature, which means it can communicate with the server, exchange data, and update the page without having to refresh the page.
> The two major features of AJAX allow you to do the following:
> - Make requests to the server without reloading the page
> - Receive and work with data from the server

Question sources

Computer Science MCQ practice collection · Question 61

Question 172 | AM0062

Which listed formats can represent structured application data for server/browser interchange, rather than document presentation or styling? Select all that apply.

A. HTML

B. CSS

C. JSON

D. XML

Hint

Identify the execution side and communication pattern, keeping runtime, transport, data format and callback roles distinct.

Answer C, D: JSON; XML

JSON represents structured values such as objects and arrays, while XML is another supported interchange format. A REST API may return either, so data interchange alone does not choose one uniquely. HTML can be delivered as a response document, but the revised question distinguishes that presentation role from the structured-data formats sought here. CSS expresses styling rules. JSON and XML therefore form the requested selection.

Why each choice is right or wrong

A - Incorrect: HTML's role here is the response document, not the requested structured-data interchange format.

B - Incorrect: CSS expresses presentation rules rather than application-data interchange.

C - Correct: JSON represents structured data values for interchange.

D - Correct: XML is another valid structured-data interchange format.

Primary note proof

Study-note section WEB35

> JSON represents objects, arrays, strings, numbers, Booleans and null; keys/strings use double quotes, and functions/undefined are not JSON values.

Study-note section WEB35

> XML is another valid interchange format.

Study-note section WEB01

> HTML supplies structure/meaning; CSS controls presentation; JavaScript supplies programmable interactivity.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Science MCQ practice collection · Question 62

Question 173 | AM0063

What is the purpose of a content management system (CMS) in web development?

A. To store and manage website files

B. To control the visual appearance of web pages

C. To handle client-side scripting

D. To provide a user-friendly interface for managing website content

Hint

Distinguish the purpose of each development or performance technique from its possible side effects.

Answer D: An editor-facing interface for managing website content.

A CMS gives editors content creation, publishing, roles, and media management without editing every source file. That directly matches D's user-facing content-management interface. File storage may support it but is not its complete purpose; CSS controls appearance and JavaScript supplies client scripting. The requested role is editorial content management.

Why each choice is right or wrong

A - Incorrect: File storage can support a CMS, but does not capture its editor-facing content creation and publishing purpose.

B - Incorrect: Visual presentation is primarily CSS's role, not the defining purpose of a CMS.

C - Incorrect: Client-side scripting is a JavaScript role rather than the CMS's defining editorial function.

D - Correct: A CMS provides editors an interface and workflow for creating, publishing, and managing site content.

Primary note proof

Study-note section WEB39

> A CMS gives editors content creation, publishing, roles and media management without editing every source file.

Study-note section WEB01

> HTML supplies structure/meaning; CSS controls presentation; JavaScript supplies programmable interactivity.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 9 | lines 13-21

> Web hosting is the place where all the files of your website live. Web hosting
> is a service that allows organizations and individuals to post a website or a web page
> onto the Internet. A web host, or web hosting service provider, is a business that
> provides the technologies and services needed for the website or webpage to be
> viewed in the Internet. Websites are hosted, or stored, on special computers called
> servers. When Internet users want to view your website, all they need to do is type
> your website address or domain (the domain name for the site has to be registered)

Web Programming module | PDF page 26 | lines 4-10

> In the previous chapter we have seen how to structure a web page using HTML.
> Now it is time to add presentation to our sites, to do that we will be using a technology
> called CSS. CSS (Cascading Style Sheets) is the code that styles web content. Using
> CSS you can apply styles to make web pages look exactly how you want. This works
> because CSS is connected to the DOM(Document Object Model). CSS is not a

programming language. It's not a markup language either. CSS is a style sheet language. CSS is what you use to selectively style HTML elements.

Question sources

Computer Science MCQ practice collection · Question 63

Question 174 | AM0064

Which technique is used to improve the performance of web applications by caching frequently accessed data or resources?

A. Compression

B. Minification

C. Caching

D. Encryption

Hint

Distinguish the purpose of each development or performance technique from its possible side effects.

Answer C: Caching

WEB39 defines caching as reusing a representation or result and requiring validity or invalidation rules. Keeping frequently accessed data for reuse is therefore Caching. Compression and minification reduce transfer or source size, while encryption protects data; none of those alone stores a reusable computed result. Cache keys and privacy still matter when using the technique safely.

Why each choice is right or wrong

A - Incorrect: Compression changes transfer encoding or size rather than retaining a result for repeated reuse.

B - Incorrect: Minification removes unnecessary source characters and does not itself store frequently reused results.

C - Correct: Caching retains a representation or result so later accesses can reuse it without repeating all prior work.

D - Incorrect: Encryption protects data confidentiality rather than supplying the result-reuse technique described.

Primary note proof

Study-note section WEB39

Caching reuses a representation/result and requires validity/invalidation rules.

Study-note section WEB39

Minification removes unnecessary source characters; bundling combines files; compression changes transfer encoding; preloading fetches anticipated resources early.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 45 | lines 28-31

As a rule, only the simplest scripts are put into HTML. More complex ones reside in separate files.
The benefit of a separate file is that the browser will download it and store it in its cache.

Question sources

Computer Science MCQ practice collection · Question 64

Question 175 | AM0065

Which protocol is used for secure communication over the web?

A. HTTP

B. FTP

C. TCP/IP

D. HTTPS

Hint

Identify the protocol layer and the intended request, response or channel semantics.

Answer D: HTTPS

WEB05 defines HTTPS as HTTP over TLS, protecting channel confidentiality and integrity and authenticating the server through certificate checks. That is the secure web-communication protocol among the main choices. Plain HTTP, FTP, and TCP/IP do not by their names supply that TLS-protected web exchange. The alternate option set places HTTPS at C, so its answer letter differs.

Why each choice is right or wrong

A - Incorrect: Plain HTTP does not by itself add TLS confidentiality, integrity, and certificate-based server authentication.

B - Incorrect: FTP is not the HTTPS protocol for TLS-protected web communication identified in the note.

C - Incorrect: TCP/IP names underlying networking protocols rather than the TLS-protected HTTP scheme requested.

D - Correct: HTTPS is HTTP over TLS and supplies the channel protections described in WEB05.

Primary note proof

Study-note section WEB05

HTTPS uses HTTP over TLS, protecting channel confidentiality/integrity and authenticating the server under certificate checks.

Study-note section WEB-S14

HTTP defines web application requests, response status codes and representations.

Study-note section WEB-S14

An HTTP exchange can use underlying TCP connections and IP addresses; naming that network stack does not identify the application-level method or status semantics.

Study-note section WEB-S14

FTP is a file-transfer application protocol.

Study-note section WEB-S14

SMTP transports electronic mail.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 58 | lines 4-8

window.location.href returns the href (URL) of the current page
window.location.hostname returns the domain name of the web host
window.location.pathname returns the path and filename of the current page
window.location.protocol returns the web protocol used (http: or https:)
window.location.assign() loads a new document

Web Programming module | PDF page 8 | lines 29-34

• The World Wide Web (WWW) is most often called the Web.
• The Web is a network of computers all over the world.
• All the computers in the Web can communicate with each other.
• All the computers use a communication standard called HTTP.
How does the WWW work?
• Web information is stored in documents called Web pages.

Variant 1 | Alternative version 1

Which protocol is used for secure communication over the web?

A. HTTP

B. FTP

C. HTTPS

D. SMTP

Answer C: HTTPS

This variant moves HTTPS to C and replaces the fourth choice with SMTP. WEB05 still identifies HTTPS as HTTP over TLS. HTTP alone lacks that channel protection, and FTP or SMTP does not name the secure web protocol requested, so the variant answer must use its own C label.

Why each choice is right or wrong

A - Incorrect: Plain HTTP does not itself provide the TLS channel protections described in WEB05.

B - Incorrect: FTP is not the TLS-protected HTTP protocol used for the requested secure web exchange.

C - Correct: HTTPS is HTTP over TLS, protecting confidentiality, integrity, and checked server identity.

D - Incorrect: SMTP is not the HTTPS web protocol and does not answer the secure HTTP communication question.

Primary note proof

Study-note section WEB05

> HTTPS uses HTTP over TLS, protecting channel confidentiality/integrity and authenticating the server under certificate checks.

Study-note section WEB-S14

> HTTP defines web application requests, response status codes and representations.

Study-note section WEB-S14

> An HTTP exchange can use underlying TCP connections and IP addresses; naming that network stack does not identify the application-level method or status semantics.

Study-note section WEB-S14

> FTP is a file-transfer application protocol.

Study-note section WEB-S14

> SMTP transports electronic mail.

Question sources

Computer Science MCQ practice collection · Question 65

Computer Science MCQ practice collection · Question 484

Question 176 | AM0066

What is the purpose of a RESTful API in web development?

A. To control the visual appearance of web pages

B. To handle client-side scripting

C. To ensure secure data transmission over the web

D. To provide a standardized interface for accessing and manipulating web resources

Hint

Identify the protocol layer and the intended request, response or channel semantics.

Answer D: A uniform interface for accessing and manipulating resources.

WEB05 describes REST constraints including client/server separation, stateless requests, and a uniform resource interface. It associates identified resources with representations and methods for reading or changing them. D expresses that purpose. CSS handles appearance, JavaScript supplies client interactivity, and HTTPS supplies channel protection; none of those is the defining role of REST itself.

Why each choice is right or wrong

A - Incorrect: Visual presentation is a CSS role, not the defining purpose of a REST resource interface.

B - Incorrect: Client-side scripting is a JavaScript role rather than the definition of REST architecture.

C - Incorrect: TLS/HTTPS protects transmission; a REST interface does not itself guarantee secure transport.

D - Correct: REST supplies a uniform resource interface for accessing representations and requesting resource operations.

Primary note proof

Study-note section WEB05

> A RESTful API follows constraints such as client/server separation, stateless requests, cacheability and a uniform resource interface.

Study-note section WEB05

> Resources have identifiers and representations; JSON is common but not required.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 44 | lines 21-28

> We can use JavaScript in coordination with Application programming interfaces (APIs). APIs provide us extra information. They are ready made code building blocks that are used to simplify programming in JavaScript. There are two types of APIs

- Third party API → are not built into the browser. We have to grab the code from the web. Examples: Twitter API, Google maps API etc.
- Browser API → are built into the browser. Examples DOM (Document object model) which is covered later in this chapter, Geolocation API, Canvas and WebGL, Audio and Video elements

Web Programming module | PDF page 89 | lines 20-24

6.3 Sending Request to PHP server
XMLHttpRequest (XHR) is an API that can be used by JavaScript and other web browser scripting languages to transfer and manipulate XML data to and from a webserver using HTTP, establishing an independent connection channel between a webpage's Client-Side and Server-Side.

Question sources

Computer Science MCQ practice collection · Question 66

Question 177 | AM0067

What is the purpose of responsive web design?

A. To control the visual appearance of web pages

B. To handle client-side scripting

C. To ensure secure data transmission over the web

D. To create websites that adapt and display correctly on different devices and screen sizes

Hint

Identify the requested presentation effect and layout context before matching the property or rule.

Answer D: To create websites that adapt and display correctly on different devices and screen sizes

The framework chapter requires support for desktop, tablet and phone screen sizes and describes responsive mobile-first websites. D directly captures this adaptation goal. Evidence: PDF p. 91.

Why each choice is right or wrong

A - Incorrect: General styling alone does not specify adaptation.

B - Incorrect: Scripting alone does not specify adaptation.

C - Incorrect: Transport security is unrelated to the described screen-size goal.

D - Correct: Exact device/screen adaptation purpose.

Primary note proof

Study-note section WEB14

Responsive design combines flexible layout, images, viewport metadata and media queries, for example @media(max-width:600px){.cards{grid-template-columns:1fr}}.

Study-note section WEB06

Meta charset declares encoding; description summarizes the page; viewport controls mobile viewport behavior.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 91 | lines 6-13

Now a days the website you build has to support all browser types and all sizes of screen (Desktop, Tablets, Phones etc..). To make that possible we use different frameworks. This part of the chapter will introduce you to the Bootstrap framework.
Bootstrap is a free front end framework for faster and easier web development.
It is s an open-source tool collection for creating responsive websites and web applications. It is the most popular HTML, CSS, and JavaScript framework for developing responsive, mobile-first websites.

Computer Science MCQ practice collection · Question 67

Question 178 | AM0068

What is the purpose of version control systems (VCS) in web development?

A. To control the visual appearance of web pages

B. To handle client-side scripting

C. To ensure secure data transmission over the web

D. To track changes to source code and collaborate on web development projects

Hint

Distinguish the purpose of each development or performance technique from its possible side effects.

Answer D: Track source changes and support collaboration.

WEB39 defines VCS through recording source history, branches, and merges for review and collaboration. That directly matches D. Styling and client-side scripting are product technologies, while transport security is an HTTPS concern. A VCS can help teams review changes, but publishing a chosen build is a separate deployment action rather than its definition.

Why each choice is right or wrong

A - Incorrect: VCS records source history; CSS rather than version control determines rendered appearance.

B - Incorrect: Version control tracks scripts as files but does not execute client-side scripting.

C - Incorrect: Version history and collaboration do not themselves provide secure web transport.

D - Correct: Source history, branching, merging, and review support tracking changes and collaborating on development.

Primary note proof

Study-note section WEB39

> A VCS records source history, branches and merges to support review/collaboration; deployment publishes a chosen build and is a separate operation.

Module passages - related reading

> layers of web technologies are stacked together nicely, HTML will let’s structure the webpage, CSS deals with the presentation of the web page and JavaScript the functionality.’

Question sources

Computer Science MCQ practice collection · Question 68

Question 179 | AM0069

Which web development concept refers to the practice of optimizing a website to rank higher in search engine results?

A. Accessibility

B. Usability

C. SEO (Search Engine Optimization)

D. Performance optimization

Hint

Distinguish the purpose of each development or performance technique from its possible side effects.

Answer C: SEO: Search Engine Optimization

WEB39 describes SEO as improving discoverability through meaningful content, headings, metadata, links, and crawlable structure. That matches the practice of improving search-result visibility. Accessibility, usability, and performance can overlap with helpful site improvements, but none is the name of this search-discoverability objective. Ranking improvement is an aim, not a guarantee from a single metadata setting.

Why each choice is right or wrong

A - Incorrect: Accessibility concerns usable access to content and controls, rather than naming the search-ranking optimization practice.

B - Incorrect: Usability concerns user experience and task completion, not specifically search-engine discoverability.

C - Correct: Search Engine Optimization names the practice of improving discoverability in search results.

D - Incorrect: Performance optimization improves resource delivery or execution speed, not the specific search-ranking practice named here.

Primary note proof

Study-note section WEB39

> SEO improves discoverability through meaningful content, headings, metadata, accessible links and crawlable structure; keyword metadata alone does not guarantee ranking.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

> 4. Portable

Question sources

Computer Science MCQ practice collection · Question 69

Question 180 | AM0070

Which activity is specifically used to detect XSS and SQL-injection weaknesses so they can then be repaired?

A. Encryption

B. Authentication

C. Authorization

D. Web application security testing

Hint

Identify the data source or security responsibility precisely, and check whether a combined source or a different control could also qualify.

Answer D: Web application security testing

Web application security testing can detect SQL injection and XSS and provide evidence for repairs. Detection does not by itself remove the flaws: safe query parameterization and context-appropriate output handling are still required. Encryption, authentication and authorization address other protection goals and do not perform the vulnerability-testing activity requested. Changing the stem from a claim of prevention to a detection task preserves the security-testing concept without overstating its effect.

Why each choice is right or wrong

A - Incorrect: Encryption protects content but is not the requested detection activity.

B - Incorrect: Authentication checks identity rather than testing for these code weaknesses.

C - Incorrect: Authorization checks permitted actions rather than conducting vulnerability tests.

D - Correct: This is the testing activity used to discover the specified weaknesses.

Primary note proof

Study-note section WEB27

> A security test can detect SQL injection or XSS but does not itself fix either.

Study-note section WEB27

> Bind SQL parameters to keep values separate from commands.

Study-note section WEB-S11

> Authentication verifies a claimed identity.

Study-note section WEB-S11

> Authorization checks whether a particular entity is permitted to perform a requested action.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 73 | lines 2-10

Form validation is done to ensure that the user has provided the relevant information. Basic validation can be done using HTML elements. For example, in the above script, the email address text box is having a type value as “email”, which prevents the user from entering the incorrect value for an email. Every form field in the above script is followed by a required attribute, which will intimate the user not to leave any field empty before submitting the form. PHP methods and arrays used in form processing are:
• isset(): This function is used to determine whether the variable or a form control is having a value or not.

Web Programming module | PDF page 80 | lines 2-15

5.13.3 Sending Query to MySQL Database using PHP
A database query from PHP is basically a MySQL command wrapped up in a tiny PHP function called mysql_query(). This is where you use the basic SQL workhorses of SELECT,
INSERT, UPDATE, and DELETE, CREATE or DROP a table (but not those to create or drop an entire database) can be used with this PHP function.
Syntax:
[$resultvar=] mysql_query(“query”,[link identifier]);
$resultvar - is an optional result variable. This is used when the query is a select statement.
Query - is any valid insert, delete, update, select, create table or drop table statement enclosed by quotes. It is a good habit to hold the query in a separate variable to add flexibility to your code.
Link identifier-is an optional link identifier

Question sources

Computer Science MCQ practice collection · Question 70

Question 181 | AM0071

A server request handler contains this fragment, with no user-defined syntax extensions:
$visitor = "Mimi";
echo "Hello, " . $visitor;
Which listed language accepts this fragment as written in its normal language environment?

A. HTML

B. CSS

C. JavaScript

D. PHP

Hint

Trace the bindings and operations in order; preserve the exact string characters and distinguish returned values from emitted output.

Answer D: PHP

The fragment uses a dollar-prefixed variable, the echo output construct and dot concatenation. Together these are valid PHP syntax, producing the greeting by joining two strings. JavaScript uses different output calls and does not use dot as this binary concatenation operator. HTML and CSS provide structure and presentation rather than directly executing this server-side statement sequence. Recognizing the actual syntax resolves the language choice without excluding JavaScript from server programming generally.

Why each choice is right or wrong

A - Incorrect: HTML markup does not execute this variable assignment and output-construct sequence.

B - Incorrect: CSS presentation rules do not execute this statement sequence.

C - Incorrect: The echo construct and dot concatenation shown are not ordinary JavaScript syntax.

D - Correct: PHP accepts the assignment, echo construct and dot concatenation as written.

Primary note proof

Study-note section WEB23

> Variables begin with $, then a letter/underscore and subsequent letters/digits/underscores; $AGE18 works but $18AGE does not.

Study-note section WEB24

> echo is a language construct with no return value and can emit comma-separated expressions.

Study-note section WEB24

> Dot concatenates; + is arithmetic.

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 60 | lines 4-10

> PHP is a server-side scripting language, which can be embedded in HTML or used as a standalone binary (although the former use is much more common). PHP stands for Hypertext Preprocessor. The product was originally named Personal Home Page Tools, and many people still think that is what the acronym stands for. But as it expanded in scope, a new and more appropriate name was selected by community vote. PHP is the language that you use to make the server generate dynamic output-output that is potentially different each time a browser re-quests a page.

Web Programming module | PDF page 92 | lines 6-9

> b. Node.js
> Node is an open source, cross platform runtime environment that allows developers to create server-side tools and applications in JavaScript. As an asynchronous event-driven JavaScript runtime, Node.js is designed to build scalable network applications.

Web Programming module | PDF page 10 | lines 9-16

> HTML (HyperText Markup Language) is the most basic building block of the Web.
> HTML is not a programming language rather it is a markup language that tells web browsers how to structure the web page. HTML consists of a series of elements, which you use to enclose, wrap or markup different parts of content to make it appear or act in a certain way.
> HTML defines the meaning and structure of web content. Other technologies besides HTML are generally used to describe a web page's appearance/presentation (CSS) or functionality/ behavior (JavaScript).

Question sources

Computer Science MCQ practice collection · Question 71

Question 182 | AM0072

Which server-side scripting language is often used for building scalable and high-performance web applications?

A. HTML

B. CSS

C. JavaScript

D. Node.js

Hint

Identify the execution side and communication pattern, keeping runtime, transport, data format and callback roles distinct.

Answer C: JavaScript, executed server-side by runtimes such as Node.js.

WEB01 directly distinguishes JavaScript as a language and Node.js as its runtime. The question asks for the language, so C is the category-correct option. WEB36 warns that long CPU work or synchronous I/O can block Node callbacks, so scalability is architectural and workload-dependent rather than a guarantee from the language name alone.

Why each choice is right or wrong

A - Incorrect: HTML is markup for structure rather than server-side application scripting.

B - Incorrect: CSS is presentation rather than the server application language requested.

C - Correct: JavaScript is the language that runs in Node-based server applications.

D - Incorrect: Node.js is a runtime, not a distinct server-side scripting language.

Primary note proof

Study-note section WEB01

> Node.js is a JavaScript runtime, not a separate language.

Study-note section WEB36

One event-loop thread can handle many waiting requests, but long CPU loops or synchronous I/O block its callbacks.

Computer Science MCQ practice collection · Question 72

Question 183 | AM0073

What is the purpose of server-side scripting languages in web development?

A. To control the visual appearance of web pages

B. To handle client-side interactivity

C. To generate dynamic content and interact with databases

D. To ensure secure data transmission over the web

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer C: To generate dynamic content and interact with databases

Server PHP generates dynamic output and connects sites to backend databases, enabling two-way communication (p.60). C combines those explicitly described purposes. Evidence: PDF p. 60, PDF p. 44.

Why each choice is right or wrong

A - Incorrect: CSS presentation role.

B - Incorrect: Client JavaScript role.

C - Correct: Exact dynamic-output/database role.

D - Incorrect: Transport security is not the stated server scripting purpose.

Primary note proof

Study-note section WEB01

> HTML supplies structure/meaning; CSS controls presentation; JavaScript supplies programmable interactivity.

Study-note section WEB01

> PHP, Python, JSP/Java and ASP.NET applications generate server responses and access databases; C# is commonly used with ASP.NET.

Module passages - related reading

Web Programming module | PDF page 60 | lines 9-19

> language that you use to make the server generate dynamic output-output that is potentially different each time a browser re-quests a page.
> Client-side scripting is the glamorous, eye-catching part of Web development. In contrast, server-side scripting is invisible to the user. Server-side Web scripting is mostly about connecting Web sites to back-end servers, such as databases. This enables the following types of two-way communication:
> ➢ Server to client: Web pages can be assembled from back end-server output.
> ➢ Client to server: Customer-entered information can be acted upon.
> Common examples of client-to-server interaction are online forms with some drop-down lists (usually the ones that require you to click a button) that the script assembles dynamically on the server.

Web Programming module | PDF page 44 | lines 13-15

> layers of web technologies are stacked together nicely, HTML will let's structure the webpage, CSS deals with the presentation of the web page and JavaScript the functionality.'

Question sources

Computer Science MCQ practice collection · Question 73

Question 184 | AM0074

Which of the following is a server-side scripting language for Microsoft's ASP.NET framework?

A. Python

B. Ruby

C. C#

D. Java

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer C: C#

WEB01 explicitly states that C# is commonly used with ASP.NET. That identifies the requested language among the main options. Python and Java can be used for server applications in other roles described here, but are not its stated ASP.NET pairing. The answer concerns language/framework association, not a claim that only one language can ever interact with the platform.

Why each choice is right or wrong

A - Incorrect: Python is a server-side language, but it is not the ASP.NET language pairing identified in WEB01.

B - Incorrect: Ruby is not the language explicitly paired with ASP.NET in the supplied note.

C - Correct: WEB01 explicitly states that C# is commonly used with ASP.NET.

D - Incorrect: The note associates Java with JSP/Java server applications, while identifying C# for ASP.NET.

Primary note proof

Study-note section WEB01

> PHP, Python, JSP/Java and ASP.NET applications generate server responses and access databases; C# is commonly used with ASP.NET.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Science MCQ practice collection · Question 74

Question 185 | AM0075

Which client-side scripting language is supported by all modern web browsers?

A. HTML

B. CSS

C. JavaScript

D. PHP

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer C: JavaScript

The JavaScript chapter describes browser functionality and modern browser JavaScript interactivity. C matches the client scripting language; HTML and CSS have different structural/presentation roles and PHP is server-side. Evidence: PDF p. 44, PDF p. 56, PDF p. 60.

Why each choice is right or wrong

A - Incorrect: Markup language, not scripting.

B - Incorrect: Stylesheet language, not scripting.

C - Correct: Browser scripting language described throughout chapter 4.

D - Incorrect: Explicit server-side language.

Primary note proof

Study-note section WEB01

HTML supplies structure/meaning; CSS controls presentation; JavaScript supplies programmable interactivity.

Study-note section WEB01

PHP, Python, JSP/Java and ASP.NET applications generate server responses and access databases; C# is commonly used with ASP.NET.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 44 | lines 9-15

> JavaScript is a scripting or programming language that allows us to implement complex features on web pages. JavaScript will enable us to display timely content updates, interactive maps, 2D/3D animated graphics etc. JavaScript is one of the three layers of web technologies which lets to add functionality to a web page. The three layers of web technologies are stacked together nicely, HTML will let's structure the webpage, CSS deals with the presentation of the web page and JavaScript the functionality.'

Web Programming module | PDF page 56 | lines 11-16

> There are no official standards for the Browser Object Model (BOM).
> Since modern browsers have implemented (almost) the same methods and properties for JavaScript interactivity, it is often referred to, as methods and properties of the BOM.
> The window object is supported by all browsers. It represents the browser's window.

Question sources

Computer Science MCQ practice collection · Question 76

Question 187 | AM0077

Which client-side scripting language is primarily used for manipulating the Document Object Model (DOM) of a web page?

A. HTML

B. CSS

C. JavaScript

D. PHP

Hint

Track which node is selected or created, and distinguish changing content from attaching a node.

Answer C: JavaScript

The module JavaScript DOM section explains accessing elements and changing document structure, style and content. That makes JavaScript the client scripting language for DOM manipulation. Evidence: PDF p. 52, PDF p. 60.

Why each choice is right or wrong

A - Incorrect: HTML supplies structure rather than the client scripting operation.

B - Incorrect: CSS styles content rather than being the scripting language.

C - Correct: Explicitly uses DOM APIs to access/change pages.

D - Incorrect: PHP executes on the server in this module.

Primary note proof

Study-note section WEB01

> HTML supplies structure/meaning; CSS controls presentation; JavaScript supplies programmable interactivity.

Study-note section WEB20

> The DOM is a hierarchy of nodes representing the document.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 52 | lines 3-20

> 4.10 JavaScript DOM (Document object Model)
> The Document Object Model (DOM) is the data representation of the objects that comprise the structure and content of a document on the web. The Document Object Model (DOM) is a programming interface for web documents. It represents the page so that programs can change the document structure, style, and content. The DOM represents the document as nodes and objects; that way, programming languages can interact with the page.
> 4.10.1 Accessing HTML elements in JavaScript

In the DOM Api, there are different methods to get access to HTML elements. We will list the available methods here, but only the most recent methods are covered here.
- getElementById(id) returns an element with that specific ID
- getElmentsByClassName(class) returns elements with that specific class
getElementsByTagName(tag) returns elements with the given tag name
- querySelector(selector) → The Document method querySelector() returns the first Element within the document that matches the specified selector, or group of selectors. If no matches are found, null is returned.
element = document.querySelector(selectors);

Web Programming module | PDF page 60 | lines 4-10

PHP is a server-side scripting language, which can be embedded in HTML or used as a standalone binary (although the former use is much more common). PHP stands for Hypertext Preprocessor. Computer Science MCQ practice collection · Question 77

Question 188 | AM0078

Which client-side scripting language is often used for validating form inputs on web pages?

A. HTML

B. CSS

C. JavaScript

D. PHP

Hint

Separate event dispatch, handler registration and cancellation of the browser default action.

Answer C: JavaScript

The module includes a JavaScript form-validation example checking an empty field and prompting the user. C identifies the scripting language performing that check. Evidence: PDF p. 55, PDF p. 73.

Why each choice is right or wrong

A - Incorrect: HTML can provide basic validation but is not the requested scripting language.

B - Incorrect: Presentation language, not this validation script.

C - Correct: Exact language of the documented validation example.

D - Incorrect: PHP validates on the server, not in the browser.

Primary note proof

Study-note section WEB01

> HTML supplies structure/meaning; CSS controls presentation; JavaScript supplies programmable interactivity.

Study-note section WEB21

> For submission, form.addEventListener("submit",e=>{if(!valid()){e.preventDefault();}}) stops the default only on failure.

Question sources

Computer Science MCQ practice collection · Question 78

Question 189 | AM0079

Which client-side scripting technique allows for loading new content into a web page without a full page reload?

A. AJAX

B. JSON

C. XML

D. Bootstrap

Hint

Identify the execution side and communication pattern, keeping runtime, transport, data format and callback roles distinct.

Answer A: AJAX

AJAX explicitly requests data and updates a page without full refresh. JSON/XML are possible exchange formats, and Bootstrap is a responsive UI framework. Evidence: PDF p. 89, PDF p. 91.

Why each choice is right or wrong

A - Correct: Exact no-refresh exchange technique.

B - Incorrect: A supported data format, not the exchange technique.

C - Incorrect: Another data format, not the technique.

D - Incorrect: Responsive framework, not the AJAX request mechanism.

Primary note proof

Study-note section WEB34

> AJAX means Asynchronous JavaScript and XML, but responses can be JSON, text, HTML or XML.

Study-note section WEB38

> Bootstrap supplies layout/components.

Study-note section WEB35

> JSON represents objects, arrays, strings, numbers, Booleans and null; keys/strings use double quotes, and functions/undefined are not JSON values.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 89 | lines 4-18

> AJAX is a web development technique for creating interactive web applications.
> AJAX stands for Asynchronous JavaScript and XML. It can send and receive
> information in various formats, including JSON, XML, HTML, and text files. AJAX

is a new technique for creating better, faster, and more interactive web applications with the help of XML, HTML, CSS, and Java Script. AJAX's most appealing characteristic is its "asynchronous" nature, which means it can communicate with the server, exchange data, and update the page without having to refresh the page.
The two major features of AJAX allow you to do the following:
- Make requests to the server without reloading the page
- Receive and work with data from the server
6.2 XMLHttpRequest Object
XMLHttpRequest (XHR) objects are used to interact with servers. You can retrieve data from a URL without having to do a full-page refresh. This enables a Web page to update just part of a page without disrupting what the user is doing. Despite its name, XMLHttpRequest can be used to retrieve any type of data, not just XML.

Web Programming module | PDF page 91 | lines 10-13

Bootstrap is a free front end framework for faster and easier web development. It is s an open-source tool collection for creating responsive websites and web applications. It is the most popular HTML, CSS, and JavaScript framework for developing responsive, mobile-first websites.

Question sources

Computer Science MCQ practice collection · Question 79

Question 190 | AM0080

A course-catalog page already has CSS that switches between one and three columns at the required viewport widths. It still needs a browser-side filter that updates the visible course cards without a full-page reload. With suitable application code, which listed technologies can implement that interaction while retaining the CSS layout? Select all that apply.

A. jQuery

B. React

C. Angular

D. Vue.js

Hint

Match the stated application requirement to the capabilities and category of each technology.

Answer A, B, C, D: jQuery; React; Angular; Vue.js

The responsive layout is already supplied by CSS; the remaining task is programmable interface behavior. jQuery can update the DOM, and React, Angular and Vue can implement the filter and visible-card updates through their interface facilities. None is uniquely required by this interaction. All four remain possible choices when suitable application code is supplied, without implying that selecting any toolkit automatically implements responsiveness or the filter itself.

Why each choice is right or wrong

A - Correct: jQuery can handle filter interaction and update existing DOM content while the CSS controls layout.

B - Correct: React can render the filtered card interface while using the supplied responsive CSS.

C - Correct: Angular can implement the filter interaction and visible-card updates with the existing layout styles.

D - Correct: Vue can update visible cards in response to filter input while retaining responsive styles.

Primary note proof

Study-note section WEB38

> jQuery simplifies DOM operations; React builds component interfaces; Angular is a component platform, distinct from older AngularJS; Vue also builds interactive interfaces.

Study-note section WEB38

> Each can contribute to a responsive interface, so those generic descriptions do not identify one unique framework.

Question sources

Computer Science MCQ practice collection · Question 80

Question 191 | AM0081

A page sends asynchronous HTTP requests and uses each response to update part of the page without a full navigation. Which listed technique names this browser request-and-update pattern?

A. AJAX

B. JSON

C. Websockets

D. RESTful API

Hint

Identify the execution side and communication pattern, keeping runtime, transport, data format and callback roles distinct.

Answer A: AJAX

AJAX is the technique of using asynchronous browser HTTP requests to obtain data and update part of a page. It can carry JSON, XML or other response formats. JSON names a data representation, while WebSocket supplies a persistent bidirectional message channel rather than the stated repeated HTTP request/response pattern. A RESTful API describes the server interface organization, not the browser update technique.

Why each choice is right or wrong

A - Correct: AJAX names the asynchronous HTTP request-and-partial-update technique described.

B - Incorrect: JSON can encode a response but does not perform browser requests or update the page.

C - Incorrect: WebSocket uses a persistent bidirectional channel; that is not the specified HTTP request/response technique.

D - Incorrect: A RESTful API can serve the requests, but names an interface style rather than the client’s request-and-update technique.

Primary note proof

Study-note section WEB34

> AJAX means Asynchronous JavaScript and XML, but responses can be JSON, text, HTML or XML.

Study-note section WEB34

> Configure an XHR with open("GET",url,true), register response/error handlers and call send().

Study-note section WEB35

WebSocket establishes a persistent bidirectional message channel after its handshake.

Study-note section WEB35

JSON represents objects, arrays, strings, numbers, Booleans and null; keys/strings use double quotes, and functions/undefined are not JSON values.

Study-note section WEB05

A RESTful API follows constraints such as client/server separation, stateless requests, cacheability and a uniform resource interface.

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 89 | lines 4-18

AJAX is a web development technique for creating interactive web applications.
AJAX stands for Asynchronous JavaScript and XML. It can send and receive information in various formats, including JSON, XML, HTML, and text files. AJAX is a new technique for creating better, faster, and more interactive web applications with the help of XML, HTML, CSS, and Java Script. AJAX's most appealing characteristic is its "asynchronous" nature, which means it can communicate with the server, exchange data, and update the page without having to refresh the page.
The two major features of AJAX allow you to do the following:
- Make requests to the server without reloading the page
- Receive and work with data from the server
6.2 XMLHttpRequest Object
XMLHttpRequest (XHR) objects are used to interact with servers. You can retrieve data from a URL without having to do a full-page refresh. This enables a Web page to update just part of a page without disrupting what the user is doing. Despite its name, XMLHttpRequest can be used to retrieve any type of data, not just XML.

Computer Science MCQ practice collection · Question 81

Question 192 | AM0082

Which techniques store data locally in a user's browser? Select all that apply.

A. Cookies

B. Local storage

C. Session storage

D. IndexedDB

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer A, B, C, D: Cookies; Local storage; Session storage; IndexedDB

All four entries are browser storage techniques, although their persistence, data model and automatic transmission behavior differ. Cookies hold browser name/value data that can accompany matching requests. localStorage persists origin-specific strings, sessionStorage is scoped to a page session or tab, and IndexedDB supports structured local data. The revised question asks for every local-storage technique rather than assuming that only the API named local storage qualifies.

Why each choice is right or wrong

A - Correct: Cookies are browser-held name/value data, even though matching requests can transmit them.

B - Correct: localStorage persists origin-specific string values until removed or cleared.

C - Correct: sessionStorage stores browser data within a page-session or tab scope.

D - Correct: IndexedDB supplies structured local browser storage.

Primary note proof

Study-note section WEB28

> Cookies are browser-held name/value data automatically attached to matching requests subject to domain, path, expiry, Secure and SameSite rules.

Study-note section WEB28

> localStorage persists origin-specific string values across sessions until removed/cleared; sessionStorage is scoped to a page session/tab.

Study-note section WEB28

> IndexedDB supplies structured local storage.

> Cookies let you store user information in web pages.
> What are Cookies?
> Cookies are data, stored in small text files, on your computer.
> When a web server has sent a web page to a browser, the connection is shut down,
> and the server forgets everything about the user. Cookies were invented to solve the
> problem "how to remember information about the user":
> When a user visits a web page, his/her name can be stored in a cookie.
> Next time the user visits the page, the cookie "remembers" his/her name.
> Cookies are saved in name-value pairs like:
> When a browser requests a web page from a server, cookies belonging to the page
> are added to the request. This way the server gets the necessary data to "remember"
> information about users.

Web Programming module | PDF page 76 | lines 2-5

> in one application. A PHP session allows you to store user information on the server for later use (i.e., username, shopping items, etc.). However, session information is temporary and will be deleted after the user has left the website. If you need a permanent storage you may want to store the data in a database.

Question sources

Computer Science MCQ practice collection · Question 82

Question 193 | AM0083

Which source-processing step removes unnecessary characters from CSS or JavaScript, distinct from bundling files together or compressing transfer encoding?

A. Compression

B. Caching

C. Minification

D. Encryption

Hint

Distinguish the purpose of each development or performance technique from its possible side effects.

Answer C: Minification

Minification removes unnecessary source characters, such as dispensable formatting, while preserving the intended program or stylesheet behavior. Bundling combines files and compression changes transfer encoding; these are separate operations even when a build pipeline performs them together. Caching instead reuses an existing representation, and encryption serves confidentiality. Restricting the question to source-character reduction makes minification the supported technique without claiming it also performs file combination.

Why each choice is right or wrong

A - Incorrect: Compression changes transfer encoding rather than performing the specified source-character reduction.

B - Incorrect: Caching reuses a representation rather than rewriting its source characters.

C - Correct: Minification is the source-character reduction step.

D - Incorrect: Encryption protects confidentiality rather than simplifying source formatting.

Primary note proof

Study-note section WEB39

> Minification removes unnecessary source characters; bundling combines files; compression changes transfer encoding; preloading fetches anticipated resources early.

Study-note section WEB39

> Caching reuses a representation/result and requires validity/invalidation rules.

> As a rule, only the simplest scripts are put into HTML. More complex ones reside in separate files.
> The benefit of a separate file is that the browser will download it and store it in its cache.

Question sources

Computer Science MCQ practice collection · Question 83

Question 194 | AM0084

Which client-side technique is used to handle and process user interactions, such as mouse clicks or keyboard inputs?

A. Event handling

B. Form validation

C. Responsive design

D. Browser compatibility

Hint

Separate event dispatch, handler registration and cancellation of the browser default action.

Answer A: Event handling

Events signal user actions and handlers run functions in response, including click events (p.53). A names this mechanism. Validation is a particular task, and responsive design/browser compatibility do not name action dispatch. Evidence: PDF p. 53.

Why each choice is right or wrong

A - Correct: Exact handler mechanism.

B - Incorrect: Checks fields rather than the general interaction mechanism.

C - Incorrect: Adapts layout rather than dispatching user actions.

D - Incorrect: Cross-browser support is not the event dispatch mechanism.

Primary note proof

Study-note section WEB21

> An event handler runs when an event occurs: click, input, keydown, mouseover, submit and load are examples.

Study-note section WEB14

Browser compatibility requires feature testing and fallbacks; responsive size handling is a different issue.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 53 | lines 4-18

4.10.3 Events in JavaScript
An event is a signal that something has happened. All DOM nodes generate such signals (but events are not limited to DOM).
Here's a list of the most useful DOM events, just to take a look at:
- click - when the mouse clicks on an element (touchscreen devices generate it on a tap).
- contextmenu - when the mouse right-clicks on an element.
- mouseover / mouseout - when the mouse cursor comes over / leaves an element.
- mousedown / mouseup - when the mouse button is pressed / released over an element.
- mousemove - when the mouse is moved.
Event Handlers
To react on events we can assign a handler - a function that runs in case of an event.
Handlers are a way to run JavaScript code in case of user actions.

Computer Science MCQ practice collection · Question 84

Question 195 | AM0085

Which client-side technique is used to ensure that a web page displays correctly across different devices and screen sizes?

A. Event handling

B. Form validation

C. Responsive design

D. Browser compatibility

Hint

Identify the requested presentation effect and layout context before matching the property or rule.

Answer C: Responsive design

Responsive websites support desktop/tablet/phone screen sizes in the Bootstrap chapter. That fits devices and screen sizes; browser compatibility is a related but different browser-engine concern. Evidence: PDF p. 91.

Why each choice is right or wrong

A - Incorrect: Handles actions rather than screen size.

B - Incorrect: Checks input rather than screen size.

C - Correct: Exact screen adaptation concept.

D - Incorrect: Different browsers are a separate axis from device dimensions.

Primary note proof

Study-note section WEB14

> Responsive design combines flexible layout, images, viewport metadata and media queries, for example @media(max-width:600px){.cards{grid-template-columns:1fr}}.

Study-note section WEB14

> Browser compatibility requires feature testing and fallbacks; responsive size handling is a different issue.

> It is s an open-source tool collection for creating responsive websites and web applications. It is the most popular HTML, CSS, and JavaScript framework for developing responsive, mobile-first websites.

Question sources

Computer Science MCQ practice collection · Question 85

Question 196 | AM0086

Which browser technique sends an asynchronous HTTP request, then processes a JSON response through a callback or promise without reloading the whole page? Choose the technique, rather than a resource-interface style or a persistent messaging protocol.

A. AJAX

B. Websockets

C. RESTful API

D. Bootstrap

Hint

Identify the execution side and communication pattern, keeping runtime, transport, data format and callback roles distinct.

Answer A: AJAX

AJAX describes asynchronous browser/server requests and response handling; despite its name, the returned data need not be XML and can be JSON. The scenario specifically uses an HTTP request with a later handler rather than a persistent bidirectional messaging channel. A RESTful API describes a resource-interface architecture that the request might use, while Bootstrap supplies interface components. Those can coexist with the interaction but do not name the requested browser technique.

Why each choice is right or wrong

A - Correct: AJAX names the asynchronous HTTP request-and-response technique described.

B - Incorrect: WebSocket is a persistent bidirectional messaging channel rather than this HTTP-request technique.

C - Incorrect: REST describes resource-interface constraints, not the requested browser execution technique.

D - Incorrect: Bootstrap supplies interface components, not this request-handling technique.

Primary note proof

Study-note section WEB34

> AJAX means Asynchronous JavaScript and XML, but responses can be JSON, text, HTML or XML.

Study-note section WEB34

> A callback is a function invoked later by the runtime/API.

Study-note section WEB35

> WebSocket establishes a persistent bidirectional message channel after its handshake.

Study-note section WEB05

> A RESTful API follows constraints such as client/server separation, stateless requests, cacheability and a uniform resource interface.

Question sources

Computer Science MCQ practice collection · Question 86

Question 197 | AM0087

Which listed technologies can implement interactive behaviors such as tooltips and modals, with suitable application code or components? Select all that apply.

A. jQuery

B. React

C. Angular

D. Vue.js

Hint

Match the stated application requirement to the capabilities and category of each technology.

Answer A, B, C, D: jQuery; React; Angular; Vue.js

Tooltips and modals are interface behaviors, not a unique signature of one library or platform. jQuery can manipulate the DOM, while React, Angular and Vue can implement such interactions through component-based application logic. The question explicitly permits suitable code or components, so it does not claim every behavior is bundled into each technology by default. All four can contribute and therefore belong in the selection.

Why each choice is right or wrong

A - Correct: jQuery DOM operations can implement the stated interactions.

B - Correct: React components can implement the stated interactions.

C - Correct: Angular components can implement the stated interactions.

D - Correct: Vue components can implement the stated interactions.

Primary note proof

Study-note section WEB38

jQuery simplifies DOM operations; React builds component interfaces; Angular is a component platform, distinct from older AngularJS; Vue also builds interactive interfaces.

3. A suite of developer tools to help you develop, build, test, and update your code

Question sources

Computer Science MCQ practice collection · Question 87

Question 198 | AM0088

Which client-side technique is used to create visually appealing and responsive layouts for web pages?

A. HTML

B. CSS

C. JavaScript

D. PHP

Hint

Identify the requested presentation effect and layout context before matching the property or rule.

Answer B: CSS

CSS is explicitly presentation code, including layout properties; HTML supplies structure, JavaScript behavior and PHP server processing. B is the intended layout-styling technology. Evidence: PDF p. 26, PDF p. 37, PDF p. 60.

Why each choice is right or wrong

A - Incorrect: Structure rather than the principal styling layer.

B - Correct: Styles and layout match the CSS presentation role.

C - Incorrect: Behavior rather than primary layout styling.

D - Incorrect: Server output rather than browser styling rules.

Primary note proof

Study-note section WEB01

> HTML supplies structure/meaning; CSS controls presentation; JavaScript supplies programmable interactivity.

Study-note section WEB14

> Responsive design combines flexible layout, images, viewport metadata and media queries, for example @media(max-width:600px){.cards{grid-template-columns:1fr}}.

Web Programming module | PDF page 26 | lines 4-16

> In the previous chapter we have seen how to structure a web page using HTML.
> Now it is time to add presentation to our sites, to do that we will be using a technology called CSS. CSS (Cascading Style Sheets) is the code that styles web content. Using CSS you can apply styles to make web pages look exactly how you want. This works because CSS is connected to the DOM(Document Object Model). CSS is not a programming language. It's not a markup language either. CSS is a style sheet

language. CSS is what you use to selectively style HTML elements.
p {
color: red;
}
3.1.1 Introduction to CSS
CSS stands for Cascading Style Sheet. It is a stylesheet language used to describe the presentation of a document written in HTML. Styles define how to display HTML

Web Programming module | PDF page 37 | lines 15-18

Display
The display CSS property sets whether an element is treated as a block or inline element and the layout used for its children, such as flow layout, grid or flex. Formally, the display property sets an element's inner and outer display types. The

Web Programming module | PDF page 60 | lines 4-10

PHP is a server-side scripting language, which can be embedded in HTML or used as a standalone binary (although the former use is much more common). PHP stands for Hypertext Preprocessor. The product was originally named Personal Home Page Tools, and many people still think that is what the acronym stands for. But as it expanded in scope, a new and more appropriate name was selected by community vote. PHP is the language that you use to make the server generate dynamic output-output that is potentially different each time a browser re-quests a page.

Question sources

Computer Science MCQ practice collection · Question 88

Question 199 | AM0089

Which client-side technique is used to optimize web page loading speed by preloading resources in advance?

A. Compression

B. Minification

C. Caching

D. Preloading

Hint

Distinguish the purpose of each development or performance technique from its possible side effects.

Answer D: Preloading

WEB39 defines preloading as fetching anticipated resources early. That exactly matches preloading resources in advance in the stem. Compression and minification change transfer or source size, while caching reuses a representation already obtained. Preloading can help loading speed when chosen well, but excessive early fetching can compete with critical work, so performance should be measured.

Why each choice is right or wrong

A - Incorrect: Compression changes transfer representation or size rather than initiating anticipated resource fetches early.

B - Incorrect: Minification removes unnecessary source characters rather than prefetching resources before demand.

C - Incorrect: Caching reuses retained results; it is distinct from initiating an early fetch of anticipated resources.

D - Correct: Preloading fetches anticipated resources early, matching the advance-loading technique described.

Primary note proof

Study-note section WEB39

> Minification removes unnecessary source characters; bundling combines files; compression changes transfer encoding; preloading fetches anticipated resources early.

Study-note section WEB39

> Measure performance because excess preloading/bundling may compete with critical work.

Question 200 | AM0090

Which client-side technique is used to ensure that a web page displays correctly in different web browsers?

A. Event handling

B. Form validation

C. Responsive design

D. Browser compatibility

Hint

Identify the requested presentation effect and layout context before matching the property or rule.

Answer D: Browser compatibility

The framework chapter says sites must support all browser types as well as screen sizes. Different-browser correctness is browser compatibility; responsive design concerns the separate size/device aspect. Evidence: PDF p. 91.

Why each choice is right or wrong

A - Incorrect: Handles interactions rather than browser differences.

B - Incorrect: Checks form input rather than browser rendering support.

C - Incorrect: Screen-size adaptation is a separate requirement.

D - Correct: Names the cross-browser correctness requirement.

Primary note proof

Study-note section WEB14

> Browser compatibility requires feature testing and fallbacks; responsive size handling is a different issue.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Question sources

Computer Science MCQ practice collection · Question 90

Question 201 | AM0091

What is the purpose of HTML in web programming?

A. To control the visual appearance of web pages

B. To handle server-side processing and database interactions

C. To specify the structure and content of web pages

D. To add interactivity and dynamic behavior to web pages

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer C: To specify the structure and content of web pages

HTML defines the meaning and structure of web content. The module separately assigns appearance to CSS and behavior to JavaScript, while PHP handles server-side output. Evidence: PDF p. 10, PDF p. 60.

Why each choice is right or wrong

A - Incorrect: CSS presentation role.

B - Incorrect: Server scripting/database role.

C - Correct: Exact HTML structure/content role.

D - Incorrect: JavaScript behavior role.

Primary note proof

Study-note section WEB01

> HTML supplies structure/meaning; CSS controls presentation; JavaScript supplies programmable interactivity.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 10 | lines 9-16

> HTML (HyperText Markup Language) is the most basic building block of the Web.
> HTML is not a programming language rather it is a markup language that tells web browsers how to structure the web page. HTML consists of a series of elements, which you use to enclose, wrap or markup different parts of content to make it appear or act in a certain way.
> HTML defines the meaning and structure of web content. Other technologies besides HTML are generally used to describe a web page's appearance/presentation (CSS) or functionality/ behavior (JavaScript).

Web Programming module | PDF page 60 | lines 11-16

Client-side scripting is the glamorous, eye-catching part of Web development. In contrast, server-side scripting is invisible to the user. Server-side Web scripting is mostly about connecting Web sites to back-end servers, such as databases. This enables the following types of two-way communication:
➢ Server to client: Web pages can be assembled from back end-server output.
➢ Client to server: Customer-entered information can be acted upon.

Question sources

Computer Science MCQ practice collection · Question 91

Question 202 | AM0092

Which HTML element is used to create a heading in a web page?

A. <p>

B.

C. <h1>

D. <a>

Hint

Use the element or attribute meaning and document structure, rather than appearance or a similar-looking name.

Answer C: <h1>

Heading formats range from h1 to h6 (p.15). The displayed h1 choice is one of these; p is paragraph, a is link, and div is not identified as a heading format. Evidence: PDF p. 15, PDF p. 15, PDF p. 14.

Why each choice is right or wrong

A - Incorrect: Paragraph rather than heading.

B - Incorrect: Not one of the documented heading tags.

C - Correct: Documented heading tag.

D - Incorrect: Anchor/link rather than heading.

Primary note proof

Study-note section WEB06

Heading levels h1-h6 express hierarchy, with h6 conventionally smallest in default styling, not a mandatory CSS size.

Study-note section WEB06

<p> marks paragraphs;
 is a line break and <hr> a thematic break.

Study-note section WEB07

Use Read for a link; href is the destination, not url/link.

Computer Science MCQ practice collection · Question 93

Question 204 | AM0094

Which HTML element is used to create an unordered list in a web page?

A.

B.

C.

D. <a>

Hint

Use the element or attribute meaning and document structure, rather than appearance or a similar-looking name.

Answer A:

The module names ul unordered lists and shows li nested inside it. ol is ordered, while a provides hyperlinks. Evidence: PDF p. 18, PDF p. 19, PDF p. 19, PDF p. 14.

Why each choice is right or wrong

A - Correct: Unordered-list container.

B - Incorrect: List item rather than container.

C - Incorrect: Ordered-list container.

D - Incorrect: Link rather than list container.

Primary note proof

Study-note section WEB08

> Unordered <ul> and ordered <ol> contain <li> items.

Study-note section WEB07

> Use Read for a link; href is the destination, not url/link.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 18 | lines 38-40

> 2.2.8 Ordered and Unordered List in HTML
> Lists
> I. Unordered Lists (ul) - define bulleted lists

Question 205 | AM0095

Which HTML element is used to create a link in a web page?

A. <h1>

B.

C. <p>

D. <a>

Hint

Use the element or attribute meaning and document structure, rather than appearance or a similar-looking name.

Answer D: <a>

An HTML hyperlink wraps its text in an a element with href (p.14). D names that anchor element. Evidence: PDF p. 14, PDF p. 15, PDF p. 15.

Why each choice is right or wrong

A - Incorrect: Heading, not link element.

B - Incorrect: Not the documented anchor element.

C - Incorrect: Paragraph, not anchor.

D - Correct: Exact anchor/link element.

Primary note proof

Study-note section WEB07

> Use Read for a link; href is the destination, not url/link.

Study-note section WEB06

> marks paragraphs;
 is a line break and <hr> a thematic break.

> The browser inserts a new line before and after the text in the paragraph tag.

Question sources

Computer Science MCQ practice collection · Question 95

Question 206 | AM0096

Which CSS property is used to control the spacing between elements in a web page?

A. color

B. font-size

C. margin

D. padding

Hint

Identify the requested presentation effect and layout context before matching the property or rule.

Answer C: margin

The margin is expressly whitespace between a box and other elements, outside border and padding. Padding surrounds content within the box, so C fits spacing between elements. Evidence: PDF p. 36, PDF p. 34.

Why each choice is right or wrong

A - Incorrect: Foreground color, not spacing.

B - Incorrect: Text size, not external spacing.

C - Correct: Exact outer whitespace between elements.

D - Incorrect: Internal whitespace around content, not outer margin.

Primary note proof

Study-note section WEB13

> color sets text color; background-color sets background; font-size size, font-family face, font-style italic, font-weight weight, text-align inline-content alignment, and text-decoration effects such as underline.

Study-note section WEB13

> Margin lies outside the border; padding lies inside; border surrounds content/padding.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 36 | lines 26-37

> The Box Model defines how the different parts of a box - margin, border, padding, and content - work together to create a box that you can see on a page.
> Parts of a box
> - Content box: The area where your content is displayed, which can be sized using properties like width and height.
> - Padding box: The padding sits around the content as white space; its size can be controlled using padding and related properties.
> - Border box: The border box wraps the content and any padding. Its size and style can be controlled using border and related properties.
> - Margin box: The margin is the outermost layer, wrapping the content, padding, and border as whitespace between this box and other elements. Its size can be controlled using margin and related properties.

Web Programming module | PDF page 34 | lines 20-26

> The color property sets the color of the foreground content of the selected elements
> 3.3.2 Font and Text Properties

The font CSS shorthand property sets all the different properties of an element's font. Alternatively, it sets an element's font to a system font. The property is a shorthand for the following properties
- font-family
- font-size

Question 207 | AM0097

Which CSS property is used to change the color of text in a web page?

A. color

B. font-size

C. margin

D. padding

Hint

Identify the requested presentation effect and layout context before matching the property or rule.

Answer A: color

The module explicitly defines color as setting foreground content color. Font size controls dimensions; margin/padding control whitespace. Evidence: PDF p. 34, PDF p. 36.

Why each choice is right or wrong

A - Correct: Exact foreground/text color property.

B - Incorrect: Size rather than color.

C - Incorrect: External whitespace rather than color.

D - Incorrect: Internal whitespace rather than color.

Primary note proof

Study-note section WEB13

color sets text color; background-color sets background; font-size size, font-family face, font-style italic, font-weight weight, text-align inline-content alignment, and text-decoration effects such as underline.

Study-note section WEB13

Margin lies outside the border; padding lies inside; border surrounds content/padding.

Computer Science MCQ practice collection · Question 97

Question 208 | AM0098

Which CSS property is used to change the size of text in a web page?

A. color

B. font-size

C. margin

D. padding

Hint

Identify the requested presentation effect and layout context before matching the property or rule.

Answer B: font-size

Font-size is explicitly listed as the font-size component, required in a multi-property font shorthand. B controls text size; the alternatives control color or whitespace. Evidence: PDF p. 34, PDF p. 36.

Why each choice is right or wrong

A - Incorrect: Foreground color instead of size.

B - Correct: Exact size component.

C - Incorrect: External whitespace instead of text dimensions.

D - Incorrect: Internal whitespace instead of text dimensions.

Primary note proof

Study-note section WEB13

color sets text color; background-color sets background; font-size size, font-family face, font-style italic, font-weight weight, text-align inline-content alignment, and text-decoration effects such as underline.

Study-note section WEB13

Margin lies outside the border; padding lies inside; border surrounds content/padding.

The color property sets the color of the foreground content of the selected elements
3.3.2 Font and Text Properties
The font CSS shorthand property sets all the different properties of an element's font. Alternatively, it sets an element's font to a system font. The property is a shorthand for the following properties
- font-family
- font-size
- font-stretch
- font-style
- font-variant
- font-weight
- line-height
If font is specified as a shorthand for several font-related properties, then:
- it must include values for:
<font-size>
<font-family>

Web Programming module | PDF page 36 | lines 31-37

- Padding box: The padding sits around the content as white space; its size can be controlled using padding and related properties.
- Border box: The border box wraps the content and any padding. Its size and style can be controlled using border and related properties.
- Margin box: The margin is the outermost layer, wrapping the content, padding, and border as whitespace between this box and other elements. Its size can be controlled using margin and related properties.

Question sources

Computer Science MCQ practice collection · Question 98

Question 209 | AM0099

In an ordinary horizontal-writing table layout, which property vertically aligns content within a table cell?

A. text-align

B. vertical-align

C. align-content

D. justify-content

Hint

Identify the requested presentation effect and layout context before matching the property or rule.

Answer B: vertical-align

vertical-align applies in table-cell and inline contexts. With an ordinary horizontal-writing table cell specified, it controls the vertical placement of the cell's content. text-align handles inline-content text alignment, while flex or grid alignment properties have their own axis and line-distribution contexts. The table-cell qualifier is essential because vertical-align does not vertically center arbitrary block containers simply because they contain content.

Why each choice is right or wrong

A - Incorrect: text-align handles inline-content alignment rather than vertical cell placement.

B - Correct: vertical-align applies to the specified table-cell context.

C - Incorrect: align-content distributes applicable lines or tracks, not ordinary table-cell content.

D - Incorrect: justify-content follows a flex/grid main-axis context rather than this table-cell mechanism.

Primary note proof

Study-note section WEB14

> vertical-align applies to inline/table-cell contexts and does not center every block.

Study-note section WEB14

> Flexbox arranges direct children on a main axis; justify-content follows that axis, align-items the cross axis.

Study-note section WEB13

> color sets text color; background-color sets background; font-size size, font-family face, font-style italic, font-weight weight, text-align inline-content alignment, and text-decoration effects such as underline.

Question 210 | AM0100

Which CSS property is used to create a border around an element in a web page?

A. color

B. font-size

C. border

D. padding

Hint

Identify the requested presentation effect and layout context before matching the property or rule.

Answer C: border

The border box wraps content and padding and is controlled with border properties (p.36). The table section also explicitly says border sets borders. Evidence: PDF p. 36, PDF p. 38.

Why each choice is right or wrong

A - Incorrect: Foreground color rather than border.

B - Incorrect: Text size rather than border.

C - Correct: Exact enclosing-border property.

D - Incorrect: Whitespace inside the border, not the border itself.

Primary note proof

Study-note section WEB13

> color sets text color; background-color sets background; font-size size, font-family face, font-style italic, font-weight weight, text-align inline-content alignment, and text-decoration effects such as underline.

Study-note section WEB13

> Margin lies outside the border; padding lies inside; border surrounds content/padding.

Question 211 | AM0101

Which CSS property is used to control the space inside the border of an element in a web page?

A. color

B. font-size

C. margin

D. padding

Hint

Identify the requested presentation effect and layout context before matching the property or rule.

Answer D: padding

Padding sits around the content as whitespace; the border wraps that padding. Therefore the internal space inside an element border is padding. Evidence: PDF p. 36.

Why each choice is right or wrong

A - Incorrect: Foreground color, not space.

B - Incorrect: Text dimensions, not space.

C - Incorrect: Outermost whitespace beyond the border.

D - Correct: Exact whitespace surrounding content inside border.

Primary note proof

Study-note section WEB13

> color sets text color; background-color sets background; font-size size, font-family face, font-style italic, font-weight weight, text-align inline-content alignment, and text-decoration effects such as underline.

Study-note section WEB13

Computer Science MCQ practice collection · Question 101

Question 212 | AM0102

Which web technology is commonly used for managing the content of information-rich websites?

A. HTML

B. CSS

C. JavaScript

D. Content Management System (CMS)

Hint

Distinguish the purpose of each development or performance technique from its possible side effects.

Answer D: Content Management System

A CMS gives editors tools to create, publish, and manage content without editing each source file. That is the technology aimed at information-rich website content management. HTML structures documents, CSS styles them, and JavaScript adds behavior, but those technologies alone do not supply the complete editorial management interface described.

Why each choice is right or wrong

A - Incorrect: HTML structures document content but does not by itself provide an editorial management workflow.

B - Incorrect: CSS controls presentation rather than managing editorial content creation, publication, and roles.

C - Incorrect: JavaScript can implement behavior but is not itself the complete content-management system requested.

D - Correct: A CMS provides editor-facing creation, publishing, role, and media tools for managing website content.

Primary note proof

Study-note section WEB39

> A CMS gives editors content creation, publishing, roles and media management without editing every source file.

Study-note section WEB01

> HTML supplies structure/meaning; CSS controls presentation; JavaScript supplies programmable interactivity.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 10 | lines 9-16

HTML (HyperText Markup Language) is the most basic building block of the Web. HTML is not a programming language rather it is a markup language that tells web browsers how to structure the web page. HTML consists of a series of elements, which you use to enclose, wrap or markup different parts of content to make it appear or act in a certain way.
HTML defines the meaning and structure of web content. Other technologies besides HTML are generally used to describe a web page's appearance/presentation (CSS) or functionality/ behavior (JavaScript).

Web Programming module | PDF page 9 | lines 13-21

Web hosting is the place where all the files of your website live. Web hosting is a service that allows organizations and individuals to post a website or a web page onto the Internet. A web host, or web hosting service provider, is a business that provides the technologies and services needed for the website or webpage to be viewed in the Internet. Websites are hosted, or stored, on special computers called servers. When Internet users want to view your website, all they need to do is type your website address or domain (the domain name for the site has to be registered) into their browser. Their computer will then connect to your server and your webpages will be delivered to them through the browser.

Question sources

Computer Science MCQ practice collection · Question 102

Question 213 | AM0103

What is the database’s direct role in a web application?

A. To control the visual appearance of web pages

B. To store persistent application data and support queries over that data

C. To specify the structure and content of web pages

D. To add interactivity and dynamic behavior to web pages

Hint

Identify the API and operation first, then distinguish connection setup, statement execution and result processing.

Answer B: To store persistent application data and support queries over that data

A database stores persistent structured application facts and supports operations that retrieve or change them. It is not the whole application server, which also performs validation, authorization and response generation. HTML describes document structure, CSS controls visual presentation and browser scripting supplies client interaction. The option states the database’s actual storage/query role rather than attributing all server-side processing to it.

Why each choice is right or wrong

A - Incorrect: Visual presentation is the role of CSS.

B - Correct: Persistent data storage and queries are the database's direct role.

C - Incorrect: Document structure is the role of HTML.

D - Incorrect: Client-side interactivity is a scripting role rather than the database's direct purpose.

Primary note proof

Study-note section WEB31

> MySQL is a relational DBMS; a database persists structured application data and supports concurrent clients.

Study-note section WEB39

> A database stores persistent facts; it is not itself the whole server application.

Study-note section WEB01

> HTML supplies structure/meaning; CSS controls presentation; JavaScript supplies programmable interactivity.

> 5.13.3 Sending Query to MySQL Database using PHP
> A database query from PHP is basically a MySQL command wrapped up in a tiny
> PHP function called mysql_query(). This is where you use the basic SQL workhorses
> of SELECT,
> INSERT, UPDATE, and DELETE, CREATE or DROP a table (but not those to create
> or drop an entire database) can be used with this PHP function.
> Syntax:
> [$resultvar=] mysql_query(“query”,[link identifier]);
> $resultvar - is an optional result variable. This is used when the query is a select
> statement.
> Query - is any valid insert, delete, update, select, create table or drop table
> statement enclosed by quotes. It is a good habit to hold the query in a separate variable

to add flexibility to your code.
Link identifier-is an optional link identifier

Web Programming module | PDF page 80 | lines 24-29

Example: assume the student table has three attrubutes - id,name and department.
$query=”select * from student”;
$result=mysql_query($query);
while($row=mysql_fetch_row($result)){
echo “$row[0].$row[1].$row[2]”;//counting
starts from 0 not 1

Question sources

Computer Science MCQ practice collection · Question 104

Question 215 | AM0105

A server starts by executing the following CommonJS source directly and registers a callback for incoming HTTP requests:
const http = require("node:http");
http.createServer((req, res) => { res.end("Ready"); }).listen(8000);
Which listed programming language is executing this request handler?

A. HTML

B. CSS

C. JavaScript

D. PHP

Hint

Identify the execution side and communication pattern, keeping runtime, transport, data format and callback roles distinct.

Answer C: JavaScript

The CommonJS server runs in Node.js, which is a JavaScript runtime rather than a separate programming language. The require call loads the HTTP module, and the callback passed to createServer handles incoming requests and ends each response. PHP can also generate server responses, but this particular source uses the Node JavaScript API and syntax. HTML and CSS do not execute the handler as a server program.

Why each choice is right or wrong

A - Incorrect: HTML supplies document structure rather than executing the module load and request callback.

B - Incorrect: CSS supplies presentation rules rather than this executable request handler.

C - Correct: Node.js executes this CommonJS request handler as JavaScript.

D - Incorrect: PHP supports server programming but does not directly execute this CommonJS source.

Primary note proof

Study-note section WEB01

> Node.js is a JavaScript runtime, not a separate language.

Study-note section WEB36

> A minimal CommonJS Node server can use const http=require("node:http"); http.createServer((req,res)=>{res.writeHead(200,{"Content-Type":"text/plain"});res.end("Hello");}).listen(8000);.

Study-note section WEB36

> The request listener runs for incoming requests; end completes the response.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 60 | lines 4-10

> PHP is a server-side scripting language, which can be embedded in HTML or used as a standalone binary (although the former use is much more common). PHP stands for Hypertext Preprocessor. The product was originally named Personal Home Page Tools, and many people still think that is what the acronym stands for. But as it expanded in scope, a new and more appropriate name was selected by community vote. PHP is the language that you use to make the server generate dynamic output-output that is potentially different each time a browser re-quests a page.

Web Programming module | PDF page 92 | lines 6-9

> b. Node.js
> Node is an open source, cross platform runtime environment that allows developers to create server-side tools and applications in JavaScript. As an asynchronous event-driven JavaScript runtime, Node.js is designed to build scalable network applications.

Web Programming module | PDF page 10 | lines 9-16

> HTML (HyperText Markup Language) is the most basic building block of the Web. HTML is not a programming language rather it is a markup language that tells web browsers how to structure the web page. HTML consists of a series of elements, which you use to enclose, wrap or markup different parts of content to make it appear or act in a certain way.

Question 216 | AM0106

Which HTML form element is used to create a text input field?

A. <input type="text">

B. <input type="checkbox">

C. <input type="radio">

D. <input type="submit">

Hint

Separate the control role, displayed content, submitted value and form destination.

Answer A: <input type="text">

The input type list identifies text as the usual text input and distinguishes checkbox/radio. The example on p.56 uses input type=text with a Name field. Evidence: PDF p. 22, PDF p. 56, PDF p. 22.

Why each choice is right or wrong

A - Correct: Exact text-input type.

B - Incorrect: Checkbox type instead.

C - Incorrect: Radio type instead.

D - Incorrect: Button submission type instead of text entry.

Primary note proof

Study-note section WEB-S02

> In an input element, type="text" creates text entry, type="checkbox" an independently selectable checkbox, type="radio" a radio choice, and type="submit" a submit button.

Study-note section WEB09

> Same-name radio buttons form a single-choice group; checkboxes permit independent selections.

Study-note section WEB09

> submit submits; button has no submission action by itself.

Question 217 | AM0107

Which HTML form element is used to create a checkbox?

A. <input type="text">

B. <input type="checkbox">

C. <input type="radio">

D. <input type="submit">

Hint

Separate the control role, displayed content, submitted value and form destination.

Answer B: <input type="checkbox">

The module input type list includes Checkbox separately from Text and Radio. Therefore input type=checkbox is the checkbox control, not a text field, radio choice or submit button. Evidence: PDF p. 22, PDF p. 22.

Why each choice is right or wrong

A - Incorrect: Text entry control.

B - Correct: Exact checkbox type.

C - Incorrect: Radio control instead.

D - Incorrect: Submit button instead.

Primary note proof

Study-note section WEB-S02

In an input element, type="text" creates text entry, type="checkbox" an independently selectable checkbox, type="radio" a radio choice, and type="submit" a submit button.

Study-note section WEB09

Same-name radio buttons form a single-choice group; checkboxes permit independent selections.

Study-note section WEB09

submit submits; button has no submission action by itself.

Module passages - related reading

Question 218 | AM0108

Which HTML form element is used to create a radio button?

A. <input type="text">

B. <input type="checkbox">

C. <input type="radio">

D. <input type="submit">

Hint

Separate the control role, displayed content, submitted value and form destination.

Answer C: <input type="radio">

The module distinguishes the Radio input type from Text and Checkbox. C therefore specifies a radio button. Evidence: PDF p. 22, PDF p. 22.

Why each choice is right or wrong

A - Incorrect: Text entry instead.

B - Incorrect: Checkbox instead.

C - Correct: Exact radio input type.

D - Incorrect: Submit button instead.

Primary note proof

Study-note section WEB-S02

> In an input element, type="text" creates text entry, type="checkbox" an independently selectable checkbox, type="radio" a radio choice, and type="submit" a submit button.

Study-note section WEB09

> Same-name radio buttons form a single-choice group; checkboxes permit independent selections.

Study-note section WEB09

> submit submits; button has no submission action by itself.

Question 219 | AM0109

Which HTML form element is used to create a button that submits a form?

A. <input type="text">

B. <input type="checkbox">

C. <input type="radio">

D. <input type="submit">

Hint

Separate the control role, displayed content, submitted value and form destination.

Answer D: <input type="submit">

The button-controls list includes Submit as an input type. Combined with the form submission description, D is the form-submitting button; the others collect text or selections. Evidence: PDF p. 22, PDF p. 21, PDF p. 22.

Why each choice is right or wrong

A - Incorrect: Text input, not submission button.

B - Incorrect: Checkbox selection, not submission button.

C - Incorrect: Radio selection, not submission button.

D - Correct: Submit button as listed in the controls section.

Primary note proof

Study-note section WEB-S02

> In an input element, type="text" creates text entry, type="checkbox" an independently selectable checkbox, type="radio" a radio choice, and type="submit" a submit button.

Study-note section WEB09

> Same-name radio buttons form a single-choice group; checkboxes permit independent selections.

Study-note section WEB09

> submit submits; button has no submission action by itself.

Web Programming module | PDF page 21 | lines 13-20

> 2.2.10 HTML Form and Form Controls
> The <form> HTML element represents a document section containing interactive controls for submitting information. An HTML form is a section of a document containing normal content, markup, special elements called controls (checkboxes, radio buttons, menus, etc.) and labels on those controls. HTML Forms are required, when we want to collect data from a user. Using forms, we can build a website with user registration. We take the information collected from the user and then post it to the backend application such as php.

Web Programming module | PDF page 22 | lines 2-7

> 1. Text inputs create using the <input> tag, an input control can take many forms using the type attribute. Possible values for type attribute
> - Text - most common used for text inputs
> - Password - for password fields
> - Checkbox
> - Radio

Question sources

Computer Science MCQ practice collection · Question 109

Question 220 | AM0110

Which client-side programming language can run a custom submit handler that compares two form fields and cancels submission when they disagree?

A. HTML

B. CSS

C. JavaScript

D. PHP

Hint

Separate event dispatch, handler registration and cancellation of the browser default action.

Answer C: JavaScript

JavaScript can run browser event handlers, inspect field values and call preventDefault when a custom validity check fails. This supports a comparison between fields before submission. HTML supplies native constraints such as required or type=email, but those constraints are not the custom scripted comparison requested. CSS controls presentation, and PHP processes server requests after submission rather than running the browser handler.

Why each choice is right or wrong

A - Incorrect: HTML supplies native field constraints, but is not the programming language executing the custom comparison handler.

B - Incorrect: CSS controls presentation rather than executing submit-handler logic.

C - Correct: JavaScript executes the browser submit handler and can cancel the default submission on a failed comparison.

D - Incorrect: PHP runs the server-side processing, not this browser event handler.

Primary note proof

Study-note section WEB21

> For submission, form.addEventListener("submit",e=>{if(!valid()){e.preventDefault();}}) stops the default only on failure.

Study-note section WEB09

> type=email/required give browser validation feedback; arbitrary clients can bypass it.

Study-note section WEB01

> HTML supplies structure/meaning; CSS controls presentation; JavaScript supplies programmable interactivity.

Study-note section WEB01

> PHP, Python, JSP/Java and ASP.NET applications generate server responses and access databases; C# is commonly used with ASP.NET.

> Now inside the submit event handler function we call the event.preventDefault()
> method to prevent the default behavior and avoid a form submit to reload the page,
> this gives us control. After we gain control over the submit event we can all kind of
> stuff, like form validation
> Here is a simple but different way of validating a form using javascript
> Form Validation
> <html>
> <head>
> <title>Form Validation</title>
> <script type = "text/javascript">
> if(document.myForm.Name.value == "") {
> alert("Please provide your name!");
> document.myForm.Name.focus() ;
> return false;
> }

Web Programming module | PDF page 73 | lines 2-7

> Form validation is done to ensure that the user has provided the relevant information.
> Basic validation can be done using HTML elements. For example, in the above
> script, the email address text box is having a type value as “email”, which prevents

the user from entering the incorrect value for an email. Every form field in the above script is followed by a required attribute, which will intimate the user not to leave any field empty before submitting the form. PHP methods and arrays used in form

Web Programming module | PDF page 72 | lines 25-33

5.10 Form Processing using PHP
Handling a form is a multipart process. First a form is created, into which a user can enter the required details. This data is then sent to the web server, where it is interpreted,
often with some error checking. If the PHP code identifies one or more fields that require
reentering, the form may be redisplayed with an error message. When the code is satisfied with the accuracy of the input, it takes some action that usually involves the database.

Question sources

Computer Science MCQ practice collection · Question 110

Question 221 | AM0111

Which description defines client-server roles without requiring a particular physical-machine arrangement?

A. Client and server must be the same physical machine

B. A client requests resources or services and a server receives requests and returns responses; they may share a machine

C. Any two different browser instances automatically form client and server roles

D. Any two pages on a website automatically form client and server roles

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer B: A client requests resources or services and a server receives requests and returns responses; they may share a machine

Client and server describe interacting roles: the client requests a resource or service and the server handles the request and returns a response. These roles can run on separate machines or on the same machine. Physical location therefore does not define the relationship. Two browser instances or two web pages also do not automatically establish a request-serving role pair. The corrected definition focuses on behavior while retaining the deployment distinction as a distractor.

Why each choice is right or wrong

A - Incorrect: The roles can share a machine, but sameness is not required.

B - Correct: This states the request/response roles and permits either physical arrangement.

C - Incorrect: Two browser instances do not automatically make one a server.

D - Incorrect: Different pages are resources, not automatically request and serving roles.

Primary note proof

Study-note section WEB01

> A browser/user agent requests resources and renders HTML/CSS, then runs permitted JavaScript.

Study-note section WEB01

> A web/HTTP server receives requests and returns representations, sometimes invoking application code.

Study-note section WEB01

> Client and server are roles and can run on the same machine.

Question sources

Computer Science MCQ practice collection · Question 111

Question 222 | AM0112

A browser sends a GET request and the web server replies with a status code and resource representation. Which application-layer protocol gives this exchange its semantics?

A. HTTP

B. FTP

C. TCP/IP

D. SMTP

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer A: HTTP

GET and the returned status code belong to HTTP's web request/response semantics. TCP/IP may carry that exchange, but it does not define the application method or response-status meaning. FTP and SMTP serve different application purposes. The scenario therefore identifies HTTP without depending on an unstated assumption about which networking layer is being tested.

Why each choice is right or wrong

A - Correct: HTTP defines GET requests, response status codes and resource representations.

B - Incorrect: FTP does not define the stated web GET/status exchange.

C - Incorrect: TCP/IP can carry the exchange but does not define its application-level GET or status semantics.

D - Incorrect: SMTP is a mail-transfer application protocol, not the stated web request/response semantics.

Primary note proof

Study-note section WEB01

> The Internet connects networks; the Web is a resource system commonly using HTTP.

Study-note section WEB-S14

> HTTP defines web application requests, response status codes and representations.

Study-note section WEB-S14

> An HTTP exchange can use underlying TCP connections and IP addresses; naming that network stack does not identify the application-level method or status semantics.

Study-note section WEB-S14

> FTP is a file-transfer application protocol.

Study-note section WEB-S14

> SMTP transports electronic mail.

> • All the computers use a communication standard called HTTP.

How does the WWW work?
• Web information is stored in documents called Web pages.

Question sources

Computer Science MCQ practice collection · Question 112

Question 223 | AM0113

Which method in HTTP is used to retrieve a resource from a server?

A. GET

B. POST

C. PUT

D. DELETE

Hint

Identify the protocol layer and the intended request, response or channel semantics.

Answer A: GET

WEB04 defines GET as retrieving a representation with safe semantics. That is the retrieval operation requested. POST asks a target to process supplied content, PUT creates or replaces the identified representation, and DELETE requests removal. These are intended method semantics; a badly designed server does not change which method the standard retrieval role belongs to.

Why each choice is right or wrong

A - Correct: GET is the HTTP method whose intended semantics retrieve a resource representation.

B - Incorrect: POST requests processing of supplied content rather than naming the standard safe retrieval operation.

C - Incorrect: PUT creates or replaces an identified representation instead of simply retrieving it.

D - Incorrect: DELETE requests removal of a resource association rather than reading its representation.

Primary note proof

Study-note section WEB04

GET retrieves a representation with safe semantics; do not implement an intentional state-changing action as a GET link.

Study-note section WEB04

POST asks the target to process supplied content.

Study-note section WEB04

PUT creates/replaces the identified resource representation; DELETE requests removal of its association.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 89 | lines 25-31

In order to make an HTTP request to the server with JavaScript, you need an instance of an XMLHttpRequest Object. We make a request to the sever, by calling the open() and send() methods of the HTTP request object, like this:
httpRequest.open('GET', 'http://www.example.org/some.file', true);
httpRequest.send();
open() takes three parameters, the first is the HTTP request method and the second is the URL. The optional third parameter sets whether the request is asynchronous.

Web Programming module | PDF page 73 | lines 11-16

• $_GET[]: It is used the retrieve the information from the form control through the parameters sent in the URL. It takes the attribute given in the url as the parameter.
• $_POST[]: It is used the retrieve the information from the form control through the HTTP POST method. IT takes name attribute of corresponding form control as the parameter.

Question sources

Computer Science MCQ practice collection · Question 113

Question 224 | AM0114

Which method in HTTP is used to send data to a server for processing?

A. GET

B. POST

C. PUT

D. DELETE

Hint

Identify the protocol layer and the intended request, response or channel semantics.

Answer B: POST requests processing of supplied content.

WEB04 explicitly says POST asks the target to process supplied content, matching the intended HTTP method role. GET retrieves safely, PUT creates or replaces an identified representation, and DELETE removes an association. Those methods can carry protocol details, but the generic processing semantics in the stem are POST's specific definition.

Why each choice is right or wrong

A - Incorrect: GET's intended semantics retrieve a representation rather than request arbitrary content processing.

B - Correct: POST asks the target resource to process the supplied content.

C - Incorrect: PUT specifies creating or replacing the identified representation rather than the generic processing role.

D - Incorrect: DELETE requests removal of a resource association rather than the stated content-processing semantics.

Primary note proof

Study-note section WEB04

> GET retrieves a representation with safe semantics; do not implement an intentional state-changing action as a GET link.

Study-note section WEB04

> POST asks the target to process supplied content.

Study-note section WEB04

> PUT creates/replaces the identified resource representation; DELETE requests removal of its association.

Module passages - related reading

> - target → Specify the target window or frame where the result of the script will be displayed. It takes values like _blank, _self, _parent etc.
> - enctype → tells how the browser encodes data. Possible values
> 1. application/x-www-form-urlencoded → most common and used from simple scenarios
> 2. mutlipart/form-data → used to upload binary data

Question sources

Computer Science MCQ practice collection · Question 114

Question 225 | AM0115

Which HTTP status code indicates a successful request?

A. 200

B. 300

C. 400

D. 500

Hint

Identify the protocol layer and the intended request, response or channel semantics.

Answer A: 200

WEB04 explicitly maps 200 to success, 400 to a malformed request, and 500 to unexpected server failure. A 3xx code belongs to redirection rather than ordinary successful representation delivery. Therefore 200 is the listed status indicating a successful request. Other 2xx successes exist, but they are not among these options.

Why each choice is right or wrong

A - Correct: The note explicitly identifies 200 as a successful request status.

B - Incorrect: A 3xx code represents redirection behavior rather than the listed ordinary success status.

C - Incorrect: 400 indicates a malformed request, not successful processing.

D - Incorrect: 500 indicates an unexpected server failure, not success.

Primary note proof

Study-note section WEB04

> 200 indicates success, 201 creation, 204 success without content, 301 permanent redirection, 400 malformed request, 401 missing/invalid authentication, 403 refusal, 404 unavailable/not found, and 500 an unexpected server failure.

Study-note section WEB-S10

> The first digit of an HTTP status code identifies its class: 2xx means successful handling, 3xx means redirection or further action, 4xx indicates a client-error condition, and 5xx indicates a server-error condition.

res.setHeader('Content-Type', 'text/plain');
res.end('Hello World');
});
```

Question sources

Computer Science MCQ practice collection · Question 115

Question 226 | AM0116

Which HTTP status code indicates that the requested resource is not found on the server?

A. 200

B. 300

C. 400

D. 404

Hint

Identify the protocol layer and the intended request, response or channel semantics.

Answer D: 404

WEB04 explicitly identifies 404 as unavailable or not found. That directly matches the requested missing-resource case. The alternatives represent success, redirection, or a malformed request rather than the not-found status. A not-found response describes what is reported to the client; it does not require explaining every possible server-side reason for the absence.

Why each choice is right or wrong

A - Incorrect: 200 reports success rather than the missing-resource condition in the stem.

B - Incorrect: 300 is a redirection-class code, not the note's not-found status.

C - Incorrect: 400 concerns a malformed request rather than the unavailable resource identified here.

D - Correct: 404 is explicitly mapped to unavailable or not found in WEB04.

Primary note proof

Study-note section WEB04

> 200 indicates success, 201 creation, 204 success without content, 301 permanent redirection, 400 malformed request, 401 missing/invalid authentication, 403 refusal, 404 unavailable/not found, and 500 an unexpected server failure.

Study-note section WEB-S10

> The first digit of an HTTP status code identifies its class: 2xx means successful handling, 3xx means redirection or further action, 4xx indicates a client-error condition, and 5xx indicates a server-error condition.

Question sources

Computer Science MCQ practice collection · Question 116

Question 227 | AM0117

Which situations demonstrate concurrency when their requests make overlapping progress? Here simultaneously means overlapping progress, not necessarily execution at the same instant. Select all that apply.

A. The ability of the server to handle multiple clients simultaneously

B. The ability of the client to handle multiple servers simultaneously

C. The ability of the server to handle multiple requests from a single client

D. The ability of the client to handle multiple requests to a single server

Hint

Identify the execution side and communication pattern, keeping runtime, transport, data format and callback roles distinct.

Answer A, B, C, D: The ability of the server to handle multiple clients simultaneously; The ability of the client to handle multiple servers simultaneously; The ability of the server to handle multiple requests from a single client; The ability of the client to handle multiple requests to a single server

Concurrency means overlapping progress, whereas parallelism requires execution at the same instant. A server can overlap work for several clients or several requests from one client. A client can likewise overlap interactions with several servers or multiple requests to one server. The question explicitly supplies overlap for each situation, making every listed arrangement an example of concurrency without asserting that all work physically runs in parallel.

Why each choice is right or wrong

A - Correct: Overlapping server work for several clients is concurrent.

B - Correct: Overlapping client interactions with several servers are concurrent.

C - Correct: Several overlapping requests from one client can create server concurrency.

D - Correct: A client can overlap multiple requests to the same server.

Primary note proof

Study-note section WEB36

> Concurrency means overlapping progress; parallelism means execution at the same instant.

Study-note section WEB36

> Multiple clients, or one client with overlapping requests, can both create concurrency.

Module passages - related reading

> 3. Thousands of reusable packages
> 4. Portable

Question sources

Computer Science MCQ practice collection · Question 117

Question 228 | AM0118

What is a race condition in the context of concurrency?

A. A condition where two or more clients compete to establish a connection with the server

B. A condition where two or more servers compete to respond to a client request

C. A condition where multiple threads or processes access shared resources in an unpredictable manner

D. A condition where multiple clients send duplicate requests to the server

Hint

Identify the shared-state invariant and the operations that must be coordinated.

Answer C: Shared-resource correctness depends on execution interleaving.

WEB37 describes two requests reading stock one, both accepting a sale, and both writing zero. The final correctness depends on their interleaving, which is the race-condition mechanism captured most closely by C's unpredictable shared-resource access. Competing connections, multiple responders, or duplicate requests are not themselves sufficient; they become races only when shared-state correctness depends on timing.

Why each choice is right or wrong

A - Incorrect: Competition to establish a connection is not by itself a shared-state correctness failure caused by interleaving.

B - Incorrect: Several servers responding does not alone establish a race on shared mutable state.

C - Correct: This is the closest option: shared-state access can make correctness depend on the execution interleaving.

D - Incorrect: Duplicate requests can cause other problems, but duplication alone is not the defining race-condition mechanism.

Primary note proof

Study-note section WEB37

> Suppose two requests read a stock count1, both decide it is available and both write0: two sales consumed one item.

Study-note section WEB37

> Correctness depends on interleaving, even if each callback has only a short synchronous body.

Module passages - related reading

Computer Science MCQ practice collection · Question 118

Question 229 | AM0119

Which technique directly protects one shared-state critical section with an exclusive lock that does not rely on busy waiting? Choose the exclusive-lock primitive, rather than a bounded-access counter or a messaging design.

A. Mutex locks

B. Spinlocks

C. Semaphores

D. Message queues

Hint

Identify the shared-state invariant and the operations that must be coordinated.

Answer A: Mutex locks

A mutex directly protects a critical section by allowing only one holder at a time. The question distinguishes that exclusive-lock abstraction from spinlock busy waiting, semaphore bounded-access counting and message-queue designs. A semaphore can also enforce exclusion when configured suitably, but it is not the specific exclusive-lock primitive requested. Choosing a primitive does not by itself guarantee application correctness: every conflicting update must use the protected critical section.

Why each choice is right or wrong

A - Correct: A mutex is the requested exclusive-lock primitive.

B - Incorrect: A spinlock relies on busy waiting, which the stem excludes.

C - Incorrect: A semaphore is the bounded-access counter abstraction excluded by the requested category.

D - Incorrect: A message queue is a messaging design rather than the requested lock primitive.

Primary note proof

Study-note section WEB37

> A mutex protects one critical section; semaphores can coordinate bounded access; spinlocks busy-wait and are unsuitable for blocking a browser/event-loop thread.

Computer Science MCQ practice collection · Question 119

Question 230 | AM0120

In an asynchronous browser request, what is the response callback's role?

A. A function invoked by the browser runtime or API when the response becomes available

B. A function that is called by the client to request a specific operation from the server

C. A function that is called by the server to handle concurrent client requests

D. A function that is called by the client to synchronize with the server

Hint

Identify the execution side and communication pattern, keeping runtime, transport, data format and callback roles distinct.

Answer A: A function invoked by the browser runtime or API when the response becomes available

The callback is registered for later invocation by the browser runtime or API when the response becomes available. The remote server sends response data; it does not directly execute the browser function. A function that starts a request or a server request-handler function has a different role in the described interaction. The answer states both the owning execution environment and the event that causes invocation.

Why each choice is right or wrong

A - Correct: This states who invokes the browser response callback and when.

B - Incorrect: Starting a request is not the response callback's role.

C - Incorrect: A server request handler is a different callback in a different environment.

D - Incorrect: A callback need not perform client/server synchronization.

Primary note proof

Study-note section WEB34

A callback is a function invoked later by the runtime/API.

Study-note section WEB34

The browser invokes its response handler when the response is available; the remote server does not directly execute browser code.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 90 | lines 2-10

> 6.4 Handling Response from Server
> Before making a request to the server we have to write a callback function which will handle the response. But Because Ajax calls are asynchronous, we can't be sure when the response will come, so we must write code to wait for the response and handle it when it arrives. That is what the callback function is used for
> At this stage, we need to tell the XMLHttpRequest object which JavaScript function will handle the response, by setting the onreadystatechange property of the object and naming it after the function to call when the request changes state, like this:
> httpRequest.onreadystatechange = nameOfTheFunction;

Question 231 | AM0121

Which application-level protocol provides a persistent bidirectional message channel after its handshake?

A. HTTP

B. FTP

C. TCP/IP

D. WebSocket

Hint

Identify the execution side and communication pattern, keeping runtime, transport, data format and callback roles distinct.

Answer D: WebSocket

WebSocket establishes a persistent bidirectional channel on which either endpoint can exchange messages after the handshake. HTTP requests can also be issued asynchronously, but asynchronous programming alone does not supply this specific channel model. FTP has a different transfer role, and TCP/IP names lower-level networking foundations rather than the requested application protocol. The revised interaction requirement therefore distinguishes WebSocket without claiming it is the only way to avoid blocking a client.

Why each choice is right or wrong

A - Incorrect: Asynchronous HTTP requests do not by themselves define this persistent bidirectional message channel.

B - Incorrect: FTP is not the specified WebSocket-style application messaging protocol.

C - Incorrect: TCP/IP refers to lower-level networking rather than this application-level channel protocol.

D - Correct: WebSocket supplies the described persistent bidirectional channel.

Primary note proof

Study-note section WEB35

WebSocket establishes a persistent bidirectional message channel after its handshake.

Study-note section WEB35

Either HTTP-based AJAX or WebSockets can support nonblocking user interaction and carry JSON, so generic questions may be nonexclusive.

Study-note section WEB-S14

HTTP defines web application requests, response status codes and representations.

Study-note section WEB-S14

An HTTP exchange can use underlying TCP connections and IP addresses; naming that network stack does not identify the application-level method or status semantics.

Study-note section WEB-S14

FTP is a file-transfer application protocol.

Study-note section WEB-S14

SMTP transports electronic mail.

Web Programming module | PDF page 89 | lines 20-31

6.3 Sending Request to PHP server
XMLHttpRequest (XHR) is an API that can be used by JavaScript and other web browser scripting languages to transfer and manipulate XML data to and from a webserver using HTTP, establishing an independent connection channel between a webpage's Client-Side and Server-Side.
In order to make an HTTP request to the server with JavaScript, you need an instance of an XMLHttpRequest Object. We make a request to the sever, by calling the open() and send() methods of the HTTP request object, like this:
httpRequest.open('GET', 'http://www.example.org/some.file', true);
httpRequest.send();
open() takes three parameters, the first is the HTTP request method and the second is the URL. The optional third parameter sets whether the request is asynchronous.

Question sources

Computer Science MCQ practice collection · Question 121

Question 232 | AM0122

What is long polling in client-server communication?

A. A technique where the server continuously sends updates to the client

B. A technique where the client continuously sends requests to the server for updates

C. A technique where the server holds a request from the client until new data is available

D. A technique where the client holds a request from the server until new data is available

Hint

Identify the execution side and communication pattern, keeping runtime, transport, data format and callback roles distinct.

Answer C: The server holds a client request until data is available or timeout occurs.

WEB35 defines long polling as holding a client request until an event or timeout, returning a response, and then reconnecting from the client. C captures that defining held-request step. It is not continuous unsolicited streaming on a finished response, repeated short polling without a held request, or a reversed arrangement in which a client holds a server-originated request.

Why each choice is right or wrong

A - Incorrect: Continuous unsolicited server updates describe streaming-like behavior rather than the held-request long-polling cycle.

B - Incorrect: Repeated immediate polling requests describe short polling rather than holding each request until an event or timeout.

C - Correct: Holding the client's request until new data or timeout is the defining long-polling behavior.

D - Incorrect: This reverses the roles; the server holds a request initiated by the client.

Primary note proof

Study-note section WEB35

> Short polling repeatedly requests updates.

Study-note section WEB35

> Long polling holds one client request until an event or timeout, returns a response, then the client reconnects; it is not continuous unsolicited streaming on that same finished response.

> In order to make an HTTP request to the server with JavaScript, you need an instance of an XMLHttpRequest Object. We make a request to the sever, by calling the open() and send() methods of the HTTP request object, like this:
> httpRequest.open('GET', 'http://www.example.org/some.file', true);

httpRequest.send();
open() takes three parameters, the first is the HTTP request method and the second is the URL. The optional third parameter sets whether the request is asynchronous.

Web Programming module | PDF page 90 | lines 2-6

6.4 Handling Response from Server
Before making a request to the server we have to write a callback function which will handle the response. But Because Ajax calls are asynchronous, we can't be sure when the response will come, so we must write code to wait for the response and handle it when it arrives. That is what the callback function is used for

Question 233 | AM0124

Which programming language is commonly used for client-side scripting in web programming?

A. HTML

B. CSS

C. JavaScript

D. PHP

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer C: JavaScript

The JavaScript chapter identifies the browser behavior/scripting layer as JavaScript. HTML provides structure, CSS appearance and PHP server-side output. Evidence: PDF p. 44, PDF p. 60.

Why each choice is right or wrong

A - Incorrect: Markup rather than scripting.

B - Incorrect: Stylesheet rather than scripting.

C - Correct: Exact client scripting language.

D - Incorrect: Explicit server-side language.

Primary note proof

Study-note section WEB01

HTML supplies structure/meaning; CSS controls presentation; JavaScript supplies programmable interactivity.

Study-note section WEB01

PHP, Python, JSP/Java and ASP.NET applications generate server responses and access databases; C# is commonly used with ASP.NET.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 44 | lines 9-15

JavaScript is a scripting or programming language that allows us to implement complex features on web pages. JavaScript will enable us to display timely content updates, interactive maps, 2D/3D animated graphics etc. JavaScript is one of the three layers of web technologies which lets to add functionality to a web page. The three layers of web technologies are stacked together nicely, HTML will let's structure the webpage, CSS deals with the presentation of the web page and JavaScript the functionality.'

Web Programming module | PDF page 60 | lines 4-10

PHP is a server-side scripting language, which can be embedded in HTML or used as a standalone binary (although the former use is much more common). PHP stands for Hypertext Preprocessor. The product was originally named Personal Home Page Tools, and many people still think that is what the acronym stands for. But as it expanded in scope, a new and more appropriate name was selected by community vote. PHP is the language that you use to make the server generate dynamic output-output that is potentially different each time a browser re-quests a page.

Computer Science MCQ practice collection · Question 124

Question 234 | AM0125

Which protocol is commonly used for secure communication between a client and server?

A. HTTP

B. FTP

C. TCP/IP

D. HTTPS

Hint

Identify the protocol layer and the intended request, response or channel semantics.

Answer D: HTTPS

WEB05 defines HTTPS as HTTP over TLS with channel confidentiality, integrity, and certificate-based server authentication. It is the offered protocol for a protected web client/server exchange. Plain HTTP and the TCP/IP networking family do not supply those protections by themselves, and FTP is not the secure HTTP protocol being described. These protections do not replace application validation or authorization.

Why each choice is right or wrong

A - Incorrect: Plain HTTP lacks the TLS protections that distinguish secure web communication in WEB05.

B - Incorrect: FTP is not the HTTPS protocol identified for TLS-protected web exchanges.

C - Incorrect: TCP/IP supplies underlying networking rather than the specific protected HTTP channel requested.

D - Correct: HTTPS adds TLS confidentiality, integrity, and checked server identity to HTTP communication.

Primary note proof

Study-note section WEB05

> HTTPS uses HTTP over TLS, protecting channel confidentiality/integrity and authenticating the server under certificate checks.

Study-note section WEB-S14

> HTTP defines web application requests, response status codes and representations.

Study-note section WEB-S14

> An HTTP exchange can use underlying TCP connections and IP addresses; naming that network stack does not identify the application-level method or status semantics.

Study-note section WEB-S14

> FTP is a file-transfer application protocol.

Study-note section WEB-S14

> SMTP transports electronic mail.

> window.location.pathname returns the path and filename of the current page
> window.location.protocol returns the web protocol used (http: or https:)
> window.location.assign() loads a new document

Web Programming module | PDF page 8 | lines 29-34

• The World Wide Web (WWW) is most often called the Web.
• The Web is a network of computers all over the world.
• All the computers in the Web can communicate with each other.
• All the computers use a communication standard called HTTP.
How does the WWW work?
• Web information is stored in documents called Web pages.

Question sources

Computer Science MCQ practice collection · Question 125

Question 235 | AM0126

What is a load balancer in the context of client-server systems?

A. A device that balances the load between multiple clients

B. A device that balances the load between multiple servers

C. A device that balances the load between the client and server

D. A device that balances the load between different network protocols

Hint

Identify the execution side and communication pattern, keeping runtime, transport, data format and callback roles distinct.

Answer B: Distribute work across multiple server instances.

WEB36 says workers or processes and a load balancer distribute work across server instances. That directly supports B. The balancing target is the pool of servers handling incoming work, rather than clients, the two communication roles, or protocol types. The note also warns that distributing requests does not automatically coordinate shared data or session state.

Why each choice is right or wrong

A - Incorrect: The described load-balancing role distributes server work rather than balancing computational load among clients.

B - Correct: A load balancer distributes incoming work across multiple server instances.

C - Incorrect: It does not divide one application’s work equally between the abstract client and server roles.

D - Incorrect: Balancing among network protocol types is not the server-instance distribution role defined in WEB36.

Primary note proof

Study-note section WEB36

Workers/processes and a load balancer distribute work across server instances; they do not automatically coordinate shared data or session state.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 9 | lines 13-21

> Web hosting is the place where all the files of your website live. Web hosting is a service that allows organizations and individuals to post a website or a web page onto the Internet. A web host, or web hosting service provider, is a business that provides the technologies and services needed for the website or webpage to be viewed in the Internet. Websites are hosted, or stored, on special computers called servers. When Internet users want to view your website, all they need to do is type your website address or domain (the domain name for the site has to be registered) into their browser. Their computer will then connect to your server and your webpages will be delivered to them through the browser.

Web Programming module | PDF page 92 | lines 6-14

> b. Node.js

> 2. Uses plain old JavaScript
> 3. Thousands of reusable packages
> 4. Portable

Question sources

Computer Science MCQ practice collection · Question 126

Question 236 | AM0127

Which browser-stored mechanism normally carries an opaque session identifier automatically on matching requests, without adding that token to each URL?

A. Cookies

B. HTML forms

C. URL parameters

D. Server-side caching

Hint

Follow the identifier and server-side state through the stated lifecycle or access check; distinguish client-controlled claims from server decisions.

Answer A: Cookies

A cookie stores browser-side name/value data and is automatically attached to requests that match its scope and security rules. It can carry the opaque identifier used to find server-side session state. Forms or URL parameters can explicitly transmit identifiers, but do not provide the automatic matching-request behavior specified. Server-side caching stores server data rather than supplying this browser identifier carrier.

Why each choice is right or wrong

A - Correct: A matching cookie is automatically attached to requests and can carry the opaque session identifier.

B - Incorrect: A form submits explicit values when submitted, rather than automatically attaching stored data to all matching requests.

C - Incorrect: A URL parameter must be included in a URL; the scenario explicitly keeps the token out of URLs.

D - Incorrect: Server caching concerns retained server-side data, not the browser mechanism that automatically carries the identifier.

Primary note proof

Study-note section WEB28

> Cookies are browser-held name/value data automatically attached to matching requests subject to domain, path, expiry, Secure and SameSite rules.

Study-note section WEB29

> Normally the browser holds an opaque session identifier while data resides in server-controlled storage.

Study-note section WEB29

> Protect session IDs, regenerate after login, expire appropriately and avoid putting sensitive tokens in URLs.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 58 | lines 14-23

> Cookies are data, stored in small text files, on your computer.
> When a web server has sent a web page to a browser, the connection is shut down,
> and the server forgets everything about the user. Cookies were invented to solve the
> problem "how to remember information about the user":
> When a user visits a web page, his/her name can be stored in a cookie.
> Next time the user visits the page, the cookie "remembers" his/her name.
> Cookies are saved in name-value pairs like:
> When a browser requests a web page from a server, cookies belonging to the page
> are added to the request. This way the server gets the necessary data to "remember"
> information about users.

Web Programming module | PDF page 77 | lines 17-21

> What is a Cookie?
> A cookie is often used to identify a user. A cookie is a small file that the server embeds on the user's computer. Each time the same computer requests a page with a browser, it will send the cookie too. With PHP, you can both create and retrieve cookie values.

Web Programming module | PDF page 76 | lines 2-5

> in one application. A PHP session allows you to store user information on the server for later use (i.e., username, shopping items, etc.). However, session information is temporary and will be deleted after the user has left the website. If you need a permanent storage you may want to store the data in a database.

Computer Science MCQ practice collection · Question 127

Question 237 | AM0128

What is AJAX in web programming?

A. A programming language for server-side scripting

B. A database management system

C. A technique for asynchronous client-server communication

D. A web server software

Hint

Identify the execution side and communication pattern, keeping runtime, transport, data format and callback roles distinct.

Answer C: A technique for asynchronous client-server communication

AJAX is a web-development technique with asynchronous server communication and page updates without refresh. It combines technologies instead of being a server language, database system or server software. Evidence: PDF p. 89.

Why each choice is right or wrong

A - Incorrect: Not the module classification.

B - Incorrect: Not the module classification.

C - Correct: Exact asynchronous communication technique.

D - Incorrect: Not the module classification.

Primary note proof

Study-note section WEB34

> AJAX means Asynchronous JavaScript and XML, but responses can be JSON, text, HTML or XML.

Study-note section WEB34

It is a technique, not a language, standalone framework or mandatory XML protocol.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 89 | lines 4-13

AJAX is a web development technique for creating interactive web applications.
AJAX stands for Asynchronous JavaScript and XML. It can send and receive information in various formats, including JSON, XML, HTML, and text files. AJAX is a new technique for creating better, faster, and more interactive web applications with the help of XML, HTML, CSS, and Java Script. AJAX's most appealing characteristic is its "asynchronous" nature, which means it can communicate with the server, exchange data, and update the page without having to refresh the page.
The two major features of AJAX allow you to do the following:
- Make requests to the server without reloading the page
- Receive and work with data from the server

Computer Science MCQ practice collection · Question 128

Question 238 | AM0129

What is a RESTful API?

A. An API that supports real-time communication between client and server

B. An API that uses the REST architectural style for client-server communication

C. An API that only supports server-to-server communication

D. An API that is used for database management

Hint

Identify the protocol layer and the intended request, response or channel semantics.

Answer B: An API following the REST architectural style.

WEB05 describes REST through client/server separation, stateless requests, cacheability, and a uniform resource interface. B is the definition matching those architectural constraints. Real-time delivery is not required, server-to-server-only use is not a REST limitation, and database management is only a possible implementation domain. Returning JSON alone also does not establish REST.

Why each choice is right or wrong

A - Incorrect: Real-time communication is not the defining constraint or requirement of a RESTful API.

B - Correct: Following REST architectural constraints is what makes an API RESTful.

C - Incorrect: REST is not restricted to server-to-server communication; browsers can access resource interfaces too.

D - Incorrect: Database management is one possible domain, not the architectural definition of REST.

Primary note proof

Study-note section WEB05

> A RESTful API follows constraints such as client/server separation, stateless requests, cacheability and a uniform resource interface.

Study-note section WEB05

> Resources have identifiers and representations; JSON is common but not required.

Module passages - related reading

Question 239 | AM0130

What is server-side caching in client-server systems?

A. A technique to store client-side data on the server

B. A technique to store server-side data on the client

C. A technique to store frequently accessed server-side data in memory for faster retrieval

D. A technique to store client and server data in a separate cache server

Hint

Distinguish the purpose of each development or performance technique from its possible side effects.

Answer C: Retain frequently accessed server-side results for faster reuse.

WEB39 describes caching as reusing a representation or result and explicitly gives server caching of rendered pages or expensive query results. C matches that faster-retrieval purpose. The cache need not be a separate server, and merely transferring client data to a server or server data to a client is not the defining reuse mechanism. Validity, privacy, and cache keys still matter.

Why each choice is right or wrong

A - Incorrect: Storing client-originated data on a server does not by itself establish result reuse or caching.

B - Incorrect: Placing server data on a client describes client-side storage rather than server-side caching.

C - Correct: Retaining frequently reused server-side results avoids repeated work and accelerates later retrieval.

D - Incorrect: A separate cache server is optional; the defining property is reusable results, not a mandatory deployment topology.

Primary note proof

Study-note section WEB39

> Caching reuses a representation/result and requires validity/invalidation rules.

Study-note section WEB39

> Server caching can hold rendered pages or expensive query results; never share private user content under an unsafe common key.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 45 | lines 28-31

> As a rule, only the simplest scripts are put into HTML. More complex ones reside in separate files.
> The benefit of a separate file is that the browser will download it and store it in its cache.

Web Programming module | PDF page 76 | lines 2-5

> in one application. A PHP session allows you to store user information on the server for later use (i.e., username, shopping items, etc.). Question sources

Computer Science MCQ practice collection · Question 130

Question 240 | CS0032

Which form METHOD value normally places submitted name/value pairs in the request body rather than the URL query?

A. GET

B. INPUT

C. ACTION

D. POST

Hint

Separate the control role, displayed content, submitted value and form destination.

Answer D: POST

For ordinary HTML forms, GET usually puts successful name/value pairs in the URL query, while POST places form data in the request body. METHOD does not specify an element-at-a-time parser; parsing depends on encoding and the receiving implementation. INPUT is a control element name and ACTION is a form attribute, so neither is a method value. The corrected question tests the supported form-submission distinction rather than the unsupported parsing premise.

Why each choice is right or wrong

A - Incorrect: GET normally places the pairs in the URL query.

B - Incorrect: INPUT names a control element rather than a METHOD value.

C - Incorrect: ACTION identifies a separate form attribute rather than a METHOD value.

D - Correct: POST normally puts submitted form data in the request body.

Primary note proof

Study-note section WEB04

> GET forms usually put name/value pairs in the URL query; POST forms put them in the body.

Study-note section WEB09

> A form’s action identifies its processing URL, method its submission method, and enctype its encoding.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 21 | lines 23-31

Form attributes:
- action → Backend script ready to process the data collected
- method → method used to upload Data. The most frequently used
- target → Specify the target window or frame where the result of the script will be displayed. It takes values like _blank, _self, _parent etc.
- enctype → tells how the browser encodes data. Possible values
1. application/x-www-form-urlencoded → most common and used from simple scenarios
2. mutlipart/form-data → used to upload binary data

Web Programming module | PDF page 73 | lines 11-16

• $_GET[]: It is used the retrieve the information from the form control through the parameters sent in the URL. It takes the attribute given in the url as the parameter.
• $_POST[]: It is used the retrieve the information from the form control through the HTTP POST method. IT takes name attribute of corresponding form control as the parameter.

Question sources

Computer Science Exit Exam practice collection · Question 32

Question 241 | CS0033

Which claim is false about HTML as an open-standard text markup format?

A. It supports interoperability, though feature support varies across platforms and browsers

B. Its text can be transmitted over a network as a web representation

C. Its source represents document structure using text markup rather than requiring a fixed small file size

D. Because it is proprietary technology

Hint

Use the element or attribute meaning and document structure, rather than appearance or a similar-looking name.

Answer D: Because it is proprietary technology

HTML supplies document structure in a text markup representation within the open Web standards setting. That supports interoperability but does not guarantee identical feature support in every browser, a tiny document size or a fixed transfer speed. The alternatives remove those universal promises. Calling HTML proprietary contradicts the stated open-standard setting, while the other choices now make qualified claims about its representation and delivery.

Why each choice is right or wrong

A - Incorrect: Qualified interoperability is consistent with differing feature support.

B - Incorrect: A web representation can transmit HTML text without promising a fixed speed.

C - Incorrect: Text markup expresses structure without guaranteeing a small size.

D - Correct: The proprietary characterization conflicts with the open-standard setting.

Primary note proof

Study-note section WEB02

> Open standards do not guarantee identical support for every feature in every browser.

Study-note section WEB06

> HTML means HyperText Markup Language.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Web Programming module | PDF page 10 | lines 17-26

> HTML has been in use by the World-Wide Web (WWW) global information initiative since 1990. It is a simple markup language used to create hypertext documents that are platform independent. HTML markup can represent hypertext news, mail, documentations, and hyper media; menus of options; database query results;
> This document covers html versions ranging from 2 up to 5
> HTML is composed of several tags. HTML Document:-
> - A text document containing markup tags
> - The tags tell the browser how to display the document
> - Should have an .htm or .html file name extension
> - Can be created using a simple text editor

Question sources

Computer Science Exit Exam practice collection · Question 33

Question 242 | CS0034

What is the output of the following JavaScript fragment? for (n = 1; n < 7; n++) { if (n % 5 == 0) { document.write(n + " is multiple of 5"); } }

A. 5 is multiple of 5

B. 1 2 3 4 5 is multiple of 5 6

C. 5 is multiple of 5 6 7

D. 1 2 3 4 5 6

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer A: 5 is multiple of 5

The loop starts at 1 and visits integers 1 through 6 because n<7 excludes 7. The p.49 arithmetic table shows % as remainder, including 8%3=2. Among these values only 5 has remainder zero on division by 5, so the conditional writes once: 5 is multiple of 5. This uses the conventional n++ loop step; the module shows for begin/condition/step but does not separately define postfix value semantics, which are immaterial because the step value is discarded. Evidence: PDF p. 49, PDF p. 49, PDF p. 50, PDF p. 47.

Why each choice is right or wrong

A - Correct: Exactly the single matching value 5.

B - Incorrect: Prints values outside the if branch; no unconditional write exists.

C - Incorrect: Adds 6 and 7 even though 6 fails and 7 is excluded.

D - Incorrect: Ignores the conditional and omits the literal message.

Primary note proof

Study-note section WEB19

> for(initialization;test;update) initializes once, checks before each iteration, then updates after each body.

Study-note section WEB-S13

> For nonnegative integers n and positive d, n % d gives the remainder after division; zero tests divisibility.

3. The write() method
- The write() method writes HTML expressions or JavaScript code to a document.
- The write() method is mostly used for testing: If it is used after an HTML document is fully loaded, it will delete all existing HTML.
Usage:
document.write(expr)

Question sources

Computer Science Exit Exam practice collection · Question 34

Question 243 | CS0035

In an ordinary browser page, which statements about document.write("Hello World") are true? Classify properties and values inclusively: a method is also a function-valued property. Select all that apply.

A. write is a property

B. write is a method

C. document is a property

D. write is an object

Hint

Track the value and type at each operation, applying the stated conversion, indexing or mathematical rule.

Answer A, B, C, D: write is a property; write is a method; document is a property; write is an object

document.write is a method and also a function-valued property of document. In a normal browser page, document is exposed as a property of window. Functions are objects in JavaScript, so the write function value is also an object. These descriptions are compatible views of the same expression rather than mutually exclusive categories. All four statements are therefore true under the explicit inclusive-classification convention.

Why each choice is right or wrong

A - Correct: write is a function-valued property of document.

B - Correct: Calling that function through document is a method invocation.

C - Correct: document is the browsing context’s document property.

D - Correct: The write function value is an object because JavaScript functions are objects.

Primary note proof

Study-note section WEB22

> In a normal browser page, window exposes the browsing context and document is its document property.

Study-note section WEB22

> document.write is a method/function property; writing after document load can replace the document.

Study-note section WEB16

> JavaScript primitives are undefined, null, Boolean, Number, BigInt, String and Symbol; objects include arrays, functions and dates.

Web Programming module | PDF page 56 | lines 17-25

> All global JavaScript objects, functions, and variables automatically become members of the window object.
> Global variables are properties of the window object
> Global functions are methods of the window object.
> Even the document object (of the HTML DOM) is a property of the window object:
> window.document.getElementById("header");
> is the same as:
> document.getElementById("header");

Question sources

Computer Science Exit Exam practice collection · Question 35

Question 244 | NS0284

Consider
nav ul {
list-style-type: none;
margin: 0;
padding: 0;
}
What problem does this solve when creating a navigation bar?

A. Removes bullet points and default spacing, allowing custom layout

B. Aligns the navbar to the right of the page

C. Adds hover effects to list items

D. Converts the list into a dropdown menu

Hint

Use the element or attribute meaning and document structure, rather than appearance or a similar-looking name.

Answer A: Remove list bullets and default margin/padding.

This rule resets navigation-list styling. list-style-type:none removes markers, and zero margin/padding removes default list spacing. None of those declarations specifies alignment, hover styling, or dropdown behavior. Thus A describes the actual effect, leaving layout and interaction to additional rules.

Why each choice is right or wrong

A - Correct: These declarations remove markers and default spacing so later layout rules can start from a clean list.

B - Incorrect: No text alignment, flex justification, or positioning rule aligns the navbar right.

C - Incorrect: No :hover selector or hover-specific declaration is present.

D - Incorrect: A dropdown needs additional layout and interaction rules, not just this reset.

Primary note proof

Study-note section WEB08

> Resetting nav ul with list-style-type:none; margin:0; padding:0 removes bullets and default spacing only; it does not itself arrange links horizontally or create a dropdown.

Question sources

Computer Science Exit Exam · 2018 · Question 1

Question 245 | NS0311

Which PHP superglobal is dedicated to URL query parameters, excluding configurable combined-source arrays?

A. $_REQUEST

B. $_POST

C. $_GET

D. isset()

Hint

Identify the data source or security responsibility precisely, and check whether a combined source or a different control could also qualify.

Answer C: $_GET

$_GET is the dedicated query-parameter source. $_REQUEST can also contain GET values depending on configuration, but it is a combined-source array and is explicitly excluded by this question. $_POST represents supported form POST data, while isset tests existence and non-null rather than acting as an input-data container. Removing placeholder brackets makes the array names clear without inventing a particular field name or request value.

Why each choice is right or wrong

A - Incorrect: This combines configured request sources rather than being dedicated to query parameters.

B - Incorrect: This is the supported form POST source.

C - Correct: This is the dedicated URL-query source.

D - Incorrect: This tests whether a variable or entry exists and is non-null.

Primary note proof

Study-note section WEB27

> $_GET contains query parameters; $_POST contains supported form POST data; $_FILES upload metadata; $_SERVER request/environment details; $_COOKIE cookie values; $_SESSION session data after startup.

Study-note section WEB27

> $_REQUEST may combine GET/POST/cookie data according to configuration; it is not a database interface and has ambiguous precedence, so prefer the intended source.

Study-note section WEB27

> isset tests existence and non-null, not truth or valid syntax.

Question sources

Computer Science Exit Exam · 2018 · Question 32

Question 246 | NS0332

_____is a service that allows organizations and individuals to post a website or a web page onto the Internet.

A. Web hosting

B. Internet service provider

C. Web client

D. Domain name registration

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer A: Web hosting

WEB02 defines hosting as supplying the environment where a website is served. This is the service enabling an organization’s site or page to be made available online. An ISP supplies connectivity, domain registration reserves a name, and a web client requests resources. Those supporting roles are not the hosting service described.

Why each choice is right or wrong

A - Correct: Hosting supplies an environment in which the site is served to users.

B - Incorrect: An ISP provides connectivity rather than necessarily the environment serving the website.

C - Incorrect: A web client requests resources instead of providing the publishing environment.

D - Incorrect: Domain registration reserves a name rather than serving the site’s content.

Primary note proof

Study-note section WEB02

> Hosting supplies an environment where a site is served; domain registration reserves a name, and DNS maps names to network records.

Study-note section WEB02

> An ISP provides connectivity.

Question sources

Computer Science Exit Exam · 2018 · Question 59

Question 247 | NS0340

Which protocol is mostly used for communication between client and server in a web application?

A. FTP

B. SMTP

C. HTTP

D. SSH

Hint

Identify the protocol layer and the intended request, response or channel semantics.

Answer C: HTTP

WEB01 describes the Web as a resource system commonly using HTTP, and WEB03 details its request/response exchange. HTTPS adds TLS protection to HTTP but does not make one of the other offered protocols the ordinary web exchange. Among these choices, HTTP is the application protocol used to request and return web resources.

Why each choice is right or wrong

A - Incorrect: FTP is not the HTTP request/response web protocol described in the note.

B - Incorrect: SMTP is not the webpage request/response protocol developed in WEB03.

C - Correct: HTTP carries the web resource requests and responses described in the complete note.

D - Incorrect: SSH is not the ordinary webpage request/response protocol identified here.

Primary note proof

Study-note section WEB01

> The Internet connects networks; the Web is a resource system commonly using HTTP.

Study-note section WEB03

> An HTTP/1.1 request begins with method, request-target and version, followed by header fields, a blank line, and an optional body.

Study-note section WEB-S14

> HTTP defines web application requests, response status codes and representations.

Study-note section WEB-S14

> An HTTP exchange can use underlying TCP connections and IP addresses; naming that network stack does not identify the application-level method or status semantics.

Study-note section WEB-S14

> FTP is a file-transfer application protocol.

Study-note section WEB-S14

SMTP transports electronic mail.

Question sources

Computer Science Exit Exam · 2018 · Question 71

Question 248 | NS0342

What is the extension of JavaScript file?

A. .javaS

B. .JS

C. .java

D. CSS

Hint

Check exact language syntax, declaration rules and execution context before reasoning about the result.

Answer B: .js is the conventional JavaScript source extension.

WEB15 uses an external app.js script and explicitly calls it a .js file. B identifies that extension family despite its uppercase printed letters. Actual filename case must match the deployed resource where paths are case-sensitive; the conventional spelling is lowercase .js. The other choices name different or invented file extensions rather than JavaScript source.

Why each choice is right or wrong

A - Incorrect: The invented .javaS suffix is not the conventional .js extension specified by WEB15.

B - Correct: This identifies the JS extension; use conventional lowercase .js and preserve actual filename case in paths.

C - Incorrect: .java is not the .js source-file extension used for JavaScript in the note.

D - Incorrect: CSS identifies stylesheet source rather than the JavaScript file extension.

Primary note proof

Study-note section WEB15

> Use <script src="app.js"></script> for an external .js file; script content has no HTML closing-tag syntax inside its JavaScript source.

Study-note section WEB15

> JavaScript originated at Netscape; it is distinct from Java and supports sophisticated applications through prototype-based objects and first-class functions.

Question sources

Computer Science Exit Exam · 2018 · Question 73

Question 249 | NS0355

A web application has two protected endpoints. The profile endpoint checks a valid session identifier and its server-side user record on every request. The transfer endpoint grants access whenever the editable logged_in cookie equals 1 and ignores session validation. An unauthenticated attacker has no valid session and sets logged_in=1. Which result follows from these access checks?

A. The cookie edit can bypass the transfer endpoint, but does not grant access to the profile endpoint

B. The cookie edit grants access to both endpoints because both receive the same cookie

C. Neither endpoint can be bypassed unless the attacker first obtains a genuine session identifier

D. HTTPS alone prevents either endpoint from accepting a forged logged_in value

Hint

Follow the identifier and server-side state through the stated lifecycle or access check; distinguish client-controlled claims from server decisions.

Answer A: The cookie edit can bypass the transfer endpoint, but does not grant access to the profile endpoint

The two endpoints use different trust paths. The transfer endpoint trusts an attacker-controlled flag, so the forged value satisfies its stated access check without a valid session. The profile endpoint requires authenticated server-side state, which the attacker lacks, so the unrelated cookie does not grant access there. HTTPS protects transport rather than validating the truth of a client-generated login claim. The bypass therefore affects the transfer endpoint only.

Why each choice is right or wrong

A - Correct: Only the transfer endpoint relies solely on the forgeable flag; the profile endpoint still requires a valid session.

B - Incorrect: Receiving the same cookie does not make the endpoints apply the same authorization rule.

C - Incorrect: The transfer check requires no genuine session identifier, so stealing one is unnecessary for that bypass.

D - Incorrect: HTTPS does not prevent a client from submitting a false authorization flag.

Primary note proof

Study-note section WEB29

> A client cookie logged_in=1 is attacker-controlled.

Study-note section WEB29

> If the server trusts it alone, authorization can be bypassed.

Study-note section WEB29

If the server checks a valid session ID and its server-side user/role on every protected action, editing that unrelated flag does not grant rights.

Study-note section WEB29

HTTPS does not make client-generated claims trustworthy.

Question sources

Computer Science Exit Exam · 2018 · Question 93

Question 250 | NS0360

Why should form <input> elements include an associated <label> with the for attribute?

A. It enables offline form storage

B. It encrypts user data

C. It increases form submission speed

D. It improves accessibility: screen readers announce the label when the input is focused

Hint

Separate the control role, displayed content, submitted value and form destination.

Answer D: Provide an accessible label associated with the input.

WEB09 links a label's for to the control id, and WEB07 requires programmatic control labels. That association lets assistive technology identify the input and announce its label. It does not alter storage, encryption, or network submission speed. D states the accessibility purpose directly, rather than confusing it with unrelated browser or transport features.

Why each choice is right or wrong

A - Incorrect: Label association does not create offline storage for form values.

B - Incorrect: Labels do not encrypt data or replace HTTPS transport protection.

C - Incorrect: Associating a label does not accelerate form submission over the network.

D - Correct: The programmatic label identifies the focused input for screen readers and other assistive technology.

Primary note proof

Study-note section WEB09

> A label's for matches the control's id; name identifies its submitted field.

Study-note section WEB07

> Give controls programmatic labels, clear link text and keyboard access; visual styling alone does not establish accessibility.

Question sources

Computer Science Exit Exam · 2018 · Question 99

Question 251 | NS0795

What is the difference between GET and POST methods? When would you use each?

Hint

Identify the protocol layer and the intended request, response or channel semantics.

Answer: GET retrieves safely and usually places form values in the query; POST asks the target to process body content.

WEB04 recommends GET for reading representations rather than intentional state changes. POST suits submitted processing or actions such as enrollment with proper authorization and CSRF controls. Neither method encrypts data; use HTTPS for channel protection. POST body values remain visible to tools and subject to configured size limits rather than becoming secret or unlimited.

Primary note proof

Study-note section WEB04

> GET retrieves a representation with safe semantics; do not implement an intentional state-changing action as a GET link.

Study-note section WEB04

> POST asks the target to process supplied content.

Study-note section WEB04

> GET forms usually put name/value pairs in the URL query; POST forms put them in the body.

Study-note section WEB40

> For an enrollment action use POST with CSRF controls, server authorization, capacity checks and a transaction; show success only after commit.

Question sources

Web Programming review questions · Question 1

Question 252 | NS0796

Why is client-side validation alone not enough for security?

Hint

Separate event dispatch, handler registration and cancellation of the browser default action.

Answer: Clients can bypass or alter browser checks, so the server must validate and authorize again.

WEB27 requires server checks for required fields, type, length, and range, plus authentication and authorization before processing. Browser validation improves feedback but arbitrary clients can submit different requests. Bind SQL values and encode output for its context as well; encryption or merely connecting to a database does not replace these application controls.

Primary note proof

Study-note section WEB27

> Read input, check required fields/type/length/range, authenticate and authorize, then process.

Study-note section WEB27

> Bind SQL parameters to keep values separate from commands.

Study-note section WEB27

> Encode output for HTML/attribute/JS context; textContent handles plain browser text.

Study-note section WEB21

> Browser checks improve feedback; repeat validation and authorization on the server.

Question sources

Web Programming review questions · Question 2

Question 253 | NS0797

What is the DOM and why is it important for web development?

Hint

Track which node is selected or created, and distinguish changing content from attaching a node.

Answer: The DOM is the document's node hierarchy, enabling scripts to inspect and update page content and behavior.

WEB20 selects nodes, creates elements, and attaches them to that hierarchy. Creating a node does not itself insert it, and missing lookups must be guarded. textContent safely inserts untrusted plain text, whereas innerHTML reparses markup and can replace descendant state. The DOM connects document structure to interactive browser updates.

Primary note proof

Study-note section WEB20

> The DOM is a hierarchy of nodes representing the document.

Study-note section WEB20

> Creation alone does not insert it.

Study-note section WEB20

> innerHTML parses/replaces descendants, so += reparses/replaces the prior descendant content too and can destroy listeners/state.

Study-note section WEB20

> Use textContent for untrusted plain text.

Question sources

Web Programming review questions · Question 3

Question 254 | NS0798

A user closes their browser and reopens it. They are still logged in. How is this possible?

Hint

Follow the identifier and server-side state through the stated lifecycle or access check; distinguish client-controlled claims from server decisions.

Answer: A persistent remember/session token or browser restoration can preserve the login flow.

WEB28 says reopening while logged in may use persistent session or remember tokens or browser restoration. The browser can retain an identifier, but the server still has to accept and validate it against its authorization state. Local persistence alone is not proof of authenticated access, and the observation does not identify one unique storage mechanism.

Primary note proof

Study-note section WEB28

> Being logged in after reopening may use a persistent session/remember token or browser restoration; storage alone does not prove server acceptance.

Study-note section WEB29

> If the server checks a valid session ID and its server-side user/role on every protected action, editing that unrelated flag does not grant rights.

Question sources

Web Programming review questions · Question 4

Question 255 | NS0799

Why would a developer choose local storage over cookies?

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer: localStorage persists origin data without automatically attaching it to every matching request.

WEB28 contrasts localStorage's persistent strings with cookies' automatic request transmission. It can avoid transmitting data needed only by the client. JavaScript can still send stored tokens explicitly, so localStorage is not inherently incapable of session designs. Script-access risks and persistence policies must be considered; neither mechanism is universally preferable for sensitive authentication data.

Primary note proof

Study-note section WEB28

> localStorage persists origin-specific string values across sessions until removed/cleared; sessionStorage is scoped to a page session/tab.

Study-note section WEB28

> Neither is automatically transmitted like matching cookies, but JavaScript can send stored data explicitly.

Study-note section WEB28

> Thus all four are client storage techniques, and localStorage can participate in token-based session designs, with script-access risks.

Question sources

Web Programming review questions · Question 5

Question 256 | NS0800

What does HTML stand for?

A. Hyper Text Markup Language

B. High Tech Modern Language

C. Hyper Transfer Markup Language

D. Home Tool Markup Language

Hint

Use the element or attribute meaning and document structure, rather than appearance or a similar-looking name.

Answer A: HyperText Markup Language

WEB06 directly expands HTML as HyperText Markup Language. The name identifies markup used for document structure and meaning rather than a general programming or transfer protocol. The other phrases substitute different words and are not the expansion in the note. This vocabulary answer does not depend on a browser version or an implementation choice.

Why each choice is right or wrong

A - Correct: Hyper Text Markup Language matches the note's expansion, with only spacing variation in HyperText.

B - Incorrect: High Tech Modern Language is not the expansion given in WEB06.

C - Incorrect: Transfer replaces the required word Text and gives the wrong expansion.

D - Incorrect: Home Tool Markup Language is not the HTML expansion in the note.

Primary note proof

Study-note section WEB06

> HTML means HyperText Markup Language.

Question sources

Web Programming review questions · Question 1

Question 257 | NS0801

Which HTML tag creates a hyperlink?

A. <link>

B. <href>

C. <a>

D. <url>

Hint

Identify which elements a rule targets and distinguish selector syntax from declaration syntax.

Answer C: <a> with an href destination.

WEB07 gives Read as the link pattern. The anchor element creates the user-facing hyperlink; href is its destination attribute, not a standalone tag. link is used for relationships such as external stylesheets, and url is not the anchor element. Thus C names the correct element among the supplied choices.

Why each choice is right or wrong

A - Incorrect: link is used for resource relationships such as external stylesheets rather than the shown user-facing anchor.

B - Incorrect: href is an attribute on an anchor, not the hyperlink element itself.

C - Correct: The anchor element with href creates the hyperlink described in WEB07.

D - Incorrect: url is not the supported HTML anchor tag.

Primary note proof

Study-note section WEB07

> Use Read for a link; href is the destination, not url/link.

Study-note section WEB11

> An external sheet uses <link rel="stylesheet" href="styles.css"> in head; an internal sheet uses style; an inline declaration uses an element’s style attribute.

Question sources

Web Programming review questions · Question 2

Question 258 | NS0802

What is the correct HTML tag for inserting a line break?

A. <break>

B. <lb>

C.

D. <newline>

Hint

Use the element or attribute meaning and document structure, rather than appearance or a similar-looking name.

Answer C:

 creates a line break, <p> defines a paragraph, and <hr> represents a thematic break. C is the defined break element; the other options invent element names not defined as HTML elements. A line break is an HTML structure operation rather than a requirement to insert a physical newline into the source file.

Why each choice is right or wrong

A - Incorrect: break is not the HTML line-break element defined in WEB06.

B - Incorrect: lb is not the supported line-break element spelling.

C - Correct: br is explicitly the HTML line-break element.

D - Incorrect: newline is not the HTML line-break element defined in the note.

Primary note proof

Study-note section WEB06

> <p> marks paragraphs;
 is a line break and <hr> a thematic break.

Question sources

Web Programming review questions · Question 3

Question 259 | NS0803

Which tag preserves whitespace and line breaks exactly as written?

A. <p>

B. <pre>

C. <code>

D.

Hint

Use the element or attribute meaning and document structure, rather than appearance or a similar-looking name.

Answer B: <pre>

WEB06 gives <pre> the whitespace-preservation role. It is therefore the appropriate element for text whose source spaces and line breaks should be retained. code marks code semantics but does not itself guarantee preformatted whitespace, while paragraph and emphasis elements have other meanings. Custom CSS can alter defaults, but the question concerns the native tag role.

Why each choice is right or wrong

A - Incorrect: A paragraph does not itself preserve all source spacing and line breaks.

B - Correct: pre is the element explicitly defined to preserve source whitespace.

C - Incorrect: code marks code semantics; preformatted whitespace preservation is a separate role.

D - Incorrect: em expresses stress emphasis rather than preformatted source layout.

Primary note proof

Study-note section WEB06

> <pre> preserves source whitespace; <code> marks code.

Study-note section WEB06

> indicates importance and stress; <b>/<i> have other text semantics and are not identical to importance/emphasis.

Question sources

Web Programming review questions · Question 4

Question 260 | NS0804

What is the highest-level heading tag in HTML?

A. <h6>

B. <heading>

C. <h0>

D. <h1>

Hint

Use the element or attribute meaning and document structure, rather than appearance or a similar-looking name.

Answer D: <h1>

WEB06 defines heading levels h1 through h6 as a hierarchy. h1 is the highest level and h6 the lowest, regardless of CSS choices that can change their visual size. heading and h0 are not the defined heading-level tags. The answer is semantic rank, not whichever text happens to be styled largest.

Why each choice is right or wrong

A - Incorrect: h6 is the lowest of the defined heading levels, not the highest.

B - Incorrect: heading is not one of the defined h1-h6 heading-level tags.

C - Incorrect: h0 is outside the defined heading levels in WEB06.

D - Correct: h1 is the highest semantic heading level in the h1-h6 hierarchy.

Primary note proof

Study-note section WEB06

> Heading levels h1-h6 express hierarchy, with h6 conventionally smallest in default styling, not a mandatory CSS size.

Question sources

Web Programming review questions · Question 5

Question 261 | NS0805

Which element is the root element of an HTML page?

A. <head>

B. <body>

C. <html>

D. <root>

Hint

Use the element or attribute meaning and document structure, rather than appearance or a similar-looking name.

Answer C: <html>

WEB06 explicitly identifies html as the document root, with head holding metadata and body containing document content. Those two elements are inside the document rather than replacing its root. root is not the HTML tag used for this role. Thus the root-element question directly selects C.

Why each choice is right or wrong

A - Incorrect: head holds metadata and is not the document root.

B - Incorrect: body holds document content but is not the document's root element.

C - Correct: html is explicitly defined as the document root in WEB06.

D - Incorrect: root is not the HTML root tag given here.

Primary note proof

Study-note section WEB06

> <!DOCTYPE html> selects modern standards mode; <html> is the document root, <head> holds metadata, and <body> contains document content.

Question sources

Web Programming review questions · Question 6

Question 262 | NS0806

Which attribute provides alternative text for an image?

A. title

B. src

C. alt

D. caption

Hint

Use the element or attribute meaning and document structure, rather than appearance or a similar-looking name.

Answer C: alt

WEB07 gives img a src for its resource and alt for alternative text. Informative images need meaningful alternatives; decorative ones use empty alt. A title is not a replacement for alt, and a caption is separate visible context rather than the requested attribute. Therefore C names the accessibility text attribute.

Why each choice is right or wrong

A - Incorrect: title is not a replacement for the image’s alternative-text attribute.

B - Incorrect: src identifies the image resource rather than its alternative text.

C - Correct: alt supplies the image’s alternative text, or an empty value for purely decorative images.

D - Incorrect: caption is not the requested image alternative-text attribute.

Primary note proof

Study-note section WEB07

> <img src="photo.jpg" alt="Students in a lab"> supplies source and alternative text.

Study-note section WEB07

> Use empty alt for purely decorative images; informative images need meaningful alternatives.

Study-note section WEB07

> Width/height reserve dimensions; title is not a replacement for alt.

Question sources

Web Programming review questions · Question 7

Question 263 | NS0807

What does target="_blank" do in a link?

A. Opens the link in the same window

B. Opens the link in a new tab or window

C. Closes the current window

D. Opens the link in a parent frame

Hint

Use the element or attribute meaning and document structure, rather than appearance or a similar-looking name.

Answer B: Open a new browsing context, commonly a new tab or window.

WEB07 maps _blank to a new context, _self to current, and _parent to parent. Browser preferences decide tab versus window, so B correctly allows either. The target does not close the current window or select the parent frame. This is a browsing-context request rather than a guaranteed window-management UI behavior.

Why each choice is right or wrong

A - Incorrect: The current context is selected by _self rather than _blank.

B - Correct: _blank requests a new context, with tab versus window determined by browser behavior.

C - Incorrect: The target does not request that the current window be closed.

D - Incorrect: The parent context is selected by _parent rather than _blank.

Primary note proof

Study-note section WEB07

> target="_self" uses the current context, _blank a new context, _parent its parent and _top the top-level context.

Study-note section WEB07

> Browser preferences determine tab versus window.

Question sources

Web Programming review questions · Question 8

Question 264 | NS0808

Which HTML tag is used for an unordered list?

A.

B.

C.

D. <list>

Hint

Use the element or attribute meaning and document structure, rather than appearance or a similar-looking name.

Answer C:

WEB08 defines ul as unordered and ol as ordered, with li items inside either. C therefore supplies the requested container. li is only an item, and list is not the defined HTML list-container name. Presentation of markers can be changed with CSS without changing whether the element is the unordered-list structure.

Why each choice is right or wrong

A - Incorrect: ol is an ordered-list container, not the unordered-list container requested.

B - Incorrect: li marks an item inside a list rather than the list container itself.

C - Correct: ul is explicitly the unordered-list container in WEB08.

D - Incorrect: list is not the unordered-list element spelling defined here.

Primary note proof

Study-note section WEB08

> Unordered <ul> and ordered <ol> contain <li> items.

Question sources

Web Programming review questions · Question 9

Question 265 | NS0809

What HTML tag defines a table row?

A. <td>

B. <th>

C. <table>

D. <tr>

Hint

Use the element or attribute meaning and document structure, rather than appearance or a similar-looking name.

Answer D: <tr>

WEB08 distinguishes the table element, row elements, and header/data cells. tr defines one row, while th and td are cells placed within rows. table contains the complete tabular structure. Therefore D is the row tag, independent of how many columns or spans the cells in that row occupy.

Why each choice is right or wrong

A - Incorrect: td defines a data cell, not the containing row.

B - Incorrect: th defines a header cell, not the containing row.

C - Incorrect: table defines the whole table rather than one row.

D - Correct: tr is the table-row element explicitly identified in WEB08.

Primary note proof

Study-note section WEB08

> <table> contains rows <tr>, header cells <th> and data cells <td>; a td is not the table itself.

Question sources

Web Programming review questions · Question 10

Question 266 | NS0810

What does the colspan attribute do in a table?

A. Sets the column color

B. Merges cells across multiple columns

C. Sets the column width

D. Merges cells across multiple rows

Hint

Use the element or attribute meaning and document structure, rather than appearance or a similar-looking name.

Answer B: Make one cell span multiple columns.

WEB08 explicitly distinguishes colspan from rowspan. colspan allocates a cell across columns, often described informally as merging cells horizontally; it does not change a column's color or width rule. rowspan is the vertical counterpart across rows. B therefore matches, while actual placement must still account for positions already occupied by spans.

Why each choice is right or wrong

A - Incorrect: Column color is a styling concern rather than the colspan structural span.

B - Correct: colspan makes one cell occupy positions across multiple columns.

C - Incorrect: Column width is not the meaning of the colspan count.

D - Incorrect: Spanning rows is rowspan, not colspan.

Primary note proof

Study-note section WEB08

> colspan spans columns; rowspan spans rows.

Study-note section WEB08

> Account for occupied cells before placing the next cell, and use header associations for accessible data.

Question sources

Web Programming review questions · Question 11

Question 267 | NS0811

Which meta tag is used for responsive design on mobile devices?

A. <meta name="keywords">

B. <meta name="robots">

C. <meta name="description">

D. <meta name="viewport">

Hint

Identify the requested presentation effect and layout context before matching the property or rule.

Answer D: <meta name="viewport">

WEB06 gives viewport metadata control over mobile viewport behavior, and WEB14 includes it alongside flexible layout and media queries for responsive design. Keywords and description concern metadata for content/discoverability, while robots concerns crawler directives. The viewport entry is the relevant mobile-layout metadata; it does not replace responsive CSS by itself.

Why each choice is right or wrong

A - Incorrect: Keywords metadata does not configure the mobile viewport used for responsive layout.

B - Incorrect: Robots metadata concerns crawler handling rather than the mobile viewport.

C - Incorrect: Description summarizes the page rather than controlling mobile viewport behavior.

D - Correct: Viewport metadata configures mobile viewport behavior as part of responsive design.

Primary note proof

Study-note section WEB06

> Meta charset declares encoding; description summarizes the page; viewport controls mobile viewport behavior.

Study-note section WEB14

> Responsive design combines flexible layout, images, viewport metadata and media queries, for example @media(max-width:600px){.cards{grid-template-columns:1fr}}.

Study-note section WEB-S12

> The keywords metadata name supplies terms relevant to the page, while description supplies a page summary.

Study-note section WEB-S12

> Robots metadata supplies crawler indexing or search-presentation instructions.

Question sources

Web Programming review questions · Question 12

Question 268 | NS0812

Which CSS selector targets an element with id="logo"?

A. .logo

B. logo

C. *logo

D. #logo

Hint

Identify which elements a rule targets and distinguish selector syntax from declaration syntax.

Answer D: #logo

WEB11 explicitly uses #logo as an ID selector and .notice as a class selector. Thus an element whose id is logo is targeted with #logo. A bare logo would be a type selector for an element named logo, while the starred concatenation is not the stated ID syntax. D is the correct selector.

Why each choice is right or wrong

A - Incorrect: .logo targets a class named logo rather than id="logo".

B - Incorrect: Bare logo is a type selector, not the ID selector requested.

C - Incorrect: *logo is not the defined CSS ID-selector syntax.

D - Correct: #logo is the explicit ID-selector pattern supplied in WEB11.

Primary note proof

Study-note section WEB11

> Type p selects paragraph elements, .notice selects a class, #logo an ID, h1,h2 groups selectors, nav ul selects descendants and nav>ul direct children.

Question sources

Web Programming review questions · Question 13

Question 269 | NS0813

Which CSS selector targets all elements with class="highlight"?

A. #highlight

B. .highlight

C. *highlight

D. highlight

Hint

Identify which elements a rule targets and distinguish selector syntax from declaration syntax.

Answer B: .highlight

WEB11 gives a dot-prefixed name as a class selector and a hash-prefixed name as an ID selector. Applying that rule to highlight yields .highlight. A bare word selects element type, and *highlight is not the supported class syntax. The class rule can match every element carrying that class, rather than only one unique ID.

Why each choice is right or wrong

A - Incorrect: #highlight selects an ID rather than elements with the highlight class.

B - Correct: .highlight is the dot-prefixed class selector matching the requested class.

C - Incorrect: *highlight is not the defined class-selector syntax.

D - Incorrect: Bare highlight is an element-type selector rather than a class selector.

Primary note proof

Study-note section WEB11

> Type p selects paragraph elements, .notice selects a class, #logo an ID, h1,h2 groups selectors, nav ul selects descendants and nav>ul direct children.

Question sources

Web Programming review questions · Question 14

Question 270 | NS0814

Which method of inserting CSS allows it to apply to multiple pages?

A. Inline

B. Internal

C. External

D. Embedded

Hint

Identify which elements a rule targets and distinguish selector syntax from declaration syntax.

Answer C: External stylesheet

WEB11 says external CSS promotes reuse and consistent design through a linked stylesheet. Multiple documents can link the same styles.css file, so one shared source applies across pages. Inline declarations belong to one element and internal/embedded style blocks belong to their document. They can be copied, but copying is not the shared-source attachment method requested.

Why each choice is right or wrong

A - Incorrect: Inline declarations belong to an element rather than one shared stylesheet linked by multiple pages.

B - Incorrect: An internal style block belongs to its document rather than a separately shared resource.

C - Correct: Multiple pages can link the same external stylesheet for shared rules and maintenance.

D - Incorrect: Embedded styles are document-local rather than the shared external attachment method.

Primary note proof

Study-note section WEB11

> An external sheet uses <link rel="stylesheet" href="styles.css"> in head; an internal sheet uses style; an inline declaration uses an element’s style attribute.

Study-note section WEB11

> External CSS promotes reuse, consistent design and caching; it does not guarantee that every page becomes smaller or accessible.

Question sources

Web Programming review questions · Question 15

Question 271 | NS0815

What symbol is used to group multiple selectors in CSS?

A. Semicolon (;)

B. Colon (:)

C. Comma (,)

D. Dot (.)

Hint

Identify which elements a rule targets and distinguish selector syntax from declaration syntax.

Answer C: Comma

WEB11 groups selectors using h1,h2. The comma separates alternative selectors that receive the same declaration block. Semicolons separate declarations, colons separate a property from its value or occur in pseudo syntax, and dots introduce classes. Thus C is the selector-list grouping separator, not a declaration delimiter.

Why each choice is right or wrong

A - Incorrect: Semicolons separate declarations rather than selectors in a selector list.

B - Incorrect: A colon is not the separator for grouped alternative selectors.

C - Correct: A comma groups selector alternatives, as in the note's h1,h2 example.

D - Incorrect: A dot introduces a class selector rather than grouping multiple selectors.

Primary note proof

Study-note section WEB11

> Type p selects paragraph elements, .notice selects a class, #logo an ID, h1,h2 groups selectors, nav ul selects descendants and nav>ul direct children.

Study-note section WEB11

> A rule is selector { property: value; }.

Question sources

Web Programming review questions · Question 16

Question 272 | NS0816

What does text-decoration: underline do in CSS?

A. Makes text bold

B. Makes text italic

C. Underlines text

D. Strikes through text

Hint

Identify the requested presentation effect and layout context before matching the property or rule.

Answer C: Underline the text.

WEB13 assigns text-decoration effects such as underline. The specific value underline therefore adds an underline decoration. Bold uses font-weight and italic uses font-style; a strike-through is a different decoration value. The declaration changes presentation rather than the semantic importance or stress of the underlying HTML text.

Why each choice is right or wrong

A - Incorrect: Boldness is controlled by font-weight rather than the underline decoration.

B - Incorrect: Italic styling uses font-style rather than text-decoration:underline.

C - Correct: The underline value requests an underline text decoration.

D - Incorrect: A strike-through is a different decoration, not the underline value shown.

Primary note proof

Study-note section WEB13

> color sets text color; background-color sets background; font-size size, font-family face, font-style italic, font-weight weight, text-align inline-content alignment, and text-decoration effects such as underline.

Question sources

Web Programming review questions · Question 17

Question 273 | NS0817

Which HTML tag makes text bold with semantic importance?

A. <b>

B. <bold>

C.

D.

Hint

Use the element or attribute meaning and document structure, rather than appearance or a similar-looking name.

Answer C:

WEB06 says strong expresses importance while em expresses stress, and warns that b/i are not identical to those meanings. Thus the semantic-importance requirement selects strong rather than merely a bold-looking b. Default styling is commonly bold but CSS can change appearance; the semantic distinction remains the reason for the answer.

Why each choice is right or wrong

A - Incorrect: b has different text semantics and is not the element for importance specified in WEB06.

B - Incorrect: bold is not the semantic importance element defined in the note.

C - Correct: strong explicitly indicates importance and is the requested semantic choice.

D - Incorrect: em marks stress emphasis rather than the stated importance role.

Primary note proof

Study-note section WEB06

> indicates importance and stress; <b>/<i> have other text semantics and are not identical to importance/emphasis.

Question sources

Web Programming review questions · Question 18

Question 274 | NS0818

Which HTML element is used for superscript text like E=mc²?

A. <sub>

B. <sup>

C. <small>

D.

Hint

Use the element or attribute meaning and document structure, rather than appearance or a similar-looking name.

Answer B: <sup>

WEB06 pairs sub and sup with subscript and superscript. The raised exponent in E=mc² is a superscript, so sup is the matching element. sub would lower text, and small or em have other meanings rather than expressing the exponent's raised placement. The answer identifies the markup role rather than a CSS font-size choice.

Why each choice is right or wrong

A - Incorrect: sub marks subscript, the opposite vertical placement from the raised exponent.

B - Correct: sup marks superscript such as the raised two in E=mc².

C - Incorrect: small does not identify the superscript placement required by the example.

D - Incorrect: em marks stress emphasis rather than superscript position.

Primary note proof

Study-note section WEB06

> <sub>/<sup> mark sub/superscripts.

Question sources

Web Programming review questions · Question 19

Question 275 | NS0819

What is the purpose of HTML comments?

A. They are displayed on the webpage

B. They style the content

C. They are ignored by the browser and add notes

D. They link to external files

Hint

Use the element or attribute meaning and document structure, rather than appearance or a similar-looking name.

Answer C: Comments add source notes without appearing as ordinary page content.

WEB06 states that <!-- comment --> is not displayed but remains visible in source. Thus C's ignored wording should mean ignored for ordinary visual rendering, not removed from the DOM or hidden from source inspection. Comments do not themselves style content or link an external file, so the other purposes do not match.

Why each choice is right or wrong

A - Incorrect: HTML comments are not displayed as ordinary document content.

B - Incorrect: Comments do not supply CSS declarations or style the content by themselves.

C - Correct: Comments hold source notes and are not normally rendered; they remain visible in source.

D - Incorrect: A comment is not the markup mechanism for linking external resources.

Primary note proof

Study-note section WEB06

> <!-- comment --> is not displayed but remains visible in source.

Question sources

Web Programming review questions · Question 20

Question 276 | NS0820

Which JavaScript keyword declares a block-scoped variable?

A. var

B. let

C. def

D. dim

Hint

Check exact language syntax, declaration rules and execution context before reasoning about the result.

Answer B: let

WEB15 explicitly distinguishes function/global var from block-scoped let and const. Of the offered names, let declares a block-scoped variable. const would additionally prevent rebinding but is not offered here. def and dim are not JavaScript declaration keywords in the supplied syntax. Therefore B matches the requested scope behavior.

Why each choice is right or wrong

A - Incorrect: var has function/global scope rather than the block scope requested.

B - Correct: let declares a block-scoped JavaScript variable.

C - Incorrect: def is not the JavaScript variable-declaration keyword defined in the note.

D - Incorrect: dim is not the JavaScript variable-declaration keyword defined in the note.

Primary note proof

Study-note section WEB15

> var has function/global scope; let/const are block-scoped.

Question sources

Web Programming review questions · Question 21

Question 277 | NS0821

Which JavaScript keyword declares a constant that cannot be reassigned?

A. static

B. final

C. var

D. const

Hint

Check exact language syntax, declaration rules and execution context before reasoning about the result.

Answer D: const

WEB15 says const prevents rebinding but does not prevent mutation of an object's contents. That is the precise constant-binding property in the stem. var permits reassignment, while static and final are not the declaration form described here. D therefore answers the binding question without claiming that every object assigned to const becomes deeply immutable.

Why each choice is right or wrong

A - Incorrect: static is not the const variable-declaration form for preventing rebinding.

B - Incorrect: final is not the JavaScript binding declaration defined in WEB15.

C - Incorrect: var permits reassignment and does not provide a constant binding.

D - Correct: const prevents rebinding, though object contents can still be mutated.

Primary note proof

Study-note section WEB15

> var has function/global scope; let/const are block-scoped.

Study-note section WEB15

> const prevents rebinding but not mutation of an object's contents.

Question sources

Web Programming review questions · Question 22

Question 278 | NS0822

How are single-line comments written in JavaScript?

A. <!-- comment -->

B. /* comment */

C. // comment

D. # comment

Hint

Use the element or attribute meaning and document structure, rather than appearance or a similar-looking name.

Answer C: // comment

WEB15 defines // comments as ending at the line end and /* */ as block comments. Therefore C is the single-line comment syntax. A block comment may be physically written on one line, but it remains a different delimiter form and can span lines. HTML and hash-style markers are not the single-line syntax requested in the note.

Why each choice is right or wrong

A - Incorrect: The shown marker is an HTML comment form rather than the standard JavaScript single-line form.

B - Incorrect: This is block-comment syntax, even when physically written on one line.

C - Correct: Double slash starts a JavaScript comment that ends at the line end.

D - Incorrect: A hash is not the ordinary JavaScript single-line comment delimiter given in WEB15.

Primary note proof

Study-note section WEB15

> // comments end at line end; /* */ span a block.

Study-note section WEB06

> <!-- comment --> is not displayed but remains visible in source.

Question sources

Web Programming review questions · Question 23

Question 279 | NS0823

A form uses onsubmit="return validate()". If validate() returns false, what happens to the cancelable default submission?

A. Submits the form

B. Refreshes the page

C. Prevents form submission

D. Clears all form fields

Hint

Separate event dispatch, handler registration and cancellation of the browser default action.

Answer C: Prevents form submission

The inline onsubmit convention consumes the value returned by validate. Returning false therefore cancels the form's default submission in this stated setup. It does not clear fields or explicitly refresh the page. The caller matters: returning false from a callback installed through addEventListener would not by itself cancel submission and would require preventDefault instead. The revised question includes the handler convention needed for the definite result.

Why each choice is right or wrong

A - Incorrect: The consumed false result cancels rather than initiates default submission.

B - Incorrect: No page-refresh action is requested by returning false.

C - Correct: The inline onsubmit return convention cancels the default submission.

D - Incorrect: Returning a Boolean does not clear control values.

Primary note proof

Study-note section WEB21

> Returning false from an addEventListener callback does not cancel it; return false works in an appropriate inline/onsubmit property handler whose caller uses that return.

Question sources

Web Programming review questions · Question 24

Question 280 | NS0824

Which event fires when a page finishes loading in JavaScript?

A. onclick

B. onsubmit

C. oninput

D. window.onload

Hint

Separate event dispatch, handler registration and cancellation of the browser default action.

Answer D: window.onload is the handler property for the page load event.

WEB22 says window.onload handles load, typically after dependent resources finish. D therefore names the relevant handler property, although the actual event name is load rather than window.onload. Click, submit, and input refer to other interactions. This distinction avoids confusing a property used to register a handler with the event object or event name itself.

Why each choice is right or wrong

A - Incorrect: onclick handles clicks, not completion of page resource loading.

B - Incorrect: onsubmit handles form submission, not the page load completion event.

C - Incorrect: oninput handles control input changes, not the page load completion event.

D - Correct: window.onload registers the handler for load, normally after dependent resources finish.

Primary note proof

Study-note section WEB22

> window.onload is a handler property for the load event, typically after dependent resources finish.

Study-note section WEB21

> An event handler runs when an event occurs: click, input, keydown, mouseover, submit and load are examples.

Question sources

Web Programming review questions · Question 25

Question 281 | NS0825

In PHP, how do you declare a variable named name with value 'John'?

A. var name = 'John';

B. let $name = 'John';

C. $name = 'John';

D. name = 'John';

Hint

Check exact language syntax, declaration rules and execution context before reasoning about the result.

Answer C: $name = 'John';

WEB23 requires a dollar-prefixed PHP variable name and permits dynamic typing without a preceding type declaration. C correctly assigns the single-quoted string to $name. var name and let mix other declaration syntax with PHP, while bare name lacks the required sigil. No separate JavaScript-style declaration keyword is needed for this ordinary PHP assignment.

Why each choice is right or wrong

A - Incorrect: This is not the ordinary PHP assignment syntax and lacks the dollar-prefixed variable name.

B - Incorrect: let is not the PHP declaration syntax for this assignment.

C - Correct: The dollar-prefixed variable and quoted string assignment are valid PHP syntax.

D - Incorrect: Bare name lacks the required dollar sigil for a PHP variable.

Primary note proof

Study-note section WEB23

> Variables begin with $, then a letter/underscore and subsequent letters/digits/underscores; $AGE18 works but $18AGE does not.

Study-note section WEB23

> Dynamic typing permits values of different types without a preceding type declaration, though optional declarations can constrain them.

Study-note section WEB-S06

> A complete ordinary PHP assignment statement ends with a semicolon.

Question sources

Web Programming review questions · Question 26

Question 282 | NS0826

Which PHP function returns the length of a string?

A. str_word_count()

B. strrev()

C. strlen()

D. strpos()

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer C: strlen(), measuring bytes.

WEB24 says strlen counts bytes, so it is the matching length function. For ordinary ASCII strings byte count also equals character count; multibyte Unicode can differ. strrev reverses, strpos locates a substring, and a word-count operation does not measure the string's byte length. The qualification prevents treating strlen as a universal user-perceived-character counter.

Why each choice is right or wrong

A - Incorrect: Word counting does not measure the string's byte length.

B - Incorrect: strrev reverses the byte sequence rather than returning its length.

C - Correct: strlen returns byte length, matching the requested function with the Unicode caveat.

D - Incorrect: strpos returns a substring position or false rather than a length.

Primary note proof

Study-note section WEB24

> strlen counts bytes; strpos can return integer0 or false, requiring ===false for failure.

Study-note section WEB24

> strrev reverses bytes and str_replace replaces matching content.

Question sources

Web Programming review questions · Question 27

Question 283 | NS0827

What does strrev("Hello") return in PHP?

A. Hello

B. hello

C. HELLO

D. olleH

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer D: olleH

WEB24 defines strrev as reversing bytes. Hello is ASCII, so reversing its five bytes gives o,l,l,e,H in that order, retaining the original uppercase H at the final position. The function does not perform lowercase or uppercase conversion and does not leave the sequence unchanged. D is the exact returned string.

Why each choice is right or wrong

A - Incorrect: Hello is unchanged, whereas strrev reverses the byte order.

B - Incorrect: Lowercasing is not the operation performed by strrev.

C - Incorrect: Uppercasing is not the operation performed by strrev.

D - Correct: Reversing the ASCII bytes H,e,l,l,o yields o,l,l,e,H.

Primary note proof

Study-note section WEB24

> strrev reverses bytes and str_replace replaces matching content.

Question sources

Web Programming review questions · Question 28

Question 284 | NS0828

Which PHP function finds the position of a substring within a string?

A. str_replace()

B. strpos()

C. strlen()

D. strrev()

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer B: strpos()

WEB24 identifies strpos as the substring-position function and warns that a successful position zero differs from false. Use strict ===false when checking failure so an initial-position match is not mistaken for absence. Replacement, length, and reversal functions perform different operations. Thus B names the lookup API rather than a transformation function.

Why each choice is right or wrong

A - Incorrect: str_replace changes matching content rather than reporting the match position.

B - Correct: strpos finds a substring position, returning zero legitimately or false for failure.

C - Incorrect: strlen measures byte length rather than locating a substring.

D - Incorrect: strrev reverses bytes instead of reporting a match location.

Primary note proof

Study-note section WEB24

> strlen counts bytes; strpos can return integer0 or false, requiring ===false for failure.

Study-note section WEB24

> strrev reverses bytes and str_replace replaces matching content.

Question sources

Web Programming review questions · Question 29

Question 285 | NS0829

What is the key difference between include and require in PHP?

A. include is faster than require

B. require gives a fatal error if file is missing; include gives a warning

C. include gives a fatal error; require gives a warning

D. There is no difference

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer B: include warns; failed require raises Error in PHP8 and stops normal execution if uncaught.

WEB33 distinguishes include's warning from require's critical failure. B captures the conventional contrast when require's failure is uncaught, but PHP8 raises a catchable Error rather than the older E_COMPILE_ERROR description. The distinction is failure behavior, not an inherent speed ranking. C reverses the behaviors and D denies the explicit difference.

Why each choice is right or wrong

A - Incorrect: No inherent speed advantage is the failure-handling distinction defined by WEB33.

B - Correct: This is the conventional contrast for an uncaught failure; PHP8 require raises a catchable Error.

C - Incorrect: This reverses include's warning and require's critical failure behavior.

D - Incorrect: The note explicitly distinguishes their behavior when the target file cannot be included.

Primary note proof

Study-note section WEB33

> include evaluates another file in the current scope and warns on failure; require fails critically.

Study-note section WEB33

> In PHP8 a failed require raises Error, which can be caught; uncaught it stops normal execution.

Question sources

Web Programming review questions · Question 30

Question 286 | NS0830

Which PHP superglobal is dedicated specifically to supported form data submitted through POST, rather than a configurable mixture of request sources?

A. $_GET

B. $_SESSION

C. $_POST

D. $_REQUEST

Hint

Identify the data source or security responsibility precisely, and check whether a combined source or a different control could also qualify.

Answer C: $_POST

$_POST directly represents supported form POST values. $_REQUEST can include POST values under some configurations, but it combines sources and is not dedicated to the form POST channel. $_GET represents URL query values and $_SESSION contains application session state. The source-specific wording makes C unique while preserving the fact that a configurable combined array may also expose some of the same submitted values.

Why each choice is right or wrong

A - Incorrect: $_GET supplies URL query values.

B - Incorrect: $_SESSION supplies stored session state rather than the current form POST source.

C - Correct: $_POST is dedicated to supported form POST data.

D - Incorrect: $_REQUEST may combine POST with other configured sources.

Primary note proof

Study-note section WEB27

> $_GET contains query parameters; $_POST contains supported form POST data; $_FILES upload metadata; $_SERVER request/environment details; $_COOKIE cookie values; $_SESSION session data after startup.

Study-note section WEB27

> $_REQUEST may combine GET/POST/cookie data according to configuration; it is not a database interface and has ambiguous precedence, so prefer the intended source.

Question sources

Web Programming review questions · Question 31

Question 287 | NS0831

Which SQL statement retrieves data from a database?

A. INSERT INTO

B. UPDATE

C. DELETE

D. SELECT

Hint

Identify the API and operation first, then distinguish connection setup, statement execution and result processing.

Answer D: SELECT

WEB32 directly assigns retrieval to SELECT, adding to INSERT, changing values to UPDATE, and removal to DELETE. Therefore D is the SQL statement role requested. This identifies the operation's semantics; the actual query still needs appropriate columns, filters, authorization, and safe parameter handling when incorporating submitted values.

Why each choice is right or wrong

A - Incorrect: INSERT INTO adds rows rather than naming the ordinary retrieval statement.

B - Incorrect: UPDATE changes stored values rather than the retrieval operation requested.

C - Incorrect: DELETE removes rows rather than retrieving them.

D - Correct: SELECT is explicitly the SQL operation that retrieves rows.

Primary note proof

Study-note section WEB32

> SELECT retrieves rows; INSERT adds; UPDATE ...

Question sources

Web Programming review questions · Question 32

Question 288 | NS0832

What keyword assigns new values in a SQL UPDATE statement?

A. VALUES

B. WHERE

C. SET

D. INTO

Hint

Identify the API and operation first, then distinguish connection setup, statement execution and result processing.

Answer C: SET

WEB32 gives UPDATE ... SET as the form that changes values. SET introduces the target-column assignments, while WHERE limits which rows are affected. VALUES and INTO occur in other statement roles and do not replace SET's assignment function. C therefore identifies the keyword requested, distinct from selecting the affected rows.

Why each choice is right or wrong

A - Incorrect: VALUES does not introduce assignments in the UPDATE ... SET form given here.

B - Incorrect: WHERE selects matching rows rather than assigning the new column values.

C - Correct: SET introduces the value assignments in an UPDATE statement.

D - Incorrect: INTO does not replace SET for assignments in the stated UPDATE form.

Primary note proof

Study-note section WEB32

> SELECT retrieves rows; INSERT adds; UPDATE ...

Study-note section WEB32

> WHERE limits affected/matching records; omitting it from DELETE ordinarily targets every row, subject to constraints, permissions and errors.

Question sources

Web Programming review questions · Question 33

Question 289 | NS0833

What happens if you use DELETE without a WHERE clause?

A. Nothing happens

B. Only the first record is deleted

C. An error is generated

D. All records in the table are deleted

Hint

Identify the API and operation first, then distinguish connection setup, statement execution and result processing.

Answer D: It ordinarily targets all rows for deletion, subject to constraints, permissions, and execution success.

WEB32 says WHERE limits affected rows and omitting it from DELETE ordinarily targets every row. Thus D is the intended effect of a successful unrestricted DELETE. No first-row-only rule exists, and omission is not inherently a syntax error. Permissions, constraints, or other errors can still prevent the operation, so the outcome is not an unconditional execution guarantee.

Why each choice is right or wrong

A - Incorrect: Without a filter, the statement ordinarily targets rows rather than doing nothing.

B - Incorrect: There is no implicit first-row-only restriction when WHERE is omitted.

C - Incorrect: Omitting WHERE is not by itself the stated syntax error.

D - Correct: A successful unrestricted DELETE ordinarily deletes all targeted table rows, subject to database controls.

Primary note proof

Study-note section WEB32

> WHERE limits affected/matching records; omitting it from DELETE ordinarily targets every row, subject to constraints, permissions and errors.

Question sources

Web Programming review questions · Question 34

Question 290 | NS0834

Which PHP function establishes a connection to MySQL?

A. mysql_open()

B. db_connect()

C. mysqli_connect()

D. connect_mysql()

Hint

Identify the API and operation first, then distinguish connection setup, statement execution and result processing.

Answer C: mysqli_connect()

WEB31 explicitly gives mysqli_connect(host,user,password,database,port,socket) as the MySQLi connection function. The other offered names are not the API identified here. Argument defaults and actual credentials affect connection success, so knowing the function name does not remove the need for configuration and failure handling. C is the valid connection entry point.

Why each choice is right or wrong

A - Incorrect: mysql_open() is not the MySQLi connection function given in WEB31.

B - Incorrect: db_connect() is not the standard MySQLi connection function identified here.

C - Correct: mysqli_connect() is explicitly the MySQLi connection-opening function in the note.

D - Incorrect: connect_mysql() is not the offered standard API name described by WEB31.

Primary note proof

Study-note section WEB31

> mysqli_connect(host,user,password,database,port,socket) opens a connection; selecting a database can be deferred, and defaults make several arguments technically optional.

Question sources

Web Programming review questions · Question 35

Question 291 | NS0835

Which PHP function returns the ID of the last inserted record?

A. mysqli_last_id()

B. mysqli_insert_id()

C. mysqli_get_id()

D. mysqli_row_id()

Hint

Identify the API and operation first, then distinguish connection setup, statement execution and result processing.

Answer B: mysqli_insert_id($conn), for a generated AUTO_INCREMENT value on that connection.

WEB32 identifies mysqli_insert_id($conn) as reporting the connection's generated AUTO_INCREMENT value. It is not a universal lookup of an arbitrary last row or a promise of gapless IDs. B names the correct function; the others invent different names. A connection argument and appropriate successful insertion context are needed in actual procedural code.

Why each choice is right or wrong

A - Incorrect: mysqli_last_id() is not the generated-value function named in WEB32.

B - Correct: mysqli_insert_id($conn) reports the connection's generated AUTO_INCREMENT value.

C - Incorrect: mysqli_get_id() is not the API identified for the generated insert value.

D - Incorrect: mysqli_row_id() is not the API named for a generated insert identifier.

Primary note proof

Study-note section WEB32

> mysqli_num_rows counts a result's rows; mysqli_affected_rows($conn) counts changed/inserted/deleted rows under its options; mysqli_insert_id($conn) reports a generated AUTO_INCREMENT value from the connection.

Study-note section WEB32

> AUTO_INCREMENT generates numeric values but gaps and explicit values are possible; do not promise gapless consecutive business numbering.

Question sources

Web Programming review questions · Question 36

Question 292 | NS0836

Which ordinary PHP variable scope can be accessed inside a function using a global declaration or, alternatively, the $GLOBALS array?

A. Local

B. Static

C. Global

D. Session

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer C: Global

A variable declared outside functions has global scope. A function normally has separate local bindings, so it can explicitly import such a binding with global or access it through $GLOBALS. The keyword is therefore one mechanism, not a mandatory exclusive spelling. A static local remains a function-local binding whose value persists across calls; session state belongs to a superglobal available across scopes.

Why each choice is right or wrong

A - Incorrect: Ordinary local bindings already belong to that function; this is not importing an outside binding.

B - Incorrect: A static local retains its value across calls but remains local to the function.

C - Correct: Global bindings are the outside-function bindings accessed by these two mechanisms.

D - Incorrect: Session state uses a superglobal available across scopes, rather than this ordinary binding import.

Primary note proof

Study-note section WEB25

> A variable outside a function has global scope.

Study-note section WEB25

> A function’s locals and by-value parameters are separate bindings; use global $x or $GLOBALS["x"] to refer to a global explicitly.

Study-note section WEB25

> A static local retains its value across calls during the execution lifecycle; static storage is not simply another visibility scope.

Study-note section WEB25

> Superglobals are available across scopes.

Question sources

Web Programming review questions · Question 37

Question 293 | NS0837

What is a PHP static variable?

A. A variable that cannot be changed

B. A global variable accessible everywhere

C. A local variable that retains its value between function calls

D. A variable stored in a session

Hint

Check exact language syntax, declaration rules and execution context before reasoning about the result.

Answer C: A local variable that retains its value between calls during the execution lifecycle.

WEB25 defines a static local by persistence across function calls. It remains a local binding and can change value; static is not the same as constant, global visibility, or server session storage. Thus C supplies both the local-scope and retained-state aspects, without treating static duration as an independent universal visibility scope.

Why each choice is right or wrong

A - Incorrect: Static locals can change value; static does not mean immutable.

B - Incorrect: Static persistence does not make the variable a global visible everywhere.

C - Correct: A static local retains its value across calls during the execution lifecycle.

D - Incorrect: A static local is not the same as data stored in $_SESSION.

Primary note proof

Study-note section WEB25

> A static local retains its value across calls during the execution lifecycle; static storage is not simply another visibility scope.

Study-note section WEB23

> Constants cannot normally be redefined during execution.

Question sources

Web Programming review questions · Question 38

Question 294 | NS0838

What does var_dump() do in PHP?

A. Deletes a variable

B. Displays data type and value of a variable

C. Converts a variable to a string

D. Validates a variable

Hint

Check exact language syntax, declaration rules and execution context before reasoning about the result.

Answer B: Display the variable's type and value.

WEB23 explicitly states that var_dump displays type and value. It is diagnostic output, not a deletion, validation, or conversion guarantee. Observing a value can assist debugging, but it does not prove that the input satisfies application constraints. B is therefore the direct API purpose, while the alternatives describe unrelated operations.

Why each choice is right or wrong

A - Incorrect: var_dump does not delete the variable whose diagnostic information it displays.

B - Correct: The note explicitly defines var_dump as displaying type and value.

C - Incorrect: Diagnostic display is not a conversion of the original variable binding to a string.

D - Incorrect: Displaying a value does not establish application-specific validation.

Primary note proof

Study-note section WEB23

> var_dump displays type and value.

Question sources

Web Programming review questions · Question 39

Question 295 | NS0839

Which PHP data type represents the absence of a value?

A. Boolean

B. String

C. Integer

D. NULL

Hint

Check exact language syntax, declaration rules and execution context before reasoning about the result.

Answer D: NULL

WEB23 says null means no value. Boolean represents true or false, String text, and integer numeric values; none is the same absence marker. In particular zero, false, and an empty string can be legitimate present values rather than null. D therefore matches the requested absence-of-value representation.

Why each choice is right or wrong

A - Incorrect: A Boolean is a true/false value rather than the absence marker.

B - Incorrect: A string, including an empty one, is not the null absence marker.

C - Incorrect: An integer such as zero is still a value rather than null.

D - Correct: NULL is explicitly the no-value representation identified in WEB23.

Primary note proof

Study-note section WEB23

> Scalars include int,float,string,bool; arrays/objects are structured values and null means no value.

Question sources

Web Programming review questions · Question 40

Question 296 | NS0840

For ordinary HTML form submission, which statement correctly contrasts where POST places form data with GET's URL query?

A. POST is faster than GET

B. POST data is visible in the URL

C. POST form data normally goes in the request body rather than the URL query, subject to configured size limits

D. POST is easier to implement

Hint

Identify the protocol layer and the intended request, response or channel semantics.

Answer C: POST form data normally goes in the request body rather than the URL query, subject to configured size limits

Ordinary GET forms place name/value pairs in the URL query, whereas POST forms place them in the request body. This is a placement distinction, not encryption: tools can inspect the body, and servers impose configured limits. The other claims either put POST fields in the wrong location or assert universal speed/ease advantages that do not follow from the method semantics.

Why each choice is right or wrong

A - Incorrect: Method choice does not guarantee that a POST operation is faster; this is not the placement contrast asked for.

B - Incorrect: Ordinary POST form values are placed in the body, not the URL query used by GET forms.

C - Correct: This gives the body-versus-query distinction while retaining configured limits and making no secrecy claim.

D - Incorrect: Ease of implementation is application-dependent and does not describe the form-data placement difference.

Primary note proof

Study-note section WEB04

> GET forms usually put name/value pairs in the URL query; POST forms put them in the body.

Study-note section WEB04

> Neither method encrypts data.

Study-note section WEB04

> POST bodies are visible to developer tools and subject to server/configured size limits.

Question sources

Web Programming review questions · Question 41

Question 297 | NS0841

Which HTML form input type masks characters for security?

A. type="text"

B. type="hidden"

C. type="secure"

D. type="password"

Hint

Separate the control role, displayed content, submitted value and form destination.

Answer D: type="password"

WEB09 says password inputs mask display but do not encrypt the transmitted value. D therefore supplies the intended visual masking. Hidden inputs remove visible interaction rather than offering a masked text-entry control, text displays characters normally, and secure is not the type defined here. Transport and server protection remain separate obligations.

Why each choice is right or wrong

A - Incorrect: A text input displays entered characters normally rather than applying password masking.

B - Incorrect: A hidden input is not an interactive masked-character text field.

C - Incorrect: secure is not the password input type defined in the note.

D - Correct: password masks displayed characters while leaving encryption to separate transport controls.

Primary note proof

Study-note section WEB09

> type="password" masks display but does not encrypt.

Study-note section WEB-S02

> A hidden input carries a value without displaying an editable text field; it is not a password-masking control.

Question sources

Web Programming review questions · Question 42

Question 298 | NS0842

What attribute groups radio buttons so only one can be selected?

A. id

B. value

C. name

D. group

Hint

Separate the control role, displayed content, submitted value and form destination.

Answer C: name

WEB09 explicitly groups same-name radio buttons for a single choice. id instead identifies an individual element and connects a label; value is the submitted selected value. group is not the grouping attribute defined here. Therefore C gives the shared attribute that creates the radio-choice group under the form-control model.

Why each choice is right or wrong

A - Incorrect: id identifies an individual control and associates labels rather than defining the shared radio group.

B - Incorrect: value supplies the selected control’s submitted value rather than the grouping key.

C - Correct: Radio buttons sharing the same name form a single-choice group.

D - Incorrect: group is not the radio-grouping attribute defined in WEB09.

Primary note proof

Study-note section WEB09

> A label’s for matches the control’s id; name identifies its submitted field.

Study-note section WEB09

> Same-name radio buttons form a single-choice group; checkboxes permit independent selections.

Study-note section WEB-S02

> For a text input, the value attribute supplies its initial text value; it does not specify the control’s width.

Question sources

Web Programming review questions · Question 43

Question 299 | NS0843

Which HTML element creates a dropdown menu?

A. <input type="dropdown">

B. <dropdown>

C. <select>

D. <menu>

Hint

Separate the control role, displayed content, submitted value and form destination.

Answer C: <select> containing <option> elements.

WEB09 defines select with option children as the choice control, conventionally rendered as a dropdown in its ordinary single-selection form. The input type dropdown and dropdown element are not the provided control syntax. menu is not the form-selection element requested. Additional attributes can alter select presentation, but the native form-control answer remains C.

Why each choice is right or wrong

A - Incorrect: dropdown is not the input type provided for this native selection control.

B - Incorrect: dropdown is not the native select element spelling defined by WEB09.

C - Correct: select with option children creates the native choice control commonly displayed as a dropdown.

D - Incorrect: menu is not the form-selection control defined by WEB09.

Primary note proof

Study-note section WEB09

> <select> contains <option>; textarea accepts multiple lines.

Question sources

Web Programming review questions · Question 44

Question 300 | NS0844

What does the accept attribute on a file-upload input do?

A. Automatically uploads the file

B. Hints which file types the browser’s file picker should offer

C. Sets the maximum file size

D. Validates the file name

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer B: Hints which file types the browser’s file picker should offer

accept is a browser selection hint describing file types the picker should offer. It does not guarantee what an attacker can submit or what the server actually accepts. Server-side validation must separately check upload errors, size and content before safe storage. The attribute also neither initiates transfer, sets a maximum upload size nor validates a filename. The choice states the UI role without claiming server enforcement.

Why each choice is right or wrong

A - Incorrect: The attribute does not automatically start an upload.

B - Correct: This is the browser-picker hint described in the note.

C - Incorrect: Maximum upload size requires separate controls and validation.

D - Incorrect: The attribute does not validate filenames.

Primary note proof

Study-note section WEB30

> accept hints to the browser which file types to offer; it does not enforce the server’s policy.

Study-note section WEB30

> Validate server-side size/content, inspect upload errors, use the temporary upload path, choose a safe generated destination and use move_uploaded_file.

Question sources

Web Programming review questions · Question 45

Question 301 | NS0845

Which listed HTML elements can embed supported video or other multimedia resources in a suitable environment? Select all that apply.

A. <video>

B. <media>

C. <embed>

D. <object>

Hint

Use the element or attribute meaning and document structure, rather than appearance or a similar-looking name.

Answer A, C, D: <video>; <embed>; <object>

video is the native HTML element for video, and embed and object can also embed supported resources, including multimedia in a suitable environment. The question allows these different embedding mechanisms rather than asking only for the native video element. media is not the corresponding HTML element. Browser support, resource formats and appropriate permissions still matter; the selection describes capability rather than guaranteed playback of every resource.

Why each choice is right or wrong

A - Correct: video is the native HTML video element.

B - Incorrect: media is not the HTML multimedia-embedding element identified here.

C - Correct: embed can embed supported multimedia resources.

D - Correct: object can embed supported multimedia resources.

Primary note proof

Study-note section WEB10

> Modern audio/video elements embed supported media, often with controls and fallback content; embed/object can also embed supported resources.

Question sources

Web Programming review questions · Question 46

Question 302 | NS0846

What does session_start() do in PHP?

A. Creates a new database connection

B. Starts or resumes a session to store user data

C. Starts an HTML form

D. Initializes a new variable

Hint

Follow the identifier and server-side state through the stated lifecycle or access check; distinguish client-controlled claims from server decisions.

Answer B: Start or resume PHP session handling and make $_SESSION available.

WEB29 directly defines session_start() as starting or resuming session handling. The browser normally holds an opaque identifier while server-controlled storage holds the session data. This is separate from a database connection or an HTML form. It does not simply initialize one arbitrary variable, and the server still must validate authorization for protected actions.

Why each choice is right or wrong

A - Incorrect: Session startup is separate from opening a database connection.

B - Correct: session_start starts or resumes PHP session handling and makes $_SESSION available.

C - Incorrect: It is not an HTML form-starting operation.

D - Incorrect: It initializes session handling rather than merely declaring one arbitrary variable.

Primary note proof

Study-note section WEB29

> session_start() starts/resumes PHP session handling and makes $_SESSION available.

Study-note section WEB29

> Normally the browser holds an opaque session identifier while data resides in server-controlled storage.

Question sources

Web Programming review questions · Question 47

Question 303 | NS0847

In CSS, which selector type is denoted by a dot (.)?

A. ID selector

B. Element selector

C. Group selector

D. Class selector

Hint

Identify which elements a rule targets and distinguish selector syntax from declaration syntax.

Answer D: Class selector

WEB11 defines .notice as a class selector and #logo as an ID selector. The dot is therefore the prefix for a class name, while an element selector uses its type name and grouping uses commas. D correctly identifies the selector category rather than a declaration property or an element's unique ID.

Why each choice is right or wrong

A - Incorrect: An ID selector uses # rather than a dot.

B - Incorrect: An element/type selector uses the element name without the class prefix.

C - Incorrect: Grouping uses commas between selectors, not a dot.

D - Correct: A dot prefixes a class selector, as in .notice.

Primary note proof

Study-note section WEB11

> Type p selects paragraph elements, .notice selects a class, #logo an ID, h1,h2 groups selectors, nav ul selects descendants and nav>ul direct children.

Question sources

Web Programming review questions · Question 48

Question 304 | NS0848

What does the SQL AUTO_INCREMENT property do?

A. Auto-updates a column when a record is modified

B. Generates a unique sequential number for a column

C. Automatically deletes old records

D. Automatically backs up the database

Hint

Identify the API and operation first, then distinguish connection setup, statement execution and result processing.

Answer B: Generate automatic numeric values, commonly used for keyed row identifiers; gaps are possible.

WEB32 says AUTO_INCREMENT generates numeric values and permits gaps or explicit values. B is the intended generated-number description when used with the normal keyed column design, but sequential must not mean gapless business numbering or a promise about every manually supplied value. It does not update arbitrary columns, delete records, or back up the database.

Why each choice is right or wrong

A - Incorrect: AUTO_INCREMENT does not automatically update an arbitrary column whenever a record is modified.

B - Correct: It generates numeric values commonly used for row identifiers; gaps and explicit values remain possible.

C - Incorrect: It does not automatically delete old rows.

D - Incorrect: It does not perform database backups.

Primary note proof

Study-note section WEB32

> AUTO_INCREMENT generates numeric values but gaps and explicit values are possible; do not promise gapless consecutive business numbering.

Question sources

Web Programming review questions · Question 49

Question 305 | NS0849

Which PHP function closes a MySQL database connection?

A. mysqli_end()

B. mysqli_disconnect()

C. mysqli_close()

D. db_close()

Hint

Identify the API and operation first, then distinguish connection setup, statement execution and result processing.

Answer C: mysqli_close($conn)

WEB32 explicitly gives mysqli_close as closing a connection. C names that MySQLi API; the procedural form uses the connection argument in real code. Closing a connection is separate from ending a query or deleting stored data, and the other offered function names are not the standard one identified here.

Why each choice is right or wrong

A - Incorrect: mysqli_end() is not the connection-closing function named in WEB32.

B - Incorrect: mysqli_disconnect() is not the API identified here for this operation.

C - Correct: mysqli_close closes the MySQLi connection, using its connection argument in procedural code.

D - Incorrect: db_close() is not the standard MySQLi function named in the supplied note.

Primary note proof

Study-note section WEB32

> Escape rendered cell text; use prepared statements for submitted values; mysqli_close closes the connection.

Operating System

Questions & Worked Answers

233 questions + 1 source variants

Question 1 | Q00023

Which mutual exclusion mechanism keeps track of turns to enter the critical region using an integer variable, which is initially-0, and another process waits until it turns to 1?

A. Lock variable

B. Disabling interrupts

C. Strict alteration

D. Race condition

Hint

Track who may enter and distinguish separate tests and updates from atomic operations.

Answer C: Strict alternation (option misspells it as alteration).

OS12 defines strict alternation using turn=0/1: each process waits until turn equals its identifier and passes the turn on leaving. That directly matches the described integer ownership variable. A naive lock variable instead records availability and can race during separate test/set operations. Disabling interrupts and a race condition do not implement the described turn-taking algorithm.

Why each choice is right or wrong

A - Incorrect: A naive lock variable records free/busy status rather than assigning alternating ownership to process 0 or 1.

B - Incorrect: Disabling interrupts does not implement the integer turn-owner protocol described in the stem.

C - Correct: Strict alternation uses a turn variable initialized to one process and passed to the other.

D - Incorrect: A race condition is a concurrency failure, not a mechanism providing the described alternating access.

Primary note proof

Study-note section OS12

> Strict alternation uses turn=0/1: process i waits while turn≠i, then enters and sets turn to the other process on leaving. It enforces turns but can violate progress if the other process stays outside its critical region. A naive lock-variable test followed by a separate set races because both processes can observe free before either sets it.

Study-note section OS12

Test-and-set and compare-and-swap combine checking/updating atomically; ordinary check-then-write does not. Peterson’s classic algorithm uses flags plus turn for two processes under its memory-model assumptions; a semaphore can coordinate more than two. Disabling local interrupts does not exclude other CPUs and is not a general user-space locking solution.

Study-note section OS10

A race occurs when results depend on uncoordinated interleaving of conflicting accesses.

Module passages - related reading

Operating System module | PDF page 10 | lines 23-28

• Loads a program into memory.
• Executes the program.
• Handles program's execution.
• Provides a mechanism for process synchronization.
• Provides a mechanism for process communication.
• Provides a mechanism for deadlock handling.

Operating System module | PDF page 45 | lines 10-22

The CPU hardware uses an interrupt request line wire which helps CPU to sense after executing every instruction. When the CPU checks that a controller has put a signal on the interrupt request line, the CPU saves a state, such as the current value of the instruction pointer, and jumps to the interrupt handler routine at a fixed address. The interrupt handler part determines the cause of the interrupt performs the necessary processing and executes an interrupt instruction to return the CPU to its execution state.
The basic mechanism of interrupt enables the CPU to respond to an asynchronous event, such as when a device controller becomes ready for service. Most CPUs have two interrupt request lines.
• non-maskable interrupt - Such kind of interrupts are reserved for events like unrecoverable memory errors.
• maskable interrupt - Such interrupts can be switched off by the CPU before the execution of critical instructions that must not be interrupted.

Question sources

MOE Computer Science Exit Exam · 2016 · Question 23

Question 2 | Q00031

Which one of the following messaging communication best explains the statement: "Until the message is received, the sending process is blocked'"?

A. Blocking receive

B. Non-block receive

C. Non-block sending

D. Blocking send

Hint

Identify how data moves, which participant waits and what event allows the operation to continue.

Answer D: Blocking send.

OS09 explicitly identifies a sender blocked until receipt as blocking send under rendezvous semantics. The stem describes the sending process waiting, not a receiver awaiting an incoming message. Nonblocking sending returns promptly rather than waiting for receipt, and receive modes describe the other side. The receipt condition here supplies the relevant API assumption.

Why each choice is right or wrong

A - Incorrect: Blocking receive waits on the receiving side, whereas the stem explicitly blocks the sender.

B - Incorrect: Nonblocking receive returns promptly on the receiving side and does not describe sender waiting.

C - Incorrect: Nonblocking sending returns promptly rather than keeping the sender blocked until the handoff completes.

D - Correct: Under the stated rendezvous condition, waiting until message receipt is blocking-send behavior.

Primary note proof

Study-note section OS09

> Blocking send waits for the required handoff/buffering/receipt condition defined by its API. Blocking receive waits for a message. Nonblocking operations return promptly with data, progress or a would-block result. “Sender blocked until received” identifies blocking send under rendezvous semantics.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 11 | lines 15-19

> • Two processes often require data to be transferred between them.
> • The both processes can be on the one computer or on different computer but are connected through computer network.
> • Communication may be implemented by two methods either by Shared Memory or by Message Passing.

Question sources

MOE Computer Science Exit Exam · 2016 · Question 31

Question 3 | Q00034

_____is the component of the operating system that is responsible to decide which process to run first among ready processes.

A. Memory manager

B. Inter process communication

C. Disk manager

D. Scheduler

Hint

Decide whether the process is eligible, running or waiting, then identify the responsible queue or scheduling role.

Answer D: Scheduler

The CPU scheduler selects among ready processes and allocates the CPU (PDF p20). This is precisely the selection task in the stem.

Why each choice is right or wrong

A - Incorrect: Memory allocation is a separate function (p5).

B - Incorrect: Process data exchange (p11) is not selection of the next CPU user.

C - Incorrect: Device allocation (p6) does not decide CPU order.

D - Correct: CPU scheduling selects ready processes (p20).

Primary note proof

Study-note section OS06

> The ready queue contains eligible work; device queues hold blocked requests. The broad textbook job queue contains processes in the system, while an admission queue more narrowly holds jobs awaiting memory/admission. Long-term scheduling admits jobs; medium-term scheduling suspends/swaps them; short-term scheduling selects ready work. The dispatcher performs the handoff/context restore after selection. A bare “priority” causes running→ready only if a preemptive policy chooses another process.

Study-note section OS01

> An OS allocates CPU time, memory, storage, devices and communication resources, and provides services to programs.

Study-note section OS09

> Shared memory lets processes access a common region and requires synchronization for conflicting updates. Message passing exchanges data through send/receive operations.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 20 | lines 15-21

It is also called CPU scheduler. Main objective is increasing system performance in accordance with the chosen set of criteria. It is the change of ready state to running state of the process. CPU scheduler selects process among the processes that are ready to execute and allocates CPU to one of them.
Short term scheduler also known as dispatcher, execute most frequently and makes the fine-grained decision of which process to execute next. Short term scheduler is faster than long term scheduler.

Operating System module | PDF page 5 | lines 26-36

Memory management refers to management of Primary Memory or Main Memory. Main memory is a large array of words or bytes where each word or byte has its own address. Main memory provides a fast storage that can be access directly by the CPU. So, for a program to be executed, must in the main memory.
Activities Operating System for memory management.
Keeps tracks of primary memory (i.e. what part of it are in use by whom, what part are not in use.)
In multiprogramming, OS decides which process will get memory when and how much.
Allocates the memory when the process requests it to do so.
De-allocates the memory when the process no longer needs it or has been terminated.

Operating System module | PDF page 11 | lines 15-19

• Two processes often require data to be transferred between them.
• The both processes can be on the one computer or on different computer but are connected through computer network.
• Communication may be implemented by two methods either by Shared Memory or by Message Passing.

Operating System module | PDF page 6 | lines 11-17

OS manages device communication via their respective drivers. Activities of Operating System for device management.
Keeps tracks of all devices. Program responsible for this task is known as the I/O controller.
Decides which process gets the device when and for how much time.
Allocates the device in the efficient way.
De-allocates devices.

Question sources

MOE Computer Science Exit Exam · 2016 · Question 34

Question 4 | Q00092

Which one of the following is not true?

A. kernel is the program that constitutes the central core of the operating system

B. kernel is the first part of operating system to load into memory during booting

C. kernel is made of various modules which cannot be loaded in running operating system

D. kernel remains in the memory during the entire computer session

Hint

Distinguish command interfaces, privileged core services and the stages of booting.

Answer C: The claim that kernel modules cannot load while running is false.

OS03 states that loadable modules can add drivers to a running kernel, directly contradicting option C's absolute prohibition. It describes the kernel as the core OS component and resident through the session. Option B is read as the first core OS component, rather than the first code executed at power-on: firmware and bootloader stages precede it.

Why each choice is right or wrong

A - Incorrect: The kernel implements core resource management, protection and system-call handling, so this statement is true.

B - Incorrect: As the first core OS component, the kernel is loaded at boot; firmware/bootloader execution precedes that OS boundary.

C - Correct: Modular kernels permit runtime module loading, directly refuting the statement that it cannot occur.

D - Incorrect: A resident kernel remains active throughout the session, matching the note's ordinary kernel model.

Primary note proof

Study-note section OS03

> The kernel implements core resource management, protection and system-call handling.

Study-note section OS03

> Firmware/bootloader stages execute before transferring control to a kernel loaded into RAM. The kernel is the first core OS component, not the first program ever executed at power-on. Loadable modules can add drivers to a running kernel; "kernel modules cannot be loaded while running" is false in modular systems. A resident kernel remains active through the session. Utilities such as antivirus and disk tools can combine user processes with privileged components.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 53 | lines 11-15

operating system. It is consisting of various modules and it interacts directly with the underlying hardware. Kernel provides the required abstraction to hide low level hardware details to system or application programs.
System Library - System libraries are special functions or programs using which application programs or system utilities accesses Kernel's features. These libraries

Operating System module | PDF page 32 | lines 11-14

In dynamic loading, a routine of a program is not loaded until it is called by the program. All routines are kept on disk in a re-locatable load format. The main program is loaded into memory and is executed. Other routines methods or modules are loaded on request. Dynamic loading makes better memory space utilization and unused routines are never loaded.

MOE Computer Science Exit Exam · 2016 · Question 92

Computer Science model exam · Question 95

University of Gondar model exam · Question 95

Question 5 | Q00164

One is not the goal of I/O software

A. Buffering

B. Device independence

C. Uniform naming

D. Error handling

E. None of the above

Hint

Separate device hardware, device-specific software and general event or transfer mechanisms.

Answer E: None: all four are I/O-software goals or supporting functions.

OS34 identifies device independence, uniform naming and error handling as I/O services. OS35 explains buffering as holding in-transit data to absorb speed/size differences. Each listed feature therefore supports I/O software, so none is an exclusion. Calling buffering a supporting mechanism rather than a high-level objective does not make it unrelated to I/O software’s goals.

Why each choice is right or wrong

A - Incorrect: Buffering absorbs transfer-speed and size differences, directly supporting reliable and efficient I/O software.

B - Incorrect: Device independence is an explicit I/O service that hides device-specific details from higher layers.

C - Incorrect: Uniform naming is explicitly included among the I/O services described here.

D - Incorrect: Reporting or retrying supported device failures is the error-handling responsibility of I/O software.

E - Correct: All four listed functions support I/O software, leaving no listed function to exclude.

Primary note proof

Study-note section OS34

> A driver converts OS requests into device-specific operations. Device independence and uniform naming hide brand-specific details; error handling reports/retries supported failures.

Study-note section OS35

> Buffering temporarily holds data in transit to absorb speed/transfer-size differences.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 45 | lines 28-33

> Application I/O Interface represents the structuring techniques and interfaces for the operating system to enable I/O devices to be treated in a standard, uniform way. The actual differences lies kernel level modules called device drivers which are custom tailored to corresponding devices but show one of the standard interfaces to applications. The purpose of the device-driver layer is to hide the differences among device controllers from the I/O subsystem of the kernel, such as the I/O system calls. Following are the characteristics of I/O

Operating System module | PDF page 47 | lines 5-9

> Buffering - Kernel I/O Subsystem maintains a memory area known as buffer that stores data while they are transferred between two devices or between a devices with an application operation. Buffering is done to cope with a speed mismatch between the producer and consumer of a data stream or to adapt between devices that have different data transfer sizes.

Operating System module | PDF page 47 | lines 17-18

> Error Handling - An operating system that uses protected memory can guard against many kinds of hardware and application errors.

Question sources

Addis Ababa University mock exam · Question 66

Question 6 | Q00165

Which hardware unit translates a process's logical/virtual addresses to physical memory addresses during execution?

A. MMU

B. IRQ

C. DMA

D. Cache

E. Relocation Register

Hint

Track when an address or library reference is resolved and the direction of translation.

Answer A: MMU

The MMU performs execution-time translation from a process's logical or virtual address to a physical RAM address. A relocation register can supply a base used in a simple translation, but it is a register rather than the complete translating unit. IRQ concerns interrupts, DMA moves data, and a cache stores reusable information. The corrected direction therefore identifies the MMU uniquely.

Why each choice is right or wrong

A - Correct: The MMU is the hardware unit performing logical-to-physical translation.

B - Incorrect: An IRQ signals an interrupt rather than translating process addresses.

C - Incorrect: DMA transfers data between devices and memory after setup.

D - Incorrect: A cache retains reusable contents; it is not the general address-translating unit.

E - Incorrect: A relocation register holds a base parameter used by translation hardware.

Primary note proof

Study-note section OS27

> Logical/virtual addresses are generated for a process; physical addresses select RAM. An MMU translates logical addresses to physical addresses, not the reverse.

Study-note section OS28

> In the standard base/limit model, base is that process's physical starting address and limit is its permitted length. Check 0≤logical_offset<limit, then physical=base+offset.

Study-note section OS34

> Polling checks readiness repeatedly; interrupts request CPU attention; DMA transfers blocks after setup without CPU work for every byte.

Study-note section OS35

> Caching retains copies to accelerate reuse.

Study-note section OS-S04

IRQ means interrupt request.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 33 | lines 6-13

The run-time mapping from virtual to physical address is done by the memory management unit (MMU) which is a hardware device. MMU uses following mechanism to convert virtual address to physical address.
• The value in the base register is added to every address generated by a user process which is treated as offset at the time it is sent to memory. For example, if the base register value is 10000, then an attempt by the user to use address location 100 will be dynamically reallocated to location 10100.
• The user program deals with virtual addresses; it never sees the real physical addresses.

Operating System module | PDF page 34 | lines 12-16

In this type of allocation, relocation-register scheme is used to protect user processes from each other, and from changing operating-system code and data. Relocation register contains value of smallest physical address whereas limit register contains range of logical addresses. Each logical address must be less than the limit register.

Operating System module | PDF page 45 | lines 10-22

The CPU hardware uses an interrupt request line wire which helps CPU to sense after executing every instruction. When the CPU checks that a controller has put a signal on the interrupt request line, the CPU saves a state, such as the current value of the instruction pointer, and jumps to the interrupt handler routine at a fixed address. The interrupt handler part determines the cause of the interrupt performs the necessary processing and executes an interrupt instruction to return the CPU to its execution state.
The basic mechanism of interrupt enables the CPU to respond to an asynchronous event, such as when a device controller becomes ready for service. Most CPUs have two interrupt request lines.
• non-maskable interrupt - Such kind of interrupts are reserved for events like unrecoverable memory errors.
• maskable interrupt - Such interrupts can be switched off by the CPU before the execution of critical instructions that must not be interrupted.

Operating System module | PDF page 47 | lines 10-11

Caching - Kernel maintains cache memory which is region of fast memory that holds copies of data. Access to the cached copy is more efficient than access to the original.

Question sources

Addis Ababa University mock exam · Question 67

Question 7 | Q00166

For holes of sizes 100, 500, 200 and 300 in that scan order and a request of size 180, which policy is better at minimizing this request's leftover space in its selected hole? Ignore search cost and future requests.

A. First fit algorithm is better

B. Best fit algorithm is better

C. Worst fit algorithm is better

D. All of the above

Hint

Apply the stated hole-selection or base-and-bound rule with its explicit convention.

Answer B: Best fit algorithm is better

Best-fit chooses the smallest hole large enough for the request: 200, leaving 20 unused units. First-fit stops at 500 and leaves 320 units; worst-fit also chooses 500. Under the stated objective, best-fit gives the smallest remainder for this allocation. This calculation says nothing about future fragmentation or overall search speed, which require a broader workload.

Why each choice is right or wrong

A - Incorrect: First-fit selects 500 in this scan order, leaving 320 rather than the minimum remainder.

B - Correct: Best-fit selects 200 and leaves only 20 units.

C - Incorrect: Worst-fit selects 500 and leaves 320 units.

D - Incorrect: The policies do not tie: only best-fit minimizes this request's leftover space.

Primary note proof

Study-note section OS28

> First-fit selects the first adequate hole; next-fit continues from the previous search position; best-fit selects the smallest adequate hole; worst-fit selects the largest.

Module passages - related reading

Operating System module | PDF page 34 | lines 34-45

> External
> fragmentation
> Total memory space is enough to satisfy a request or to reside a
> process in it, but it is not contiguous so it cannot be used.
> 2
> Internal
> fragmentation
> Memory block assigned to process is bigger. Some portion of memory

is left unused as it cannot be used by another process.
External fragmentation can be reduced by compaction or shuffle memory contents to place all free memory together in one large block. To make compaction feasible, relocation should be dynamic

Question sources

Addis Ababa University mock exam · Question 68

Question 8 | Q00167

All jobs arrive together at submission, have known finite CPU bursts, perform no I/O, and no further jobs arrive. Assume one CPU, zero switching overhead, known fixed priorities (smaller value is higher; non-preemptive priority), a known positive RR quantum, and listed order for ties. For which listed algorithms can each job's total waiting time be computed at submission? Choose the most complete answer.

A. Shortest job first

B. Shortest remaining time

C. Priority based

D. Round Robin

E. All of the above

Hint

Construct a timeline and distinguish completion rates from individual elapsed-time measures.

Answer E: All of the above

The closed workload and explicit policy parameters determine each scheduling timeline. SJF orders known bursts, SRTF uses remaining bursts, priority uses the supplied fixed order, and RR uses its quantum and ready queue. Completion minus arrival minus burst then gives waiting time. Each named algorithm is individually computable, so the aggregate option is the most complete answer under these assumptions.

Why each choice is right or wrong

A - Incorrect: SJF waiting is computable, but this option omits the other computable policies.

B - Incorrect: SRTF waiting is computable for the known closed workload, but this is incomplete.

C - Incorrect: Fixed-priority waiting is computable with the supplied priorities and tie rule, but this is incomplete.

D - Incorrect: RR waiting is computable with the known quantum and queue order, but this is incomplete.

E - Correct: All four schedules and their total waiting times can be computed from the fully specified finite workload.

Primary note proof

Study-note section OS13

For arrival A, first start S and completion C, response=S−A and turnaround=C−A. For a single CPU burst B with no I/O, waiting=C−A−B.

Study-note section OS16

Non-preemptive SJF/SJN chooses the shortest next burst among currently ready jobs. SRTF reconsiders on arrivals and selects the shortest remaining work; a shorter newcomer can preempt.

Study-note section OS17

Priority scheduling chooses the highest-priority ready job. Check whether a smaller or larger numeric value means higher priority. State whether a high-priority arrival preempts.

Study-note section OS18

RR serves a ready queue cyclically for at most quantum q per turn. Unfinished jobs return to the tail; completed/blocked jobs leave.

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 23 | lines 23-26

7.2 Shortest Job First (SJF)
• Best approach to minimize waiting time.
• Impossible to implement
• Processer should know in advance how much time process will take.

Operating System module | PDF page 24 | lines 10-15

7.3 Priority Based Scheduling
• Each process is assigned a priority. Process with highest priority is to be executed first and so on.
• Processes with same priority are executed on first come first serve basis.
• Priority can be decided based on memory requirements, time requirements or any other resource requirement.

Operating System module | PDF page 25 | lines 10-14

7.4 Round Robin Scheduling
• Each process is provided a fix time to execute called quantum.
• Once a process is executed for given time period. Process is preempted and other process executes for given time period.
• Context switching is used to save states of preempted processes.

Question sources

Addis Ababa University mock exam · Question 69

Question 9 | Q00168

One is not a problem caused by concurrency of processes

A. Race condition

B. Starvation

C. Deadlock

D. Mutual exclusion

E. None

Hint

Identify conflicting shared accesses and the safety or progress property required.

Answer D: Mutual exclusion is a desired safety property.

OS10 explicitly contrasts mutual exclusion, a desired safety property, with race conditions, starvation and deadlock as possible failures. Although a badly designed locking scheme can introduce deadlock, that does not turn the mutual-exclusion requirement itself into a concurrency failure. Therefore it is the single option that is not a problem in the sense used by the list.

Why each choice is right or wrong

A - Incorrect: A race is a concurrency failure caused by uncoordinated interleaving of conflicting accesses.

B - Incorrect: Starvation is a possible indefinite-delay failure of concurrent scheduling or resource competition.

C - Incorrect: Deadlock is a possible failure in which blocked participants cannot supply one another's required events.

D - Correct: Mutual exclusion is a correctness property protecting shared state, rather than a failure to be avoided.

E - Incorrect: Mutual exclusion provides a clear non-failure option, so none of the choices is not appropriate.

Primary note proof

Study-note section OS10

> A race occurs when results depend on uncoordinated interleaving of conflicting accesses. A critical section is code accessing shared state that needs protection, not the resource itself. A correct exclusion solution requires mutual exclusion, progress and bounded waiting under stated assumptions. Mutual exclusion is a desired safety property; races, starvation and deadlock are possible failures.

Study-note section OS22

A set is deadlocked when each member waits for an event/resource that only another blocked member can provide. Mere waiting for another holder is normal blocking; indefinite unfair delay can be starvation without a cycle of dependencies.

- Provides a mechanism for deadlock handling.

Question sources

Addis Ababa University mock exam · Question 70

Question 10 | Q00169

Which methods can participate in recovery after deadlock has been detected? Assume checkpoints and safe resource reclamation are available where needed. Select all that apply.

A. Kill the process

B. Rollback

C. Non-preempt the resource

D. Lock the process

Hint

Separate handling before allocation from actions taken after detection, and consider the cost of checking.

Answer A, B: Kill the process; Rollback

Terminating a selected process can release resources and break the dependency cycle. Recovery may instead reclaim safely preemptable resources and restore affected work to a checkpoint, so rollback can also participate. Merely preserving non-preemption or locking a process does not remove the deadlocked dependencies. With checkpoint and reclamation support stated, both termination and rollback are valid recovery tools.

Why each choice is right or wrong

A - Correct: Killing a selected victim can release resources and break the deadlock.

B - Correct: Rollback can restore affected work after safe resource reclamation.

C - Incorrect: Non-preemption preserves a deadlock-enabling restriction rather than recovering the processes.

D - Incorrect: Locking a blocked process does not release resources or restore progress.

Primary note proof

Study-note section OS26

> Detection asks whether the current state is deadlocked. Recovery can terminate selected processes or reclaim safely preemptable resources and roll affected work back to a checkpoint. Termination and rollback are both possible recovery tools; choose according to the resource and process conditions.

Study-note section OS22

> No resource preemption means release must be voluntary.

> • Provides a mechanism for process synchronization.
> • Provides a mechanism for process communication.
> • Provides a mechanism for deadlock handling.

Question sources

Addis Ababa University mock exam · Question 71

Question 11 | Q00170

One deadlock prevention method says, "if a process must wait for a needed resource, it drops all of its previously held resources and tries to acquire all resources gain." These attacks

A. Circular wait condition

B. No preemption conditions

C. Mutual exclusion condition

D. Hold and wait condition

E. None of the above

Hint

Identify the resource-request restriction and which necessary condition it removes.

Answer D: The policy removes hold-and-wait.

Under this policy, a process releases all previously held resources when it must wait. Releasing all resources before retrying removes simultaneous holding while waiting. The stem describes voluntary dropping, not forced withdrawal by another agent, so hold-and-wait is the directly attacked condition. It supplies no global ordering or resource-sharing rule.

Why each choice is right or wrong

A - Incorrect: The policy does not impose a global acquisition order, which is the direct circular-wait prevention method.

B - Incorrect: The stem specifies the process dropping resources, not a general rule permitting forced resource preemption.

C - Incorrect: Resources may remain nonshareable; releasing holdings does not remove mutual-exclusion requirements.

D - Correct: A process no longer retains allocated resources while waiting to acquire the rest.

E - Incorrect: Hold-and-wait is explicitly removed by the release-all-before-waiting rule, so an identified condition fits.

Primary note proof

Study-note section OS24

> Prevention constrains how requests are made. Share a resource where safe to remove mutual exclusion; request all needed resources before holding any to remove hold-and-wait; permit safe resource withdrawal/restart to attack no-preemption; impose a global acquisition order to remove circular wait. Not every physical resource is shareable or safely preemptable.

Study-note section OS24

> “If waiting, release all held resources and try again” removes simultaneous holding while waiting.

> • Provides a mechanism for deadlock handling.

Question sources

Addis Ababa University mock exam · Question 72

Question 12 | Q00229

Which statements are false? Interpret aging under a priority scheme and workload where increasing waiting jobs' priority prevents indefinite postponement. Select all that apply.

A. File system standards of various OS is the same.

B. SJF may cause starvation.

C. Aging is the solution of the starvation problem in the case of priority scheduling.

D. Critical section is a resource that cannot be accessed by multiple processes concurrently.

Hint

Identify conflicting shared accesses and the safety or progress property required.

Answer A, D: File system standards of various OS is the same.; Critical section is a resource that cannot be accessed by multiple processes concurrently.

Filesystems are not governed by one identical format across all operating systems; the notes distinguish FAT32, NTFS and ext4. A critical section is code that accesses shared state, not the resource itself. SJF can starve a long job when short work continues arriving. Aging addresses priority starvation under the stated policy assumptions, so those latter two statements are true.

Why each choice is right or wrong

A - Correct: The universal sameness claim is false; different filesystem formats exist.

B - Incorrect: SJF may starve long work under repeated short arrivals, so this statement is true.

C - Incorrect: Aging raises effective priority and addresses starvation under the specified conditions, so this statement is true.

D - Correct: A critical section is protected code rather than the shared resource, making this statement false.

Primary note proof

Study-note section OS10

> A critical section is code accessing shared state that needs protection, not the resource itself.

Study-note section OS17

> Fixed-priority scheduling can starve low-priority jobs under continued high-priority load. SJF can also starve long jobs; starvation is not exclusive to fixed-priority scheduling.

Study-note section OS17

> Aging increases waiting jobs' effective priority according to a rule, reducing indefinite postponement when the priority scheme and workload permit.

Study-note section OS36

> Sockets also support ordinary read/write, alongside socket/connect/send operations, so read is not uniquely "not a network call." FAT32, NTFS and ext4 are filesystem formats; HTTP is an application communication protocol.

Question sources

Mock exam 4 · Question 31

Question 13 | Q00230

One of the following system calls is used to create a new process.

A. Fork()

B. exit()

C. abort()

D. exec()

Hint

Separate creation, image replacement and termination; classify termination by its cause.

Answer A: fork().

OS07 states that fork() creates a child in POSIX-style systems, returning zero in the child and its PID in the parent on success. exec replaces the current process image and does not itself create another process. exit and abort terminate execution normally and abnormally respectively. Creation therefore corresponds to fork among the literal listed calls.

Why each choice is right or wrong

A - Correct: fork creates a child process rather than replacing or terminating the existing process image.

B - Incorrect: exit terminates normally through the runtime rather than creating a new process.

C - Incorrect: abort requests abnormal termination rather than allocating a new child execution instance.

D - Incorrect: exec replaces the current process image; it does not itself create another process.

Primary note proof

Study-note section OS07

> In POSIX-style systems fork() creates a child: zero is returned in the child and the child PID in the parent on success. The two have distinct address spaces, although resources may be shared through explicit mechanisms. exec replaces the current process image; it does not itself create another process.

Study-note section OS07

> Normal completion and a program-detected error exit are voluntary; an unrecoverable fault or being killed is involuntary. exit() terminates normally through the runtime; abort() requests abnormal termination.

> A newly arrived process is put in the ready queue. Processes waits in ready queue for allocating the CPU. Once the CPU is assigned to a process, then that process will execute. While executing the process, any one of the following events can occur.
> • The process could issue an I/O request and then it would be placed in an I/O queue.
> • The process could create new sub process and will wait for its termination.
> • The process could be removed forcibly from the CPU, as a result of interrupt and put back in the ready queue.

Operating System module | PDF page 16 | lines 21-24

> A program by itself is not a process. It is a static entity made up of program statement while process is a dynamic entity. Program contains the instructions to be executed by processor. A program takes a space at single place in main memory and continues to stay there. A program does not perform any action by itself.

Question sources

Mock exam 4 · Question 32

Question 14 | Q00232

Which of the following process scheduling algorithms select the next process to be executed based on each process burst time?

A. FCFS

B. Shortest Job First

C. Round robin

D. Priority scheduling algorithm

Hint

Compare the ready jobs using the stated burst or remaining-time rule.

Answer B: Shortest Job First

SJF requires knowing how long a process will take (PDF p23); that is the burst-length selection described. Priority may use time as one possible priority input (p24), but its general rule is highest assigned priority.

Why each choice is right or wrong

A - Incorrect: FCFS orders arrival (p23), not burst length.

B - Correct: SJF chooses short work based on execution duration (p23).

C - Incorrect: RR assigns a fixed quantum (p25).

D - Incorrect: Priority selects assigned priority; time requirements are only one possible input (p24).

Primary note proof

Study-note section OS16

> Non-preemptive SJF/SJN chooses the shortest next burst among currently ready jobs.

Study-note section OS15

> FCFS runs ready bursts in arrival order and ordinarily does not preempt.

Study-note section OS17

> Priority scheduling chooses the highest-priority ready job.

Study-note section OS18

> RR serves a ready queue cyclically for at most quantum q per turn.

Question sources

Mock exam 4 · Question 34

Question 15 | Q00233

_____ is a software solution of a critical section problem if the number of instances and processes are more than two.

A. Semaphore

B. Compare and swap

C. Peterson

D. Test set

Hint

Track available permits and blocked operations using the stated semaphore model.

Answer A: Semaphore.

OS12 explicitly says a semaphore can coordinate more than two processes, while classic Peterson's algorithm is for two under its memory-model assumptions. OS11 explains counting semaphores as tracking several permits, fitting multiple resource instances. Compare-and-swap and test-and-set are atomic primitives rather than the named software coordination abstraction requested by the stem.

Why each choice is right or wrong

A - Correct: Counting semaphores track multiple permits and coordinate more than two participating processes.

B - Incorrect: Compare-and-swap is an atomic checking/updating primitive, rather than the requested software semaphore abstraction.

C - Incorrect: Classic Peterson's algorithm solves the two-process case, not the stated more-than-two configuration.

D - Incorrect: Test-and-set is an atomic primitive; the software multiple-permit coordination mechanism here is a semaphore.

Primary note proof

Study-note section OS11

> A semaphore provides atomic wait/P/down and signal/V/up operations. Under the nonnegative-token model, wait consumes one available token or blocks when none is available; signal supplies a token and may wake a waiter. Implementations using negative internal counts encode waiters differently, so state the model. A binary semaphore represents one permit; a counting semaphore tracks several. A mutex normally has ownership rules that a general semaphore lacks.

Study-note section OS12

> Test-and-set and compare-and-swap combine checking/updating atomically; ordinary check-then-write does not. Peterson's classic algorithm uses flags plus turn for two processes under its memory-model assumptions; a semaphore can coordinate more than two.

Mock exam 4 · Question 35

Question 16 | Q00359

A process can be terminated due to:

A. killed by another process

B. normal exit

C. all of the mentioned

D. fatal error

Hint

Separate creation, image replacement and termination; classify termination by its cause.

Answer C: All listed causes can terminate a process.

OS07 distinguishes voluntary normal completion from involuntary faults or being killed. Each named cause is therefore a genuine termination cause, although the causes differ in who initiates them and whether completion is normal. The aggregate choice includes all three. Selecting only one named cause would omit other valid termination paths supported by the complete note.

Why each choice is right or wrong

A - Incorrect: Being killed can terminate a process, but this alone omits normal completion and fatal faults.

B - Incorrect: Normal exit is valid, but it is only one of the three supported termination causes.

C - Correct: Being killed, normal exit and fatal error all provide legitimate process-termination causes.

D - Incorrect: A fatal error can terminate execution, but the other two named causes are also valid.

Primary note proof

Study-note section OS07

> Normal completion and a program-detected error exit are voluntary; an unrecoverable fault or being killed is involuntary. exit() terminates normally through the runtime; abort() requests abnormal termination.

Question 17 | Q00360

Which named interface directly requests protected operating-system services across the user/kernel boundary, rather than merely providing application-facing wrappers?

A. library

B. system calls

C. assembly instructions

D. API

Hint

Identify the abstraction layer and separate a protected service request from an application task.

Answer B: system calls

A system call requests a protected kernel service, such as process creation or file access. An application may call an API implemented by a library, but that wrapper is distinct from the direct user/kernel service boundary. Assembly can encode the machine instructions used to enter that boundary without being its general interface name. The requested abstraction is therefore system calls.

Why each choice is right or wrong

A - Incorrect: A library can wrap system calls but is not itself the direct kernel-service boundary.

B - Correct: System calls directly request protected kernel services.

C - Incorrect: Assembly instructions are a programming representation, not the named service-interface abstraction.

D - Incorrect: An API is the application-facing interface and may wrap the direct system-call request.

Primary note proof

Study-note section OS04

> A system call requests a protected kernel service, such as creating a process, reading a file or opening a socket. A user-facing API/library may wrap that request; not every library function enters the kernel. Distinguish the application API from the direct user/kernel boundary when describing access to OS services.

Question 18 | Q00361

Which module gives control of the CPU to the process selected by the short-term scheduler?

A. Interrupt

B. Dispatcher

C. Scheduler

D. none of the mentioned

Hint

Decide whether the process is eligible, running or waiting, then identify the responsible queue or scheduling role.

Answer B: Dispatcher

The module uses overlapping terminology: it calls the short-term scheduler dispatcher on PDF p20, and describes the dispatcher selecting execution on p19. Under the conventional selection-versus-handoff reading requested by the stem, B is the matching term; p21 explains the handoff state work.

Why each choice is right or wrong

A - Incorrect: Interrupts trigger handling, not the named CPU-handoff module (p45).

B - Correct: Dispatcher is the execution-transfer role described on p19, with state switching on p21.

C - Incorrect: The stem already assigns selection to the scheduler; note that p20 loosely equates it with dispatcher.

D - Incorrect: The module explicitly names a dispatcher, so none is not appropriate.

Primary note proof

Study-note section OS06

> Long-term scheduling admits jobs; medium-term scheduling suspends/swaps them; short-term scheduling selects ready work. The dispatcher performs the handoff/context restore after selection.

Study-note section OS05

> A context switch saves one execution context and restores another; useful application work is interrupted by this overhead.

Study-note section OS34

> Polling checks readiness repeatedly; interrupts request CPU attention; DMA transfers blocks after setup without CPU work for every byte.

Module passages - related reading

Queue is implemented by using linked list. Use of dispatcher is as follows. When a process is interrupted, that process is transferred in the waiting queue. If the process has completed or aborted, the process is discarded. In either case, the dispatcher then selects a process from the queue to execute.

Operating System module | PDF page 20 | lines 15-21

> It is also called CPU scheduler. Main objective is increasing system performance in accordance with the chosen set of criteria. It is the change of ready state to running state of the process. CPU scheduler selects process among the processes that are ready to execute and allocates CPU to one of them.

Short term scheduler also known as dispatcher, execute most frequently and makes the fine-grained decision of which process to execute next. Short term scheduler is faster than long term scheduler.

Operating System module | PDF page 21 | lines 41-50

A context switch is the mechanism to store and restore the state or context of a CPU in Process Control block so that a process execution can be resumed from the same point at a later time. Using this technique, a context switcher enables multiple processes to share a single CPU. Context switching is an essential part of a multitasking operating system features.
When the scheduler switches the CPU from executing one process to execute another, the context switcher saves the content of all processor registers for the process being removed from the CPU, in its process descriptor. The context of a process is represented in the process control block of a process. Context switch time is pure overhead. Context switching can significantly affect performance as modern computers have a lot of general

Question 19 | Q00362

Which of the following condition is required for deadlock to be possible?

A. mutual exclusion

B. all of the mentioned

C. a process may hold allocated resources while awaiting assignment of other resources

D. no resource can be forcibly removed from a process holding it

Hint

Trace the resource dependencies and distinguish necessary conditions from evidence of an actual deadlock.

Answer B: All named conditions are necessary conditions.

OS22 lists mutual exclusion, hold-and-wait, no resource preemption and circular wait as necessary in the standard reusable-resource model. The three substantive choices name the first three, so all of the mentioned is the comprehensive option. Circular wait is also required despite being omitted from the list. Having these policies does not prove a particular current allocation is already deadlocked.

Why each choice is right or wrong

A - Incorrect: Mutual exclusion is necessary, but selecting it alone omits the other two necessary conditions offered.

B - Correct: Each substantive option names a standard necessary deadlock condition; the aggregate includes all offered conditions.

C - Incorrect: Retaining resources while requesting more is hold-and-wait, one valid condition among the three offered.

D - Incorrect: No forced removal is no-preemption, which is necessary but does not exclude the other valid conditions.

Primary note proof

Study-note section OS22

> Mutual exclusion allows at most one holder of a nonshareable resource. Hold-and-wait means retaining a resource while requesting another. No resource preemption means release must be voluntary. Circular wait forms a closed chain of such waits.

Study-note section OS22

> All four are necessary in the standard reusable-resource model.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 10 | lines 23-28

Computer Science model exam · Question 93

University of Gondar model exam · Question 93

Question 20 | Q00363

Which scheduling algorithm allocates the CPU first to the process that requests the CPU first?

A. first-come, first-served scheduling

B. priority scheduling

C. shortest job scheduling

D. none of the mentioned

Hint

Follow arrival order, include idle periods and distinguish waiting from completion time.

Answer A: first-come, first-served scheduling

Jobs execute first come, first served on PDF p23. The first CPU requester is consequently the first served in the FCFS queue.

Why each choice is right or wrong

A - Correct: Directly matches the arrival-order rule (p23).

B - Incorrect: Uses highest priority (p24).

C - Incorrect: Uses execution-length information (p23).

D - Incorrect: An offered policy already matches the rule.

Primary note proof

Study-note section OS15

> FCFS runs ready bursts in arrival order and ordinarily does not preempt.

Study-note section OS16

> Non-preemptive SJF/SJN chooses the shortest next burst among currently ready jobs.

Study-note section OS17

> Priority scheduling chooses the highest-priority ready job.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 23 | lines 12-17

> 7.1 First Come First Serve (FCFS)
> • Jobs are executed on first come, first serve basis.
> • Easy to understand and implement.
> • Poor in performance as average wait time is high.
> Wait time of each process is following
> Process Wait Time: Service Time - Arrival Time

Operating System module | PDF page 24 | lines 10-15

> 7.3 Priority Based Scheduling
> • Each process is assigned a priority. Process with highest priority is to be executed first and so on.
> • Processes with same priority are executed on first come first serve basis.
> • Priority can be decided based on memory requirements, time requirements or any other resource requirement.

Operating System module | PDF page 23 | lines 23-26

> 7.2 Shortest Job First (SJF)
> • Best approach to minimize waiting time.
> • Impossible to implement
> • Processer should know in advance how much time process will take.

Variant 1 | Alternative version 1

Which scheduling algorithm allocates the CPU first to the process that requests the CPU first?

A. Priority scheduling

B. Shortest job scheduling

C. First-come, first-served scheduling

D. None of above

Answer C: First-come, first-served scheduling

Apply the same study-note rule to this alternative source set; the choice contrasts below show the derivation.

Why each choice is right or wrong

A - Incorrect: Priority scheduling chooses assigned rank, not request order (PDF p24).

B - Incorrect: Shortest-job scheduling chooses duration, not request order (PDF p23).

C - Correct: FCFS serves jobs first come, first served (PDF p23). The variant moves the correct text from current A to variant C.

D - Incorrect: Variant C supplies the arrival-order policy, so none does not apply (PDF p23).

Primary note proof

Study-note section OS15

> FCFS runs ready bursts in arrival order and ordinarily does not preempt.

Study-note section OS16

> Non-preemptive SJF/SJN chooses the shortest next burst among currently ready jobs.

Study-note section OS17

> Priority scheduling chooses the highest-priority ready job.

Question sources

Computer Science model exam · Question 94

University of Gondar model exam · Question 94

Computer Science model exam 2 · Question 75

Question 21 | Q00607

Which directory implementation is used in most Operating System?

A. Single level directory structure

B. Two level directory structure

C. Tree directory structure

D. Acyclic directory structure

Hint

Follow namespace structure and distinguish names, underlying files and mounted filesystems.

Answer C: Tree directory structure, in the usual general-purpose OS sense.

OS37 states that modern general-purpose systems commonly present hierarchical namespaces and defines a tree as allowing nested directories and absolute/relative paths. That directly supports the conventional tree-directory choice. This is a general-purpose namespace convention, not a measured claim about every OS ever built; links can add graph structure without replacing the hierarchy as the basic user-visible organization.

Why each choice is right or wrong

A - Incorrect: A single namespace without nested directories does not match the common hierarchical organization described.

B - Incorrect: Separating user directories alone is less general than the nested hierarchy specified for modern general-purpose systems.

C - Correct: Nested directories and paths form the tree/hierarchical organization the note identifies as commonly presented.

D - Incorrect: Links can add graph sharing, but acyclic sharing is not the basic common directory organization identified.

Primary note proof

Study-note section OS37

> A single-level directory requires unique names in one namespace. Two-level directories separate users. A tree allows nested directories and absolute/relative paths; links can create shared graphs. Modern general-purpose systems commonly present hierarchical namespaces, but a feature name alone does not prove that every system excludes simpler arrangements.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 6 | lines 19-23

> A file system is normally organized into directories for easy navigation and usage. These directories may contain files and other directions. Operating System does the following activities for file management.
> Keeps track of information, location, uses, status etc. The collective facilities are often known as file system.

Operating System module | PDF page 54 | lines 5-17

> Portable - Portability means software can works on different types of hardware in same way. Linux kernel and application programs support their installation on any kind of hardware platform.
> Open Source - Linux source code is freely available and it is community-based

development project. Multiple teams work in collaboration to enhance the capability of Linux operating system and it is continuously evolving.
Multi-User - Linux is a multiuser system means multiple users can access system resources like memory/ ram/ application programs at same time.
Multiprogramming - Linux is a multiprogramming system means multiple applications can run at same time.
Hierarchical File System - Linux provides a standard file structure in which system files/ user files are arranged.
Shell - Linux provides a special interpreter program which can be used to execute

Question sources

Computer Science model exam · 2015 · Question 76

Question 22 | Q00696

In the basic virtual-memory models, which technique divides the address space into fixed-size units mapped to equal-size physical frames?

A. Paging

B. Segmentation

C. A&B

D. All

Hint

Split the address into page and offset, then apply the mapping and access checks.

Answer A: Paging

Paging divides addresses into fixed-size pages and maps them to physical frames of the same size. Segmentation instead uses variable-length logical units such as code and stack. Thus the fixed-size condition selects paging alone. Both combined alternatives include segmentation and therefore fail that condition; fixed partitions elsewhere in an operating system are outside the page-versus-segment comparison.

Why each choice is right or wrong

A - Correct: Paging uses fixed-size pages and corresponding equal-size frames.

B - Incorrect: Segments are variable-length logical units, so segmentation does not satisfy the fixed-unit condition.

C - Incorrect: Including segmentation makes this combined choice fail the fixed-size requirement.

D - Incorrect: All includes the variable-size segmentation alternative and is therefore incorrect.

Primary note proof

Study-note section OS30

Pages and physical frames have equal fixed size P.

Study-note section OS31

Segmentation uses logical variable-length units such as code, stack and arrays.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 34 | lines 47-56

External fragmentation is avoided by using paging technique. Paging is a technique in which physical memory is broken into blocks of the same size called pages (size is power of 2, between 512 bytes and 8192 bytes). When a process is to be executed, it's corresponding pages are loaded into any available memory frames.
Logical address space of a process can be non-contiguous and a process is allocated physical memory whenever the free memory frame is available. Operating system keeps track of all free frames. Operating system needs n free frames to run a program of size n pages.
Address generated by CPU is divided into
• Page number (p) -- page number is used as an index into a page table which contains base address of each page in physical memory.

Operating System module | PDF page 35 | lines 7-12

Segmentation is a technique to break memory into logical pieces where each piece represents a group of related information. For example, data segments or code segment for each process, data segment for operating system and so on. Segmentation can be implemented using or without using paging.
Unlike paging, segment is having varying sizes and thus eliminates internal fragmentation. External fragmentation still exists but to lesser extent.

Question sources

Computer Science model exam 2 · Question 37

Question 23 | Q00731

When does a page fault occur?

A. The page is present in memory.

B. Deadlock occurs.

C. The page does not present in memory.

D. Buffering occurs.

Hint

Separate a permitted nonresident access from an illegal access and trace the required handling steps.

Answer C: The page does not present in memory.

A demand-paging access to a nonresident page causes the trap (PDF p38). PDF p39 distinguishes a valid but absent page, which is brought in, from an invalid address, which terminates the process. C presupposes an actual reference to that page.

Why each choice is right or wrong

A - Incorrect: Resident page access proceeds normally (p38).

B - Incorrect: Deadlock is not the page-residency test on p38.

C - Correct: An accessed valid page absent from RAM causes demand paging (pp38-39).

D - Incorrect: Buffering is not the fault-triggering residency condition.

Primary note proof

Study-note section OS32

> Virtual memory provides translated, protected address spaces and allows nonresident portions of a program to be backed by storage. It does not add physical RAM or remove all capacity constraints. Demand paging brings a page in when accessed. On a nonresident access: trap, validate mapping/permissions, find a frame or choose a victim, save a dirty victim if needed, obtain contents, update mapping and restart.

Study-note section OS32

> Not every fault reads a disk: some allocate zero-filled pages or establish shared mappings. An illegal access is rejected, not automatically loaded.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 38 | lines 11-18

> Hardware support is required to distinguish between those pages that are in memory and those pages that are on the disk using the valid-invalid bit scheme. Where valid and invalid pages can be checked by checking the bit. Marking a page will have no effect if the process never attempts to access the page. While the process executes and accesses pages that are memory resident, execution proceeds normally.
> Access to a page marked invalid causes a page-fault trap. This trap is the result of the operating system's failure to bring the desired page into memory. But page fault can be handled as following.

Operating System module | PDF page 39 | lines 5-11

> Check an internal table for this process, to determine whether the reference was a valid or it was an invalid memory access.
> Step 2
> If the reference was invalid, terminate the process. If it was valid, but page have not yet brought in, page in the latter.
> Step 3 Find a free frame.
> Step 4 Schedule a disk operation to read the desired page into the newly allocated frame.

Question sources

Computer Science model exam 2 · Question 72

Computer Science model exam 2 · Question 90

Question 24 | Q00732

Which of the following is a condition that causes deadlock?

A. Mutual exclusion

B. Hold and wait

C. Circular wait

D. No preemption

E. All of these

Hint

Trace the resource dependencies and distinguish necessary conditions from evidence of an actual deadlock.

Answer E: All four are standard necessary deadlock conditions.

OS22 lists mutual exclusion, hold-and-wait, no-preemption and circular wait as the four necessary conditions in the standard reusable-resource model. Each substantive choice therefore names a valid deadlock condition, making all of these the comprehensive answer. The wording causes must not be read as saying one condition alone is sufficient; actual allocation/request dependencies still require inspection.

Why each choice is right or wrong

A - Incorrect: Mutual exclusion is one necessary condition, but the other three named conditions also belong to the standard set.

B - Incorrect: Hold-and-wait is necessary, but selecting it alone leaves out the other valid conditions.

C - Incorrect: Circular wait is part of the condition set, but it is not the sole valid listed condition.

D - Incorrect: No-preemption is necessary in this model, alongside the other three substantive choices.

E - Correct: All four substantive choices are standard necessary conditions; together their names give the complete condition set.

Primary note proof

Study-note section OS22

> Mutual exclusion allows at most one holder of a nonshareable resource. Hold-and-wait means retaining a resource while requesting another. No resource preemption means release must be voluntary. Circular wait forms a closed chain of such waits.

Study-note section OS22

All four are necessary in the standard reusable-resource model. Their availability as general system policies does not prove a deadlock exists at this instant; inspect actual allocations/requests.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 10 | lines 23-28

- Loads a program into memory.
- Executes the program.
- Handles program's execution.

- Provides a mechanism for process communication.
- Provides a mechanism for deadlock handling.

Question sources

Computer Science model exam 2 · Question 73

Question 25 | Q00733

What is an operating system?

A. System service provider to the application programs

B. Collection of programs that manages hardware resources

C. Interface between the hardware and application programs

D. All of above

Hint

Separate broad resource-management goals from individual services or applications.

Answer D: All of above

The OS manages hardware and mediates users/program execution (PDF p5), and provides services to programs (p10). Thus each of A-C is a valid aspect of the definition and D collects them.

Why each choice is right or wrong

A - Incorrect: Program services are explicitly provided (p10).

B - Incorrect: Hardware and resource management are explicit (p5).

C - Incorrect: The mediation/interface role is explicit (p5), including program execution.

D - Correct: All three descriptions agree with pp5 and 10.

Primary note proof

Study-note section OS01

An OS allocates CPU time, memory, storage, devices and communication resources, and provides services to programs. Convenience means making tasks easy through consistent interfaces, files and device abstractions. Efficiency means using resources effectively; it is not synonymous with the fastest response for every process. Application development tools use OS services but application development itself is not a core resource-management function.

Study-note section OS04

A system call requests a protected kernel service, such as creating a process, reading a file or opening a socket.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 5 | lines 6-13

An operating System (OS) is an intermediary between users and computer hardware. It provides users an environment in which a user can execute programs conveniently and efficiently. In technical terms, it is software which manages hardware. An operating System controls the allocation of resources and services such as memory, processors, devices and information.
1.1 Definition
An operating system is a program that acts as an interface between the user and the computer hardware and controls the execution of all kinds of programs.

Operating System module | PDF page 10 | lines 5-15

An Operating System provides services to both the users and to the programs.
• It provides programs, an environment to execute.
• It provides users, services to execute the programs in a convenient manner.
Operating Systems can provide the following common services:
✓ Program execution
✓ I/O operations
✓ File System manipulation
✓ Communication
✓ Error Detection
✓ Resource Allocation
✓ Protection

Question sources

Computer Science model exam 2 · Question 74

Computer Science model exam 2 · Question 36

Operating Systems practice questions · Question 1

Question 26 | Q00735

What is the ready state of a process?

A. When process is unable to run until some task has been completed

B. When process is scheduled to run after some execution

C. When process is using the CPU

D. None of the mentioned

Hint

Decide whether the process is eligible, running or waiting, then identify the responsible queue or scheduling role.

Answer B: When process is scheduled to run after some execution

Ready means waiting to be assigned a processor (PDF p16). B is the nearest paraphrase, provided scheduled to run means eligible and waiting, not already executing.

Why each choice is right or wrong

A - Incorrect: Waiting for an event is the Waiting state.

B - Correct: Eligible to receive CPU next matches Ready under the stated reading.

C - Incorrect: Using the CPU defines Running.

D - Incorrect: Ready is represented by B under the stated interpretation.

Primary note proof

Study-note section OS06

> New processes are created/admitted; ready means eligible for CPU but not currently running. Running uses a CPU. Waiting/blocked means unable to proceed until an event; terminated means execution has ended. Running→ready follows time-slice expiry or another preemption. Running→waiting follows blocking I/O. I/O completion normally gives waiting→ready, not a guaranteed immediate running state.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 16 | lines 29-39

> 1. New The process is being created.
> 2.
> Ready The process is waiting to be assigned to a processor. Ready processes are waiting to have the processor allocated to them by the operating system so that they can run.
> 3.
> Running Process instructions are being executed (i.e. The process that is currently being executed).
> 4.
> Waiting The process is waiting for some event to occur (such as the completion of an I/O

operation).
5. Terminated The process has finished execution.

Question sources

Computer Science model exam 2 · Question 76

Question 27 | Q00736

In the standard reusable-resource model, a set of processes is deadlocked when _____.

A. Each process is terminated

B. All processes are trying to kill each other

C. Each process is blocked waiting for an event or resource that only another blocked member of the set can provide

D. None of the mentioned

Hint

Trace the resource dependencies and distinguish necessary conditions from evidence of an actual deadlock.

Answer C: Each process is blocked waiting for an event or resource that only another blocked member of the set can provide

Deadlock requires blocked participants whose needed event or resource can be supplied only by another blocked participant in the same set. The closed dependency prevents any member from progressing without intervention. Terminated processes are no longer waiting, and attempts to kill one another do not establish a resource dependency. The revised blocking option states the necessary relationship rather than merely predicting permanent delay.

Why each choice is right or wrong

A - Incorrect: Termination ends execution and does not define a set of blocked dependent processes.

B - Incorrect: Attempts to kill other processes do not establish deadlocked resource waits.

C - Correct: This states the closed dependency among blocked members that defines deadlock.

D - Incorrect: The revised C explicitly gives the deadlock definition, so none is false.

Primary note proof

Study-note section OS22

A set is deadlocked when each member waits for an event/resource that only another blocked member can provide. Mere waiting for another holder is normal blocking; indefinite unfair delay can be starvation without a cycle of dependencies.

Study-note section OS07

Normal completion and a program-detected error exit are voluntary; an unrecoverable fault or being killed is involuntary. exit() terminates normally through the runtime; abort() requests abnormal termination.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 16 | lines 29-39

1. New The process is being created.
2. Ready The process is waiting to be assigned to a processor. Ready processes are waiting to have the processor allocated to them by the operating system so that they can run.
3. Running Process instructions are being executed (i.e. The process that is currently being executed).
4. Waiting The process is waiting for some event to occur (such as the completion of an I/O operation).
5. Terminated The process has finished execution.

Operating System module | PDF page 10 | lines 23-28

- Loads a program into memory.

- Provides a mechanism for deadlock handling.

Question sources

Computer Science model exam 2 · Question 77

Question 28 | Q00737

In Operating Systems, which of the following is/are CPU scheduling algorithms?

A. Priority

B. Round Robin

C. Shortest Job First

D. All of the mentioned

Hint

Compare the ready jobs using the stated burst or remaining-time rule.

Answer D: All of the mentioned

PDF pp23-25 explicitly cover priority, RR and SJF in the scheduling chapter, so D collects three genuine CPU scheduling policies.

Why each choice is right or wrong

A - Incorrect: Priority ordering is defined on p24.

B - Incorrect: Quantum-based scheduling is defined on p25.

C - Incorrect: Duration-based SJF is defined on p23.

D - Correct: All three belong to the chapter's scheduling methods.

Primary note proof

Study-note section OS16

> Non-preemptive SJF/SJN chooses the shortest next burst among currently ready jobs.

Study-note section OS17

> Priority scheduling chooses the highest-priority ready job.

Study-note section OS18

> RR serves a ready queue cyclically for at most quantum q per turn.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 23 | lines 12-17

> 7.1 First Come First Serve (FCFS)
> • Jobs are executed on first come, first serve basis.
> • Easy to understand and implement.
> • Poor in performance as average wait time is high.
> Wait time of each process is following
> Process Wait Time: Service Time - Arrival Time

Operating System module | PDF page 23 | lines 23-26

> 7.2 Shortest Job First (SJF)
> • Best approach to minimize waiting time.
> • Impossible to implement
> • Processer should know in advance how much time process will take.

Operating System module | PDF page 24 | lines 10-15

> 7.3 Priority Based Scheduling
> • Each process is assigned a priority. Process with highest priority is to be executed first and so on.
> • Processes with same priority are executed on first come first serve basis.
> • Priority can be decided based on memory requirements, time requirements or any other resource requirement.

Operating System module | PDF page 25 | lines 10-14

7.4 Round Robin Scheduling
• Each process is provided a fix time to execute called quantum.
• Once a process is executed for given time period. Process is preempted and other process executes for given time period.
• Context switching is used to save states of preempted processes.

Question sources

Computer Science model exam 2 · Question 78

Operating Systems practice questions · Question 3

Question 29 | Q00738

In which of the storage placement strategies a program is placed in the largest available hole in the main memory?

A. Best fit

B. First fit

C. Worst fit

D. Buddy

Hint

Apply the stated hole-selection or base-and-bound rule with its explicit convention.

Answer C: Worst-fit.

OS28 defines worst-fit as selecting the largest hole, directly matching the stem. Best-fit chooses the smallest adequate hole, and first-fit stops at the first adequate one rather than comparing all sizes. The buddy label does not state this largest-hole rule in the provided note. No numeric trace is necessary because the selection criterion itself is explicit.

Why each choice is right or wrong

A - Incorrect: Best-fit chooses the smallest adequate hole, which is the opposite size-selection criterion from the stem.

B - Incorrect: First-fit selects the first adequate hole in search order, not necessarily the largest available hole.

C - Correct: Worst-fit is explicitly the policy that selects the largest available adequate hole.

D - Incorrect: The supplied largest-hole criterion is defined as worst-fit; the buddy label is not that rule.

Primary note proof

Study-note section OS28

First-fit selects the first adequate hole; next-fit continues from the previous search position; best-fit selects the smallest adequate hole; worst-fit selects the largest.

Study-note section OS-S03

A buddy allocator manages power-of-two block sizes. It takes a smallest sufficient block, splitting larger blocks when necessary, and can merge a freed block with its free buddy. This is not the worst-fit rule of selecting the largest arbitrary hole.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 34 | lines 34-45

External
fragmentation
Total memory space is enough to satisfy a request or to reside a
process in it, but it is not contiguous so it cannot be used.
2
Internal
fragmentation
Memory block assigned to process is bigger. Some portion of memory
is left unused as it cannot be used by another process.
External fragmentation can be reduced by compaction or shuffle memory contents to place all free memory together in one large block. To make compaction feasible, relocation should be dynamic

Question sources

Computer Science model exam 2 · Question 79

Question 30 | Q00916

Which one of the following function of operating system is categorized under process management?

A. Allocates the device in the efficient way

B. De-allocates the resources.

C. .
Allocates the memory when the process requests it to do so.

D. Allocates the processor (CPU) to a process

Hint

Separate broad resource-management goals from individual services or applications.

Answer D: Allocates the processor (CPU) to a process

CPU allocation is explicitly process/processor management (PDF p6). Memory requests belong to memory management (p5), and device allocation belongs to device management (p6).

Why each choice is right or wrong

A - Incorrect: Device allocation is listed under device management.

B - Incorrect: Resource deallocation is too broad and appears in several management categories, not this precise processor task.

C - Incorrect: Memory allocation is explicitly under memory management (p5).

D - Correct: Allocating CPU to a process is explicitly listed under processor management (p6).

Primary note proof

Study-note section OS01

> An OS allocates CPU time, memory, storage, devices and communication resources, and provides services to programs.

Study-note section OS06

> Long-term scheduling admits jobs; medium-term scheduling suspends/swaps them; short-term scheduling selects ready work.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 6 | lines 4-9

> In multiprogramming environment, OS decides which process gets the processor when and how much time. This function is called process scheduling. Operating System does the following activities for processor management. Keeps tracks of processor and status of process. Program responsible for this task is known as traffic controller.
> Allocates the processor (CPU) to a process.
> De-allocates processor when processor is no longer required.

Operating System module | PDF page 5 | lines 26-36

> Memory management refers to management of Primary Memory or Main Memory. Main memory is a large array of words or bytes where each word or byte has its own address. Main memory provides a fast storage that can be access directly by the CPU. So, for a program to be executed, must in the main memory.
> Activities Operating System for memory management.
> Keeps tracks of primary memory (i.e. what part of it are in use by whom, what part are not in use.)
> In multiprogramming, OS decides which process will get memory when and how much.
> Allocates the memory when the process requests it to do so.
> De-allocates the memory when the process no longer needs it or has been terminated.

Operating System module | PDF page 6 | lines 11-17

> OS manages device communication via their respective drivers. Activities of Operating System for device management.
> Keeps tracks of all devices. Program responsible for this task is known as the I/O

controller.
Decides which process gets the device when and for how much time.
Allocates the device in the efficient way.
De-allocates devices.

Question sources

Computer Science Exit Exam · 2018 · Question 29

Question 31 | Q00928

What is the primary function of an operating system?

A. To connect to the internet

B. To create documents and spreadsheets

C. .
To design computer hardware

D. To act as an intermediary between users and computer hardware

Hint

Separate broad resource-management goals from individual services or applications.

Answer D: To act as an intermediary between users and computer hardware

PDF p5 defines the OS as intermediary between users and hardware and controller of program execution. D states this general role; the other options are particular applications or other activities.

Why each choice is right or wrong

A - Incorrect: Internet connection is narrower than the whole OS definition.

B - Incorrect: Document authoring is a program activity, not the definition on p5.

C - Incorrect: Hardware design is not managing hardware during execution.

D - Correct: Directly matches the intermediary definition on p5.

Primary note proof

Study-note section OS01

An OS allocates CPU time, memory, storage, devices and communication resources, and provides services to programs. Convenience means making tasks easy through consistent interfaces, files and device abstractions. Efficiency means using resources effectively; it is not synonymous with the fastest response for every process. Application development tools use OS services but application development itself is not a core resource-management function.

Study-note section OS03

A shell reads/interprets user commands; a GUI is another interface. Browsers, office tools and editors are applications.

A user installs a new printer. The OS automatically detects and configures it. This is an example of:

A. Plug-and-play functionality

B. Manual driver installation

C. .
Manual hardware management

D. Resource allocation

Hint

Separate device hardware, device-specific software and general event or transfer mechanisms.

Answer A: Plug-and-play functionality.

OS34 defines plug-and-play as discovering and configuring compatible new hardware, with the qualification that a driver may still be required. That is exactly the printer scenario. The automatic wording excludes the two manual alternatives. Resource allocation may occur during configuration, but it is broader than the specific automatic detection/configuration feature requested by the question.

Why each choice is right or wrong

A - Correct: Automatically discovering and configuring the installed printer is precisely the plug-and-play behavior described.

B - Incorrect: The scenario explicitly says automatic detection/configuration rather than manual driver installation by the user.

C - Incorrect: Manual hardware management conflicts with the automatic configuration behavior specified in the scenario.

D - Incorrect: Resources may be assigned during setup, but the specific automatic discovery feature is plug-and-play.

Primary note proof

Study-note section OS34

> Plug-and-play discovers/configures compatible new hardware but may still require a driver.

Study-note section OS34

> A driver converts OS requests into device-specific operations. Device independence and uniform naming hide brand-specific details; error handling reports/retries supported failures.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 10 | lines 30-37

> I/O subsystem comprised of I/O devices and their corresponding driver software. Drivers hides the peculiarities of specific hardware devices from the user as the device driver knows the peculiarities of the specific device.
> Operating System manages the communication between user and device drivers.
> The major activities of an operating system with respect to I/O Operation.
> • I/O operation means read or write operation with any file or any specific I/O device.
> • Program may require any I/O device while running.
> • Operating system provides the access to the required I/O device when required.

Operating System module | PDF page 47 | lines 19-26

> 12.5 Device driver
> Device driver is a program or routine developed for an I/O device. A device driver implements I/O operations or behaviors on a specific class of devices. For example a system supports one or a number of multiple brands of terminals, all slightly different terminals may have a single terminal driver. In the layered structure of I/O system, device driver lies between interrupt handler and device independent I/O software. The job of a device driver is following.
> To accept request from the device independent software above it.
> To see to it that the request is executed.

Question sources

Computer Science Exit Exam · 2018 · Question 48

Question 33 | Q00944

In asystem, resources cannot be forcibly taken from processes; they must be released voluntarily. Which deadlock condition does this represent?

A. No Preemption

B. Hold and Wait

C. .
Mutual Exclusion

D. Circular Wait

Hint

Trace the resource dependencies and distinguish necessary conditions from evidence of an actual deadlock.

Answer A: No preemption.

OS22 directly defines no resource preemption as requiring voluntary release. The stem repeats that resources cannot be forcibly taken, so the match is exact. Hold-and-wait concerns retaining one resource while requesting another, mutual exclusion concerns exclusive possession, and circular wait concerns a closed dependency chain. None of those separately states the prohibition on forced withdrawal.

Why each choice is right or wrong

A - Correct: Prohibiting forced withdrawal and requiring voluntary release is exactly the no-preemption resource condition.

B - Incorrect: Hold-and-wait concerns retaining a resource while requesting another, not whether forced removal is permitted.

C - Incorrect: Mutual exclusion limits concurrent holders; it does not itself require voluntary release.

D - Incorrect: Circular wait describes a closed chain of dependencies rather than the resource-withdrawal rule.

Primary note proof

Study-note section OS22

> Mutual exclusion allows at most one holder of a nonshareable resource. Hold-and-wait means retaining a resource while requesting another. No resource preemption means release must be voluntary. Circular wait forms a closed chain of such waits.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 10 | lines 23-28

> • Loads a program into memory.
> • Executes the program.

- Handles program's execution.

- Provides a mechanism for process communication.
- Provides a mechanism for deadlock handling.

Question sources

Computer Science Exit Exam · 2018 · Question 57

Question 34 | Q00984

How does an operating system improve efficiency in a multi-user environment?

A. By allowing only one user to access the system at a time

B. By disabling all background services

C. .
By using time-sharing and process scheduling to allocate CPU time fairly among users and processes

D. By requiring manual intervention for each task

Hint

Compare interaction, CPU sharing and deadline requirements under the stated system model.

Answer C: .
By using time-sharing and process scheduling to allocate CPU time fairly among users and processes

Time-sharing switches CPU among users and gives each a small portion of time (PDF p7), reducing idle time and giving quick response. C captures that scheduling-based allocation.

Why each choice is right or wrong

A - Incorrect: One user at a time contradicts the simultaneous time-sharing service on p7.

B - Incorrect: Disabling background services is not the mechanism described.

C - Correct: CPU scheduling and time-sharing are explicitly the mechanism on p7.

D - Incorrect: Manual intervention per task is not the CPU-switching mechanism.

Primary note proof

Study-note section OS02

Batch jobs run with little interaction after submission. Multiprogramming keeps several jobs available so another can use the CPU while one waits; it does not require fixed time slices. Time-sharing uses rapid scheduling/preemption to support interactive users. A single CPU interleaves execution; multiple CPUs can execute work truly in parallel. Shared-memory multiprocessors do not require each CPU to have private main memory.

Study-note section OS20

Fair-share scheduling allocates according to stated weights, potentially per user/group rather than per process.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 7 | lines 20-33

Time sharing is a technique which enables many people, located at various terminals, to use a particular computer system at the same time. Time-sharing or multitasking is a logical extension of multiprogramming. Processor's time which is shared among multiple users simultaneously is termed as time-sharing. The main difference between Multi-programmed Batch Systems and Time-Sharing Systems is that in case of multi-programmed batch systems, objective is to maximize processor use, whereas in Time-Sharing Systems objective is to minimize response time.
Multiple jobs are executed by the CPU by switching between them, but the switches occur so frequently. Thus, the user can receive an immediate response. For example, in a transaction processing, processor execute each user program in a short burst or quantum of computation. That is if n users are present, each user can get time quantum. When the user submits the command, the response time is in few seconds at most.
Operating system uses CPU scheduling and multiprogramming to provide each user with a small portion of a time. Computer systems that were designed primarily as batch systems

Computer Science Exit Exam · 2018 · Question 97

Question 35 | Q00994

Which exits are involuntary? Here “Terminate exit” means an externally imposed kill, “Fatal exit” means an unrecoverable execution fault, and “Error exit” means the program chooses to exit after detecting bad input. Select all that apply.

A. Normal exit

B. Terminate exit

C. Fatal exit

D. Error exit

Hint

Separate creation, image replacement and termination; classify termination by its cause.

Answer B, C: Terminate exit; Fatal exit

An externally imposed kill and an unrecoverable execution fault stop a process involuntarily. Normal completion is chosen by the program, and detecting an input error then exiting is also a voluntary program decision. The meanings separate causes of termination instead of treating every use of the word terminate as one category. Thus the external-kill and fatal-fault choices are selected.

Why each choice is right or wrong

A - Incorrect: Normal completion is a voluntary exit.

B - Correct: The defined external kill imposes termination and is involuntary.

C - Correct: An unrecoverable execution fault imposes termination and is involuntary.

D - Incorrect: The program-detected error exit is a voluntary decision under the stated meaning.

Primary note proof

Study-note section OS07

> Normal completion and a program-detected error exit are voluntary; an unrecoverable fault or being killed is involuntary. exit() terminates normally through the runtime; abort() requests abnormal termination.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 16 | lines 29-39

> 1. New The process is being created.

Question 36 | Q01085

How do we define the term Thread?

A. Device that controls input

B. Variable that controls movement

C. Controlled execution of applications

D. None of the above

Hint

Compare per-thread execution context with shared process resources and the stated thread mapping.

Answer D: None of the above

A thread is a separate flow of execution through process code with its own PC, registers and stack (PDF p27). None of A-C states that definition; controlled execution of applications is too broad to identify a thread.

Why each choice is right or wrong

A - Incorrect: A device is not the defined flow of execution.

B - Incorrect: A variable is not a flow of control with a stack and PC.

C - Incorrect: Generic controlled application execution does not distinguish thread from process or scheduler.

D - Correct: None of A-C gives the thread definition on p27.

Primary note proof

Study-note section OS08

> A thread has its own PC, registers and stack. Threads in a process share code, address space and usually open-file resources. A process can contain many threads; a thread belongs to one process at a time. Threads are not a group of processes and need not execute sequentially. Independent processes can exist; cooperating ones communicate/share data.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 27 | lines 6-14

> A thread is a flow of execution through the process code, with its own program counter, system registers and stack. A thread is also called a light weight process. Threads provide a

way to improve application performance through parallelism. Threads represent a software approach to improving performance of operating system by reducing the overhead thread is equivalent to a classical process.
Each thread belongs to exactly one process and no thread can exist outside a process. Each thread represents a separate flow of control. Threads have been successfully used in implementing network servers and web server. They also provide a suitable foundation for parallel execution of applications on shared memory multiprocessors. Following figure shows

Web Programming practice questions · Question 18

Question 37 | Q01186

Where are the list of processes that are prepared to be executed and waiting placed?

A. Job queue

B. Ready queue

C. Execution queue

D. Process queue

Hint

Decide whether the process is eligible, running or waiting, then identify the responsible queue or scheduling role.

Answer B: Ready queue

PDF p19 says processes wait in the ready queue for CPU allocation. That is exactly prepared to execute but awaiting a processor.

Why each choice is right or wrong

A - Incorrect: Job queue contains all processes in the system (p18), rather than specifically ready ones.

B - Correct: Ready queue is the explicit CPU-waiting queue (p19).

C - Incorrect: No separate execution queue is defined for this purpose.

D - Incorrect: Process queue is generic and not the specific named queue on p19.

Primary note proof

Study-note section OS06

The ready queue contains eligible work; device queues hold blocked requests. The broad textbook job queue contains processes in the system, while an admission queue more narrowly holds jobs awaiting memory/admission. Long-term scheduling admits jobs; medium-term scheduling suspends/swaps them; short-term scheduling selects ready work.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 19 | lines 6-12

> A newly arrived process is put in the ready queue. Processes waits in ready queue for allocating the CPU. Once the CPU is assigned to a process, then that process will execute. While executing the process, any one of the following events can occur.
> • The process could issue an I/O request and then it would be placed in an I/O queue.
> • The process could create new sub process and will wait for its termination.
> • The process could be removed forcibly from the CPU, as a result of interrupt and put back in the ready queue.

Operating System module | PDF page 18 | lines 13-18

> The process scheduling is the activity of the process manager that handles the removal of the running process from the CPU and the selection of another process on the basis of a particular strategy.
> Process scheduling is an essential part of a Multiprogramming operating system. Such operating systems allow more than one process to be loaded into the executable memory at a time and loaded process shares the CPU using time multiplexing.

Question sources

Computer Science model exam 2 · Question 7

Question 38 | Q01192

CPU scheduling is the basis of _____

A. Multiprogramming operating systems

B. Larger memory-sized systems

C. Multiprocessor systems

D. None of the mentioned

Hint

Compare interaction, CPU sharing and deadline requirements under the stated system model.

Answer A: Multiprogramming operating systems

Process scheduling is explicitly essential to a multiprogramming OS (PDF p18), enabling loaded processes to time-share one CPU; multiple processors or unusually large RAM are not required.

Why each choice is right or wrong

A - Correct: Multiprogramming explicitly needs this CPU sharing (pp13,18).

B - Incorrect: Large RAM is not the defining scheduling basis.

C - Incorrect: Multiprogramming can assume a single shared processor (p13).

D - Incorrect: The module explicitly names multiprogramming.

Primary note proof

Study-note section OS02

> Multiprogramming keeps several jobs available so another can use the CPU while one waits; it does not require fixed time slices. Time-sharing uses rapid scheduling/preemption to support interactive users. A single CPU interleaves execution; multiple CPUs can execute work truly in parallel.

Study-note section OS06

> Long-term scheduling admits jobs; medium-term scheduling suspends/swaps them; short-term scheduling selects ready work.

Module passages - related reading

Operating System module | PDF page 18 | lines 13-18

> The process scheduling is the activity of the process manager that handles the removal of the running process from the CPU and the selection of another process on the basis of a particular strategy.
> Process scheduling is an essential part of a Multiprogramming operating system. Such operating systems allow more than one process to be loaded into the executable memory at a time and loaded process shares the CPU using time multiplexing.

Operating System module | PDF page 13 | lines 21-25

> 4.3 Multiprogramming
> When two or more programs are residing in memory at the same time, then sharing the processor is referred to the multiprogramming. Multiprogramming assumes a single shared processor. Multiprogramming increases CPU utilization by organizing jobs so that the CPU always has one to execute.

Question sources

Computer Science model exam 2 · Question 13

Operating Systems practice questions · Question 5

Question 39 | Q01251

An OS designer must choose between checking for deadlock after every resource request and checking periodically. No detection cost, request rate or acceptable delay is specified. Which conclusion about a universally best checking schedule is justified?

A. Both checking on every request and checking periodically are always equally optimal

B. Checking at fixed time intervals is always optimal

C. Checking on every resource request is always optimal

D. Neither schedule is universally best; the choice trades detection overhead against delay

Hint

Separate handling before allocation from actions taken after detection, and consider the cost of checking.

Answer D: Neither schedule is universally best; the choice trades detection overhead against delay

Checking after every request can discover a problem promptly but incurs repeated detection overhead. Periodic checking reduces check frequency while allowing a deadlock to persist until the next check. Which tradeoff is suitable depends on workload and acceptable detection delay. Without those criteria neither schedule is universally optimal, nor is there a basis for claiming they are always equally good.

Why each choice is right or wrong

A - Incorrect: The two policies need not have equal overhead or detection delay.

B - Incorrect: Fixed intervals may suit some workloads, but no universal optimum follows.

C - Incorrect: Per-request checks can impose excessive overhead despite earlier detection.

D - Correct: This states the overhead-versus-delay tradeoff without asserting an unsupported universal optimum.

Primary note proof

Study-note section OS26

> Checking on every request versus periodically trades overhead against detection delay; no universal best interval exists.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Question sources

Computer Science model exam 2 · Question 72

Question 40 | Q01265

Which listed operation is directly an OS/tool task? Here “bad-block recovery” specifically means autonomous drive-internal sector remapping, and “booting from disk” means the initial power-on stage before the kernel has been loaded.

A. bad-block recovery

B. booting from disk

C. disk initialization

D. all of the mentioned

Hint

Identify whether data is in transit, retained for reuse or queued for a device.

Answer C: disk initialization

Disk initialization and filesystem creation are identified as OS/tool work. Firmware starts the boot sequence before the kernel takes control, while a drive may use its own firmware to remap defective sectors. The question asks about that direct responsibility boundary, rather than broad coordination of every disk-related activity. Consequently disk initialization is the only matching choice, and the aggregate is too broad.

Why each choice is right or wrong

A - Incorrect: The specified bad-sector remapping is drive-firmware work, not the requested OS/tool operation.

B - Incorrect: The stage beginning boot is firmware work before kernel control.

C - Correct: Disk initialization/filesystem preparation is OS/tool work.

D - Incorrect: The other operations include firmware responsibilities, so all is too broad.

Primary note proof

Study-note section OS35

> Disk initialization/filesystem creation is OS/tool work, firmware begins boot, and drive firmware may remap bad sectors.

Study-note section OS03

> Firmware/bootloader stages execute before transferring control to a kernel loaded into RAM.

Error Handling - An operating system that uses protected memory can guard against many kinds of hardware and application errors.

Question sources

Computer Science model exam 2 · Question 86

Question 41 | Q01274

Which method is used to prevent threads or processes from accessing a single resource?

A. PCB

B. Semaphore

C. Job Scheduler

D. Non-Contiguous Memory Allocation

Hint

Track available permits and blocked operations using the stated semaphore model.

Answer B: A semaphore can enforce one-at-a-time access.

OS11 describes a binary semaphore as one permit and gives wait(m); critical work; signal(m) with m initialized to 1. This prevents competing threads/processes from entering the protected resource operation simultaneously; it does not mean nobody can ever use the resource. A PCB stores process state, a scheduler selects jobs, and allocation layout does not enforce this resource-access rule.

Why each choice is right or wrong

A - Incorrect: A PCB records execution and resource state rather than supplying atomic mutual-exclusion operations.

B - Correct: A one-permit semaphore with atomic wait/signal can serialize entry to the protected resource operation.

C - Incorrect: A job scheduler selects admitted or ready work; it does not by itself protect shared resource accesses.

D - Incorrect: Noncontiguous memory placement changes allocation layout rather than synchronizing access to one shared resource.

Primary note proof

Study-note section OS11

A semaphore provides atomic wait/P/down and signal/V/up operations. Under the nonnegative-token model, wait consumes one available token or blocks when none is available; signal supplies a token and may wake a waiter. Implementations using negative internal counts encode waiters differently, so state the model. A binary semaphore represents one permit; a counting semaphore tracks several. A mutex normally has ownership rules that a general semaphore lacks.

Study-note section OS11

Initialize a mutex semaphore to 1. Each thread does wait(m); critical work; signal(m). For a buffer of N slots use empty=N, full=0 and mutex=1: producer waits empty then mutex, inserts, unlocks then signals full. Waiting for empty while already holding mutex can prevent the consumer from freeing a slot.

Study-note section OS05

A saved PC identifies where execution resumes.

Study-note section OS06

Long-term scheduling admits jobs; medium-term scheduling suspends/swaps them; short-term scheduling selects ready work.

• Loads a program into memory.
• Executes the program.
• Handles program's execution.
• Provides a mechanism for process synchronization.
• Provides a mechanism for process communication.
• Provides a mechanism for deadlock handling.

Operating System module | PDF page 17 | lines 4-7

Each process is represented in the operating system by a process control block (PCB) also called a task control block. PCB is the data structure used by the operating system. Operating system groups all information that needs about particular process. PCB contains many pieces of information associated with a specific process which is described below.

Operating System module | PDF page 20 | lines 15-21

It is also called CPU scheduler. Main objective is increasing system performance in accordance with the chosen set of criteria. It is the change of ready state to running state of the process. CPU scheduler selects process among the processes that are ready to execute and allocates CPU to one of them.
Short term scheduler also known as dispatcher, execute most frequently and makes the

fine-grained decision of which process to execute next. Short term scheduler is faster than long term scheduler.

Operating System module | PDF page 34 | lines 47-56

External fragmentation is avoided by using paging technique. Paging is a technique in which physical memory is broken into blocks of the same size called pages (size is power of 2, between 512 bytes and 8192 bytes). When a process is to be executed, it's corresponding pages are loaded into any available memory frames.
Logical address space of a process can be non-contiguous and a process is allocated physical memory whenever the free memory frame is available. Operating system keeps track of all free frames. Operating system needs n free frames to run a program of size n pages.
Address generated by CPU is divided into
• Page number (p) -- page number is used as an index into a page table which contains base address of each page in physical memory.

Question sources

Computer Science model exam 2 · Question 95

Question 42 | Q01283

Which of the following is not a type of operating system?

A. Windows

B. Linux

C. macOS

D. Microsoft Office

Hint

Use the stated historical or platform scope and distinguish origin from technical capability.

Answer D: Microsoft Office is an application suite.

OS40 explicitly identifies Microsoft Office as an application suite and discusses Windows, Linux and macOS as OS/kernel families. Office runs using OS services rather than providing the core resource-management platform. Thus Office is the exclusion in this list. The kernel-versus-distribution distinction for Linux does not turn it into an office application or invalidate the conventional OS-family contrast.

Why each choice is right or wrong

A - Incorrect: Windows is identified as the Microsoft operating-system family, so it is not the application-suite exclusion.

B - Incorrect: Linux names a kernel used with distributions as operating systems, unlike the Office application suite.

C - Incorrect: macOS is an operating-system product rather than a user application suite in this classification.

D - Correct: Microsoft Office is explicitly described as an application suite, not an operating system.

Primary note proof

Study-note section OS40

> Linux is a Unix-compatible kernel written from scratch by Linus Torvalds; a distribution combines it with userland, libraries and tools. Android's base kernel layer is Linux; its framework and applications are higher layers. AOSP is open source, while a shipped device can include proprietary applications/services. Windows and macOS are both proprietary products, although macOS contains open-source components, so "which is not open source?" offering both is ambiguous. Microsoft Office is an application suite.

Module passages - related reading

Operating System module | PDF page 8 | lines 21-26

> Network Operating System runs on a server and provides server the capability to manage data, users, groups, security, applications, and other networking functions. The primary purpose of the network operating system is to allow shared file and printer access among multiple computers in a network, typically a local area network (LAN), a private network or to other networks. Examples of network operating systems are Microsoft Windows Server 2003, Microsoft Windows Server 2008, UNIX, Linux, Mac OS X, Novell NetWare, and BSD.

Operating System module | PDF page 53 | lines 5-7

> Linux is one of popular version of UNIX operating System. It is open source as its source code is freely available. It is free to use. Linux was designed considering UNIX compatibility. Its functionality list is quite similar to that of UNIX.

Question sources

Operating Systems practice questions · Question 1

Question 43 | Q01284

What is the main function of an operating system?

A. To manage hardware resources

B. To manage software applications

C. To manage user accounts

D. To manage network connections

Hint

Separate broad resource-management goals from individual services or applications.

Answer A: To manage hardware resources

Hardware resource management is the general technical definition on PDF p5. Applications, accounts and connections are narrower services and cannot replace that umbrella definition.

Why each choice is right or wrong

A - Correct: Matches the hardware-management definition (p5).

B - Incorrect: Application execution is a service within that broader role.

C - Incorrect: Accounts are one aspect of network/user administration (p8).

D - Incorrect: Network connection management is narrower than OS-wide hardware management (p8).

Primary note proof

Study-note section OS01

> An OS allocates CPU time, memory, storage, devices and communication resources, and provides services to programs. Convenience means making tasks easy through consistent interfaces, files and device abstractions. Efficiency means using resources effectively; it is not synonymous with the fastest response for every process. Application development tools use OS services but application development itself is not a core resource-management function.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 5 | lines 6-13

> An operating System (OS) is an intermediary between users and computer hardware. It provides users an environment in which a user can execute programs conveniently and efficiently. In technical terms, it is software which manages hardware. An operating System controls the allocation of resources and services such as memory, processors, devices and information.
> 1.1 Definition
> An operating system is a program that acts as an interface between the user and the computer hardware and controls the execution of all kinds of programs.

Operating System module | PDF page 8 | lines 21-26

> Network Operating System runs on a server and provides server the capability to manage data, users, groups, security, applications, and other networking functions. Question sources

Operating Systems practice questions · Question 2

Question 44 | Q01285

Which of the following is not a memory management technique used in operating systems?

A. Paging

B. Segmentation

C. Swapping

D. Virtualization

Hint

Identify the abstraction layer and separate a protected service request from an application task.

Answer D: Virtualization, in the virtual-machine sense.

OS04 defines virtualization as presenting virtual machine environments and distinguishes it from virtual memory. OS27 describes swapping, OS30 paging and OS31 segmentation as memory-management mechanisms. Under the guest-machine sense used here, virtualization is therefore the option outside that list. The answer depends on that stated sense; the broader phrase memory virtualization would describe a different use of the word.

Why each choice is right or wrong

A - Incorrect: Paging maps fixed-size virtual pages to physical frames and is explicitly a memory-management mechanism.

B - Incorrect: Segmentation maps variable-length logical regions and is explicitly a memory-management mechanism.

C - Incorrect: Swapping moves a process to backing store and is a memory-management operation described here.

D - Correct: In the note's guest-machine sense, virtualization presents virtual computers rather than naming these process-memory techniques.

Primary note proof

Study-note section OS04

> Virtualization presents a virtual machine environment, often allowing guest operating systems on one host through a hypervisor. It differs from virtual memory, which translates a process's addresses. Kernel, shell, API and VM are not interchangeable labels.

Study-note section OS27

> Swapping traditionally moves a whole process to backing store; paging moves individual pages.

Study-note section OS30

> Pages and physical frames have equal fixed size P. Divide virtual address v into page=floor(v/P) and offset=v mod P. The page table maps a page to a frame and protection/status flags.

Study-note section OS31

Segmentation uses logical variable-length units such as code, stack and arrays.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 34 | lines 47-56

External fragmentation is avoided by using paging technique. Paging is a technique in which physical memory is broken into blocks of the same size called pages (size is power of 2, between 512 bytes and 8192 bytes). When a process is to be executed, it's corresponding pages are loaded into any available memory frames.
Logical address space of a process can be non-contiguous and a process is allocated physical memory whenever the free memory frame is available. Operating system keeps track of all free frames. Operating system needs n free frames to run a program of size n pages.
Address generated by CPU is divided into
• Page number (p) -- page number is used as an index into a page table which contains base address of each page in physical memory.

Operating System module | PDF page 35 | lines 7-12

Segmentation is a technique to break memory into logical pieces where each piece represents a group of related information. For example, data segments or code segment for each process, data segment for operating system and so on. Segmentation can be implemented using or without using paging.
Unlike paging, segment is having varying sizes and thus eliminates internal fragmentation. External fragmentation still exists but to lesser extent.

Operating System module | PDF page 33 | lines 15-19

Swapping is a mechanism in which a process can be swapped temporarily out of main memory to a backing store, and then brought back into memory for continued execution.
Backing store is a usually a hard disk drive or any other secondary storage which fast in access and large enough to accommodate copies of all memory images for all users. It must be capable of providing direct access to these memory images.

Operating System module | PDF page 37 | lines 6-11

Virtual memory is a technique that allows the execution of processes which are not completely available in memory. The main visible advantage of this scheme is that programs can be larger than physical memory. Virtual memory is the separation of user logical memory from physical memory.
This separation allows an extremely large virtual memory to be provided for programmers when only a smaller physical memory is available. Following are the situations, when entire

Question sources

Operating Systems practice questions · Question 3

Question 45 | Q01286

Which of the following is not a process scheduling algorithm?

A. First-Come-First-Serve (FCFS)

B. Round-Robin

C. Shortest-Job-First (SJF)

D. Binary Search Tree (BST)

Hint

Separate class assignment, movement between queues and the rule for choosing work.

Answer D: Binary Search Tree is a data structure.

OS19 explicitly states that a binary search tree may implement a queue but is not itself a CPU selection policy. FCFS, Round Robin and SJF are actual scheduling algorithms described in OS15, OS18 and OS16. Consequently BST is the exclusion. Using a tree internally to maintain priorities would not change the selection policy into an algorithm called BST.

Why each choice is right or wrong

A - Incorrect: FCFS is a scheduling policy that runs ready bursts in their arrival order.

B - Incorrect: Round Robin is a scheduling policy assigning cyclic ready-queue turns bounded by a quantum.

C - Incorrect: SJF is a scheduling policy selecting the shortest next burst among ready jobs.

D - Correct: BST is a data structure that can support queue operations rather than a CPU scheduling policy.

Primary note proof

Study-note section OS19

> A binary search tree is a data structure that might implement a queue; it is not itself a CPU selection policy.

Study-note section OS15

> FCFS runs ready bursts in arrival order and ordinarily does not preempt.

Study-note section OS16

> Non-preemptive SJF/SJN chooses the shortest next burst among currently ready jobs.

Study-note section OS18

> RR serves a ready queue cyclically for at most quantum q per turn.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 23 | lines 12-17

7.1 First Come First Serve (FCFS)
• Jobs are executed on first come, first serve basis.
• Easy to understand and implement.
• Poor in performance as average wait time is high.
Wait time of each process is following
Process Wait Time: Service Time - Arrival Time

Operating System module | PDF page 25 | lines 10-14

7.4 Round Robin Scheduling
• Each process is provided a fix time to execute called quantum.
• Once a process is executed for given time period. Process is preempted and other process executes for given time period.
• Context switching is used to save states of preempted processes.

Operating System module | PDF page 23 | lines 23-26

7.2 Shortest Job First (SJF)
• Best approach to minimize waiting time.
• Impossible to implement
• Processer should know in advance how much time process will take.

Question sources

Operating Systems practice questions · Question 4

Question 46 | Q01287

Which of the following is not a type of file system?

A. FAT32

B. NTFS

C. EXT4

D. HTTP

Hint

Distinguish a file operation, a resource handle, an offset and file metadata.

Answer D: HTTP is an application communication protocol.

OS36 explicitly names FAT32, NTFS and ext4 as filesystem formats and contrasts HTTP as an application communication protocol. Filesystems organize stored file content and metadata; a communication protocol does not become a filesystem merely because it transfers file contents. Therefore HTTP is the single option outside the stated filesystem-format category.

Why each choice is right or wrong

A - Incorrect: FAT32 is explicitly identified as a filesystem format, making it a member of the requested category.

B - Incorrect: NTFS is explicitly identified as a filesystem format, not a communication-protocol exclusion.

C - Incorrect: ext4 is explicitly identified as a filesystem format in the complete study note.

D - Correct: HTTP is an application communication protocol rather than a filesystem format for organizing stored files.

Primary note proof

Study-note section OS36

> Sockets also support ordinary read/write, alongside socket/connect/send operations, so read is not uniquely “not a network call.” FAT32, NTFS and ext4 are filesystem formats; HTTP is an application communication protocol.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 48 | lines 5-8

> 13.1 File
> A file is a named collection of related information that is recorded on secondary storage such as magnetic disks, magnetic tapes and optical disks. In general, a file is a sequence of bits, bytes, lines or records whose meaning is defined by the file’s creator and user.

Question 47 | Q01288

What is the purpose of a device driver in an operating system?

A. To manage user accounts

B. To manage hardware resources

C. To manage software applications

D. To manage network connections

Hint

Separate device hardware, device-specific software and general event or transfer mechanisms.

Answer B: To manage hardware resources

A driver implements I/O behavior for a device class and hides hardware peculiarities (PDF pp10,47). B is the closest option when hardware resources means its particular device; it should not imply one driver manages every resource.

Why each choice is right or wrong

A - Incorrect: Account administration is not the device-specific I/O job.

B - Correct: Device hardware I/O management is supported (pp10,47).

C - Incorrect: Applications use driver services but the driver does not manage applications generally.

D - Incorrect: Only a network-device driver concerns a network adapter; that is not every driver's purpose.

Primary note proof

Study-note section OS34

> A controller is device hardware exposing status, control and data registers. A driver converts OS requests into device-specific operations. Device independence and uniform naming hide brand-specific details; error handling reports/retries supported failures.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 10 | lines 30-37

> I/O subsystem comprised of I/O devices and their corresponding driver software. Drivers hides the peculiarities of specific hardware devices from the user as the device driver knows the peculiarities of the specific device.
> Operating System manages the communication between user and device drivers.
> The major activities of an operating system with respect to I/O Operation.
> • I/O operation means read or write operation with any file or any specific I/O device.
> • Program may require any I/O device while running.
> • Operating system provides the access to the required I/O device when required.

Operating System module | PDF page 47 | lines 19-26

> 12.5 Device driver
> Device driver is a program or routine developed for an I/O device. A device driver implements I/O operations or behaviors on a specific class of devices. For example a system supports one or a number of multiple brands of terminals, all slightly different terminals may have a single terminal driver. In the layered structure of I/O system, device driver lies between interrupt handler and device independent I/O software. The job of a device driver is following.
> To accept request from the device independent software above it.
> To see to it that the request is executed.

Operating Systems practice questions · Question 6

Question 48 | Q01289

Which listed forms can serve as user interfaces to an operating system? Treat possible interface forms generally, rather than features of a particular product. Select all that apply.

A. Command-line interface (CLI)

B. Graphical user interface (GUI)

C. Natural language interface (NLI)

D. Virtual reality interface (VRI)

Hint

Distinguish identity checks, permission checks and the particular security property at issue.

Answer A, B, C, D: Command-line interface (CLI); Graphical user interface (GUI); Natural language interface (NLI); Virtual reality interface (VRI)

Command lines, graphical interfaces, speech or natural-language interaction, and virtual-reality interaction are possible interface forms. An OS need not implement all of them for each form to count as a possible interface. Because the stated question asks about capability in general rather than a particular product's installed features, all four listed forms satisfy it.

Why each choice is right or wrong

A - Correct: A CLI accepts text commands as a user interface.

B - Correct: A GUI provides graphical controls for user interaction.

C - Correct: Natural-language or speech interaction is a possible interface form.

D - Correct: VR interaction is also a possible interface form.

Primary note proof

Study-note section OS39

> CLI, GUI, speech/natural language and VR are possible interfaces, not a closed list excluding the last two.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 14 | lines 18-23

> Interactivity refers that a User is capable to interact with computer system. Operating system does the following activities related to interactivity.
> • OS provides user an interface to interact with system.
> • OS managers input devices to take inputs from the user. For example, keyboard.
> • OS manages output devices to show outputs to the user. For example, Monitor.
> • OS Response time needs to be short since the user submits and waits for the result.

Operating System module | PDF page 54 | lines 18-20

commands of the operating system. It can be used to do various types of operations, call application programs etc.
Security - Linux provides user security using authentication features like password

Question sources

Operating Systems practice questions · Question 7

Question 49 | Q01290

Which of the following is not a component of an operating system kernel?

A. Process scheduler

B. Memory manager

C. File system

D. Web browser

Hint

Distinguish command interfaces, privileged core services and the stages of booting.

Answer D: Web browser.

OS03 defines the kernel through core resource management, protection and system-call handling, while explicitly calling browsers applications. Scheduling, memory management and filesystem service are core resource-management functions in the textbook kernel sense. Some systems move services outside a kernel, but a web browser remains the clear application-level exclusion from the listed ordinary kernel responsibilities.

Why each choice is right or wrong

A - Incorrect: Process scheduling is a core resource-management function in the textbook kernel model used here.

B - Incorrect: Memory management is a core resource-management function rather than the listed user application.

C - Incorrect: Filesystem service belongs to ordinary OS resource management in this textbook kernel-level comparison.

D - Correct: The note explicitly identifies browsers as applications rather than components implementing the kernel's core role.

Primary note proof

Study-note section OS03

The kernel implements core resource management, protection and system-call handling. A shell reads/interprets user commands; a GUI is another interface. Browsers, office tools and editors are applications.

Study-note section OS01

An OS allocates CPU time, memory, storage, devices and communication resources, and provides services to programs.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 53 | lines 11-15

operating system. It is consisting of various modules and it interacts directly with the underlying hardware. Kernel provides the required abstraction to hide low level hardware details to system or application programs.
System Library - System libraries are special functions or programs using which application programs or system utilities accesses Kernel's features. These libraries

Operating System module | PDF page 6 | lines 4-9

In multiprogramming environment, OS decides which process gets the processor when and how much time. This function is called process scheduling. Operating System does the following activities for processor management. Keeps tracks of processor and status of process. Program responsible for this task is known as traffic controller.
Allocates the processor (CPU) to a process.
De-allocates processor when processor is no longer required.

Operating System module | PDF page 31 | lines 24-31

Memory management is the functionality of an operating system which handles or manages primary memory. Memory management keeps track of each and every memory location either it is allocated to some process or it is free. It checks how much memory is to be allocated to processes. It decides which process will get memory at what time. It tracks whenever some memory gets freed or unallocated and correspondingly it updates the status.
Memory management provides protection by using two registers, a base register and a limit register. The base register holds the smallest legal physical memory address and the limit register specifies the size of the range. For example, if the base register holds 300000 and the

Operating Systems practice questions · Question 8

Question 50 | Q01291

Which of the following is not a type of system call used in operating systems?

A. Process control

B. File management

C. Network communication

D. Video editing

Hint

Identify the abstraction layer and separate a protected service request from an application task.

Answer D: Video editing is an application operation.

OS04 lists process control, file/device management, information retrieval and communication as service categories. It explicitly distinguishes video editing as an application operation. Network communication falls within communication services, so it is not excluded merely because it uses sockets rather than local files. The category outside generic system calls is video editing.

Why each choice is right or wrong

A - Incorrect: Process control is explicitly included among protected operating-system service categories.

B - Incorrect: File management is explicitly included among operating-system services requested through system calls.

C - Incorrect: Network communication falls within the communication service category rather than being excluded from system calls.

D - Correct: Video editing is an application-level operation, not a standard generic system-call service category.

Primary note proof

Study-note section OS04

> Process control, file/device management, information retrieval and communication are service categories. Video editing and a database-specific write_database() are application operations, not standard generic syscall categories/names.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 10 | lines 5-15

> An Operating System provides services to both the users and to the programs.
> • It provides programs, an environment to execute.
> • It provides users, services to execute the programs in a convenient manner.
> Operating Systems can provide the following common services:
> ✓ Program execution
> ✓ I/O operations
> ✓ File System manipulation
> ✓ Communication
> ✓ Error Detection
> ✓ Resource Allocation
> ✓ Protection

Operating System module | PDF page 10 | lines 23-28

> • Loads a program into memory.
> • Executes the program.

- Handles program's execution.
- Provides a mechanism for process synchronization.
- Provides a mechanism for process communication.
- Provides a mechanism for deadlock handling.

Operating System module | PDF page 11 | lines 3-8

- Program needs to read a file or write a file.
- The operating system gives the permission to the program for operation on file.
- Permission varies from read-only, read-write, denied and so on.
- Operating System provides an interface to the user to create/delete files.
- Operating System provides an interface to the user to create/delete directories.
- Operating System provides an interface to create the backup of file system.

Operating System module | PDF page 11 | lines 15-19

- Two processes often require data to be transferred between them.
- The both processes can be on the one computer or on different computer but are connected through computer network.
- Communication may be implemented by two methods either by Shared Memory or by Message Passing.

Operating Systems practice questions · Question 9

Question 51 | Q01292

What is the purpose of a shell in an operating system?

A. To manage user accounts

B. To manage hardware resources

C. To manage software applications

D. To provide a user interface

Hint

Distinguish command interfaces, privileged core services and the stages of booting.

Answer D: To provide a user interface

PDF p54 calls the shell an interface to the kernel that takes user commands. D captures its interface role rather than an individual resource-management service.

Why each choice is right or wrong

A - Incorrect: Account management may be requested through shell commands, but is not its defining role.

B - Incorrect: Kernel provides low-level hardware services (p54).

C - Incorrect: Invoking applications is supported, but does not replace the general interface role.

D - Correct: Directly follows the user-command interface description (p54).

Primary note proof

Study-note section OS03

> The kernel implements core resource management, protection and system-call handling. A shell reads/interprets user commands; a GUI is another interface. Browsers, office tools and editors are applications.

Operating System module | PDF page 54 | lines 24-30

> Hardware layer - Hardware consists of all peripheral devices (RAM/ HDD/ CPU etc.).
> Kernel - Core component of Operating System, interacts directly with hardware, provides low level services to upper layer components.
> Shell - An interface to kernel, hiding complexity of kernel's functions from users. Takes commands from user and executes kernel's functions.
> Utilities - Utility programs giving user most of the functionalities of an operating systems.

Question sources

Operating Systems practice questions · Question 10

Question 52 | Q01293

Which listed systems are proprietary OS products rather than open-source systems as a whole? Interpret Linux as the open-source kernel and Android as AOSP without vendor additions. Select all that apply.

A. Linux

B. Android

C. macOS

D. Windows

Hint

Use the stated historical or platform scope and distinguish origin from technical capability.

Answer C, D: macOS; Windows

Windows and macOS are proprietary products. The existence of open-source components within macOS does not make the complete product open source. Linux is treated here as the open-source kernel, and Android is explicitly restricted to AOSP, excluding proprietary applications or services bundled by device vendors. With that component-versus-product scope fixed, both macOS and Windows belong in the selected set.

Why each choice is right or wrong

A - Incorrect: Linux is the open-source kernel under the stated scope.

B - Incorrect: AOSP is open source; vendor additions are explicitly excluded.

C - Correct: macOS is a proprietary product even though some components are open source.

D - Correct: Windows is a proprietary OS product.

Primary note proof

Study-note section OS40

> Linux is a Unix-compatible kernel written from scratch by Linus Torvalds; a distribution combines it with userland, libraries and tools. Android's base kernel layer is Linux; its framework and applications are higher layers. AOSP is open source, while a shipped device can include proprietary applications/services. Windows and macOS are both proprietary products, although macOS contains open-source components, so "which is not open source?" offering both is ambiguous. Microsoft Office is an application suite.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 53 | lines 5-7

> Linux is one of popular version of UNIX operating System. It is open source as its source code is freely available. It is free to use. Linux was designed considering UNIX compatibility. Its functionality list is quite similar to that of UNIX.

Operating System module | PDF page 54 | lines 5-17

> Portable - Portability means software can works on different types of hardware in same way. Linux kernel and application programs support their installation on any kind of hardware platform.
> Open Source - Linux source code is freely available and it is community-based development project. Multiple teams work in collaboration to enhance the capability of Linux operating system and it is continuously evolving.
> Multi-User - Linux is a multiuser system means multiple users can access system resources like memory/ ram/ application programs at same time.
> Multiprogramming - Linux is a multiprogramming system means multiple applications can run at same time.
> Hierarchical File System - Linux provides a standard file structure in which system files/ user files are arranged.
> Shell - Linux provides a special interpreter program which can be used to execute

Question sources

Operating Systems practice questions · Question 11

Question 53 | Q01294

What is the purpose of a bootloader in an operating system?

A. To load the operating system kernel into memory

B. To manage hardware resources

C. To manage software applications

D. To provide a user interface

Hint

Distinguish command interfaces, privileged core services and the stages of booting.

Answer A: Load the OS kernel into memory.

OS03 places firmware/bootloader stages before transfer of control to a kernel loaded into RAM. This identifies loading the kernel as the bootloader purpose among the alternatives. Resource management is subsequently a kernel role, application management is a running-system function, and user interfaces are provided by shells/GUI components rather than defining the bootloader's purpose.

Why each choice is right or wrong

A - Correct: The bootloader prepares the kernel in memory and transfers control to it during the boot sequence.

B - Incorrect: Core hardware-resource management is the kernel's role after the bootloader hands over control.

C - Incorrect: Managing running applications belongs to the operating system's runtime services rather than defining the bootloader.

D - Incorrect: Shells and GUIs provide user interfaces; that is not the bootloader's principal role here.

Primary note proof

Study-note section OS03

> Firmware/bootloader stages execute before transferring control to a kernel loaded into RAM.

Study-note section OS03

> The kernel implements core resource management, protection and system-call handling. A shell reads/interprets user commands; a GUI is another interface. Browsers, office tools and editors are applications.

Module passages - related reading

Operating System module | PDF page 32 | lines 11-14

> In dynamic loading, a routine of a program is not loaded until it is called by the program. All routines are kept on disk in a re-locatable load format. The main program is loaded into memory and is executed. Other routines methods or modules are loaded on request. Dynamic loading makes better memory space utilization and unused routines are never loaded.

Question sources

Operating Systems practice questions · Question 12

Question 54 | Q01295

What is the difference between a kernel-level thread and a user-level thread?

A. Kernel-level threads are faster than user-level threads

B. Kernel-level threads are managed by the operating system, while user-level threads are managed by the application

C. Kernel-level threads can access hardware resources directly, while user-level threads cannot

D. There is no difference between a kernel-level thread and a user-level thread

Hint

Compare per-thread execution context with shared process resources and the stated thread mapping.

Answer B: Kernel-level threads are managed by the operating system, while user-level threads are managed by the application

Application management of user threads is explicit on PDF p28; kernel management is explicit on p29. Kernel threads are generally slower to create/manage, and management location does not automatically grant application thread code kernel privilege.

Why each choice is right or wrong

A - Incorrect: Opposes the p29 slower-to-create/manage comparison.

B - Correct: Exactly matches management location on pp28-29.

C - Incorrect: Confuses scheduling/management by the kernel with execution privilege; p53 distinguishes user code from kernel code.

D - Incorrect: Management location and costs explicitly differ.

Primary note proof

Study-note section OS08

User-level threads are managed by a library; kernel threads are known to the OS. In many-to-one mapping, a blocking kernel call can block all user threads and one kernel execution context cannot use multiple CPUs simultaneously. One-to-one permits another kernel thread to run when one blocks. Many-to-many multiplexes user threads over several kernel threads. Speed and reliability depend on implementation; the management layer alone guarantees neither. Application names such as browser or Excel do not prove a particular version's threading model.

Study-note section OS-S02

In the conventional library-thread comparison, user-level thread creation and switching can avoid entering the kernel. Kernel-managed thread creation and management commonly incur additional kernel work and are therefore generally slower to create and manage in this comparison. This is a typical comparison, not a universal speed or reliability guarantee.

Study-note section OS-S02

Being scheduled or managed by the kernel does not give application thread code kernel privilege. Ordinary applications and supporting utilities execute in restricted user mode and request protected services through libraries and system calls. Kernel component code executes in privileged kernel mode and performs permitted low-level hardware operations.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 28 | lines 20-29

In this case, application manages thread management kernel is not aware of the existence of threads. The thread library contains code for creating and destroying threads, for passing message and data between threads, for scheduling thread execution and for saving and restoring thread contexts. The application begins with a single thread and begins running in that thread.
Advantages
• Thread switching does not require Kernel mode privileges.
• User level thread can run on any operating system.
• Scheduling can be application specific in the user level thread.
• User level threads are fast to create and manage.

Operating System module | PDF page 29 | lines 4-16

In this case, thread management done by the Kernel. There is no thread management code in the application area. Kernel threads are supported directly by the operating system. Any application can be programmed to be multithreaded. All of the threads within an application are supported within a single process.
The Kernel maintains context information for the process as a whole and for individuals' threads within the process. Scheduling by the Kernel is done on a thread basis. The Kernel performs thread creation, scheduling and management in Kernel space. Kernel threads are

generally slower to create and manage than the user threads.
Advantages
• Kernel can simultaneously schedule multiple threads from the same process on multiple processes.
• If one thread in a process is blocked, the Kernel can schedule another thread of the same process.

Operating System module | PDF page 53 | lines 21-29

Kernel component code executes in a special privileged mode called kernel mode with full access to all resources of the computer. This code represents a single process, executes in single address space and do not require any context switch and hence is very efficient and fast. Kernel runs each process and provides system services to processes, provides protected access to hardware to processes.
Support code which is not required to run in kernel mode is in System Library. User programs and other system programs works in User Mode which has no access to system hardware and kernel code. User programs/ utilities use System libraries to access Kernel functions to get system's low level tasks.

Question sources

Operating Systems practice questions · Question 13

Question 55 | Q01296

Which listed item is a general data structure rather than a deadlock-specific avoidance method or dependency-graph analysis?

A. Banker's algorithm

B. Wait-for graph algorithm

C. Resource allocation graph algorithm

D. Binary search tree algorithm

Hint

Compute remaining needs and simulate feasible completions before deciding whether an allocation is safe.

Answer D: Binary search tree algorithm

Banker’s algorithm checks whether tentative allocations leave a safe completion sequence and is an avoidance method. Wait-for and resource-allocation graphs represent dependencies used in deadlock reasoning. A binary search tree is a general data structure and does not, by its name alone, specify deadlock handling. The broader category distinguishes the unrelated item without misclassifying avoidance or detection as strict prevention.

Why each choice is right or wrong

A - Incorrect: Banker is a deadlock-avoidance method, so it belongs to the stated handling category.

B - Incorrect: A wait-for graph directly represents process dependencies for deadlock analysis.

C - Incorrect: A resource-allocation graph represents resource requests and assignments for deadlock reasoning.

D - Correct: A binary search tree is a general search structure rather than a deadlock-specific method.

Primary note proof

Study-note section OS25

> Avoidance allows requests only if the resulting state remains safe. Banker requires maximum claims. Compute Need=Max−Allocation.

Study-note section OS23

> In a resource-allocation graph, P→R is a request and an instance R→P is an assignment. Follow these directions to form waits. No cycle implies no deadlock; with one instance of every resource type, a cycle implies deadlock. With multiple instances a cycle alone is insufficient: another instance may permit completion. A wait-for graph replaces single-instance resource nodes with P→Q when P waits for Q.

Study-note section OS19

> A binary search tree is a data structure that might implement a queue; it is not itself a CPU selection policy.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 10 | lines 23-28

> • Loads a program into memory.
> • Executes the program.
> • Handles program's execution.
> • Provides a mechanism for process synchronization.
> • Provides a mechanism for process communication.
> • Provides a mechanism for deadlock handling.

Question sources

Operating Systems practice questions · Question 14

Question 56 | Q01297

What is the general execution role of a process in an operating system, regardless of the application it runs?

A. To manage user accounts

B. To manage hardware resources

C. To execute a program instance with its own address space and resources

D. To provide a user interface

Hint

Distinguish stored instructions, an executing instance and its saved execution state.

Answer C: To execute a program instance with its own address space and resources

A process is an executing instance of a program, accompanied by an address space and resources. Its application may administer accounts, interact with hardware through services, or display a user interface, but none of those specialized jobs defines every process. The execution option expresses the general role. It also distinguishes a running instance from a program stored as instructions.

Why each choice is right or wrong

A - Incorrect: Account administration is only one possible application responsibility.

B - Incorrect: Hardware management is an OS responsibility rather than the general role of every process.

C - Correct: Executing a program instance with an address space and resources is the process abstraction.

D - Incorrect: Many processes run without providing a user interface.

Primary note proof

Study-note section OS05

> A program is stored instructions; a process is an executing instance with address space and resources. A process does not universally “manage applications” or “provide a user interface.” The PCB records identity, state, PC/registers, scheduling information, memory/accounting details and I/O/open-resource state.

Study-note section OS01

> An OS allocates CPU time, memory, storage, devices and communication resources, and provides services to programs.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 16 | lines 6-9

A process is a program in execution. The execution of a process must progress in a sequential fashion. Definition of process is following.
• A process is defined as an entity which represents the basic unit of work to be implemented in the system.

Operating System module | PDF page 5 | lines 6-13

An operating System (OS) is an intermediary between users and computer hardware. It provides users an environment in which a user can execute programs conveniently and efficiently. In technical terms, it is software which manages hardware. An operating System controls the allocation of resources and services such as memory, processors, devices and information.
1.1 Definition
An operating system is a program that acts as an interface between the user and the computer hardware and controls the execution of all kinds of programs.

Question sources

Operating Systems practice questions · Question 15

Question 57 | Q01298

Which of the following is not a type of process state in an operating system?

A. Ready

B. Running

C. Blocked

D. Sleeping Beauty

Hint

Decide whether the process is eligible, running or waiting, then identify the responsible queue or scheduling role.

Answer D: Sleeping Beauty

The state list on PDF p16 contains Ready, Running and Waiting. Interpret Blocked as the waiting-for-event state. Sleeping Beauty is not one of this module's five named states.

Why each choice is right or wrong

A - Incorrect: Ready is explicitly listed.

B - Incorrect: Running is explicitly listed.

C - Incorrect: Blocked is the conventional paraphrase of waiting for an event; Waiting is the module's exact term.

D - Correct: Not present in the five-state model, and not a defined state term.

Primary note proof

Study-note section OS06

New processes are created/admitted; ready means eligible for CPU but not currently running. Running uses a CPU. Waiting/blocked means unable to proceed until an event; terminated means execution has ended. Running→ready follows time-slice expiry or another preemption. Running→waiting follows blocking I/O. I/O completion normally gives waiting→ready, not a guaranteed immediate running state.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 16 | lines 29-39

1. New The process is being created.
2. Ready The process is waiting to be assigned to a processor. Ready processes are waiting to have the processor allocated to them by the operating system so that they can run.
3. Running Process instructions are being executed (i.e. The process that is currently being executed).
4. Waiting The process is waiting for some event to occur (such as the completion of an I/O operation).
5. Terminated The process has finished execution.

Operating Systems practice questions · Question 16

Question 58 | Q01299

What is the difference between a process and a thread in an operating system?

A. A process is a unit of execution, while a thread is a unit of scheduling

B. A process is a unit of scheduling, while a thread is a unit of execution

C. There is no difference between a process and a thread

D. A process can have multiple threads, while a thread can only belong to one process

Hint

Compare per-thread execution context with shared process resources and the stated thread mapping.

Answer D: A process can have multiple threads, while a thread can only belong to one process

PDF p27 says every thread belongs to exactly one process and separate flows improve parallel execution; p29 supports multiple threads within one process. D directly expresses that relationship.

Why each choice is right or wrong

A - Incorrect: Processes and threads can both be scheduled (pp20,29); this is not an exclusive distinction.

B - Incorrect: Both may participate in scheduling and execution; reversal does not define their containment.

C - Incorrect: PDF p27 explicitly distinguishes heavy processes from light threads.

D - Correct: Directly follows the one-process-per-thread and multithreaded-process definitions (pp27,29).

Primary note proof

Study-note section OS08

> A thread has its own PC, registers and stack. Threads in a process share code, address space and usually open-file resources. A process can contain many threads; a thread belongs to one process at a time. Threads are not a group of processes and need not execute sequentially. Independent processes can exist; cooperating ones communicate/share data.

Study-note section OS08

> User-level threads are managed by a library; kernel threads are known to the OS. In many-to-one mapping, a blocking kernel call can block all user threads and one kernel execution context cannot use multiple CPUs simultaneously. One-to-one permits another kernel thread to run when one blocks. Many-to-many multiplexes user threads over several kernel threads.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 27 | lines 6-14

> A thread is a flow of execution through the process code, with its own program counter, system registers and stack. A thread is also called a light weight process. Threads provide a way to improve application performance through parallelism. Threads represent a software approach to improving performance of operating system by reducing the overhead thread is equivalent to a classical process.
> Each thread belongs to exactly one process and no thread can exist outside a process. Each thread represents a separate flow of control. Threads have been successfully used in implementing network servers and web server. They also provide a suitable foundation for parallel execution of applications on shared memory multiprocessors. Following figure shows

Operating System module | PDF page 29 | lines 4-16

> In this case, thread management done by the Kernel. There is no thread management code in the application area. Kernel threads are supported directly by the operating system. Any application can be programmed to be multithreaded. All of the threads within an application are supported within a single process.
> The Kernel maintains context information for the process as a whole and for individuals' threads within the process. Scheduling by the Kernel is done on a thread basis. The Kernel performs thread creation, scheduling and management in Kernel space. Kernel threads are generally slower to create and manage than the user threads.

Advantages
• Kernel can simultaneously schedule multiple threads from the same process on multiple processes.
• If one thread in a process is blocked, the Kernel can schedule another thread of the same process.

Operating System module | PDF page 20 | lines 15-21

It is also called CPU scheduler. Main objective is increasing system performance in accordance with the chosen set of criteria. It is the change of ready state to running state of the process. CPU scheduler selects process among the processes that are ready to execute and allocates CPU to one of them.
Short term scheduler also known as dispatcher, execute most frequently and makes the fine-grained decision of which process to execute next. Short term scheduler is faster than long term scheduler.

Operating Systems practice questions · Question 17

Question 59 | Q01300

Which of the following is not a type of synchronization mechanism used in operating systems?

A. Mutex

B. Semaphore

C. Monitor

D. Keyboard

Hint

Track available permits and blocked operations using the stated semaphore model.

Answer D: Keyboard.

OS10 describes monitors as protected operations with condition synchronization, and OS11 explains mutex/semaphore exclusion mechanisms. These coordinate concurrent execution. A keyboard is an input device rather than such a coordination abstraction. Interrupts generated by hardware may participate in event handling, but that does not make the keyboard itself a mutex, semaphore or monitor mechanism.

Why each choice is right or wrong

A - Incorrect: A mutex provides owned mutual exclusion and is a synchronization mechanism in the note.

B - Incorrect: A semaphore coordinates participants through atomic wait and signal operations, so it is a synchronization mechanism.

C - Incorrect: A monitor combines protected operations and condition synchronization, making it a genuine synchronization abstraction.

D - Correct: A keyboard is a physical input device rather than a process/thread synchronization abstraction.

Primary note proof

Study-note section OS11

> A semaphore provides atomic wait/P/down and signal/V/up operations. Under the nonnegative-token model, wait consumes one available token or blocks when none is available; signal supplies a token and may wake a waiter. Implementations using negative internal counts encode waiters differently, so state the model. A binary semaphore represents one permit; a counting semaphore tracks several. A mutex normally has ownership rules that a general semaphore lacks.

Study-note section OS10

> A barrier waits until a defined set of participants reaches a point; a monitor encapsulates protected operations with condition synchronization.

Study-note section OS34

> Input/output/storage/NIC devices are OS-managed hardware; user accounts are identities.

Module passages - related reading

Operating Systems practice questions · Question 18

Question 60 | Q01301

What is the purpose of a context switch in an operating system?

A. To save the state of a process or thread and switch to another process or thread

B. To manage hardware resources

C. To manage software applications

D. To provide a user interface

Hint

Distinguish stored instructions, an executing instance and its saved execution state.

Answer A: To save the state of a process or thread and switch to another process or thread

PDF p21 defines saving/restoring CPU context so execution can resume, enabling multiple processes to share a CPU. A identifies that specific operation.

Why each choice is right or wrong

A - Correct: Directly states save state and switch execution (p21).

B - Incorrect: Resource management is the wider OS purpose, not the specific state operation.

C - Incorrect: Application management is broader and omits saved execution state.

D - Incorrect: A user interface is not what a context switch provides.

Primary note proof

Study-note section OS05

> A context switch saves one execution context and restores another; useful application work is interrupted by this overhead.

Study-note section OS08

> A thread has its own PC, registers and stack.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 21 | lines 41-50

> A context switch is the mechanism to store and restore the state or context of a CPU in Process Control block so that a process execution can be resumed from the same point at a later time. Using this technique, a context switcher enables multiple processes to share a single CPU. Context switching is an essential part of a multitasking operating system features.
> When the scheduler switches the CPU from executing one process to execute another, the context switcher saves the content of all processor registers for the process being removed from the CPU, in its process descriptor. The context of a process is represented in the

process control block of a process. Context switch time is pure overhead. Context switching can significantly affect performance as modern computers have a lot of general

Operating Systems practice questions · Question 19

Question 61 | Q01302

Which item is an application-layer protocol rather than a primitive OS IPC mechanism such as a stream, shared region or message queue?

A. Pipes

B. Shared memory

C. Message queues

D. HTTP requests

Hint

Identify how data moves, which participant waits and what event allows the operation to continue.

Answer D: HTTP requests

Pipes provide streams, shared memory provides a common region, and message queues preserve messages. These are primitive IPC mechanisms in the stated classification. HTTP is an application protocol that can use an underlying communication mechanism such as sockets. It can certainly carry interprocess communication, but it is the only listed application-layer protocol rather than one of the primitive mechanisms requested here.

Why each choice is right or wrong

A - Incorrect: Pipes are primitive stream-based IPC mechanisms.

B - Incorrect: Shared memory is a primitive common-region IPC mechanism.

C - Incorrect: Message queues are primitive message-preserving IPC mechanisms.

D - Correct: HTTP requests use an application-layer protocol over an underlying mechanism.

Primary note proof

Study-note section OS09

Shared memory lets processes access a common region and requires synchronization for conflicting updates. Message passing exchanges data through send/receive operations. Pipes provide streams; message queues preserve messages; sockets connect endpoints; RPC requests a remote operation. HTTP is an application protocol over a communication mechanism and can carry interprocess communication, so it is not universally “not IPC.”

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 11 | lines 15-19

> • Two processes often require data to be transferred between them.
> • The both processes can be on the one computer or on different computer but are connected through computer network.
> • Communication may be implemented by two methods either by Shared Memory or by Message Passing.

Question sources

Operating Systems practice questions · Question 20

Question 62 | Q01303

What is the general purpose of a system call in an operating system?

A. To manage user accounts

B. To request a protected kernel service

C. To manage software applications

D. To provide a user interface

Hint

Identify the abstraction layer and separate a protected service request from an application task.

Answer B: To request a protected kernel service

A system call is the mechanism through which executing code requests a protected kernel service. Process creation, file reads and socket operations are examples. A program that manages accounts, applications or a user interface may use system calls, but those tasks are not the mechanism’s general purpose. The option captures the common role without restricting it to one kind of resource.

Why each choice is right or wrong

A - Incorrect: Account management can use system calls but does not define their general purpose.

B - Correct: Requesting a protected kernel service states the general purpose.

C - Incorrect: Managing applications is a possible use rather than the system-call mechanism’s definition.

D - Incorrect: A UI may issue calls, but providing a UI is not the general system-call role.

Primary note proof

Study-note section OS04

A system call requests a protected kernel service, such as creating a process, reading a file or opening a socket. A user-facing API/library may wrap that request; not every library function enters the kernel.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 53 | lines 16-19

implement most of the functionalities of the operating system and do not requires kernel module's code access rights.
System Utility - System Utility programs are responsible to do specialized, individual level tasks.

Operating System module | PDF page 45 | lines 28-33

Application I/O Interface represents the structuring techniques and interfaces for the operating system to enable I/O devices to be treated in a standard, uniform way. The actual differences lies kernel level modules called device drivers which are custom tailored to corresponding devices but show one of the standard interfaces to applications. The purpose of the device-driver layer is to hide the differences among device controllers from the I/O subsystem of the kernel, such as the I/O system calls. Following are the characteristics of I/O

Question sources

Operating Systems practice questions · Question 21

Question 63 | Q01305

Which of the following is not a type of scheduling policy used in operating systems?

A. Preemptive

B. Non-preemptive

C. Cooperative

D. Infinite

Hint

Check whether the running burst can be interrupted before completion or blocking.

Answer D: Infinite is not a scheduling-policy category.

OS14 distinguishes preemptive and non-preemptive scheduling and explains cooperative scheduling as relying on voluntary release. OS19 explicitly rejects Infinite as a standard scheduling-policy category. Thus the first three labels describe genuine scheduling approaches, whereas infinite does not identify a selection or preemption rule. It should not be confused with a possible unbounded waiting-time outcome.

Why each choice is right or wrong

A - Incorrect: Preemptive scheduling can interrupt running work and return it to the ready state.

B - Incorrect: Non-preemptive scheduling retains a running burst until completion, blocking or voluntary release.

C - Incorrect: Cooperative scheduling is the recognized approach relying on voluntary release of execution.

D - Correct: Infinite names no scheduling selection or preemption policy in the provided note.

Primary note proof

Study-note section OS14

> Non-preemptive scheduling keeps a running CPU burst until completion, blocking or voluntary yielding. Preemptive scheduling can return running work to ready, usually after a timer quantum or a more urgent arrival. FCFS and non-preemptive SJF are non-preemptive; RR and SRTF are preemptive. Priority can be either, so its name alone cannot decide. Cooperative describes relying on voluntary release.

Study-note section OS19

> “Infinite” is not a standard scheduling-policy category.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 25 | lines 10-14

> 7.4 Round Robin Scheduling
> • Each process is provided a fix time to execute called quantum.
> • Once a process is executed for given time period. Process is preempted and other process executes for given time period.
> • Context switching is used to save states of preempted processes.

Operating System module | PDF page 23 | lines 12-17

> 7.1 First Come First Serve (FCFS)
> • Jobs are executed on first come, first serve basis.
> • Easy to understand and implement.
> • Poor in performance as average wait time is high.
> Wait time of each process is following
> Process Wait Time: Service Time - Arrival Time

Question sources

Operating Systems practice questions · Question 23

Question 64 | Q01306

24.What is the purpose of a page table in memory management?

A. To translate virtual addresses to physical addresses

B. To manage user accounts

C. To manage software applications

D. To provide a user interface

Hint

Split the address into page and offset, then apply the mapping and access checks.

Answer A: To translate virtual addresses to physical addresses

Page number indexes a table containing physical page bases (PDF p34); combining the base with the page offset yields the physical address (p35). Thus a page table participates in virtual-to-physical translation, A.

Why each choice is right or wrong

A - Correct: Matches page-table address lookup (pp34-35).

B - Incorrect: User accounts are not the page-number-to-frame mapping.

C - Incorrect: Application management is broader than the translation data structure.

D - Incorrect: An execution address map does not provide the user interface.

Primary note proof

Study-note section OS30

> Pages and physical frames have equal fixed size P. Divide virtual address v into page=floor(v/P) and offset=v mod P. The page table maps a page to a frame and protection/status flags. Physical address=frame×P+offset. A TLB caches translations; a TLB miss may require a table walk while the page is already resident.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 34 | lines 47-56

> External fragmentation is avoided by using paging technique. Paging is a technique in which physical memory is broken into blocks of the same size called pages (size is power of 2, between 512 bytes and 8192 bytes). When a process is to be executed, it's corresponding pages are loaded into any available memory frames.
> Logical address space of a process can be non-contiguous and a process is allocated physical memory whenever the free memory frame is available. Operating system keeps track of all free frames. Operating system needs n free frames to run a program of size n pages.
> Address generated by CPU is divided into
> • Page number (p) -- page number is used as an index into a page table which contains base address of each page in physical memory.

Operating System module | PDF page 33 | lines 6-13

> The run-time mapping from virtual to physical address is done by the memory management unit (MMU) which is a hardware device. MMU uses following mechanism to convert virtual address to physical address.
> • The value in the base register is added to every address generated by a user process which is treated as offset at the time it is sent to memory. For example, if the base register value is 10000, then an attempt by the user to use address location 100 will be dynamically reallocated to location 10100.
> • The user program deals with virtual addresses; it never sees the real physical addresses.

Operating System module | PDF page 35 | lines 3-4

> • Page offset (d) -- page offset is combined with base address to define the physical memory address.

Question sources

Operating Systems practice questions · Question 24

Question 65 | Q01308

What is the purpose of a system monitor in an operating system?

A. To manage user accounts

B. To manage hardware resources

C. To manage software applications

D. To provide information about system performance and resource usage

Hint

Identify whether data is in transit, retained for reuse or queued for a device.

Answer D: Report performance and resource usage.

OS35 says a system monitor reports CPU, memory, storage and network usage and measures rather than creating more resources. This matches providing information about performance and usage. User-account administration, hardware allocation and application management are broader OS/administration functions, not the monitor's defining reporting role. Observing a resource is distinct from allocating or increasing it.

Why each choice is right or wrong

A - Incorrect: Account management is an administration function, not the monitor's specified performance-reporting purpose.

B - Incorrect: The monitor measures hardware usage rather than serving as the general resource-allocation manager.

C - Incorrect: Application management is broader than the monitor's role of reporting system performance and consumption.

D - Correct: Reporting system performance and resource usage directly matches the monitor definition in the note.

Primary note proof

Study-note section OS35

> A system monitor reports CPU, memory, storage and network usage; it measures rather than directly creating more resources.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 6 | lines 31-35

> Control over system performance -- Recording delays between request for a service and response from the system.
> Job accounting -- Keeping track of time and resources used by various jobs and users.
> Error detecting aids -- Production of dumps, traces, error messages and other debugging and error detecting aids.

Question 66 | Q01309

What is the difference between a kernel and a shell in an operating system?

A. A kernel is the core of the operating system, while a shell provides a user interface

B. A kernel provides a user interface, while a shell manages hardware resources

C. There is no difference between a kernel and a shell

D. A kernel manages hardware resources, while a shell manages software applications

Hint

Distinguish command interfaces, privileged core services and the stages of booting.

Answer A: A kernel is the core of the operating system, while a shell provides a user interface

The kernel is the core interacting with hardware (PDF p53); the shell takes user commands and interfaces to the kernel (p54). A preserves both roles.

Why each choice is right or wrong

A - Correct: Both halves match pp53-54.

B - Incorrect: Reverses the explicit roles.

C - Incorrect: The module lists and distinguishes the two layers.

D - Incorrect: First half is supported; invoking applications is only part of shell use, and omits its defining command interface.

Primary note proof

Study-note section OS03

> The kernel implements core resource management, protection and system-call handling. A shell reads/interprets user commands; a GUI is another interface. Browsers, office tools and editors are applications.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 53 | lines 11-15

> operating system. It is consisting of various modules and it interacts directly with the underlying hardware. Kernel provides the required abstraction to hide low level hardware details to system or application programs.
> System Library - System libraries are special functions or programs using which application programs or system utilities accesses Kernel's features. These libraries

Operating System module | PDF page 54 | lines 18-20

> commands of the operating system. It can be used to do various types of operations, call application programs etc.
> Security - Linux provides user security using authentication features like password

Operating System module | PDF page 54 | lines 24-30

> Hardware layer - Hardware consists of all peripheral devices (RAM/ HDD/ CPU etc.).
> Kernel - Core component of Operating System, interacts directly with hardware, provides low level services to upper layer components.
> Shell - An interface to kernel, hiding complexity of kernel's functions from users. Takes commands from user and executes kernel's functions.
> Utilities - Utility programs giving user most of the functionalities of an operating systems.

Question sources

Operating Systems practice questions · Question 27

Question 67 | Q01310

Which of the following is not a type of system call used in file management?

A. open()

B. close()

C. read()

D. write_database()

Hint

Distinguish a file operation, a resource handle, an offset and file metadata.

Answer D: write_database() is not a standard generic file-management system call.

OS36 identifies open, close and read as ordinary file operations, and OS04 explicitly distinguishes database-specific write_database() as an application operation rather than a standard generic syscall name. A database operation may internally use actual file syscalls, but that composition does not make its application-specific name a generic kernel file-management call.

Why each choice is right or wrong

A - Incorrect: open obtains an open-file reference and is a standard file-management operation described here.

B - Incorrect: close releases an open-file reference and is a standard file-management operation.

C - Incorrect: read transfers bytes from an open resource and is a standard generic file operation.

D - Correct: write_database is an application-specific database operation rather than a standard generic file-management syscall.

Primary note proof

Study-note section OS36

> A file has content and metadata such as name, size, owner, permissions and timestamps. open obtains an open-file reference, read/write transfer bytes, seek changes an offset, close releases a reference, truncate changes size and unlink removes a name.

Study-note section OS04

> Process control, file/device management, information retrieval and communication are service categories. Video editing and a database-specific write_database() are application operations, not standard generic syscall categories/names.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 11 | lines 3-8

> • Program needs to read a file or write a file.
> • The operating system gives the permission to the program for operation on file.
> • Permission varies from read-only, read-write, denied and so on.
> • Operating System provides an interface to the user to create/delete files.
> • Operating System provides an interface to the user to create/delete directories.
> • Operating System provides an interface to create the backup of file system.

Question sources

Operating Systems practice questions · Question 28

Question 68 | Q01311

Which item is a hardware/CPU event-notification mechanism rather than a high-level lock, participant rendezvous, or protected-operation abstraction?

A. Locks

B. Barriers

C. Monitors

D. Interrupts

Hint

Identify conflicting shared accesses and the safety or progress property required.

Answer D: Interrupts

Locks coordinate entry to protected state, barriers wait for participants to reach a common point, and monitors encapsulate protected operations with conditions. Interrupts notify the CPU of events and may help coordinate work, but belong to a different abstraction level. The classification therefore selects interrupts without denying that interrupts can participate in synchronization or completion notification.

Why each choice is right or wrong

A - Incorrect: A lock is a high-level mutual-exclusion abstraction.

B - Incorrect: A barrier is a participant rendezvous abstraction.

C - Incorrect: A monitor encapsulates protected operations and condition synchronization.

D - Correct: An interrupt is a CPU event-notification mechanism, the different abstraction level requested.

Primary note proof

Study-note section OS10

> Keep critical regions small and ensure every conflicting access uses the same protection. A barrier waits until a defined set of participants reaches a point; a monitor encapsulates protected operations with condition synchronization.

Study-note section OS11

> A mutex normally has ownership rules that a general semaphore lacks.

Study-note section OS34

> Polling checks readiness repeatedly; interrupts request CPU attention; DMA transfers blocks after setup without CPU work for every byte.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 10 | lines 23-28

• Loads a program into memory.
• Executes the program.
• Handles program's execution.
• Provides a mechanism for process synchronization.
• Provides a mechanism for process communication.
• Provides a mechanism for deadlock handling.

Operating System module | PDF page 45 | lines 10-22

The CPU hardware uses an interrupt request line wire which helps CPU to sense after executing every instruction. When the CPU checks that a controller has put a signal on the interrupt request line, the CPU saves a state, such as the current value of the instruction pointer, and jumps to the interrupt handler routine at a fixed address. The interrupt handler part determines the cause of the interrupt performs the necessary processing and executes an interrupt instruction to return the CPU to its execution state.
The basic mechanism of interrupt enables the CPU to respond to an asynchronous event, such as when a device controller becomes ready for service. Most CPUs have two interrupt request lines.
• non-maskable interrupt - Such kind of interrupts are reserved for events like unrecoverable memory errors.
• maskable interrupt - Such interrupts can be switched off by the CPU before the execution of critical instructions that must not be interrupted.

Question sources

Operating Systems practice questions · Question 29

Question 69 | Q01312

What is the purpose of a virtual machine in an operating system?

A. To manage user accounts

B. To manage hardware resources

C. To manage software applications

D. To provide a virtualized environment for running multiple operating systems on a single physical machine

Hint

Identify the abstraction layer and separate a protected service request from an application task.

Answer D: A virtualized environment can run guest operating systems on one physical host.

OS04 defines virtualization as presenting a virtual machine environment, often allowing guest operating systems on one host through a hypervisor. That is exactly the complete description in D. Account, hardware and application management may occur within host or guest systems, but those broad administrative roles do not define why a virtual machine is provided.

Why each choice is right or wrong

A - Incorrect: User-account management is not the defining purpose of presenting a virtual machine environment.

B - Incorrect: Hardware is mediated, but general hardware management alone omits the guest-machine environment requested.

C - Incorrect: Application management does not define a virtual machine or distinguish it from an ordinary running OS.

D - Correct: Providing guest-machine environments on one physical host directly matches the note's virtualization definition.

Primary note proof

Study-note section OS04

> Virtualization presents a virtual machine environment, often allowing guest operating systems on one host through a hypervisor. It differs from virtual memory, which translates a process's addresses. Kernel, shell, API and VM are not interchangeable labels.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 37 | lines 6-11

> Virtual memory is a technique that allows the execution of processes which are not completely available in memory. The main visible advantage of this scheme is that programs can be larger than physical memory. Virtual memory is the separation of user logical memory from physical memory.
> This separation allows an extremely large virtual memory to be provided for programmers when only a smaller physical memory is available. Following are the situations, when entire

Question sources

Operating Systems practice questions · Question 30

Question 70 | Q01313

Which item coordinates access but does not itself transfer arbitrary data payloads or request an operation in another process?

A. Message passing

B. Shared memory

C. Remote procedure call (RPC)

D. File locking

Hint

Identify how data moves, which participant waits and what event allows the operation to continue.

Answer D: File locking

Message passing transfers messages, shared memory carries data through a common region, and RPC requests an operation in another process or machine. File locking instead coordinates who may access a file or region. Locks can therefore be part of IPC synchronization while not being a payload-transfer mechanism themselves. The narrower wording makes file locking the unique match without denying its coordination role.

Why each choice is right or wrong

A - Incorrect: Message passing transfers data using send/receive operations.

B - Incorrect: Shared memory carries data in a common accessible region.

C - Incorrect: RPC communicates a request to perform another process's operation.

D - Correct: File locking coordinates access rather than carrying arbitrary payloads itself.

Primary note proof

Study-note section OS09

> Shared memory lets processes access a common region and requires synchronization for conflicting updates. Message passing exchanges data through send/receive operations. Pipes provide streams; message queues preserve messages; sockets connect endpoints; RPC requests a remote operation.

Study-note section OS09

> File locks coordinate access rather than transfer arbitrary payloads, though locking is synchronization within IPC.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 11 | lines 15-19

> • Two processes often require data to be transferred between them.
> • The both processes can be on the one computer or on different computer but are connected through computer network.
> • Communication may be implemented by two methods either by Shared Memory or by Message Passing.

Operating Systems practice questions · Question 31

Question 71 | Q01314

What is the purpose of a file system in an operating system?

A. To manage user accounts

B. To manage hardware resources

C. To manage software applications

D. To manage files and directories on storage devices

Hint

Distinguish a file operation, a resource handle, an offset and file metadata.

Answer D: To manage files and directories on storage devices

The file system tracks file information and locations and organizes directories (PDF p6); files store information on secondary storage (p48). D captures these functions.

Why each choice is right or wrong

A - Incorrect: Account administration manages user identities and accounts, rather than organizing stored file contents and directory names.

B - Incorrect: Hardware-resource management spans processors, memory and devices; it is broader than the file system's file-and-directory responsibility.

C - Incorrect: Application management does not describe file/directory organization.

D - Correct: Matches locations, directory organization and secondary storage (pp6,48).

Primary note proof

Study-note section OS36

> A file has content and metadata such as name, size, owner, permissions and timestamps. open obtains an open-file reference, read/write transfer bytes, seek changes an offset, close releases a reference, truncate changes size and unlink removes a name.

Study-note section OS37

> A single-level directory requires unique names in one namespace. Two-level directories separate users. A tree allows nested directories and absolute/relative paths; links can create shared graphs. Modern general-purpose systems commonly present hierarchical namespaces, but a feature name alone does not prove that every system excludes simpler arrangements.

Module passages - related reading

Operating Systems practice questions · Question 32

Question 72 | Q01315

In this question only, "task" means a thread within a process. Which statement describes the process-task ownership relationship?

A. There is no difference between a process and a task

B. A process is a unit of execution, while a task is a unit of scheduling

C. A process can have multiple tasks, while a task can only belong to one process

D. A task is a unit of execution, while a process is a unit of scheduling

Hint

Compare per-thread execution context with shared process resources and the stated thread mapping.

Answer C: A process can have multiple tasks, while a task can only belong to one process

With task explicitly defined to mean thread, a process may contain several tasks while each task belongs to one process at a time. The tasks share the process address space but have their own execution context. This ownership relationship does not follow from the word task universally; it follows from the definition supplied here. Execution-versus-scheduling slogans do not state that relationship.

Why each choice is right or wrong

A - Incorrect: A thread/task is not identical to its containing process under this definition.

B - Incorrect: The execution-versus-scheduling description does not express the defined ownership relationship.

C - Correct: A process can contain multiple threads/tasks, each belonging to one process at a time.

D - Incorrect: The reversed execution/scheduling labels do not describe thread ownership.

Primary note proof

Study-note section OS08

> A thread has its own PC, registers and stack. Threads in a process share code, address space and usually open-file resources. A process can contain many threads; a thread belongs to one process at a time. Threads are not a group of processes and need not execute sequentially. Independent processes can exist; cooperating ones communicate/share data.

Study-note section OS05

> Task is OS-specific terminology: it may mean process, thread or schedulable entity.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 16 | lines 6-9

> A process is a program in execution. The execution of a process must progress in a sequential fashion. Definition of process is following.
> • A process is defined as an entity which represents the basic unit of work to be implemented in the system.

Operating System module | PDF page 17 | lines 4-7

> Each process is represented in the operating system by a process control block (PCB) also called a task control block. PCB is the data structure used by the operating system. Operating system groups all information that needs about particular process. PCB contains many pieces of information associated with a specific process which is described below.

Question sources

Operating Systems practice questions · Question 33

Question 73 | Q01316

Which of the following is not a type of memory allocation algorithm used in operating systems?

A. First-Fit

B. Best-Fit

C. Next-Fit

D. Binary-Fit

Hint

Apply the stated hole-selection or base-and-bound rule with its explicit convention.

Answer D: Binary-Fit is not one of the standard fit-policy names.

OS28 defines first-fit, next-fit, best-fit and worst-fit, then explicitly says binary-fit is not one of these standard names. First-fit, best-fit and next-fit therefore belong to the allocation-policy category used by the question. Binary-fit is the supported exclusion; it should not be invented as a synonym for another algorithm merely because the word binary is familiar.

Why each choice is right or wrong

A - Incorrect: First-fit selects the first adequate hole and is an explicitly defined memory-allocation policy.

B - Incorrect: Best-fit chooses the smallest adequate hole and is an explicitly defined memory-allocation policy.

C - Incorrect: Next-fit resumes search from the previous position and is an explicitly defined allocation policy.

D - Correct: The note explicitly excludes binary-fit from the standard memory-allocation fit-policy names.

Primary note proof

Study-note section OS28

> First-fit selects the first adequate hole; next-fit continues from the previous search position; best-fit selects the smallest adequate hole; worst-fit selects the largest. No policy universally optimizes both search time and future storage utilization. Binary-fit is not one of these standard names.

Module passages - related reading

Operating Systems practice questions · Question 34

Question 74 | Q01317

What is the purpose of a system call interface in an operating system?

A. To manage user accounts

B. To manage hardware resources

C. To manage software applications

D. To provide a standardized interface for application programs to make system calls

Hint

Identify the abstraction layer and separate a protected service request from an application task.

Answer D: Provide the interface through which applications request system calls.

OS04 defines a system call as requesting a protected kernel service and distinguishes an API/library wrapper from the direct boundary. Option D describes the interface that applications use to make those requests. Account, hardware and application management can be services reached through it; they are not the general purpose of the interface itself.

Why each choice is right or wrong

A - Incorrect: Account operations may be exposed as services, but account management does not define the interface itself.

B - Incorrect: Hardware operations may be requested through services; general hardware management is not the interface definition.

C - Incorrect: Application management is a possible service use rather than the purpose of the syscall interface.

D - Correct: The interface supplies the application-to-system-call request path for protected kernel services.

Primary note proof

Study-note section OS04

> A system call requests a protected kernel service, such as creating a process, reading a file or opening a socket. A user-facing API/library may wrap that request; not every library function enters the kernel. Distinguish the application API from the direct user/kernel boundary when describing access to OS services.

Operating System module | PDF page 45 | lines 28-33

> Application I/O Interface represents the structuring techniques and interfaces for the operating system to enable I/O devices to be treated in a standard, uniform way. The actual differences lies kernel level modules called device drivers which are custom tailored to corresponding devices but show one of the standard interfaces to applications. The purpose of

the device-driver layer is to hide the differences among device controllers from the I/O subsystem of the kernel, such as the I/O system calls. Following are the characteristics of I/O

Operating System module | PDF page 53 | lines 16-19

implement most of the functionalities of the operating system and do not requires kernel module's code access rights.
System Utility - System Utility programs are responsible to do specialized, individual level tasks.

Question sources

Operating Systems practice questions · Question 35

Question 75 | Q01319

What is the purpose of a dispatcher in an operating system?

A. To manage user accounts

B. To manage hardware resources

C. To manage software applications

D. To switch the context of execution from one process to another

Hint

Decide whether the process is eligible, running or waiting, then identify the responsible queue or scheduling role.

Answer D: To switch the context of execution from one process to another

PDF p19 describes the dispatcher transferring execution to a queued process; p21 defines the context save/restore mechanism. D is the specific execution handoff rather than a broad management service.

Why each choice is right or wrong

A - Incorrect: Account management does not identify execution handoff.

B - Incorrect: Hardware management is a broad OS responsibility.

C - Incorrect: Application management is not the specific handoff operation.

D - Correct: Switching saved execution contexts matches pp19,21.

Primary note proof

Study-note section OS06

Long-term scheduling admits jobs; medium-term scheduling suspends/swaps them; short-term scheduling selects ready work. The dispatcher performs the handoff/context restore after selection.

Study-note section OS05

A context switch saves one execution context and restores another; useful application work is interrupted by this overhead.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 19 | lines 20-25

Non-Running Processes that are not running are kept in queue, waiting for their turn to execute. Each entry in the queue is a pointer to a particular process. Queue is implemented by using linked list. Use of dispatcher is as follows. When a process is interrupted, that process is transferred in the waiting queue. If the process has completed or aborted, the process is discarded. In either case, the dispatcher then selects a process from the queue to execute.

Operating System module | PDF page 21 | lines 41-50

A context switch is the mechanism to store and restore the state or context of a CPU in Process Control block so that a process execution can be resumed from the same point at a later time. Using this technique, a context switcher enables multiple processes to share a single CPU. Context switching is an essential part of a multitasking operating system features.
When the scheduler switches the CPU from executing one process to execute another, the context switcher saves the content of all processor registers for the process being removed from the CPU, in its process descriptor. The context of a process is represented in the process control block of a process. Context switch time is pure overhead. Context switching can significantly affect performance as modern computers have a lot of general

Question sources

Operating Systems practice questions · Question 37

Question 76 | Q01320

Which listed item is not a hardware resource managed by an operating system?

A. CPU

B. Memory

C. Keyboard

D. User account

Hint

Separate broad resource-management goals from individual services or applications.

Answer D: User account

CPU time, memory and input devices such as a keyboard are hardware resources allocated or controlled by the OS. A user account is an identity used in administration and protection, rather than a hardware device. The OS may manage accounts too, but that does not put them in the hardware-resource category. Completing the stem and replacing one option gives a unique exclusion.

Why each choice is right or wrong

A - Incorrect: The CPU is a managed processing resource.

B - Incorrect: Memory is a managed storage resource used during execution.

C - Incorrect: A keyboard is a managed input device.

D - Correct: A user account is an identity rather than a hardware resource.

Primary note proof

Study-note section OS01

> An OS allocates CPU time, memory, storage, devices and communication resources, and provides services to programs.

Study-note section OS34

> Input/output/storage/NIC devices are OS-managed hardware; user accounts are identities.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 5 | lines 6-13

> An operating System (OS) is an intermediary between users and computer hardware. It provides users an environment in which a user can execute programs conveniently and efficiently. In technical terms, it is software which manages hardware. An operating System controls the allocation of resources and services such as memory, processors, devices and information.
> 1.1 Definition
> An operating system is a program that acts as an interface between the user and the computer hardware and controls the execution of all kinds of programs.

Operating System module | PDF page 43 | lines 7-10

> Computers operate on many kinds of devices. General types include storage devices (disks, tapes), transmission devices (network cards, modems), and human-interface devices (screen, keyboard, mouse). Other devices are more specialized. A device communicates with a computer system by sending signals over a cable or even through the air.

Question sources

Operating Systems practice questions · Question 38

Question 77 | Q01321

39.What is the difference between a process and a program in an operating system?

A. There is no difference between a process and a program

B. A process is a running instance of a program, while a program is a set of instructions

C. A program is a running instance of a process, while a process is a set of instructions

D. A program is a unit of execution, while a process is a unit of scheduling

Hint

Distinguish stored instructions, an executing instance and its saved execution state.

Answer B: A process is a running instance of a program, while a program is a set of instructions

PDF p16 directly contrasts a dynamic executing process with a static program containing processor instructions. B states that distinction.

Why each choice is right or wrong

A - Incorrect: Contradicted by the explicit static/dynamic contrast.

B - Correct: Matches the definitions on p16.

C - Incorrect: Reverses program and process.

D - Incorrect: Program is static instructions, not itself an executing unit (p16).

Primary note proof

Study-note section OS05

> A program is stored instructions; a process is an executing instance with address space and resources. A process does not universally “manage applications” or “provide a user interface.” The PCB records identity, state, PC/registers, scheduling information, memory/accounting details and I/O/open-resource state.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 16 | lines 6-9

> A process is a program in execution. The execution of a process must progress in a sequential fashion. Definition of process is following.
> • A process is defined as an entity which represents the basic unit of work to be implemented in the system.

Operating System module | PDF page 16 | lines 21-24

A program by itself is not a process. It is a static entity made up of program statement while process is a dynamic entity. Program contains the instructions to be executed by processor. A program takes a space at single place in main memory and continues to stay there. A program does not perform any action by itself.

Question sources

Operating Systems practice questions · Question 39

Question 78 | Q01322

Which listed operation can receive bytes from a socket while also serving as a generic file-input operation in the descriptor model?

A. socket()

B. connect()

C. read()

D. send()

Hint

Distinguish a file operation, a resource handle, an offset and file metadata.

Answer C: read()

Sockets can support the ordinary read/write interface as well as specialized socket operations. A read therefore need not be confined to disk files: it can receive bytes from a socket descriptor. socket creates an endpoint, connect establishes a connection, and send transmits data. Only read matches both the generic file-input role and the ability to receive socket data in this model.

Why each choice is right or wrong

A - Incorrect: socket creates a communication endpoint rather than reading bytes from it.

B - Incorrect: connect establishes a connection rather than receiving its data.

C - Correct: read is generic descriptor input and can receive bytes from a socket.

D - Incorrect: send transmits data rather than performing the requested input operation.

Primary note proof

Study-note section OS36

Sockets also support ordinary read/write, alongside socket/connect/send operations, so read is not uniquely “not a network call.” FAT32, NTFS and ext4 are filesystem formats; HTTP is an application communication protocol.

Study-note section OS-S04

In the descriptor-based socket API, socket() creates a communication endpoint and returns its descriptor. connect() associates the socket with the requested peer address; send() transmits data

to another socket. Receiving through read() uses the ordinary descriptor-input interface described in the file-services lesson.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 11 | lines 15-19

• Two processes often require data to be transferred between them.
• The both processes can be on the one computer or on different computer but are connected through computer network.
• Communication may be implemented by two methods either by Shared Memory or by Message Passing.

Operating System module | PDF page 11 | lines 3-8

• Program needs to read a file or write a file.
• The operating system gives the permission to the program for operation on file.
• Permission varies from read-only, read-write, denied and so on.
• Operating System provides an interface to the user to create/delete files.
• Operating System provides an interface to the user to create/delete directories.
• Operating System provides an interface to create the backup of file system.

Operating Systems practice questions · Question 40

Question 79 | Q01323

What is the purpose of a system clock in an operating system?

A. To manage user accounts

B. To manage hardware resources

C. To manage software applications

D. To provide a reference for measuring time and scheduling processes and events

Hint

Identify whether data is in transit, retained for reuse or queued for a device.

Answer D: To provide a reference for measuring time and scheduling processes and events

The clock driver maintains time and decrements the quantum counter to invoke the scheduler (PDF p46, section 12.3 Clocks). D is the matching time-and-scheduling purpose.

Why each choice is right or wrong

A - Incorrect: Accounts are not the clock's task.

B - Incorrect: Generic resource management omits the clock's time reference.

C - Incorrect: Software management is not its stated task.

D - Correct: Time of day and quantum expiration are both clock-driver functions on p46.

Primary note proof

Study-note section OS35

> The clock/timer supports timekeeping, timeouts, accounting and preemptive scheduling.

Study-note section OS-S04

> IRQ means interrupt request. A controller can raise an interrupt to request CPU attention. In a clock-tick scheduler, the scheduler initializes a running process's quantum counter; each clock interrupt decrements it, and reaching zero triggers scheduling. Clock support also maintains time of day and usage accounting.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 46 | lines 19-33

> Maintaining the time
> of the day

Operating Systems practice questions · Question 41

Question 80 | Q01324

42.Which of the following is not a type of device managed by an operating system?

A. Input devices

B. Output devices

C. Storage devices

D. User accounts

Hint

Separate device hardware, device-specific software and general event or transfer mechanisms.

Answer D: User accounts

PDF p43 lists storage, transmission and human-interface hardware. User accounts concern authentication (p50), rather than physical I/O device categories.

Why each choice is right or wrong

A - Incorrect: Human input devices are listed (p43).

B - Incorrect: Screens and related human-interface devices are listed (p43).

C - Incorrect: Disks and tapes are storage devices (p43).

D - Correct: A user identity/account is authenticated, not a physical device (p50).

Primary note proof

Study-note section OS34

> Input/output/storage/NIC devices are OS-managed hardware; user accounts are identities.

Study-note section OS39

> Authentication verifies identity; authorization checks permitted operations.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 43 | lines 7-10

> Computers operate on many kinds of devices. General types include storage devices (disks, tapes), transmission devices (network cards, modems), and human-interface devices (screen, keyboard, mouse). Other devices are more specialized. A device communicates with a computer system by sending signals over a cable or even through the air.

Operating System module | PDF page 50 | lines 18-28

> Authentication refers to identifying each user of the system and associating the executing programs with those users. It is the responsibility of the Operating System to create a protection system which ensures that a user who is running a particular program is authentic. Operating Systems generally identifies/authenticates users using following three ways:
> Username / Password - User need to enter a registered username and password with Operating system to login into the system.
> User card/key - User need to punch card in card slot, or enter key generated by key generator in option provided by operating system to login into the system.
> User attribute - fingerprint/ eye retina pattern/ signature - User need to pass his/her attribute via designated input device used by operating system to login into the system.

Question sources

Operating Systems practice questions · Question 42

Question 81 | Q01325

What is the purpose of a file descriptor in an operating system?

A. To manage user accounts

B. To manage hardware resources

C. To manage software applications

D. To provide a reference to an open file or communication endpoint

Hint

Distinguish a file operation, a resource handle, an offset and file metadata.

Answer D: A process-local reference to an open file or communication endpoint.

OS36 defines a file descriptor as a process-local integer handle and separately places offset and access mode in associated open-file state. It also describes sockets supporting ordinary descriptor I/O. The descriptor therefore refers to an open resource or endpoint; it is not an account manager, hardware manager or application manager. D is the specific role matching that definition.

Why each choice is right or wrong

A - Incorrect: A descriptor identifies an open resource within a process, rather than managing user accounts.

B - Incorrect: A descriptor is a handle used to access a resource, not a general hardware-management component.

C - Incorrect: Descriptors support resource I/O and do not manage application lifecycles or software installations.

D - Correct: An open-file or socket reference is the resource-handle purpose of a file descriptor.

Primary note proof

Study-note section OS36

> A file has content and metadata such as name, size, owner, permissions and timestamps. open obtains an open-file reference, read/write transfer bytes, seek changes an offset, close releases a reference, truncate changes size and unlink removes a name. A file descriptor is a process-local integer handle; the associated open-file state contains the current offset and access mode.

Study-note section OS36

> Sockets also support ordinary read/write, alongside socket/connect/send operations, so read is not uniquely “not a network call.” FAT32, NTFS and ext4 are filesystem formats; HTTP is an application communication protocol.

Module passages - related reading

Operating System module | PDF page 48 | lines 5-8

13.1 File
A file is a named collection of related information that is recorded on secondary storage such as magnetic disks, magnetic tapes and optical disks. In general, a file is a sequence of bits, bytes, lines or records whose meaning is defined by the file's creator and user.

Operating System module | PDF page 11 | lines 3-8

- Program needs to read a file or write a file.
- The operating system gives the permission to the program for operation on file.
- Permission varies from read-only, read-write, denied and so on.
- Operating System provides an interface to the user to create/delete files.
- Operating System provides an interface to the user to create/delete directories.
- Operating System provides an interface to create the backup of file system.

Question sources

Operating Systems practice questions · Question 43

Question 82 | Q01454

What is the main function of the command interpreter?

A. to provide the interface between the API and application program

B. to handle the files in the operating system

C. to get and execute the next user-specified command

D. none of the mentioned

Hint

Distinguish command interfaces, privileged core services and the stages of booting.

Answer C: to get and execute the next user-specified command

The shell is a special interpreter that executes OS commands and application programs (PDF p54), taking user commands to kernel functions. C states that command-interpreter loop role.

Why each choice is right or wrong

A - Incorrect: The module places the shell between user commands and kernel, not API and application.

B - Incorrect: File handling is one possible command activity, not the interpreter's general function.

C - Correct: Getting and executing user commands matches p54.

D - Incorrect: C already matches the supplied definition.

Primary note proof

Study-note section OS03

The kernel implements core resource management, protection and system-call handling. A shell reads/interprets user commands; a GUI is another interface. Browsers, office tools and editors are applications.

Study-note section OS04

A user-facing API/library may wrap that request; not every library function enters the kernel.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 54 | lines 18-20

commands of the operating system. It can be used to do various types of operations, call application programs etc.
Security - Linux provides user security using authentication features like password

Operating System module | PDF page 54 | lines 24-30

Hardware layer - Hardware consists of all peripheral devices (RAM/ HDD/ CPU etc.).
Kernel - Core component of Operating System, interacts directly with hardware, provides low level services to upper layer components.
Shell - An interface to kernel, hiding complexity of kernel's functions from users. Takes commands from user and executes kernel's functions.
Utilities - Utility programs giving user most of the functionalities of an operating systems.

Question sources

Operating Systems practice questions · Question 2

Question 83 | Q01458

Which failures can OS software report or handle while it continues executing on powered hardware? C means complete power loss with no backup supply or advance notification. Select all that apply.

A. lack of paper in printer

B. connection failure in the network

C. power failure

D. all of the mentioned

Hint

Separate device hardware, device-specific software and general event or transfer mechanisms.

Answer A, B: lack of paper in printer; connection failure in the network

OS I/O services can report or respond to a printer running out of paper and to a network connection failure. Complete unannounced loss of power without backup prevents the processor from continuing to run the OS, so software alone cannot handle it during continued execution. The aggregate option includes that unsupported case. Under the explicit power assumptions, the printer and network choices are selected.

Why each choice is right or wrong

A - Correct: The OS can report or handle an out-of-paper printer condition while running.

B - Correct: The OS can report or handle a network connection failure while running.

C - Incorrect: Complete unannounced power loss without backup prevents continued software execution.

D - Incorrect: All includes the excluded total-power-loss case and is therefore incorrect.

Primary note proof

Study-note section OS34

> Printer-paper and network errors can be handled/reported, but continued operation during total power loss requires hardware support, not OS software alone.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 47 | lines 17-18

> Error Handling - An operating system that uses protected memory can guard against many kinds of hardware and application errors.

Operating System module | PDF page 45 | lines 10-22

> The CPU hardware uses an interrupt request line wire which helps CPU to sense after executing every instruction. When the CPU checks that a controller has put a signal on the interrupt request line, the CPU saves a state, such as the current value of the instruction pointer, and jumps to the interrupt handler routine at a fixed address. The interrupt handler part determines the cause of the interrupt performs the necessary processing and executes an interrupt instruction to return the CPU to its execution state.
> The basic mechanism of interrupt enables the CPU to respond to an asynchronous event, such as when a device controller becomes ready for service. Most CPUs have two interrupt request lines.
> • non-maskable interrupt - Such kind of interrupts are reserved for events like unrecoverable memory errors.
> • maskable interrupt - Such interrupts can be switched off by the CPU before the execution of critical instructions that must not be interrupted.

Operating Systems practice questions · Question 6

Question 84 | Q01459

Who among the following is credited as a co-creator of the UNIX operating system at Bell Labs, together with Ken Thompson?

A. Charles Babbage

B. Alan Turing

C. Tim Berners-Lee

D. Dennis Ritchie

Hint

Compare the stated historical clues and distinguish origin, characteristic era and technical capability.

Answer D: Dennis Ritchie

Dennis Ritchie is credited alongside Ken Thompson in Bell Labs' account of UNIX's creation. The other listed people are not that co-creator.

Why each choice is right or wrong

A - Incorrect: Babbage is not the UNIX co-creator alongside Thompson identified by Bell Labs.

B - Incorrect: Turing is not the UNIX co-creator alongside Thompson identified by Bell Labs.

C - Incorrect: Berners-Lee is not the UNIX co-creator alongside Thompson identified by Bell Labs.

D - Correct: Dennis Ritchie is the Bell Labs co-creator associated with Ken Thompson.

Primary note proof

Study-note section OS-S01

> UNIX development began at Bell Labs in 1969, led by Ken Thompson and Dennis Ritchie with other collaborators. Ritchie is therefore a co-creator, not the sole inventor of the first operating system.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 53 | lines 5-7

> Linux is one of popular version of UNIX operating System. It is open source as its source code is freely available. It is free to use. Linux was designed considering UNIX compatibility. Its functionality list is quite similar to that of UNIX.

Question sources

Operating Systems practice questions · Question 7

Question 85 | Q01460

Which operating system was developed by Microsoft as a successor to MS-DOS?

A. macOS

B. Windows

C. Linux

D. Solaris

Hint

Use the stated historical or platform scope and distinguish origin from technical capability.

Answer B: Windows.

OS40 explicitly identifies Windows as the Microsoft family commonly described as succeeding the MS-DOS desktop era. That directly matches the stem's company and predecessor clues. Linux is separately attributed to Linus Torvalds, Solaris to Sun, and macOS is a different proprietary OS product. No additional market-history claim is needed to resolve the listed alternatives.

Why each choice is right or wrong

A - Incorrect: macOS is not the Microsoft family identified as succeeding the MS-DOS desktop era.

B - Correct: The note explicitly identifies Windows as Microsoft's successor family to the MS-DOS desktop era.

C - Incorrect: Linux is separately attributed to Linus Torvalds, not the Microsoft MS-DOS desktop succession.

D - Incorrect: Solaris originated at Sun rather than being Microsoft's MS-DOS successor family.

Primary note proof

Study-note section OS40

> Windows is the Microsoft family commonly described as succeeding the MS-DOS desktop era; Solaris originated at Sun.

Study-note section OS40

> Linux is a Unix-compatible kernel written from scratch by Linus Torvalds; a distribution combines it with userland, libraries and tools.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 8 | lines 21-26

> Network Operating System runs on a server and provides server the capability to manage data, users, groups, security, applications, and other networking functions. The primary purpose of the network operating system is to allow shared file and printer access among multiple computers in a network, typically a local area network (LAN), a private network or

to other networks. Examples of network operating systems are Microsoft Windows Server 2003, Microsoft Windows Server 2008, UNIX, Linux, Mac OS X, Novell NetWare, and BSD.

Question sources

Operating Systems practice questions · Question 8

Question 86 | Q01461

Which listed operating-system family originated at Bell Labs in 1969 and later provided multiuser time-sharing with asynchronous processes? This asks for that system's identity, not the first-ever invention of multitasking.

A. MS-DOS

B. macOS

C. Windows

D. UNIX

Hint

Compare the stated historical clues and distinguish origin, characteristic era and technical capability.

Answer D: UNIX

UNIX began at Bell Labs in 1969. Ritchie and Thompson's primary paper describes the later system as multiuser and interactive, with asynchronous processes. These historical identifying facts come from the supplementary sources. OS40 supplies the related caution that UNIX was not the first system ever to multitask. The revised question preserves the history and multitasking focus while dropping that false priority claim.

Why each choice is right or wrong

A - Incorrect: MS-DOS is not the Bell Labs system originating in 1969.

B - Incorrect: macOS is not the original Bell Labs system identified by that history.

C - Incorrect: Windows is not the Bell Labs system described by Ritchie and Thompson.

D - Correct: UNIX matches the Bell Labs origin and the later multiuser time-sharing description.

Primary note proof

Study-note section OS-S01

UNIX development began at Bell Labs in 1969, led by Ken Thompson and Dennis Ritchie with other collaborators. Ritchie is therefore a co-creator, not the sole inventor of the first operating system.

Study-note section OS-S01

The later UNIX time-sharing system described by Ritchie and Thompson is multiuser and interactive and supports asynchronous processes. Its later versions incorporated multiprogramming. This history does not make UNIX the first system ever to multitask.

Operating System module | PDF page 13 | lines 21-25

4.3 Multiprogramming
When two or more programs are residing in memory at the same time, then sharing the processor is referred to the multiprogramming. Multiprogramming assumes a single shared processor. Multiprogramming increases CPU utilization by organizing jobs so that the CPU always has one to execute.

Operating System module | PDF page 7 | lines 20-33

Time sharing is a technique which enables many people, located at various terminals, to use a particular computer system at the same time. Time-sharing or multitasking is a logical extension of multiprogramming. Processor's time which is shared among multiple users simultaneously is termed as time-sharing. The main difference between Multi-programmed Batch Systems and Time-Sharing Systems is that in case of multi-programmed batch systems, objective is to maximize processor use, whereas in Time-Sharing Systems objective is to minimize response time.
Multiple jobs are executed by the CPU by switching between them, but the switches occur so frequently. Thus, the user can receive an immediate response. For example, in a transaction processing, processor execute each user program in a short burst or quantum of computation. That is if n users are present, each user can get time quantum. When the user submits the command, the response time is in few seconds at most.
Operating system uses CPU scheduling and multiprogramming to provide each user with a small portion of a time. Computer systems that were designed primarily as batch systems

Question 87 | Q01462

Which operating system was developed by Linus Torvalds and is based on the UNIX operating system?

A. Linux

B. Windows

C. macOS

D. Solaris

Hint

Use the stated historical or platform scope and distinguish origin from technical capability.

Answer A: Linux, Unix-compatible and written from scratch.

OS40 attributes Linux to Linus Torvalds and calls it a Unix-compatible kernel written from scratch. The developer clue therefore uniquely identifies Linux. The phrase based on UNIX must be read as compatible/inspired in interface and design, rather than asserting copied UNIX source. The other named families do not match the explicit creator attribution given here.

Why each choice is right or wrong

A - Correct: Linux matches Linus Torvalds and Unix compatibility; the note explicitly says it was written from scratch.

B - Incorrect: Windows is the Microsoft family, not the kernel explicitly attributed here to Linus Torvalds.

C - Incorrect: macOS does not match the note's explicit Torvalds attribution for the Unix-compatible kernel.

D - Incorrect: Solaris originated at Sun rather than being the kernel developed by Linus Torvalds.

Primary note proof

Study-note section OS40

> Linux is a Unix-compatible kernel written from scratch by Linus Torvalds; a distribution combines it with userland, libraries and tools.

Study-note section OS40

> Windows is the Microsoft family commonly described as succeeding the MS-DOS desktop era; Solaris originated at Sun.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 53 | lines 5-7

> Linux is one of popular version of UNIX operating System. It is open source as its source code is freely available. It is free to use. Linux was designed considering UNIX compatibility. Its functionality list is quite similar to that of UNIX.

Question sources

Operating Systems practice questions · Question 10

Question 88 | Q01463

Which operating system was developed by Sun Microsystems and is known for its scalability and reliability?

A. Linux

B. Windows

C. macOS

D. Solaris

Hint

Use the stated historical or platform scope and distinguish origin from technical capability.

Answer D: Solaris.

OS40 directly states that Solaris originated at Sun. That developer clue resolves the choices even though the note does not quantify Solaris's reliability or scalability relative to other systems. The answer relies on the explicit origin, not on assuming those broad positive attributes uniquely distinguish one OS. Linux and Windows have separately identified developer lineages in the same section.

Why each choice is right or wrong

A - Incorrect: Linux is attributed to Linus Torvalds rather than being the Sun-originated OS requested here.

B - Incorrect: Windows is identified as the Microsoft family, not the Sun-originated product.

C - Incorrect: macOS does not match the explicit Sun-origin attribution provided by the complete note.

D - Correct: Solaris is explicitly stated to have originated at Sun, matching the decisive developer clue.

Primary note proof

Study-note section OS40

> Windows is the Microsoft family commonly described as succeeding the MS-DOS desktop era; Solaris originated at Sun.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 29 | lines 4-16

> In this case, thread management done by the Kernel. There is no thread management code in the application area. Kernel threads are supported directly by the operating system. Any application can be programmed to be multithreaded. All of the threads within an application are supported within a single process.
> The Kernel maintains context information for the process as a whole and for individuals' threads within the process. Scheduling by the Kernel is done on a thread basis. The Kernel

performs thread creation, scheduling and management in Kernel space. Kernel threads are generally slower to create and manage than the user threads.
Advantages
• Kernel can simultaneously schedule multiple threads from the same process on multiple processes.
• If one thread in a process is blocked, the Kernel can schedule another thread of the same process.

Operating Systems practice questions · Question 11

Question 89 | Q01464

Which listed mobile operating-system platform uses Linux as its base kernel layer and has an open-source base called AOSP?

A. iOS

B. Android

C. Windows Phone

D. BlackBerry OS

Hint

Use the stated historical or platform scope and distinguish origin from technical capability.

Answer B: Android

Android uses Linux at its base kernel layer, with framework and application layers above it. Its open-source base is AOSP, although shipped devices may contain proprietary services or applications. Those architectural facts identify Android without needing an unspecified population or a dated market-share claim. The other listed mobile systems are not the platform identified by this particular combination of Linux and AOSP.

Why each choice is right or wrong

A - Incorrect: iOS is not the platform identified by the Linux/AOSP combination.

B - Correct: Android has the Linux base layer and the AOSP open-source base.

C - Incorrect: Windows Phone is not the Linux/AOSP platform described.

D - Incorrect: BlackBerry OS is not the Linux/AOSP platform described.

Primary note proof

Study-note section OS40

Android’s base kernel layer is Linux; its framework and applications are higher layers. AOSP is open source, while a shipped device can include proprietary applications/services.

Operating Systems practice questions · Question 12

Question 90 | Q01471

Using the first four generations described in NYU's OS-history notes (vacuum tubes; transistors; integrated circuits; personal computers), which generation is associated with resident uniprogrammed batch operating systems, following the manual/no-resident-OS era?

A. First Generation

B. Second Generation

C. Third Generation

D. Fourth Generation

Hint

Compare the stated historical clues and distinguish origin, characteristic era and technical capability.

Answer B: Second Generation

The first four generations in NYU's historical taxonomy associates second-generation transistor machines with uniprogrammed batch systems whose OS remains resident between jobs. The first era has no separate resident OS; the third emphasizes ICs and multiprogramming, and the fourth personal computers. OS02 explains batch operation, while the generation mapping is supplied by the supplementary university notes. This is a scoped teaching convention rather than a universal first-OS claim.

Why each choice is right or wrong

A - Incorrect: The first era is the manual/no-separate-resident-OS era in this taxonomy.

B - Correct: The second era pairs transistor machines with resident uniprogrammed batch systems.

C - Incorrect: The third era emphasizes ICs and multiprogramming rather than the initial resident batch stage.

D - Incorrect: The fourth era emphasizes personal computers and follows the batch-monitor era.

Primary note proof

Study-note section OS-S01

> In the first four generations of the cited NYU teaching taxonomy, the first generation uses vacuum tubes and manual single-user operation without a separate resident OS. The second generation pairs transistors with uniprogrammed batch systems; the resident OS starts successive jobs without being reloaded for every job.

Study-note section OS-S01

> The third generation pairs integrated circuits with multiprogramming. The fourth emphasizes personal computers. These are characteristic-era associations, not claims that each feature existed exclusively in one era.

Operating Systems practice questions · Question 19

Question 91 | Q01475

What is the primary function of a kernel in an operating system?

A. Provide a user-friendly interface

B. Manage system resources and provide core services

C. Run user applications

D. Facilitate communication with external devices

Hint

Distinguish command interfaces, privileged core services and the stages of booting.

Answer B: Manage system resources and provide core services

The kernel is the core, responsible for major activities and direct hardware interaction (PDF p53), providing services with privileged access. B summarizes this rather than a particular interface or device subset.

Why each choice is right or wrong

A - Incorrect: The shell supplies the user-command interface (p54).

B - Correct: Core services and resource access match p53.

C - Incorrect: The kernel runs processes, but application execution alone omits its wider central role.

D - Incorrect: External-device communication is one hardware activity, not the entire primary role.

Primary note proof

Study-note section OS03

> The kernel implements core resource management, protection and system-call handling. A shell reads/interprets user commands; a GUI is another interface. Browsers, office tools and editors are applications.

Operating Systems practice questions · Question 23

Question 92 | Q01476

Which component of an operating system is responsible for memory management and process scheduling?

A. Kernel

B. User program

C. Compiler

D. File system

Hint

Distinguish command interfaces, privileged core services and the stages of booting.

Answer A: Kernel

Kernel is the major-activity core (PDF p53); memory management and ready-process selection are OS functions (pp31,20). Under the module's architecture, A is the component responsible for these core services.

Why each choice is right or wrong

A - Correct: Kernel provides the core resource services (p53).

B - Incorrect: User programs request services rather than being the core manager (p53).

C - Incorrect: Compilation is not the ready-process or memory manager described.

D - Incorrect: File organization does not substitute for memory/CPU management.

Primary note proof

Study-note section OS03

The kernel implements core resource management, protection and system-call handling.

Study-note section OS01

An OS allocates CPU time, memory, storage, devices and communication resources, and provides services to programs.

Study-note section OS06

Long-term scheduling admits jobs; medium-term scheduling suspends/swaps them; short-term scheduling selects ready work.

Study-note section OS-S05

A compiler translates source code toward an executable representation. For example, the conventional GCC toolchain distinguishes preprocessing, compilation proper, assembly and linking. A compiler uses operating-system services as a development tool; it is not the runtime kernel component that selects ready processes, manages memory or handles protected service requests.

Operating System module | PDF page 31 | lines 24-31

Memory management is the functionality of an operating system which handles or manages primary memory. Memory management keeps track of each and every memory location either it is allocated to some process or it is free. It checks how much memory is to be allocated to processes. It decides which process will get memory at what time. It tracks whenever some memory gets freed or unallocated and correspondingly it updates the status.
Memory management provides protection by using two registers, a base register and a limit register. The base register holds the smallest legal physical memory address and the limit register specifies the size of the range. For example, if the base register holds 300000 and the

Operating System module | PDF page 20 | lines 15-21

It is also called CPU scheduler. Main objective is increasing system performance in accordance with the chosen set of criteria. It is the change of ready state to running state of the process. CPU scheduler selects process among the processes that are ready to execute and allocates CPU to one of them.
Short term scheduler also known as dispatcher, execute most frequently and makes the fine-grained decision of which process to execute next. Short term scheduler is faster than long term scheduler.

Operating Systems practice questions · Question 24

Question 93 | Q01477

In the module’s conventional architecture, where device drivers are kernel components and ordinary applications run with restricted privilege, which item normally executes in kernel mode?

A. User programs

B. Device drivers

C. Text editors

D. Web browsers

Hint

Distinguish command interfaces, privileged core services and the stages of booting.

Answer B: Device drivers

Kernel components perform privileged operating-system work. In the stated architecture, device drivers are such components, so they execute in kernel mode. User programs, text editors and web browsers are ordinary applications and execute in restricted user mode, requesting protected services when needed. User-space driver designs exist, which is why the architecture is stated rather than treating every driver implementation as privileged.

Why each choice is right or wrong

A - Incorrect: Ordinary user programs execute in restricted user mode.

B - Correct: The specified drivers are kernel components and therefore execute with kernel privilege.

C - Incorrect: A text editor is an ordinary application, so it runs in user mode under this architecture.

D - Incorrect: A web browser is an ordinary application and does not acquire kernel privilege merely by using OS services.

Primary note proof

Study-note section OS03

> Browsers, office tools and editors are applications. Device drivers are commonly kernel components, although user-space drivers also exist.

Study-note section OS-S02

> Being scheduled or managed by the kernel does not give application thread code kernel privilege. Ordinary applications and supporting utilities execute in restricted user mode and request protected services through libraries and system calls. Kernel component code executes in privileged kernel mode and performs permitted low-level hardware operations.

> Support code which is not required to run in kernel mode is in System Library. User programs and other system programs works in User Mode which has no access to system hardware and kernel code. User programs/ utilities use System libraries to access Kernel functions to get system's low level tasks.

Question sources

Operating Systems practice questions · Question 25

Question 94 | Q01478

In the operating system’s user/kernel privilege model, which standard term names the restricted level used by ordinary application code? Classify execution privilege, rather than processor addressing modes.

A. Kernel mode

B. Supervisor mode

C. User mode

D. Protected mode

Hint

Distinguish where threads are managed from the privilege of the code they execute.

Answer C: User mode

Ordinary application code runs at the restricted user level and obtains protected services through libraries and system calls. Kernel mode is the privileged level; supervisor mode is commonly another name for that privileged level. Protected mode is not the name of the restricted application privilege level in the stated user/kernel classification. The question therefore selects User mode without making a claim about every processor’s architectural modes.

Why each choice is right or wrong

A - Incorrect: Kernel mode permits privileged OS operations and is not the restricted application level.

B - Incorrect: Supervisor mode denotes the privileged context in this model, rather than ordinary application privilege.

C - Correct: User mode is the restricted application level in the user/kernel privilege model.

D - Incorrect: The requested restricted privilege level is user mode; an architectural mode label does not name that level in this classification.

Primary note proof

Study-note section OS-S02

> Being scheduled or managed by the kernel does not give application thread code kernel privilege. Ordinary applications and supporting utilities execute in restricted user mode and request protected services through libraries and system calls. Kernel component code executes in privileged kernel mode and performs permitted low-level hardware operations.

Study-note section OS03

> Kernel mode has privileged operations; supervisor mode often means the same privileged mode, so offering both as exclusive answers is ambiguous.

Operating Systems practice questions · Question 26

Question 95 | Q01479

In the teaching module’s architecture, which broad core component provides protected file-system operations for applications?

A. Kernel

B. User program

C. Device driver

D. Compiler

Hint

Distinguish command interfaces, privileged core services and the stages of booting.

Answer A: Kernel

The kernel provides core protected services and handles system calls, including the operating system’s file operations in this architecture. Applications request those services. A device driver translates requests into device-specific operations beneath the file-service layer, while a compiler translates program source. These supporting roles do not make either the broad core provider of protected file-system operations.

Why each choice is right or wrong

A - Correct: The kernel provides the protected OS service and system-call layer in the stated architecture.

B - Incorrect: Applications request file services rather than being the protected core service provider.

C - Incorrect: Drivers perform device-specific operations beneath the broader file-service layer.

D - Incorrect: A compiler translates program source; it is not the runtime protected file-service provider.

Primary note proof

Study-note section OS03

> The kernel implements core resource management, protection and system-call handling.

Study-note section OS36

> A file has content and metadata such as name, size, owner, permissions and timestamps. open obtains an open-file reference, read/write transfer bytes, seek changes an offset, close releases a reference, truncate changes size and unlink removes a name.

Study-note section OS34

> A driver converts OS requests into device-specific operations.

Study-note section OS-S05

> A compiler translates source code toward an executable representation. For example, the conventional GCC toolchain distinguishes preprocessing, compilation proper, assembly and

linking. A compiler uses operating-system services as a development tool; it is not the runtime kernel component that selects ready processes, manages memory or handles protected service requests.

Operating Systems practice questions · Question 27

Question 96 | Q01480

During a conventional disk-based boot, the bootloader reads the kernel image from disk. Into which main execution-memory region is it loaded before control is transferred to it?

A. RAM

B. Hard disk

C. CPU cache

D. ROM

Hint

Distinguish command interfaces, privileged core services and the stages of booting.

Answer A: RAM

In the stated boot sequence, firmware and bootloader stages run before control passes to the kernel loaded into RAM. The disk supplies the stored image, while RAM is its main execution-memory destination. CPU cache can retain copies of memory contents for faster reuse, but that is distinct from the image's main-memory loading location. ROM is not the RAM destination specified by this conventional boot model.

Why each choice is right or wrong

A - Correct: RAM is the main execution-memory destination for the loaded kernel image in the stated boot sequence.

B - Incorrect: The hard disk is the source of the stored image here, not its main-memory loading destination.

C - Incorrect: Cache retains copies for reuse; it is not the bootloader's main-memory image region.

D - Incorrect: ROM does not identify the writable RAM destination of the kernel image in this stated disk-boot model.

Primary note proof

Study-note section OS03

> Firmware/bootloader stages execute before transferring control to a kernel loaded into RAM.

Study-note section OS35

> Caching retains copies to accelerate reuse.

It decides which process will get memory at what time. It tracks whenever some

memory gets freed or unallocated and correspondingly it updates the status.
Memory management provides protection by using two registers, a base register and a limit register. The base register holds the smallest legal physical memory address and the limit register specifies the size of the range. For example, if the base register holds 300000 and the

Operating System module | PDF page 33 | lines 25-28

9.5 Memory Allocation
Main memory usually has two partitions
• Low Memory -- Operating system resides in this memory.
• High Memory -- User processes then held in high memory.

Question sources

Operating Systems practice questions · Question 28

Question 97 | Q01481

In a conventional monolithic OS, which listed utilities can have user-space program components that invoke privileged OS services, even if the complete product also includes privileged helpers? Treat “device driver” and “interrupt handler” here as kernel-resident components. Select all that apply.

A. Device driver

B. Antivirus software

C. Disk partition manager

D. Interrupt handler

Hint

Distinguish command interfaces, privileged core services and the stages of booting.

Answer B, C: Antivirus software; Disk partition manager

Antivirus and disk-management products can combine ordinary user processes with privileged helper components. Their user-space components count as user programs even though some work requires kernel services. The stem explicitly confines the driver and interrupt-handler options to kernel-resident components, avoiding architectures with user-space drivers. Thus antivirus software and the partition-manager utility are both valid examples under the stated component-level interpretation.

Why each choice is right or wrong

A - Incorrect: The driver is explicitly kernel-resident in this question.

B - Correct: Antivirus software can have a user-process component alongside privileged helpers.

C - Correct: A disk partition manager can have a user-process component invoking privileged services.

D - Incorrect: The interrupt handler is explicitly kernel-resident in this question.

Primary note proof

Study-note section OS03

> Utilities such as antivirus and disk tools can combine user processes with privileged components.

Study-note section OS-S02

> Being scheduled or managed by the kernel does not give application thread code kernel privilege. Ordinary applications and supporting utilities execute in restricted user mode and request protected services through libraries and system calls. Kernel component code executes in privileged kernel mode and performs permitted low-level hardware operations.

Module passages - related reading

Operating System module | PDF page 47 | lines 19-26

> 12.5 Device driver
> Device driver is a program or routine developed for an I/O device. A device driver implements I/O operations or behaviors on a specific class of devices. For example a system supports one or a number of multiple brands of terminals, all slightly different terminals may have a single terminal driver. In the layered structure of I/O system, device driver lies between interrupt handler and device independent I/O software. The job of a device driver is following.
> To accept request from the device independent software above it.
> To see to it that the request is executed.

Operating System module | PDF page 45 | lines 10-22

> The CPU hardware uses an interrupt request line wire which helps CPU to sense after executing every instruction. When the CPU checks that a controller has put a signal on the interrupt request line, the CPU saves a state, such as the current value of the instruction pointer, and jumps to the interrupt handler routine at a fixed address. The interrupt handler part determines the cause of the interrupt performs the necessary processing and executes an interrupt instruction to return the CPU to its execution state.
> The basic mechanism of interrupt enables the CPU to respond to an asynchronous event, such as when a device controller becomes ready for service. Most CPUs have two interrupt request lines.

• non-maskable interrupt - Such kind of interrupts are reserved for events like unrecoverable memory errors.
• maskable interrupt - Such interrupts can be switched off by the CPU before the execution of critical instructions that must not be interrupted.

Question sources

Operating Systems practice questions · Question 29

Question 98 | Q01482

In the module's operating-system architecture, which broad core component performs privileged interaction with underlying hardware?

A. Kernel

B. User program

C. Compiler

D. File system

Hint

Distinguish where threads are managed from the privilege of the code they execute.

Answer A: Kernel

The kernel performs privileged low-level hardware operations and supplies protected services. Ordinary applications use those services from user mode. A compiler translates source code, and the file system provides a particular family of storage services rather than naming the broad hardware-facing OS core. The question asks for that broad core component, not a particular device-specific driver.

Why each choice is right or wrong

A - Correct: The kernel is the privileged OS core that performs permitted low-level hardware operations.

B - Incorrect: Ordinary user programs request protected services rather than directly obtaining kernel privilege.

C - Incorrect: A compiler performs source translation, a development-tool role rather than privileged OS-core hardware management.

D - Incorrect: A file system supplies specific storage services, not the broad hardware-facing OS core requested.

Primary note proof

Study-note section OS-S02

Being scheduled or managed by the kernel does not give application thread code kernel privilege. Ordinary applications and supporting utilities execute in restricted user mode and

request protected services through libraries and system calls. Kernel component code executes in privileged kernel mode and performs permitted low-level hardware operations.

Study-note section OS-S05

A compiler translates source code toward an executable representation. For example, the conventional GCC toolchain distinguishes preprocessing, compilation proper, assembly and linking. A compiler uses operating-system services as a development tool; it is not the runtime kernel component that selects ready processes, manages memory or handles protected service requests.

Operating System module | PDF page 53 | lines 11-15

operating system. It is consisting of various modules and it interacts directly with the underlying hardware. Kernel provides the required abstraction to hide low level hardware details to system or application programs.
System Library - System libraries are special functions or programs using which application programs or system utilities accesses Kernel's features. These libraries

Operating System module | PDF page 53 | lines 21-29

Kernel component code executes in a special privileged mode called kernel mode with full access to all resources of the computer. This code represents a single process, executes in single address space and do not require any context switch and hence is very efficient and fast.
Kernel runs each process and provides system services to processes, provides protected access to hardware to processes.
Support code which is not required to run in kernel mode is in System Library. User programs and other system programs works in User Mode which has no access to system hardware and kernel code. User programs/ utilities use System libraries to access Kernel functions to get system's low level tasks.

Question sources

Operating Systems practice questions · Question 30

Question 99 | Q01483

In a two-level privilege model where “kernel mode” and “supervisor mode” are synonymous names for the privileged execution level, which listed names denote that level? “Protected mode” denotes a processor operating mode that can include restricted user execution. Select all that apply.

A. Kernel mode

B. User mode

C. Supervisor mode

D. Protected mode

Hint

Distinguish command interfaces, privileged core services and the stages of booting.

Answer A, C: Kernel mode; Supervisor mode

The note states that kernel mode permits privileged operations and that supervisor mode commonly denotes the same privileged mode. The stated model makes those names explicitly synonymous. User mode is restricted. Protected mode is defined here as a broader processor mode that can still run user code, so its name alone does not identify the privileged execution level. Both kernel and supervisor are selected.

Why each choice is right or wrong

A - Correct: Kernel mode denotes the privileged execution level.

B - Incorrect: User mode is the restricted level.

C - Correct: Supervisor mode is explicitly synonymous with kernel mode in this model.

D - Incorrect: Protected mode is not a privilege level under the supplied definition.

Primary note proof

Study-note section OS03

> Kernel mode has privileged operations; supervisor mode often means the same privileged mode, so offering both as exclusive answers is ambiguous.

Study-note section OS-S02

> Being scheduled or managed by the kernel does not give application thread code kernel privilege. Ordinary applications and supporting utilities execute in restricted user mode and request protected services through libraries and system calls. Kernel component code executes in privileged kernel mode and performs permitted low-level hardware operations.

Module passages - related reading

Question 100 | Q01484

Which of the following is responsible for handling system calls made by user programs?

A. Kernel

B. User program

C. Compiler

D. File system

Hint

Distinguish command interfaces, privileged core services and the stages of booting.

Answer A: Kernel

PDF p53 says the kernel provides system services and protected hardware access to processes; libraries let user code reach kernel functions. Thus the handling component is the kernel, not the application caller or compiler.

Why each choice is right or wrong

A - Correct: Kernel provides the requested process services (p53).

B - Incorrect: User program is the requester using libraries (p53).

C - Incorrect: Compiler is not the runtime service handler.

D - Incorrect: File system handles one service category, not all kernel requests.

Primary note proof

Study-note section OS03

> The kernel implements core resource management, protection and system-call handling.

Study-note section OS04

> A system call requests a protected kernel service, such as creating a process, reading a file or opening a socket. A user-facing API/library may wrap that request; not every library function enters the kernel.

Study-note section OS-S05

> A compiler translates source code toward an executable representation. For example, the conventional GCC toolchain distinguishes preprocessing, compilation proper, assembly and linking. A compiler uses operating-system services as a development tool; it is not the runtime kernel component that selects ready processes, manages memory or handles protected service requests.

> System Utility - System Utility programs are responsible to do specialized, individual level tasks.

Question sources

Operating Systems practice questions · Question 32

Question 101 | Q01506

A scheduler selects the next process to be executed from one of the following.

A. Ready queue

B. Job queue

C. Device queue

D. None of the choices is correct

Hint

Decide whether the process is eligible, running or waiting, then identify the responsible queue or scheduling role.

Answer A: Ready queue

PDF pp19-20 place processes waiting for CPU in the ready queue and select among ready processes. The question is about the next CPU execution, hence A rather than job admission.

Why each choice is right or wrong

A - Correct: Ready queue contains eligible CPU waiters.

B - Incorrect: Job queue includes all processes/admission work, not just eligible CPU contenders.

C - Incorrect: Device queue contains I/O waiters (p18).

D - Incorrect: Ready queue is explicitly supplied.

Primary note proof

Study-note section OS06

The ready queue contains eligible work; device queues hold blocked requests. The broad textbook job queue contains processes in the system, while an admission queue more narrowly holds jobs awaiting memory/admission. Long-term scheduling admits jobs; medium-term scheduling suspends/swaps them; short-term scheduling selects ready work.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 19 | lines 6-12

A newly arrived process is put in the ready queue. Processes waits in ready queue for allocating the CPU. Once the CPU is assigned to a process, then that process will execute. While executing the process, any one of the following events can occur.
• The process could issue an I/O request and then it would be placed in an I/O queue.
• The process could create new sub process and will wait for its termination.
• The process could be removed forcibly from the CPU, as a result of interrupt and put back in the ready queue.

Operating System module | PDF page 20 | lines 15-21

It is also called CPU scheduler. Main objective is increasing system performance in accordance with the chosen set of criteria. It is the change of ready state to running state of the process. CPU scheduler selects process among the processes that are ready to execute and allocates CPU to one of them.
Short term scheduler also known as dispatcher, execute most frequently and makes the fine-grained decision of which process to execute next. Short term scheduler is faster than long term scheduler.

Question sources

Mock exam 1 · Question 22

Question 102 | Q01507

Under preemptive priority scheduling, which event sends a currently running, unfinished process back to the ready state?

A. Arrival of a higher-priority ready process that preempts it

B. Completion of its final CPU burst

C. Suspension while waiting for an event

D. Issuing a blocking I/O request

Hint

Decide whether the process is eligible, running or waiting, then identify the responsible queue or scheduling role.

Answer A: Arrival of a higher-priority ready process that preempts it

Preemption removes the CPU from a running process that can still execute, returning it to ready. In the stated priority policy, arrival of a higher-priority ready process triggers that handoff. Final completion ends execution, while a blocking I/O request makes the process wait for an event. Suspension while waiting also does not describe ordinary readiness, so only the explicit preemption event fits.

Why each choice is right or wrong

A - Correct: The higher-priority arrival preempts the runnable process and returns it to ready.

B - Incorrect: Final completion transitions to terminated, not ready.

C - Incorrect: Suspended waiting work is not eligible for the ordinary ready queue.

D - Incorrect: Blocking I/O transitions running to waiting.

Primary note proof

Study-note section OS06

> New processes are created/admitted; ready means eligible for CPU but not currently running. Running uses a CPU. Waiting/blocked means unable to proceed until an event; terminated means execution has ended. Running→ready follows time-slice expiry or another preemption. Running→waiting follows blocking I/O. I/O completion normally gives waiting→ready, not a guaranteed immediate running state.

Study-note section OS17

> Priority scheduling chooses the highest-priority ready job. Check whether a smaller or larger numeric value means higher priority. State whether a high-priority arrival preempts.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 19 | lines 6-12

> A newly arrived process is put in the ready queue. Processes waits in ready queue for allocating the CPU. Once the CPU is assigned to a process, then that process will execute. While executing the process, any one of the following events can occur.
> • The process could issue an I/O request and then it would be placed in an I/O queue.
> • The process could create new sub process and will wait for its termination.
> • The process could be removed forcibly from the CPU, as a result of interrupt and put back in the ready queue.

Operating System module | PDF page 24 | lines 10-15

> 7.3 Priority Based Scheduling
> • Each process is assigned a priority. Process with highest priority is to be executed first and so on.
> • Processes with same priority are executed on first come first serve basis.
> • Priority can be decided based on memory requirements, time requirements or any other resource requirement.

Operating System module | PDF page 16 | lines 29-39

1. New The process is being created.
2.
Ready The process is waiting to be assigned to a processor. Ready processes are waiting to have the processor allocated to them by the operating system so that they can run.
3.
Running Process instructions are being executed (i.e. The process that is currently being executed).
4.
Waiting The process is waiting for some event to occur (such as the completion of an I/O operation).
5. Terminated The process has finished execution.

Question sources

Mock exam 1 · Question 23

Question 103 | Q01508

One of the following deadlock handling methods is used if it occurs rarely and is insignificant.

A. Prevention

B. waiting

C. recovery

D. Ignorance

Hint

Separate handling before allocation from actions taken after detection, and consider the cost of checking.

Answer D: Ignorance, the intentional ignoring/ostrich policy.

The ostrich or ignoring policy accepts the risk of a sufficiently rare, insignificant deadlock problem when systematic handling is not worthwhile. That is the intended meaning of Ignorance. Prevention instead constrains requests to break a necessary deadlock condition, and recovery acts after detection. Merely waiting is not the same as deliberately choosing to tolerate the rare problem.

Why each choice is right or wrong

A - Incorrect: Prevention constrains resource requests to remove a necessary deadlock condition; it does not deliberately ignore the problem.

B - Incorrect: Waiting describes a process behavior, not the deliberate policy of accepting rare deadlocks.

C - Incorrect: Recovery takes action after deadlock detection rather than choosing to ignore the rare problem.

D - Correct: Ignorance names the intentional ignoring or ostrich policy in this context.

Primary note proof

Study-note section OS26

> Ignoring a sufficiently rare problem is sometimes called the ostrich policy, but real systems still prevent or detect selected deadlocks. “Deadlock acceptance” can mean intentional ignoring, not necessarily an invalid approach.

Study-note section OS24

> Prevention constrains how requests are made. Share a resource where safe to remove mutual exclusion; request all needed resources before holding any to remove hold-and-wait; permit safe resource withdrawal/restart to attack no-preemption; impose a global acquisition order to remove circular wait.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 10 | lines 23-28

> • Loads a program into memory.

> • Provides a mechanism for process synchronization.
> • Provides a mechanism for process communication.
> • Provides a mechanism for deadlock handling.

Question sources

Mock exam 1 · Question 24

Question 104 | Q01587

One of the following is false about linked allocation.

A. Is based on sequential file access

B. Use pointer concept

C. No external fragmentation

D. The size of the file should be set in advanced

Hint

Trace how logical file blocks reach physical blocks and account for pointer metadata.

Answer D: The size of the file should be set in advanced

PDF p49 says linked allocation carries links to disk blocks, is effective for sequential access and has no external fragmentation. No advance contiguous size reservation is part of that linked structure; D confuses it with a fixed extent requirement.

Why each choice is right or wrong

A - Incorrect: Sequential access effectiveness is explicitly stated on p49.

B - Incorrect: Links/pointers are explicitly stated on p49.

C - Incorrect: No external fragmentation is explicitly stated on p49.

D - Correct: A chain can link another block without requiring one pre-sized contiguous extent; no advance-size requirement follows from the p49 linked structure.

Primary note proof

Study-note section OS38

> Contiguous allocation uses consecutive blocks; logical block i is start+i and supports direct access, but growth and external fragmentation are problems. Extents allow several contiguous runs. Linked allocation chains blocks and supports growth without reserving a complete contiguous file; locating block i requires traversing preceding links. FAT stores chains in a table; caching that table does not change the chain into a direct arithmetic mapping.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 49 | lines 30-35

> 13.3.2 Linked Allocation
> Each file carries a list of links to disk blocks.
> Directory contains link / pointer to first block of a file.
> No external fragmentation
> Effectively used in sequential access file.
> Inefficient in case of direct access file.

Operating System module | PDF page 48 | lines 5-8

> 13.1 File
> A file is a named collection of related information that is recorded on secondary storage such as magnetic disks, magnetic tapes and optical disks. In general, a file is a sequence of bits, bytes, lines or records whose meaning is defined by the file’s creator and user.

Question sources

Mock exam 3 · Question 19

Question 105 | Q01588

Consider three specified implementations: an Excel application process with several worker threads, a client-browser process with multiple threads sharing its address space, and a server process using only its single main thread. Which listed process does not use multithreading?

A. Excel application

B. Client browser

C. Server

D. None of the choices is correct

Hint

Compare per-thread execution context with shared process resources and the stated thread mapping.

Answer C: Server

Multithreading means that one process contains multiple threads of execution. The described spreadsheet and browser processes each have several threads sharing their process resources. The specified server implementation has only its main thread and therefore is not multithreaded. This conclusion follows from the supplied designs, not from a universal claim about every version of Excel, every browser, or every server.

Why each choice is right or wrong

A - Incorrect: The specified Excel process has several worker threads and is multithreaded.

B - Incorrect: The specified browser process has multiple threads and is multithreaded.

C - Correct: The specified server has only one thread and is not multithreaded.

D - Incorrect: C is a valid non-multithreaded implementation, so none is incorrect.

Primary note proof

Study-note section OS08

> A thread has its own PC, registers and stack. Threads in a process share code, address space and usually open-file resources. A process can contain many threads; a thread belongs to one process at a time. Threads are not a group of processes and need not execute sequentially.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 27 | lines 6-14

> A thread is a flow of execution through the process code, with its own program counter, system registers and stack. A thread is also called a light weight process. Threads provide a way to improve application performance through parallelism. Threads represent a software approach to improving performance of operating system by reducing the overhead thread is equivalent to a classical process.
> Each thread belongs to exactly one process and no thread can exist outside a process. Each

thread represents a separate flow of control. Threads have been successfully used in implementing network servers and web server. They also provide a suitable foundation for parallel execution of applications on shared memory multiprocessors. Following figure shows

Question sources

Mock exam 3 · Question 20

Question 106 | Q01589

One of the following security techniques is not supported by modern operating systems.

A. Cryptography

B. Authentication

C. Firewall

D. None of the above

Hint

Distinguish identity checks, permission checks and the particular security property at issue.

Answer D: None: modern OS families can support all three techniques.

OS39 states that modern OS families can support cryptography, authentication and firewalls, while support/configuration depends on product. Therefore none of the three is categorically unsupported by modern operating systems. The answer is a capability-category statement, not a guarantee that every installation includes every feature or enables it by default. Each technique has a distinct security role.

Why each choice is right or wrong

A - Incorrect: Cryptography is explicitly a capability that modern OS families can support, though configuration varies.

B - Incorrect: Authentication is explicitly supported as a modern OS capability for verifying identity.

C - Incorrect: Firewalls are explicitly within modern OS support capabilities, even though product and configuration matter.

D - Correct: All three techniques can be supported; none is categorically outside modern operating-system security capabilities.

Primary note proof

Study-note section OS39

Password hashing verifies secrets without storing plaintext; one-time passwords expire after use. Encryption protects confidentiality under correct key use but does not automatically provide integrity. Trojans masquerade as useful software, worms propagate independently and viruses

attach to hosts; denial of service harms availability. Modern OS families can support cryptography, authentication and firewalls, but support/configuration depends on product.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 50 | lines 18-28

Authentication refers to identifying each user of the system and associating the executing programs with those users. It is the responsibility of the Operating System to create a protection system which ensures that a user who is running a particular program is authentic. Operating Systems generally identifies/authenticates users using following three ways:
Username / Password - User need to enter a registered username and password with Operating system to login into the system.
User card/key - User need to punch card in card slot, or enter key generated by key generator in option provided by operating system to login into the system.
User attribute - fingerprint/ eye retina pattern/ signature - User need to pass his/her attribute via designated input device used by operating system to login into the system.

Operating System module | PDF page 54 | lines 5-17

Portable - Portability means software can works on different types of hardware in same way. Linux kernel and application programs support their installation on any kind of hardware platform.
Open Source - Linux source code is freely available and it is community-based development project. Multiple teams work in collaboration to enhance the capability of Linux operating system and it is continuously evolving.
Multi-User - Linux is a multiuser system means multiple users can access system resources like memory/ ram/ application programs at same time.

Security - Linux provides user security using authentication features like password protection/ controlled access to specific files/ encryption of data.

Question sources

Mock exam 3 · Question 21

Question 107 | Q01627

Under the basic fixed-page and variable-length-segment memory models, which listed differences are correct? Select all that apply.

A. Paging leads to internal fragmentation whereas segmentation leads external fragmentation

B. The size of block is fixed in the case of paging but variable in the case of segmentation

C. Paging use page table whereas segmentation use segmentation table

D. Paging is visible to user whereas segmentation is invisible to user

Hint

Check the logical region and offset bound before computing its physical location.

Answer A, B, C: Paging leads to internal fragmentation whereas segmentation leads external fragmentation; The size of block is fixed in the case of paging but variable in the case of segmentation; Paging use page table whereas segmentation use segmentation table

Basic paging uses fixed-size pages and page tables, and its final allocated page can contain unused space. Basic segmentation uses variable-length logical units and segment tables, so free holes can cause external fragmentation. Those properties make A, B and C valid contrasts. D reverses the usual abstraction relationship: segments reflect program structure, while ordinary page placement is largely transparent to the application.

Why each choice is right or wrong

A - Correct: Paging can waste space internally; variable-length segmentation can fragment externally.

B - Correct: Pages have a fixed size while segments have variable lengths.

C - Correct: Paging uses page tables and segmentation uses segment tables.

D - Incorrect: Segments reflect program structure; ordinary pages are largely transparent, reversing this option.

Primary note proof

Study-note section OS31

Under the basic models, paging uses fixed units/page tables and can waste space internally; segmentation uses variable logical units/segment tables and can fragment externally. Segments reflect program structure whereas ordinary pages are largely transparent to applications. Apply all three contrasts when comparing paging and segmentation.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 34 | lines 47-56

External fragmentation is avoided by using paging technique. Paging is a technique in which physical memory is broken into blocks of the same size called pages (size is power of 2, between 512 bytes and 8192 bytes). When a process is to be executed, it's corresponding pages are loaded into any available memory frames.
Logical address space of a process can be non-contiguous and a process is allocated physical memory whenever the free memory frame is available. Operating system keeps track of all free frames. Operating system needs n free frames to run a program of size n pages.
Address generated by CPU is divided into
• Page number (p) -- page number is used as an index into a page table which contains base address of each page in physical memory.

Operating System module | PDF page 34 | lines 34-45

External
fragmentation
Total memory space is enough to satisfy a request or to reside a
process in it, but it is not contiguous so it cannot be used.
2
Internal
fragmentation
Memory block assigned to process is bigger. Some portion of memory
is left unused as it cannot be used by another process.
External fragmentation can be reduced by compaction or shuffle memory contents to place all free memory together in one large block. To make compaction feasible, relocation should be dynamic

Operating System module | PDF page 35 | lines 7-12

Segmentation is a technique to break memory into logical pieces where each piece represents a group of related information. For example, data segments or code segment for each process, data segment for operating system and so on. Segmentation can be implemented using or without using paging.
Unlike paging, segment is having varying sizes and thus eliminates internal fragmentation. External fragmentation still exists but to lesser extent.

Operating System module | PDF page 36 | lines 3-7

Address generated by CPU is divided into
• Segment number (s) -- segment number is used as an index into a segment table which contains base address of each segment in physical memory and a limit of segment.

• Segment offset (o) -- segment offset is first checked against limit and then is combined with base address to define the physical memory address.

Question sources

Mock exam 2 · Question 16

Question 108 | Q01628

One of the following IO services is used store data in memory while transferring between devices.

A. Buffering

B. Scheduling

C. Caching

D. Spooling

Hint

Identify whether data is in transit, retained for reuse or queued for a device.

Answer A: Buffering

PDF p47 defines buffering as retaining data while transferred between devices or an application and device. This is A; caching stores reusable copies and spooling queues a noninterleavable output stream.

Why each choice is right or wrong

A - Correct: Directly matches transfer-time storage (p47).

B - Incorrect: Scheduling reorders requests, rather than providing transfer storage.

C - Incorrect: Caching keeps copies for more efficient access, not specifically transfer mismatch handling.

D - Incorrect: Spooling holds queued device output, a specialized buffer use; no printer/output serialization is specified in the stem.

Primary note proof

Study-note section OS35

Buffering temporarily holds data in transit to absorb speed/transfer-size differences. Caching retains copies to accelerate reuse. Spooling queues jobs for a device such as a printer, usually on disk, so producers need not own it throughout job creation. These have different purposes even if one implementation combines them.

Study-note section OS06

Long-term scheduling admits jobs; medium-term scheduling suspends/swaps them; short-term scheduling selects ready work.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 47 | lines 5-9

> Buffering - Kernel I/O Subsystem maintains a memory area known as buffer that stores data while they are transferred between two devices or between a devices with an application operation. Buffering is done to cope with a speed mismatch between the producer and consumer of a data stream or to adapt between devices that have different data transfer sizes.

Operating System module | PDF page 47 | lines 10-11

> Caching - Kernel maintains cache memory which is region of fast memory that holds copies of data. Access to the cached copy is more efficient than access to the original.

Operating System module | PDF page 47 | lines 12-16

> Spooling and Device Reservation - A spool is a buffer that holds output for a device, such as a printer, that cannot accept interleaved data streams. The spooling system copies the queued spool files to the printer one at a time. In some operating systems, spooling is managed by a system daemon process. In other operating systems, it is handled by an in kernel thread.

Question sources

Mock exam 2 · Question 17

Question 109 | Q01629

Which directory structure describes the commonly presented namespace of modern general-purpose operating systems, with nested directories and absolute or relative paths? Choose the structural category, not every simpler arrangement that might also be implemented.

A. multi-level

B. All choices are correct

C. two level

D. Single level

Hint

Follow namespace structure and distinguish names, underlying files and mounted filesystems.

Answer A: multi-level

A multilevel or tree namespace supports nested directories and paths that can be absolute or relative. That is the structure the notes identify as commonly presented by modern general-purpose systems. A two-level structure separates users but does not express arbitrary nesting, and a single-level structure has only one namespace level. The aggregate therefore includes structures that do not match the requested hierarchical category.

Why each choice is right or wrong

A - Correct: Multilevel describes the hierarchical nested namespace.

B - Incorrect: Single-level and two-level arrangements do not both describe the requested nested tree, so all is incorrect.

C - Incorrect: Two-level separates users without providing the general nested hierarchy asked for.

D - Incorrect: Single-level has no nested directory hierarchy.

Primary note proof

Study-note section OS37

> A single-level directory requires unique names in one namespace. Two-level directories separate users. A tree allows nested directories and absolute/relative paths; links can create shared graphs. Modern general-purpose systems commonly present hierarchical namespaces, but a feature name alone does not prove that every system excludes simpler arrangements.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 6 | lines 19-23

> A file system is normally organized into directories for easy navigation and usage. These directories may contain files and other directions. Operating System does the following activities for file management.
> Keeps track of information, location, uses, status etc. The collective facilities are often known as file system.

Operating System module | PDF page 54 | lines 5-17

> Portable - Portability means software can works on different types of hardware in same way. Linux kernel and application programs support their installation on any kind of hardware platform.
> Open Source - Linux source code is freely available and it is community-based development project. Multiple teams work in collaboration to enhance the capability of Linux operating system and it is continuously evolving.
> Multi-User - Linux is a multiuser system means multiple users can access system resources like memory/ ram/ application programs at same time.
> Multiprogramming - Linux is a multiprogramming system means multiple applications can run at same time.
> Hierarchical File System - Linux provides a standard file structure in which system files/ user files are arranged.
> Shell - Linux provides a special interpreter program which can be used to execute

Question sources

Mock exam 2 · Question 18

Question 110 | SM0001

For the first four generations described in NYU's OS-history notes, which pairings incorrectly identify the defining historical characteristic of the named generation? Judge characteristic era, not whether a feature could also exist later. Select all that apply.

A. Second generation -> multiprogramming

B. Fourth generation -> real time systems

C. First generation → manual single-user operation without a separate resident OS

D. Third generation → uniprogrammed batch systems

Hint

Compare the stated historical clues and distinguish origin, characteristic era and technical capability.

Answer A, B, D: Second generation -> multiprogramming; Fourth generation -> real time systems; Third generation → uniprogrammed batch systems

The first four generations in NYU's teaching taxonomy associates the first era with one user and no separate OS, the second with uniprogrammed batch systems, the third with IC-based multiprogramming, and the fourth with personal computers. Thus A, B and D mismatch the characteristic eras, while C fits. OS02 supplies the operating-mode background; the generation associations come from the supplementary university history notes rather than the unchanged master note.

Why each choice is right or wrong

A - Correct: Multiprogramming characterizes the third era, so pairing it with the second is wrong.

B - Correct: The fourth-era heading is personal computers, not the introduction of real-time systems.

C - Incorrect: Manual single-user operation without a separate OS matches the first era.

D - Correct: Uniprogrammed batch characterizes the second era, not the defining third-era advance.

Primary note proof

Study-note section OS-S01

> In the first four generations of the cited NYU teaching taxonomy, the first generation uses vacuum tubes and manual single-user operation without a separate resident OS. The second generation pairs transistors with uniprogrammed batch systems; the resident OS starts successive jobs without being reloaded for every job.

Study-note section OS-S01

> The third generation pairs integrated circuits with multiprogramming. The fourth emphasizes personal computers. These are characteristic-era associations, not claims that each feature existed exclusively in one era.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 7 | lines 20-33

> Time sharing is a technique which enables many people, located at various terminals, to use a particular computer system at the same time. Time-sharing or multitasking is a logical extension of multiprogramming. Processor's time which is shared among multiple users simultaneously is termed as time-sharing. The main difference between Multi-programmed Batch Systems and Time-Sharing Systems is that in case of multi-programmed batch systems, objective is to maximize processor use, whereas in Time-Sharing Systems objective is to minimize response time.
> Multiple jobs are executed by the CPU by switching between them, but the switches occur so frequently. Thus, the user can receive an immediate response. For example, in a transaction processing, processor execute each user program in a short burst or quantum of computation. That is if n users are present, each user can get time quantum. When the user submits the command, the response time is in few seconds at most.
> Operating system uses CPU scheduling and multiprogramming to provide each user with a small portion of a time. Computer systems that were designed primarily as batch systems

Operating System module | PDF page 13 | lines 21-25

> 4.3 Multiprogramming
> When two or more programs are residing in memory at the same time, then sharing the processor is referred to the multiprogramming. Multiprogramming assumes a single shared processor. Multiprogramming increases CPU utilization by organizing jobs so that the CPU always has one to execute.

Operating System module | PDF page 7 | lines 5-7

> operating systems are there from the very first computer generation. Operating systems keep evolving over the period of time. Following are few of the important types of operating system which are most commonly used.

Question 111 | SM0002

Which one of the following is asynchronous in message communication?

A. Non-block receive

B. Blocking receive

C. Blocking send

D. Direct message

Hint

Identify how data moves, which participant waits and what event allows the operation to continue.

Answer A: Nonblocking receive.

OS09 defines nonblocking operations as returning promptly with data, progress or a would-block result. Among the options, nonblocking receive therefore supplies the asynchronous/non-waiting behavior being contrasted. Blocking receive waits for a message, blocking send waits for its defined completion condition, and direct message concerns how endpoints are addressed rather than whether the call blocks.

Why each choice is right or wrong

A - Correct: Nonblocking receive returns promptly instead of waiting until a message arrives, matching this asynchronous contrast.

B - Incorrect: Blocking receive waits for a message rather than providing the non-waiting behavior requested.

C - Incorrect: Blocking send waits for its defined handoff or receipt condition rather than returning promptly.

D - Incorrect: Direct messaging describes endpoint addressing, not whether sending or receiving blocks.

Primary note proof

Study-note section OS09

> Blocking send waits for the required handoff/buffering/receipt condition defined by its API. Blocking receive waits for a message. Nonblocking operations return promptly with data, progress or a would-block result. “Sender blocked until received” identifies blocking send under rendezvous semantics.

Study-note section OS-S04

> Direct message communication names the receiving process explicitly. Indirect communication uses a mailbox or port. This naming distinction is independent of whether a send or receive blocks: naming a destination does not determine synchronization semantics.

Question 112 | SM0011

Which one of the following is NOT correct about threads?

A. Threads are the entities scheduled for execution on the CPU

B. It is a group of processes

C. Threads have program counters

D. Threads have registers to hold their working memory

Hint

Compare per-thread execution context with shared process resources and the stated thread mapping.

Answer B: It is a group of processes

PDF p27 defines a thread as a flow within one process, with its own PC and registers; p29 says kernel scheduling occurs on a thread basis. B incorrectly inverts containment by calling a thread a group of processes.

Why each choice is right or wrong

A - Incorrect: Thread-basis scheduling is explicit on p29.

B - Correct: Each thread belongs to exactly one process, not a collection of processes (p27).

C - Incorrect: Own program counter is explicit (p27).

D - Incorrect: Own system registers are explicit (p27); working memory should mean saved execution values rather than all shared process memory.

Primary note proof

Study-note section OS08

A thread has its own PC, registers and stack. Threads in a process share code, address space and usually open-file resources. A process can contain many threads; a thread belongs to one process at a time. Threads are not a group of processes and need not execute sequentially. Independent processes can exist; cooperating ones communicate/share data.

Study-note section OS08

User-level threads are managed by a library; kernel threads are known to the OS. In many-to-one mapping, a blocking kernel call can block all user threads and one kernel execution context cannot use multiple CPUs simultaneously. One-to-one permits another kernel thread to run when one blocks. Many-to-many multiplexes user threads over several kernel threads.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 27 | lines 6-14

A thread is a flow of execution through the process code, with its own program counter, system registers and stack. A thread is also called a light weight process. Threads provide a way to improve application performance through parallelism. Threads represent a software approach to improving performance of operating system by reducing the overhead thread is equivalent to a classical process.
Each thread belongs to exactly one process and no thread can exist outside a process. Each thread represents a separate flow of control. Threads have been successfully used in implementing network servers and web server. They also provide a suitable foundation for parallel execution of applications on shared memory multiprocessors. Following figure shows

Operating System module | PDF page 29 | lines 4-16

In this case, thread management done by the Kernel. There is no thread management code in the application area. Kernel threads are supported directly by the operating system. Any application can be programmed to be multithreaded. All of the threads within an application are supported within a single process.
The Kernel maintains context information for the process as a whole and for individuals' threads within the process. Scheduling by the Kernel is done on a thread basis. The Kernel performs thread creation, scheduling and management in Kernel space. Kernel threads are generally slower to create and manage than the user threads.
Advantages
• Kernel can simultaneously schedule multiple threads from the same process on multiple processes.
• If one thread in a process is blocked, the Kernel can schedule another thread of the same process.

Question 113 | SM0029

A computer expert would like to know the number of processes that are completed per hour to assess the performance of a machine. Which one of the following best describes the expert's assessment?

A. Waiting time

B. System throughput

C. Turnaround time

D. Response time

Hint

Construct a timeline and distinguish completion rates from individual elapsed-time measures.

Answer B: System throughput.

OS13 defines throughput as completed jobs divided by elapsed time. Counting process completions per hour is exactly that rate. Waiting, turnaround and response are delays associated with an individual process or an average of such delays; they are not completion counts per hour. The stated measurement therefore identifies system throughput without any scheduling trace.

Why each choice is right or wrong

A - Incorrect: Waiting time measures ready-queue delay, not the number of processes completed in an hour.

B - Correct: Completed processes divided by hours elapsed is system throughput here’s definition.

C - Incorrect: Turnaround measures arrival-to-completion duration for a process rather than a system completion rate.

D - Incorrect: Response measures arrival-to-first-start delay, not the number of jobs finished per unit time.

Primary note proof

Study-note section OS13

> For arrival A, first start S and completion C, response=S−A and turnaround=C−A. For a single CPU burst B with no I/O, waiting=C−A−B. With I/O, subtract all CPU and blocked time to isolate ready-queue waiting. Throughput=completed jobs/elapsed time; CPU utilization=busy time/elapsed time. Minimize response/turnaround/waiting under the selected goal and maximize useful throughput/utilization.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 6 | lines 31-35

Control over system performance -- Recording delays between request for a service and response from the system.
Job accounting -- Keeping track of time and resources used by various jobs and users.
Error detecting aids -- Production of dumps, traces, error messages and other debugging and error detecting aids.

Operating System module | PDF page 37 | lines 6-11

Virtual memory is a technique that allows the execution of processes which are not completely available in memory. The main visible advantage of this scheme is that programs can be larger than physical memory. Virtual memory is the separation of user logical memory from physical memory.
This separation allows an extremely large virtual memory to be provided for programmers when only a smaller physical memory is available. Following are the situations, when entire

Operating System module | PDF page 37 | lines 20-26

• Less number of I/O would be needed to load or swap each user program into memory.
• A program would no longer be constrained by the amount of physical memory that is available.
• Each user program could take less physical memory, more programs could be run the same time, with a corresponding increase in CPU utilization and throughput.
Virtual memory is commonly implemented by demand paging. It can also be implemented in a segmentation system. Demand segmentation can also be used to provide virtual memory.

Question 114 | SM0075

A process is terminated by the operating system due to a reference to non-existing memory. Which one of the following best explains the process termination?

A. Normal exit

B. Error exit

C. Terminated by another process

D. Fatal exit

Hint

Separate creation, image replacement and termination; classify termination by its cause.

Answer D: Fatal exit.

OS07 explicitly identifies a reference to nonexistent/protected memory as a fatal fault. Here the OS terminates the process because of that fault, so this is involuntary fatal termination. It is not the program's voluntary error exit, normal completion or a kill request by another ordinary process. The cause in the stem resolves the otherwise loose exit terminology.

Why each choice is right or wrong

A - Incorrect: Normal exit is voluntary completion, unlike OS-enforced termination for an invalid memory reference.

B - Incorrect: A program-detected error exit is voluntary; the stem specifies an unrecoverable memory-access fault.

C - Incorrect: The stated cause is a fault handled by the OS, not a kill request from another process.

D - Correct: The note explicitly classifies nonexistent-memory access as a fatal fault causing involuntary termination.

Primary note proof

Study-note section OS07

> Normal completion and a program-detected error exit are voluntary; an unrecoverable fault or being killed is involuntary. exit() terminates normally through the runtime; abort() requests abnormal termination. A reference to nonexistent/protected memory is a fatal fault, unlike an application deciding to exit after bad input.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 39 | lines 5-11

> Check an internal table for this process, to determine whether the reference was a valid or it was an invalid memory access.
> Step 2
> If the reference was invalid, terminate the process. If it was valid, but page have not yet brought in, page in the latter.
> Step 3 Find a free frame.
> Step 4 Schedule a disk operation to read the desired page into the newly allocated frame.

Operating System module | PDF page 16 | lines 29-39

> 1. New The process is being created.
> 2.
> Ready The process is waiting to be assigned to a processor. Ready processes are waiting to have the processor allocated to them by the operating system so that they can run.
> 3.
> Running Process instructions are being executed (i.e. The process that is currently being executed).
> 4.

Waiting The process is waiting for some event to occur (such as the completion of an I/O operation).
5. Terminated The process has finished execution.

Question 115 | SM0207

What is a characteristic feature of round-robin scheduling?

A. It assigns priorities to tasks based on their relative importance

B. It always selects the task with the shortest remaining time

C. It favors short tasks over long tasks

D. It guarantees fairness by providing each task with an equal time slice

Hint

Trace bounded turns in ready-queue order and include the stated overhead and arrivals.

Answer D: It guarantees fairness by providing each task with an equal time slice

PDF p25 gives each process a fixed quantum and preempts after it. D identifies that equal-turn mechanism; it guarantees equal-sized opportunities, not identical lifetime CPU totals for unequal jobs.

Why each choice is right or wrong

A - Incorrect: Priority rank is the p24 policy, not the RR criterion.

B - Incorrect: Remaining-time selection is not RR's fixed quantum.

C - Incorrect: Short-job preference is not RR's fixed quantum rule.

D - Correct: Equal quantum per turn is precisely the p25 definition.

Primary note proof

Study-note section OS18

RR serves a ready queue cyclically for at most quantum q per turn. Unfinished jobs return to the tail; completed/blocked jobs leave.

Study-note section OS17

Priority scheduling chooses the highest-priority ready job.

Study-note section OS16

Non-preemptive SJF/SJN chooses the shortest next burst among currently ready jobs. SRTF reconsiders on arrivals and selects the shortest remaining work; a shorter newcomer can preempt.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 25 | lines 10-14

7.4 Round Robin Scheduling
• Each process is provided a fix time to execute called quantum.
• Once a process is executed for given time period. Process is preempted and other process executes for given time period.
• Context switching is used to save states of preempted processes.

Operating System module | PDF page 24 | lines 10-15

7.3 Priority Based Scheduling
• Each process is assigned a priority. Process with highest priority is to be executed first and so on.
• Processes with same priority are executed on first come first serve basis.
• Priority can be decided based on memory requirements, time requirements or any other resource requirement.

Operating System module | PDF page 23 | lines 23-26

7.2 Shortest Job First (SJF)
• Best approach to minimize waiting time.
• Impossible to implement
• Processer should know in advance how much time process will take.

Question 116 | SM0220

Which objective of modern operating systems involves providing a consistent and convenient environment for running applications?

A. Maximizing hardware utilization

B. Ensuring fault tolerance

C. Providing security and protection

D. Providing a user-friendly interface

Hint

Separate broad resource-management goals from individual services or applications.

Answer D: Providing a user-friendly interface

PDF p5 emphasizes a convenient program-execution environment; p14 supplies a user interface with short interactive response. D is the option specifically about user convenience.

Why each choice is right or wrong

A - Incorrect: Utilization concerns efficiency rather than the stated convenient interaction goal.

B - Incorrect: Fault tolerance concerns failure behavior, not ordinary interaction convenience.

C - Incorrect: Security controls authorization (p6), not the named convenience goal.

D - Correct: Interface support is the module's interaction/convenience role (pp5,14).

Primary note proof

Study-note section OS01

> An OS allocates CPU time, memory, storage, devices and communication resources, and provides services to programs. Convenience means making tasks easy through consistent interfaces, files and device abstractions. Efficiency means using resources effectively; it is not synonymous with the fastest response for every process. Application development tools use OS services but application development itself is not a core resource-management function.

Study-note section OS01

> Updates and monitoring help administration, but automatic updates are not a defining property of every OS.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 5 | lines 6-13

> An operating System (OS) is an intermediary between users and computer hardware. It provides users an environment in which a user can execute programs conveniently and efficiently. In technical terms, it is software which manages hardware. An operating System controls the allocation of resources and services such as memory, processors, devices and information.
> 1.1 Definition
> An operating system is a program that acts as an interface between the user and the computer hardware and controls the execution of all kinds of programs.

Operating System module | PDF page 14 | lines 18-23

> Interactivity refers that a User is capable to interact with computer system. Operating system does the following activities related to interactivity.
> • OS provides user an interface to interact with system.
> • OS managers input devices to take inputs from the user. For example, keyboard.

• OS manages output devices to show outputs to the user. For example, Monitor.
• OS Response time needs to be short since the user submits and waits for the result.

Computer Science Exit Exam practice collection · Question 224

Question 117 | SM0228

All of the following are scheduling criteria EXCEPT:

A. CPU utilization

B. Min Turnaround Time

C. Max Throughput

D. Max Response Time

Hint

Construct a timeline and distinguish completion rates from individual elapsed-time measures.

Answer D: Maximizing response time is the wrong optimization direction.

OS13 says to minimize response, turnaround and waiting while maximizing useful throughput/utilization under the chosen objective. Thus maximum response time is the mismatched criterion: making first response later worsens responsiveness. The other alternatives name a standard metric or its conventional optimization direction. The question is about preferred direction, not whether response time itself is measurable.

Why each choice is right or wrong

A - Incorrect: CPU utilization is a standard scheduling metric measuring the fraction of elapsed time the CPU is busy.

B - Incorrect: Minimizing turnaround is the conventional goal for reducing arrival-to-completion delay.

C - Incorrect: Maximizing useful throughput is a conventional goal for increasing completed work per unit time.

D - Correct: Response delay should ordinarily be minimized; maximizing it reverses the responsiveness objective.

Primary note proof

Study-note section OS13

For arrival A, first start S and completion C, response=S−A and turnaround=C−A. For a single CPU burst B with no I/O, waiting=C−A−B. With I/O, subtract all CPU and blocked time to isolate ready-queue waiting. Throughput=completed jobs/elapsed time; CPU utilization=busy

time/elapsed time. Minimize response/turnaround/waiting under the selected goal and maximize useful throughput/utilization.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 7 | lines 20-33

Time sharing is a technique which enables many people, located at various terminals, to use a particular computer system at the same time. Time-sharing or multitasking is a logical extension of multiprogramming. Processor's time which is shared among multiple users simultaneously is termed as time-sharing. The main difference between Multi-programmed Batch Systems and Time-Sharing Systems is that in case of multi-programmed batch systems, objective is to maximize processor use, whereas in Time-Sharing Systems objective is to minimize response time.
Multiple jobs are executed by the CPU by switching between them, but the switches occur so frequently. Thus, the user can receive an immediate response. For example, in a transaction processing, processor execute each user program in a short burst or quantum of computation. That is if n users are present, each user can get time quantum. When the user submits the command, the response time is in few seconds at most.
Operating system uses CPU scheduling and multiprogramming to provide each user with a small portion of a time. Computer systems that were designed primarily as batch systems

Operating System module | PDF page 13 | lines 21-25

4.3 Multiprogramming
When two or more programs are residing in memory at the same time, then sharing the processor is referred to the multiprogramming. Multiprogramming assumes a single shared processor. Multiprogramming increases CPU utilization by organizing jobs so that the CPU always has one to execute.

Operating System module | PDF page 23 | lines 23-26

7.2 Shortest Job First (SJF)
• Best approach to minimize waiting time.
• Impossible to implement
• Processer should know in advance how much time process will take.

Operating System module | PDF page 37 | lines 20-26

• Less number of I/O would be needed to load or swap each user program into memory.
• A program would no longer be constrained by the amount of physical memory that is available.
• Each user program could take less physical memory, more programs could be run the same time, with a corresponding increase in CPU utilization and throughput.
Virtual memory is commonly implemented by demand paging. It can also be implemented in a segmentation system. Demand segmentation can also be used to provide virtual memory.

Computer Science Exit Exam practice collection · Question 225

Question 118 | SM0241

Which umbrella function of modern operating systems allocates and coordinates hardware resources such as CPU time, memory and I/O devices?

A. File Management

B. Resource Management

C. Process Management

D. Security Management

Hint

Separate broad resource-management goals from individual services or applications.

Answer B: Resource Management

An OS allocates CPU time, memory, storage, devices and communication resources. The umbrella term for coordinating these allocations is resource management. File, process and security management cover narrower responsibilities, so none alone names the full scope of the question. Replacing device management with the umbrella category preserves the combined CPU/memory/I/O concept and gives the item one complete answer.

Why each choice is right or wrong

A - Incorrect: File management concerns files and storage abstractions rather than all named resources.

B - Correct: Resource management spans CPU time, memory and I/O devices.

C - Incorrect: Process management covers execution and CPU scheduling but is narrower than the combined scope.

D - Incorrect: Security management controls protection and permissions rather than naming all allocation functions.

Primary note proof

Study-note section OS01

> An OS allocates CPU time, memory, storage, devices and communication resources, and provides services to programs.

Study-note section OS06

> Long-term scheduling admits jobs; medium-term scheduling suspends/swaps them; short-term scheduling selects ready work.

Study-note section OS36

A file has content and metadata such as name, size, owner, permissions and timestamps. open obtains an open-file reference, read/write transfer bytes, seek changes an offset, close releases a reference, truncate changes size and unlink removes a name.

Study-note section OS39

Authentication verifies identity; authorization checks permitted operations.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 6 | lines 4-9

In multiprogramming environment, OS decides which process gets the processor when and how much time. This function is called process scheduling. Operating System does the following activities for processor management. Keeps tracks of processor and status of process. Program responsible for this task is known as traffic controller.
Allocates the processor (CPU) to a process.
De-allocates processor when processor is no longer required.

Operating System module | PDF page 5 | lines 26-36

Memory management refers to management of Primary Memory or Main Memory. Main memory is a large array of words or bytes where each word or byte has its own address. Main memory provides a fast storage that can be access directly by the CPU. So, for a program to be executed, must in the main memory.
Activities Operating System for memory management.
Keeps tracks of primary memory (i.e. what part of it are in use by whom, what part are not in use.)
In multiprogramming, OS decides which process will get memory when and how much.
Allocates the memory when the process requests it to do so.
De-allocates the memory when the process no longer needs it or has been terminated.

Operating System module | PDF page 6 | lines 11-17

OS manages device communication via their respective drivers. Activities of Operating System for device management.
Keeps tracks of all devices. Program responsible for this task is known as the I/O controller.
Decides which process gets the device when and for how much time.
Allocates the device in the efficient way.
De-allocates devices.

Computer Science Exit Exam · Sene 2016 · Question 13-3

Computer Science Exit Exam practice collection · Question 223

Question 119 | SM0268

Which scheduling algorithm is commonly associated with the concept of aging, where the priority of a task increases the longer it waits in the ready queue?

A. Round Robin (RR)

B. Shortest Job Next (SJN)

C. Priority Scheduling

D. Shortest Remaining Time First (SRTF)

Hint

Check priority direction, preemption and whether waiting can change effective rank.

Answer C: Priority scheduling.

OS17 describes aging as increasing waiting jobs' effective priority to reduce indefinite postponement. That is a direct adjustment within a priority scheme and matches the stem exactly. RR rotates turns, SJN selects the shortest next burst, and SRTF selects the shortest remaining work. Those policies may be modified, but they are not the named priority-aging mechanism requested.

Why each choice is right or wrong

A - Incorrect: RR cycles ready jobs by quantum rather than defining aging through increasing priority.

B - Incorrect: SJN chooses shortest next bursts; aging refers specifically to adjusting the effective priority of waiting work.

C - Correct: Priority scheduling can raise a waiting task's effective priority through aging to reduce starvation.

D - Incorrect: SRTF compares remaining bursts rather than increasing priority solely because a task has waited longer.

Primary note proof

Study-note section OS17

> Aging increases waiting jobs' effective priority according to a rule, reducing indefinite postponement when the priority scheme and workload permit.

Study-note section OS18

> RR serves a ready queue cyclically for at most quantum q per turn.

Study-note section OS16

> Non-preemptive SJF/SJN chooses the shortest next burst among currently ready jobs. SRTF reconsiders on arrivals and selects the shortest remaining work; a shorter newcomer can preempt.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 24 | lines 10-15

> 7.3 Priority Based Scheduling
> • Each process is assigned a priority. Process with highest priority is to be executed first and so on.
> • Processes with same priority are executed on first come first serve basis.
> • Priority can be decided based on memory requirements, time requirements or any other resource requirement.

Question sources

Computer Science Exit Exam · Sene 2016 · Question 22-2

Computer Science Exit Exam practice collection · Question 222

Question 120 | SM0278

In a system susceptible to deadlock, what does the 'no preemption' condition imply?

A. Resources can be preempted and assigned to other processes

B. Processes cannot request additional resources while holding others

C. Resources cannot be preempted while they are in use

D. Processes must release all resources when blocked

Hint

Trace the resource dependencies and distinguish necessary conditions from evidence of an actual deadlock.

Answer C: Allocated resources cannot be forcibly withdrawn.

OS22 defines no resource preemption as requiring voluntary release by the holder. C states that resources cannot be preempted while in use and therefore matches. A reverses the condition. B and D describe policies attacking hold-and-wait by limiting requests or requiring release; they are different from the no-preemption property itself.

Why each choice is right or wrong

A - Incorrect: Permitting withdrawal and reassignment is resource preemption, directly reversing the condition requested.

B - Incorrect: Forbidding additional requests while holding resources attacks hold-and-wait rather than defining no-preemption.

C - Correct: The holder retains the resource until voluntary release, so it cannot simply be forcibly withdrawn.

D - Incorrect: Requiring release when blocked removes holding-while-waiting; it is not the no-preemption definition.

Primary note proof

Study-note section OS22

> Mutual exclusion allows at most one holder of a nonshareable resource. Hold-and-wait means retaining a resource while requesting another. No resource preemption means release must be voluntary. Circular wait forms a closed chain of such waits.

Study-note section OS24

> “If waiting, release all held resources and try again” removes simultaneous holding while waiting.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Science Exit Exam practice collection · Question 227

Question 121 | SS106

When a process is in a "Blocked" state waiting for some Input-Output services and afterthe service is completed, it will goes to a state known as:

A. Terminated

B. Suspended

C. Ready

D. Running

Hint

Decide whether the process is eligible, running or waiting, then identify the responsible queue or scheduling role.

Answer C: Ready

After I/O completion the process no longer waits for that event but must obtain CPU allocation, so it becomes Ready (PDF pp16,19-20). Running follows only when the scheduler actually selects it.

Why each choice is right or wrong

A - Incorrect: Completion of an I/O request is not completion of the process.

B - Incorrect: Suspension concerns memory removal/swapping, not an inevitable I/O-completion transition.

C - Correct: Ready means eligible and waiting for processor assignment (p16).

D - Incorrect: It can run after scheduling; I/O completion alone does not allocate CPU (p20).

Primary note proof

Study-note section OS06

> New processes are created/admitted; ready means eligible for CPU but not currently running. Running uses a CPU. Waiting/blocked means unable to proceed until an event; terminated means execution has ended. Running→ready follows time-slice expiry or another preemption. Running→waiting follows blocking I/O. I/O completion normally gives waiting→ready, not a guaranteed immediate running state.

Study-note section OS06

> Long-term scheduling admits jobs; medium-term scheduling suspends/swaps them; short-term scheduling selects ready work.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 16 | lines 29-39

> 1. New The process is being created.
> 2.
> Ready The process is waiting to be assigned to a processor. Ready processes are waiting to have the processor allocated to them by the operating system so that they can run.
> 3.
> Running Process instructions are being executed (i.e. The process that is currently being executed).
> 4.
> Waiting The process is waiting for some event to occur (such as the completion of an I/O operation).
> 5. Terminated The process has finished execution.

Operating System module | PDF page 19 | lines 6-12

> A newly arrived process is put in the ready queue. Processes waits in ready queue for allocating the CPU. Once the CPU is assigned to a process, then that process will execute. While executing the process, any one of the following events can occur.
> • The process could issue an I/O request and then it would be placed in an I/O queue.
> • The process could create new sub process and will wait for its termination.
> • The process could be removed forcibly from the CPU, as a result of interrupt and put back in the ready queue.

Operating System module | PDF page 20 | lines 15-21

It is also called CPU scheduler. Main objective is increasing system performance in accordance with the chosen set of criteria. It is the change of ready state to running state of the process. CPU scheduler selects process among the processes that are ready to execute and allocates CPU to one of them.
Short term scheduler also known as dispatcher, execute most frequently and makes the fine-grained decision of which process to execute next. Short term scheduler is faster than long term scheduler.

Computer Science model exam collection · Question 13

Question 122 | SS107

A memory management policy that decisions must be made as to which page or pages are to be supplanted when a memory is full is known as:

A. Cleaning policy

B. Fetch policy

C. Load policy

D. Replacement policy

Hint

Trace every reference, distinguish hits from faults and update the policy state consistently.

Answer D: Replacement policy

Page replacement chooses which memory pages to swap out when allocation requires unavailable free space (PDF p40). D names that victim-selection policy.

Why each choice is right or wrong

A - Incorrect: Cleaning concerns writing dirty contents; it does not identify victim selection in the p40 definition.

B - Incorrect: Fetching concerns bringing data in, rather than selecting a resident victim.

C - Incorrect: Loading concerns admission/bringing in work, rather than selecting pages to evict.

D - Correct: Replacement is explicitly the decision of which pages to swap out (p40).

Primary note proof

Study-note section OS33

Replacement chooses a victim when no suitable free frame is available.

Study-note section OS-S03

A fetch policy decides when contents are brought into memory; demand paging fetches a valid nonresident page when it is accessed. A cleaning policy concerns writing modified contents to

backing storage. A replacement policy chooses which resident page to evict. These decisions can cooperate during one page fault, but they are different decisions.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 40 | lines 7-20

Page replacement algorithms are the techniques using which Operating System decides which memory pages to swap out, write to disk when a page of memory needs to be allocated.
Paging happens whenever a page fault occurs and a free page cannot be used for allocation purpose accounting to reason that pages are not available or the number of free pages is lower than required pages.
When the page that was selected for replacement and was paged out, is referenced again then it has to read in from disk, and this requires for I/O completion. This process determines the quality of the page replacement algorithm: the lesser the time waiting for page-ins, the better is the algorithm. A page replacement algorithm looks at the limited information about accessing the pages provided by hardware, and tries to select which pages should be replaced to minimize the total number of page misses, while balancing it with the costs of primary storage and processor time of the algorithm itself. There are many different page replacement algorithms. We evaluate an algorithm by running it on a particular string of memory reference and computing the number of page faults.

Computer Science model exam collection · Question 14

Question 123 | SS122

Which of the following is not a principal event that cause processes to be created?

A. Multiple execution of processes

B. Execution of a process-creation system call by a running process

C. System initialization

D. Auser request to create a new process

Hint

Separate creation, image replacement and termination; classify termination by its cause.

Answer A: Multiple execution is not itself a process-creation event.

OS07 lists initialization, user requests, service requests and a running process's creation call as creation causes. B, C and D match that list. Multiple execution of processes describes work being run, not an explicit request or initialization event creating a new process. Existing processes can execute repeatedly without creating a child, so A is the unsupported creation trigger.

Why each choice is right or wrong

A - Correct: Executing existing processes multiple times is not itself the explicit creation trigger identified here.

B - Incorrect: A running process's creation system call is explicitly one of the listed process-creation causes.

C - Incorrect: System initialization is explicitly listed as a time when processes are created.

D - Incorrect: A user request to create a process is explicitly a valid process-creation cause.

Primary note proof

Study-note section OS07

> Processes arise during initialization, user requests, service requests or a running process's creation call.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 19 | lines 6-12

> A newly arrived process is put in the ready queue. Processes waits in ready queue for allocating the CPU. Once the CPU is assigned to a process, then that process will execute. While executing the process, any one of the following events can occur.
> • The process could issue an I/O request and then it would be placed in an I/O queue.
> • The process could create new sub process and will wait for its termination.
> • The process could be removed forcibly from the CPU, as a result of interrupt and put back in the ready queue.

Operating System module | PDF page 16 | lines 6-9

> A process is a program in execution. The execution of a process must progress in a sequential fashion. Definition of process is following.
> • A process is defined as an entity which represents the basic unit of work to be implemented in the system.

Question sources

Computer Science model exam collection · Question 29

Question 124 | SS125

Which statement about Banker's algorithm is false?

A. It is a CPU scheduling algorithm

B. It uses each process's declared maximum resource claims

C. Its safety test simulates completions to check whether every process can finish

D. It checks a received resource request before granting it

Hint

Compute remaining needs and simulate feasible completions before deciding whether an allocation is safe.

Answer A: It is a CPU scheduling algorithm

Banker's algorithm is a deadlock-avoidance technique, not a CPU scheduling policy. It requires maximum resource claims, computes remaining needs, and simulates possible completions to check for a safe sequence. A request is evaluated after receipt and before being granted, including checks against need and availability. The factual alternatives therefore describe the supported safety procedure, leaving only the CPU-scheduling classification false.

Why each choice is right or wrong

A - Correct: Banker is deadlock avoidance rather than CPU scheduling, so this statement is false.

B - Incorrect: Maximum resource claims are required input, so this statement is true.

C - Incorrect: The safety test repeatedly simulates feasible completions, so this statement is true.

D - Incorrect: A request is checked before granting it, so this statement is true.

Primary note proof

Study-note section OS25

> Avoidance allows requests only if the resulting state remains safe. Banker requires maximum claims. Compute Need=Max−Allocation. Set Work=Available and repeatedly find an unfinished process with Need≤Work componentwise; simulate completion by adding its Allocation to Work. Finishing all gives a safe sequence. Tentatively grant a request only if it is within Need and Available and the safety test succeeds. Unsafe does not mean already deadlocked. Banker is avoidance, not CPU scheduling, detection or prevention by breaking a condition.

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 10 | lines 23-28

> • Loads a program into memory.
> • Executes the program.
> • Handles program's execution.
> • Provides a mechanism for process synchronization.
> • Provides a mechanism for process communication.
> • Provides a mechanism for deadlock handling.

Question sources

Computer Science model exam collection · Question 32

Question 125 | SS138

A set of processes is blocked: each holds a resource and waits for another resource that only another blocked member of the set can release. No member can proceed without intervention. This state is called:

A. Deadlock

B. Queuing

C. Preemption

D. Overloading

Hint

Trace the resource dependencies and distinguish necessary conditions from evidence of an actual deadlock.

Answer A: Deadlock

The specified set has a closed dependency: every member is waiting for something only another blocked member can provide. None can reach the release operation needed by another, so the state is deadlock. Queuing can occur during ordinary waits that eventually finish; preemption withdraws or reallocates a resource; overload concerns excessive demand. The added dependency condition makes the deadlock interpretation definite.

Why each choice is right or wrong

A - Correct: The closed dependency among blocked members defines deadlock.

B - Incorrect: Ordinary queuing does not require a dependency that prevents every member from progressing.

C - Incorrect: Preemption is resource withdrawal or reassignment rather than this blocked state.

D - Incorrect: Overload does not by itself create the specified closed dependency.

Primary note proof

Study-note section OS22

> A set is deadlocked when each member waits for an event/resource that only another blocked member can provide. Mere waiting for another holder is normal blocking; indefinite unfair delay can be starvation without a cycle of dependencies.

Study-note section OS24

> Prevention constrains how requests are made. Share a resource where safe to remove mutual exclusion; request all needed resources before holding any to remove hold-and-wait; permit safe resource withdrawal/restart to attack no-preemption; impose a global acquisition order to remove circular wait.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 16 | lines 29-39

1. New The process is being created.
2.
Ready The process is waiting to be assigned to a processor. Ready processes are waiting to have the processor allocated to them by the operating system so that they can run.
3.
Running Process instructions are being executed (i.e. The process that is currently being executed).
4.
Waiting The process is waiting for some event to occur (such as the completion of an I/O operation).
5. Terminated The process has finished execution.

Operating System module | PDF page 19 | lines 6-12

A newly arrived process is put in the ready queue. Processes waits in ready queue for allocating the CPU. Once the CPU is assigned to a process, then that process will execute. While executing the process, any one of the following events can occur.
• The process could issue an I/O request and then it would be placed in an I/O queue.
• The process could create new sub process and will wait for its termination.
• The process could be removed forcibly from the CPU, as a result of interrupt and put back in the ready queue.

• Provides a mechanism for process communication.
• Provides a mechanism for deadlock handling.

Question sources

Computer Science model exam collection · Question 45

Question 126 | SS183

Identify the lowest layer of Android architecture.

A. Application

B. Application Framework

C. Database

D. Linux Kernel

Hint

Use the stated historical or platform scope and distinguish origin from technical capability.

Answer D: Linux kernel.

OS40 directly states that Android's base kernel layer is Linux and places framework and applications above it. Thus Linux Kernel is the lowest offered layer. A database is not identified as the kernel foundation in this model. The answer rests on Android's architecture, not on a separate claim about Android's current market share.

Why each choice is right or wrong

A - Incorrect: Applications sit above the framework and kernel rather than forming Android's base layer.

B - Incorrect: The application framework is explicitly a higher layer than the Linux kernel foundation.

C - Incorrect: A database is not the base kernel layer identified here's Android architecture description.

D - Correct: The note explicitly names Linux as Android's base kernel layer beneath framework and applications.

Primary note proof

Study-note section OS40

> Android's base kernel layer is Linux; its framework and applications are higher layers. AOSP is open source, while a shipped device can include proprietary applications/services.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 54 | lines 24-30

> Hardware layer - Hardware consists of all peripheral devices (RAM/ HDD/ CPU etc.).
> Kernel - Core component of Operating System, interacts directly with hardware, provides low level services to upper layer components.
> Shell - An interface to kernel, hiding complexity of kernel's functions from users. Takes commands from user and executes kernel's functions.
> Utilities - Utility programs giving user most of the functionalities of an operating systems.

Question sources

Computer Science model exam collection · Question 90

Question 127 | AM0654

Which objective specifically concerns efficient allocation of CPU time, memory, storage and devices among competing programs?

A. To provide an interface for users to interact with the hardware

B. To manage and allocate system resources efficiently

C. To ensure data security and protection

D. To optimize program execution speed

Hint

Separate broad resource-management goals from individual services or applications.

Answer B: To manage and allocate system resources efficiently

Resource management allocates CPU time, memory, storage, devices and communications to programs. That directly matches efficient management and allocation in B. User interfaces support convenience, protection controls permitted access, and execution speed is a performance concern. Those are related goals, but the stated question asks specifically for the allocation objective rather than ranking every legitimate OS goal as universally most important.

Why each choice is right or wrong

A - Incorrect: Providing an interface concerns convenience rather than the specific allocation objective.

B - Correct: Efficient management and allocation directly names the requested resource objective.

C - Incorrect: Security and protection concern access control rather than allocation efficiency itself.

D - Incorrect: Program speed is a performance concern and is not equivalent to efficient allocation of all resources.

Primary note proof

Study-note section OS01

> An OS allocates CPU time, memory, storage, devices and communication resources, and provides services to programs. Convenience means making tasks easy through consistent interfaces, files and device abstractions. Efficiency means using resources effectively; it is not synonymous with the fastest response for every process. Application development tools use OS services but application development itself is not a core resource-management function.

Study-note section OS39

> Authentication verifies identity; authorization checks permitted operations.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 5 | lines 6-13

An operating System (OS) is an intermediary between users and computer hardware. It provides users an environment in which a user can execute programs conveniently and efficiently. In technical terms, it is software which manages hardware. An operating System controls the allocation of resources and services such as memory, processors, devices and information.
1.1 Definition
An operating system is a program that acts as an interface between the user and the computer hardware and controls the execution of all kinds of programs.

Question sources

Computer Science MCQ practice collection · Question 654

Question 128 | AM0655

Which of the following is not a function of an operating system?

A. Process management

B. File management

C. Network management

D. Application development

Hint

Separate broad resource-management goals from individual services or applications.

Answer D: Application development is not a core OS resource-management function.

OS01 explicitly distinguishes application-development tools using OS services from application development itself as a core OS function. Processes, files and communication resources are managed by the OS. Therefore D is the exclusion in the intended resource-management scope. Providing compilers, editors or development APIs does not mean the operating system itself performs application development as its defining resource function.

Why each choice is right or wrong

A - Incorrect: Managing execution/process resources belongs to the OS's core resource-management responsibilities.

B - Incorrect: File and storage management are core OS services rather than the requested non-function.

C - Incorrect: Communication/network resource management belongs to the OS responsibilities described in the note.

D - Correct: The note explicitly separates developing applications from the OS functions used by development tools.

Primary note proof

Study-note section OS01

An OS allocates CPU time, memory, storage, devices and communication resources, and provides services to programs. Convenience means making tasks easy through consistent interfaces, files and device abstractions. Efficiency means using resources effectively; it is not synonymous with the fastest response for every process. Application development tools use OS services but application development itself is not a core resource-management function.

Study-note section OS04

Process control, file/device management, information retrieval and communication are service categories.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 6 | lines 4-9

In multiprogramming environment, OS decides which process gets the processor when and how much time. This function is called process scheduling. Operating System does the following activities for processor management. Keeps tracks of processor and status of process. Program responsible for this task is known as traffic controller.
Allocates the processor (CPU) to a process.
De-allocates processor when processor is no longer required.

Operating System module | PDF page 6 | lines 19-23

A file system is normally organized into directories for easy navigation and usage. These directories may contain files and other directions. Operating System does the following activities for file management.
Keeps track of information, location, uses, status etc. The collective facilities are often known as file system.

Operating System module | PDF page 8 | lines 21-26

Network Operating System runs on a server and provides server the capability to manage data, users, groups, security, applications, and other networking functions. The primary purpose of the network operating system is to allow shared file and printer access among multiple computers in a network, typically a local area network (LAN), a private network or to other networks. Examples of network operating systems are Microsoft Windows Server 2003, Microsoft Windows Server 2008, UNIX, Linux, Mac OS X, Novell NetWare, and BSD.

Operating System module | PDF page 10 | lines 5-15

An Operating System provides services to both the users and to the programs.
• It provides programs, an environment to execute.
• It provides users, services to execute the programs in a convenient manner.
Operating Systems can provide the following common services:
✓ Program execution
✓ I/O operations
✓ File System manipulation
✓ Communication
✓ Error Detection

✓ Resource Allocation
✓ Protection

Question sources

Computer Science MCQ practice collection · Question 655

Question 129 | AM0656

What is the purpose of memory management in an operating system?

A. To provide an interface for users to interact with the computer system

B. To manage the execution of multiple processes simultaneously

C. To allocate and deallocate memory for processes and data

D. To ensure data integrity and security

Hint

Read the cited conceptual rules, state the model, and apply them before comparing the alternatives.

Answer C: To allocate and deallocate memory for processes and data

PDF pp5 and 31 say memory management tracks primary memory, decides allocations, and updates status when memory is freed. C is the specific allocation/deallocation function.

Why each choice is right or wrong

A - Incorrect: User interaction is a separate interface function.

B - Incorrect: Multiple-process execution is process/scheduling work; memory management supports it but does not define execution control.

C - Correct: Allocation and deallocation are the direct memory-management tasks (pp5,31).

D - Incorrect: Protection is supported by base/limit registers, but data integrity/security is too broad to identify the principal allocation role.

Primary note proof

Study-note section OS-S03

Memory management tracks which primary-memory regions are free or in use, assigns memory to processes and data, and deallocates it when no longer needed or when a process terminates. Allocation and deallocation concern memory ownership; CPU selection belongs to scheduling.

Study-note section OS28

In the standard base/limit model, base is that process's physical starting address and limit is its permitted length. Check 0≤logical_offset<limit, then physical=base+offset.

Study-note section OS03

A shell reads/interprets user commands; a GUI is another interface.

Study-note section OS06

Long-term scheduling admits jobs; medium-term scheduling suspends/swaps them; short-term scheduling selects ready work.

Study-note section OS39

Authentication verifies identity; authorization checks permitted operations.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 31 | lines 24-31

Memory management is the functionality of an operating system which handles or manages primary memory. Memory management keeps track of each and every memory location either it is allocated to some process or it is free. It checks how much memory is to be allocated to processes. It decides which process will get memory at what time. It tracks whenever some memory gets freed or unallocated and correspondingly it updates the status.
Memory management provides protection by using two registers, a base register and a limit register. The base register holds the smallest legal physical memory address and the limit register specifies the size of the range. For example, if the base register holds 300000 and the

Operating System module | PDF page 5 | lines 26-36

Memory management refers to management of Primary Memory or Main Memory. Main memory is a large array of words or bytes where each word or byte has its own address. Main memory provides a fast storage that can be access directly by the CPU. So, for a program to be executed, must in the main memory.
Activities Operating System for memory management.
Keeps tracks of primary memory (i.e. what part of it are in use by whom, what part are not in use.)
In multiprogramming, OS decides which process will get memory when and how much.
Allocates the memory when the process requests it to do so.
De-allocates the memory when the process no longer needs it or has been terminated.

Question sources

Computer Science MCQ practice collection · Question 656

Question 130 | AM0657

Which OS component converts generic I/O requests into operations specific to a particular device, rather than naming the kernel as a whole?

A. Kernel

B. Scheduler

C. File system

D. Device drivers

Hint

Separate device hardware, device-specific software and general event or transfer mechanisms.

Answer D: Device drivers

A device driver translates OS I/O requests into the particular operations a device requires. The kernel provides broader resource management and can contain drivers, but the question asks for that specific hardware-facing component. The scheduler selects runnable work and the filesystem organizes file abstractions. Neither performs the general per-device request translation described, making device drivers the precise answer.

Why each choice is right or wrong

A - Incorrect: The kernel is the larger system containing or coordinating the specific component.

B - Incorrect: The scheduler chooses runnable CPU work rather than translating device commands.

C - Incorrect: The filesystem organizes files rather than translating requests for every device type.

D - Correct: Drivers convert OS requests into device-specific operations.

Primary note proof

Study-note section OS34

> A controller is device hardware exposing status, control and data registers. A driver converts OS requests into device-specific operations. Device independence and uniform naming hide brand-specific details; error handling reports/retries supported failures.

Study-note section OS03

> The kernel implements core resource management, protection and system-call handling.

Study-note section OS06

> Long-term scheduling admits jobs; medium-term scheduling suspends/swaps them; short-term scheduling selects ready work.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 47 | lines 19-26

12.5 Device driver
Device driver is a program or routine developed for an I/O device. A device driver implements I/O operations or behaviors on a specific class of devices. For example a system supports one or a number of multiple brands of terminals, all slightly different terminals may have a single terminal driver. In the layered structure of I/O system, device driver lies between interrupt handler and device independent I/O software. The job of a device driver is following.
To accept request from the device independent software above it.
To see to it that the request is executed.

Operating System module | PDF page 45 | lines 28-33

Application I/O Interface represents the structuring techniques and interfaces for the operating system to enable I/O devices to be treated in a standard, uniform way. The actual differences lies kernel level modules called device drivers which are custom tailored to corresponding devices but show one of the standard interfaces to applications. The purpose of the device-driver layer is to hide the differences among device controllers from the I/O subsystem of the kernel, such as the I/O system calls. Following are the characteristics of I/O

Operating System module | PDF page 47 | lines 5-9

Buffering - Kernel I/O Subsystem maintains a memory area known as buffer that stores data while they are transferred between two devices or between a devices with an application operation. Buffering is done to cope with a speed mismatch between the producer and consumer of a data stream or to adapt between devices that have different data transfer sizes.

Question sources

Computer Science MCQ practice collection · Question 657

Question 131 | AM0658

What is the role of the file system in an operating system?

A. To manage system resources and allocate them to processes

B. To provide a user interface for interacting with the computer system

C. To store and organize files on secondary storage devices

D. To schedule and prioritize the execution of processes

Hint

Distinguish a file operation, a resource handle, an offset and file metadata.

Answer C: To store and organize files on secondary storage devices

Files are related information on secondary storage (PDF p48); file management tracks locations and organizes directories (p6). C gives that role.

Why each choice is right or wrong

A - Incorrect: System-wide allocation is broader than organizing files.

B - Incorrect: A user interface is not the file system's stored-information role.

C - Correct: Matches secondary storage and organization (pp6,48).

D - Incorrect: Process execution ordering belongs to schedulers (p20), not file organization.

Primary note proof

Study-note section OS36

> A file has content and metadata such as name, size, owner, permissions and timestamps. open obtains an open-file reference, read/write transfer bytes, seek changes an offset, close releases a reference, truncate changes size and unlink removes a name.

Study-note section OS37

> A single-level directory requires unique names in one namespace. Two-level directories separate users. A tree allows nested directories and absolute/relative paths; links can create shared graphs. Modern general-purpose systems commonly present hierarchical namespaces, but a feature name alone does not prove that every system excludes simpler arrangements.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 48 | lines 5-8

> 13.1 File
> A file is a named collection of related information that is recorded on secondary storage such as magnetic disks, magnetic tapes and optical disks. In general, a file is a sequence of bits, bytes, lines or records whose meaning is defined by the file's creator and user.

Operating System module | PDF page 6 | lines 19-23

> A file system is normally organized into directories for easy navigation and usage. These directories may contain files and other directions. Operating System does the following activities for file management.
> Keeps track of information, location, uses, status etc. The collective facilities are often known as file system.

Question sources

Computer Science MCQ practice collection · Question 658

Question 132 | AM0659

Which scheduling algorithm is based on assigning a fixed time slice to each process in a round-robin manner?

A. First-Come, First-Served (FCFS) scheduling

B. Shortest Job Next (SJN) scheduling

C. Priority scheduling

D. Round-Robin scheduling

Hint

Trace bounded turns in ready-queue order and include the stated overhead and arrivals.

Answer D: Round-Robin scheduling

PDF p25 explicitly defines a fixed execution quantum followed by preemption and another process's turn. D is that round-robin policy.

Why each choice is right or wrong

A - Incorrect: FCFS uses arrival order without this specified repeating quantum (p23).

B - Incorrect: SJN selects short jobs using known execution length (p23).

C - Incorrect: Priority uses assigned rank (p24).

D - Correct: Fixed quantum plus repeated turns is the p25 RR definition.

Primary note proof

Study-note section OS18

> RR serves a ready queue cyclically for at most quantum q per turn. Unfinished jobs return to the tail; completed/blocked jobs leave.

Study-note section OS15

> FCFS runs ready bursts in arrival order and ordinarily does not preempt.

Study-note section OS16

> Non-preemptive SJF/SJN chooses the shortest next burst among currently ready jobs.

Study-note section OS17

> Priority scheduling chooses the highest-priority ready job.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 25 | lines 10-14

> 7.4 Round Robin Scheduling
> • Each process is provided a fix time to execute called quantum.
> • Once a process is executed for given time period. Process is preempted and other process executes for given time period.
> • Context switching is used to save states of preempted processes.

Operating System module | PDF page 23 | lines 12-17

> 7.1 First Come First Serve (FCFS)
> • Jobs are executed on first come, first serve basis.
> • Easy to understand and implement.
> • Poor in performance as average wait time is high.
> Wait time of each process is following
> Process Wait Time: Service Time - Arrival Time

Operating System module | PDF page 23 | lines 23-26

7.2 Shortest Job First (SJF)
• Best approach to minimize waiting time.
• Impossible to implement
• Processer should know in advance how much time process will take.

Operating System module | PDF page 24 | lines 10-15

7.3 Priority Based Scheduling
• Each process is assigned a priority. Process with highest priority is to be executed first and so on.
• Processes with same priority are executed on first come first serve basis.
• Priority can be decided based on memory requirements, time requirements or any other resource requirement.

Question sources

Computer Science MCQ practice collection · Question 659

Question 133 | AM0660

What is the primary goal of file-access authorization in an operating system?

A. To ensure the availability of files for authorized users

B. To prevent unauthorized access to files and data

C. To optimize file storage and retrieval performance

D. To minimize the impact of system failures on file operations

Hint

Distinguish identity checks, permission checks and the particular security property at issue.

Answer B: To prevent unauthorized access to files and data

Authorization checks whether a user or other principal is permitted to perform an operation on a file. Preventing unauthorized access is therefore the direct goal. Availability and recovery protect access through failures or disruption, while storage optimization concerns performance. Those are useful objectives, but they are distinct from deciding who may read, write or otherwise access a particular file.

Why each choice is right or wrong

A - Incorrect: Availability keeps files accessible when needed; it is distinct from deciding whether an attempted access is authorized.

B - Correct: Preventing unauthorized access directly follows from checking permitted operations and file rights.

C - Incorrect: Storage and retrieval performance do not determine a caller’s access rights.

D - Incorrect: Limiting failure impact concerns resilience and recovery, rather than the access-permission decision.

Primary note proof

Study-note section OS39

> Authentication verifies identity; authorization checks permitted operations. An ACL lists principals and rights; owner/group/other bits are a simpler policy model, not universal defaults granting all owners full access or everyone read. Read, write, execute, append and delete are different rights, with filesystem-specific rules.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 6 | lines 29-30

> Security -- By means of password and similar other techniques, preventing unauthorized access to programs and data.

Operating System module | PDF page 11 | lines 3-8

> • Program needs to read a file or write a file.
> • The operating system gives the permission to the program for operation on file.
> • Permission varies from read-only, read-write, denied and so on.
> • Operating System provides an interface to the user to create/delete files.
> • Operating System provides an interface to the user to create/delete directories.
> • Operating System provides an interface to create the backup of file system.

Question sources

Computer Science MCQ practice collection · Question 660

Question 134 | AM0661

What is the purpose of virtual memory in an operating system?

A. To provide a virtualized environment for running multiple operating systems

B. To increase the physical memory capacity of a computer system

C. To allow the execution of programs without any memory constraints

D. To create a separate memory space for each running process

Hint

Separate a permitted nonresident access from an illegal access and trace the required handling steps.

Answer D: Provide translated, protected per-process address spaces.

OS32 defines virtual memory as translated/protected address spaces with nonresident portions backed by storage. D is the option matching separate process memory spaces. A describes machine virtualization; B falsely adds physical RAM and C falsely removes all memory constraints. Isolation and translation are the supported purpose, with backing storage providing flexibility within finite resource limits.

Why each choice is right or wrong

A - Incorrect: Running multiple guest OSs describes machine virtualization, explicitly distinguished from process virtual memory.

B - Incorrect: Virtual memory does not physically add RAM; it maps address spaces using existing RAM and backing storage.

C - Incorrect: The note explicitly retains capacity constraints; virtual memory does not make execution memory-unlimited.

D - Correct: Separate translated/protected process address spaces match the virtual-memory purpose described here.

Primary note proof

Study-note section OS32

> Virtual memory provides translated, protected address spaces and allows nonresident portions of a program to be backed by storage. It does not add physical RAM or remove all capacity constraints.

Study-note section OS04

> Virtualization presents a virtual machine environment, often allowing guest operating systems on one host through a hypervisor. It differs from virtual memory, which translates a process's addresses.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 37 | lines 6-11

> Virtual memory is a technique that allows the execution of processes which are not completely available in memory. The main visible advantage of this scheme is that programs can be larger than physical memory. Virtual memory is the separation of user logical memory from physical memory.
> This separation allows an extremely large virtual memory to be provided for programmers when only a smaller physical memory is available. Following are the situations, when entire

Computer Science MCQ practice collection · Question 661

Question 135 | AM0662

What is the role of the shell in an operating system?

A. To manage and allocate system resources

B. To provide a graphical user interface for interacting with the system

C. To act as an interface between the user and the operating system kernel

D. To schedule and prioritize the execution of processes

Hint

Distinguish command interfaces, privileged core services and the stages of booting.

Answer C: To act as an interface between the user and the operating system kernel

The shell takes user commands and invokes kernel functions (PDF p54), making C the exact interface relationship. A and D describe other core functions; B imposes a GUI-only restriction absent from the command-interpreter definition.

Why each choice is right or wrong

A - Incorrect: System resources are the kernel/OS management role, not the shell's defining interface.

B - Incorrect: The module describes command interpretation, not a requirement that the shell be graphical.

C - Correct: Directly matches the user-to-kernel interface (p54).

D - Incorrect: CPU ordering is scheduling, not the shell definition.

Primary note proof

Study-note section OS03

> The kernel implements core resource management, protection and system-call handling. A shell reads/interprets user commands; a GUI is another interface. Browsers, office tools and editors are applications.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 54 | lines 18-20

> commands of the operating system. It can be used to do various types of operations,
> call application programs etc.
> Security - Linux provides user security using authentication features like password

Operating System module | PDF page 54 | lines 24-30

> Hardware layer - Hardware consists of all peripheral devices (RAM/ HDD/ CPU etc.).
> Kernel - Core component of Operating System, interacts directly with hardware,
> provides low level services to upper layer components.
> Shell - An interface to kernel, hiding complexity of kernel's functions from users. Takes

commands from user and executes kernel's functions.
Utilities - Utility programs giving user most of the functionalities of an operating systems.

Question sources

Computer Science MCQ practice collection · Question 662

Question 136 | AM0663

What is the primary purpose of process synchronization when processes perform conflicting accesses to shared state?

A. To prevent deadlock situations

B. To ensure fair allocation of system resources

C. To enable parallel execution of multiple processes

D. To coordinate shared-state access and required operation ordering safely

Hint

Identify conflicting shared accesses and the safety or progress property required.

Answer D: To coordinate shared-state access and required operation ordering safely

Conflicting accesses need coordination so interleaving does not corrupt shared state or violate required operation order. Critical-section protection provides mutual exclusion, with progress and bounded waiting required under the stated solution assumptions. Synchronization does not automatically eliminate deadlock; inconsistent lock acquisition can introduce it. It may also serialize work rather than create parallelism, so safe shared-access coordination is the precise primary purpose.

Why each choice is right or wrong

A - Incorrect: Locking can itself deadlock, so universal deadlock prevention is not the primary definition.

B - Incorrect: General resource-allocation fairness is broader than coordinating shared-state operations.

C - Incorrect: Synchronization can serialize conflicting operations and does not itself create parallel execution.

D - Correct: Coordinating shared accesses and required ordering safely captures the primary purpose.

Primary note proof

Study-note section OS10

A race occurs when results depend on uncoordinated interleaving of conflicting accesses. A critical section is code accessing shared state that needs protection, not the resource itself. A

correct exclusion solution requires mutual exclusion, progress and bounded waiting under stated assumptions. Mutual exclusion is a desired safety property; races, starvation and deadlock are possible failures.

Study-note section OS10

Keep critical regions small and ensure every conflicting access uses the same protection. A barrier waits until a defined set of participants reaches a point; a monitor encapsulates protected operations with condition synchronization. Locking can itself introduce deadlock if acquisition order is inconsistent.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 10 | lines 23-28

- Loads a program into memory.
- Executes the program.
- Handles program's execution.
- Provides a mechanism for process synchronization.
- Provides a mechanism for process communication.
- Provides a mechanism for deadlock handling.

Question sources

Computer Science MCQ practice collection · Question 663

Question 137 | AM0664

What is the main function of an operating system in terms of convenience?

A. Providing an easy-to-use graphical user interface

B. Optimizing program execution speed

C. Managing system resources efficiently

D. Ensuring data security and protection

Hint

Separate broad resource-management goals from individual services or applications.

Answer A: An easy-to-use interface is the convenience example.

OS01 defines convenience as making tasks easy through consistent interfaces and abstractions. A directly exemplifies that user-facing goal, although a GUI is one possible interface rather than a universal requirement. B and C concern speed/resource efficiency, and D protection. Those are worthwhile OS objectives but do not match the convenience dimension specifically named in the stem.

Why each choice is right or wrong

A - Correct: An easy-to-use GUI is an example of making user tasks convenient through an interface.

B - Incorrect: Optimizing execution speed concerns performance rather than the user-facing convenience dimension requested.

C - Incorrect: Efficient allocation is a resource-use objective, distinguished from convenience in the note.

D - Incorrect: Security/protection is a separate OS objective rather than the interface-usability example of convenience.

Primary note proof

Study-note section OS01

> An OS allocates CPU time, memory, storage, devices and communication resources, and provides services to programs. Convenience means making tasks easy through consistent interfaces, files and device abstractions. Efficiency means using resources effectively; it is not synonymous with the fastest response for every process. Application development tools use OS services but application development itself is not a core resource-management function.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 5 | lines 6-13

> An operating System (OS) is an intermediary between users and computer hardware. It provides users an environment in which a user can execute programs conveniently and efficiently. In technical terms, it is software which manages hardware. An operating System controls the allocation of resources and services such as memory, processors, devices and information.
> 1.1 Definition
> An operating system is a program that acts as an interface between the user and the computer hardware and controls the execution of all kinds of programs.

Operating System module | PDF page 14 | lines 18-23

> Interactivity refers that a User is capable to interact with computer system. Operating system does the following activities related to interactivity.
> • OS provides user an interface to interact with system.
> • OS managers input devices to take inputs from the user. For example, keyboard.
> • OS manages output devices to show outputs to the user. For example, Monitor.
> • OS Response time needs to be short since the user submits and waits for the result.

Question sources

Computer Science MCQ practice collection · Question 664

Question 138 | AM0665

How does an operating system improve efficiency in a computer system?

A. By allocating system resources to processes effectively

B. By providing a wide range of software applications

C. By supporting multiple programming languages

D. By ensuring data integrity and security

Hint

Separate broad resource-management goals from individual services or applications.

Answer A: By allocating system resources to processes effectively

Efficient use follows the module's allocation of processor time and memory to processes (PDF pp5-6,31). A states this mechanism rather than the quantity of applications or languages.

Why each choice is right or wrong

A - Correct: Directly matches resource allocation and scheduling responsibilities.

B - Incorrect: More applications alone does not establish allocation efficiency.

C - Incorrect: Language variety alone does not establish allocation efficiency.

D - Incorrect: Security is a distinct access-control function, not the stated allocation mechanism.

Primary note proof

Study-note section OS01

> An OS allocates CPU time, memory, storage, devices and communication resources, and provides services to programs. Convenience means making tasks easy through consistent interfaces, files and device abstractions. Efficiency means using resources effectively; it is not synonymous with the fastest response for every process.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 5 | lines 6-13

> An operating System (OS) is an intermediary between users and computer hardware. It provides users an environment in which a user can execute programs conveniently and efficiently. In technical terms, it is software which manages hardware. An operating System controls the allocation of resources and services such as memory, processors, devices and information.
> 1.1 Definition
> An operating system is a program that acts as an interface between the user and the computer hardware and controls the execution of all kinds of programs.

Operating System module | PDF page 6 | lines 4-9

In multiprogramming environment, OS decides which process gets the processor when and how much time. This function is called process scheduling. Operating System does the following activities for processor management. Keeps tracks of processor and status of process. Program responsible for this task is known as traffic controller.
Allocates the processor (CPU) to a process.
De-allocates processor when processor is no longer required.

Operating System module | PDF page 31 | lines 24-31

Memory management is the functionality of an operating system which handles or manages primary memory. Memory management keeps track of each and every memory location either it is allocated to some process or it is free. It checks how much memory is to be allocated to processes. It decides which process will get memory at what time. It tracks whenever some memory gets freed or unallocated and correspondingly it updates the status.
Memory management provides protection by using two registers, a base register and a limit register. The base register holds the smallest legal physical memory address and the limit register specifies the size of the range. For example, if the base register holds 300000 and the

Question sources

Computer Science MCQ practice collection · Question 665

Question 139 | AM0666

What does it mean for an operating system to have the ability to evolve?

A. It can adapt to changing hardware configurations

B. It can support multiple operating systems simultaneously

C. It can run legacy software without compatibility issues

D. It can automatically update itself with new features and bug fixes

Hint

Separate broad resource-management goals from individual services or applications.

Answer A: Adapt to changing hardware configurations.

OS01 defines ability to evolve as adding hardware support, features and repairs through maintainable interfaces/modules. Adaptation to hardware configurations is therefore the direct example. Running multiple guest OSs describes virtualization. Backward compatibility preserves supported behavior rather than guaranteeing every legacy binary, and automatic updating is not a defining property of all operating systems.

Why each choice is right or wrong

A - Correct: Adding support for changing hardware is a direct example of maintainable OS evolution.

B - Incorrect: Supporting multiple guest operating systems describes virtualization rather than the definition of ability to evolve.

C - Incorrect: The absolute absence of compatibility issues is not guaranteed by evolution or supported backward compatibility.

D - Incorrect: Automatic updates may be provided, but the note explicitly rejects them as a defining property of every OS.

Primary note proof

Study-note section OS01

> Ability to evolve means adding hardware support, features and repairs through maintainable interfaces/modules. Backward compatibility preserves supported older application behavior; it is not a promise that every old binary works.

Study-note section OS04

> Virtualization presents a virtual machine environment, often allowing guest operating systems on one host through a hypervisor.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 8 | lines 28-31

> • Centralized servers are highly stable.
> • Security is server managed.
> • Upgrades to new technologies and hardware can be easily integrated into the system.
> • Remote access to servers is possible from different locations and types of systems.

Operating System module | PDF page 54 | lines 5-17

> Portable - Portability means software can works on different types of hardware in same way. Linux kernel and application programs support their installation on any kind of hardware platform.
> Open Source - Linux source code is freely available and it is community-based development project. Multiple teams work in collaboration to enhance the capability of Linux operating system and it is continuously evolving.
> Multi-User - Linux is a multiuser system means multiple users can access system resources like memory/ ram/ application programs at same time.
> Multiprogramming - Linux is a multiprogramming system means multiple applications can run at same time.
> Hierarchical File System - Linux provides a standard file structure in which system files/ user files are arranged.

Question sources

Computer Science MCQ practice collection · Question 666

Question 140 | AM0667

Which file-management feature directly helps users locate files and navigate among organized groups of files?

A. By providing advanced encryption techniques for file security

B. By allowing users to organize files in a hierarchical structure

C. By automatically backing up files to remote servers

D. By optimizing file storage to maximize disk space utilization

Hint

Follow namespace structure and distinguish names, underlying files and mounted filesystems.

Answer B: By allowing users to organize files in a hierarchical structure

A hierarchical directory tree gives users nested groups and paths for locating files and navigating between directories. This directly supplies the requested organizational convenience. Encryption protects confidentiality, backups preserve additional copies for recovery, and storage optimization concerns space utilization. Those functions may also be useful, but they do not themselves define the navigable directory organization asked for here.

Why each choice is right or wrong

A - Incorrect: Encryption protects confidentiality; it does not supply nested directory paths for navigation.

B - Correct: Hierarchical directories organize files into nested groups reachable through paths.

C - Incorrect: Remote backup concerns additional stored copies, rather than the structure used to navigate the working file namespace.

D - Incorrect: Maximizing disk-space utilization is an allocation goal rather than a directory-navigation feature.

Primary note proof

Study-note section OS37

> A single-level directory requires unique names in one namespace. Two-level directories separate users. A tree allows nested directories and absolute/relative paths; links can create shared graphs.

Study-note section OS39

> Encryption protects confidentiality under correct key use but does not automatically provide integrity.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 6 | lines 19-23

A file system is normally organized into directories for easy navigation and usage. These directories may contain files and other directions. Operating System does the following activities for file management.
Keeps track of information, location, uses, status etc. The collective facilities are often known as file system.

Operating System module | PDF page 54 | lines 5-17

Portable - Portability means software can works on different types of hardware in same way. Linux kernel and application programs support their installation on any kind of hardware platform.
Open Source - Linux source code is freely available and it is community-based development project. Multiple teams work in collaboration to enhance the capability of Linux operating system and it is continuously evolving.
Multi-User - Linux is a multiuser system means multiple users can access system resources like memory/ ram/ application programs at same time.

Question sources

Computer Science MCQ practice collection · Question 667

Question 141 | AM0668

What is the role of device drivers in an operating system's convenience factor?

A. They allow users to customize the appearance of the graphical user interface.

B. They provide compatibility with a wide range of hardware devices.

C. They optimize system performance for resource-intensive applications.

D. They enhance data security and encryption for sensitive files.

Hint

Separate device hardware, device-specific software and general event or transfer mechanisms.

Answer B: They provide compatibility with a wide range of hardware devices.

Drivers hide peculiarities of device hardware (PDF p10); p47 even explains a terminal driver supporting differing brands. Standard interfaces on p45 let applications use differing controllers, matching B.

Why each choice is right or wrong

A - Incorrect: GUI appearance is not the device-specific I/O abstraction.

B - Correct: Device compatibility through hardware-specific implementation and common interfaces matches pp10,45,47.

C - Incorrect: Application performance may benefit, but optimizing all resource-intensive applications is not the driver definition.

D - Incorrect: Encryption is not the driver's general stated I/O responsibility.

Primary note proof

Study-note section OS34

A controller is device hardware exposing status, control and data registers. A driver converts OS requests into device-specific operations. Device independence and uniform naming hide brand-specific details; error handling reports/retries supported failures.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 10 | lines 30-37

I/O subsystem comprised of I/O devices and their corresponding driver software. Drivers hides the peculiarities of specific hardware devices from the user as the device driver knows the peculiarities of the specific device.
Operating System manages the communication between user and device drivers.
The major activities of an operating system with respect to I/O Operation.
• I/O operation means read or write operation with any file or any specific I/O device.
• Program may require any I/O device while running.
• Operating system provides the access to the required I/O device when required.

Operating System module | PDF page 47 | lines 19-26

12.5 Device driver
Device driver is a program or routine developed for an I/O device. A device driver implements I/O operations or behaviors on a specific class of devices. For example a system supports one or a number of multiple brands of terminals, all slightly different terminals may have a single terminal driver. In the layered structure of I/O system, device driver lies between interrupt handler and device independent I/O software. The job of a device driver is following.
To accept request from the device independent software above it.
To see to it that the request is executed.

Operating System module | PDF page 45 | lines 28-33

Application I/O Interface represents the structuring techniques and interfaces for the operating system to enable I/O devices to be treated in a standard, uniform way. The actual differences lies kernel level modules called device drivers which are custom tailored to corresponding devices but show one of the standard interfaces to applications. The purpose of the device-driver layer is to hide the differences among device controllers from the I/O subsystem of the kernel, such as the I/O system calls. Following are the characteristics of I/O

Question sources

Computer Science MCQ practice collection · Question 668

Question 142 | AM0669

How does an operating system improve efficiency in terms of process management?

A. By providing a comprehensive programming environment

B. By executing processes in parallel on multiple CPUs

C. By automatically compressing files to reduce storage space

D. By enabling users to schedule program execution at specific times

Hint

Compare interaction, CPU sharing and deadline requirements under the stated system model.

Answer B: By executing processes in parallel on multiple CPUs

PDF p29 says the kernel can simultaneously schedule threads from one process across multiple processors, while p27 explains parallel performance benefits. B is the relevant offered mechanism when suitable parallel work and CPUs exist.

Why each choice is right or wrong

A - Incorrect: A programming environment does not itself describe parallel process execution.

B - Correct: Scheduling work across multiple CPUs exploits parallelism (pp27,29).

C - Incorrect: File compression is unrelated to CPU process management here.

D - Incorrect: User-chosen execution times are not the multiprocessor-efficiency mechanism.

Primary note proof

Study-note section OS02

> A single CPU interleaves execution; multiple CPUs can execute work truly in parallel. Shared-memory multiprocessors do not require each CPU to have private main memory.

Study-note section OS08

> In many-to-one mapping, a blocking kernel call can block all user threads and one kernel execution context cannot use multiple CPUs simultaneously. One-to-one permits another kernel thread to run when one blocks. Many-to-many multiplexes user threads over several kernel threads.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 29 | lines 4-16

> In this case, thread management done by the Kernel. There is no thread management code in the application area. Kernel threads are supported directly by the operating system. Any application can be programmed to be multithreaded. All of the threads within an application are supported within a single process.
> The Kernel maintains context information for the process as a whole and for individuals' threads within the process. Scheduling by the Kernel is done on a thread basis. The Kernel

performs thread creation, scheduling and management in Kernel space. Kernel threads are generally slower to create and manage than the user threads.
Advantages
• Kernel can simultaneously schedule multiple threads from the same process on multiple processes.
• If one thread in a process is blocked, the Kernel can schedule another thread of the same process.

Operating System module | PDF page 27 | lines 6-14

A thread is a flow of execution through the process code, with its own program counter, system registers and stack. A thread is also called a light weight process. Threads provide a way to improve application performance through parallelism. Threads represent a software approach to improving performance of operating system by reducing the overhead thread is equivalent to a classical process.
Each thread belongs to exactly one process and no thread can exist outside a process. Each thread represents a separate flow of control. Threads have been successfully used in implementing network servers and web server. They also provide a suitable foundation for parallel execution of applications on shared memory multiprocessors. Following figure shows

Question sources

Computer Science MCQ practice collection · Question 669

Question 143 | AM0670

In the context of operating systems, what is the meaning of scalability?

A. The ability to run on different hardware platforms

B. The ability to support multiple programming languages

C. The ability to handle increasing workloads and resources

D. The ability to provide a user-friendly interface

Hint

Separate broad resource-management goals from individual services or applications.

Answer C: Handle increasing workloads and resources.

OS01 directly defines scalability as handling greater workloads/resources. Running on different hardware platforms is portability, and providing an easy interface is convenience. Programming-language support does not itself establish either increasing capacity or workload handling. The wording in C matches the supplied definition without assuming scalability guarantees limitless growth or unchanged performance.

Why each choice is right or wrong

A - Incorrect: Adapting to other hardware platforms is portability, explicitly distinguished from scalability.

B - Incorrect: Supporting programming languages does not define the ability to handle growing workload or resources.

C - Correct: Handling increasing workloads and resources directly matches the note’s definition of scalability.

D - Incorrect: A user-friendly interface concerns convenience rather than scaling capacity as demand grows.

Primary note proof

Study-note section OS01

> Scalability means handling greater workload/resources; portability means adapting to other platforms.

Study-note section OS01

> Convenience means making tasks easy through consistent interfaces, files and device abstractions.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Question sources

Computer Science MCQ practice collection · Question 670

Question 144 | AM0671

How does an operating system ensure convenience in terms of software installation and management?

A. By providing an intuitive software development environment

B. By offering automatic software updates and patches

C. By optimizing the execution speed of software applications

D. By allowing users to customize the appearance of the graphical user interface

Hint

Separate broad resource-management goals from individual services or applications.

Answer B: Automatic updates and patches can make software maintenance convenient.

OS01 defines convenience as making tasks easy and notes that updates help administration. Among the alternatives, offering automatic updates and patches directly reduces routine software-management effort. This is an example of a convenience feature, not a universal guarantee that every OS updates automatically. Development environments, speed optimization and appearance customization address different activities from installation/maintenance in the stem.

Why each choice is right or wrong

A - Incorrect: A development environment assists creating software rather than directly providing installation and maintenance convenience.

B - Correct: Automating updates and patches can reduce routine software-management work, though the feature is not universal.

C - Incorrect: Execution-speed optimization concerns performance, not the installation/maintenance convenience specifically requested.

D - Incorrect: Customizing GUI appearance changes presentation rather than automating software installation or maintenance tasks.

Primary note proof

Study-note section OS01

> Convenience means making tasks easy through consistent interfaces, files and device abstractions.

Study-note section OS01

> Updates and monitoring help administration, but automatic updates are not a defining property of every OS.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 8 | lines 28-31

Question sources

Computer Science MCQ practice collection · Question 671

Question 145 | AM0672

What does it mean for an operating system to provide fault tolerance?

A. It continues correct service despite the specified failures it is designed to tolerate

B. It can handle multiple user requests simultaneously.

C. It can optimize system performance for resource-intensive tasks.

D. It can provide a secure environment for sensitive data.

Hint

Separate broad resource-management goals from individual services or applications.

Answer A: It continues correct service despite the specified failures it is designed to tolerate

Fault tolerance means that correct service continues despite specified failures within the system's fault model. Recovery restores service after a failure and may be useful without providing uninterrupted correct service. Multiple-user handling concerns concurrency, resource-intensive performance concerns efficiency, and sensitive-data protection concerns security. The revised continuation option therefore states the specific property rather than substituting quick recovery for fault tolerance.

Why each choice is right or wrong

A - Correct: Continued correct service despite specified faults is the fault-tolerance property.

B - Incorrect: Simultaneous user requests concern concurrency rather than surviving failures.

C - Incorrect: Performance optimization does not define continued service under faults.

D - Incorrect: Security protects data but does not itself define fault tolerance.

Primary note proof

Study-note section OS01

> Fault tolerance continues correct service despite specified failures; recovery restores service afterward.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 8 | lines 15-16

> • If one site fails in a distributed system, the remaining sites can potentially continue operating.

> Error Handling - An operating system that uses protected memory can guard against many kinds of hardware and application errors.

Question sources

Computer Science MCQ practice collection · Question 672

Question 146 | AM0673

How does an operating system support the ability to evolve in terms of software compatibility?

A. By providing a wide range of pre-installed software applications

B. By offering backward compatibility for legacy software

C. By optimizing the execution speed of software applications

D. By allowing users to customize system settings and preferences

Hint

Separate broad resource-management goals from individual services or applications.

Answer B: Backward compatibility for supported legacy software.

OS01 defines backward compatibility as preserving supported older application behavior. That is the software-compatibility aspect of evolution asked here. Preinstalled applications, execution speed and preference customization do not establish that older software's supported behavior remains available. The answer must retain the support qualification; it does not promise all legacy binaries run without any compatibility issues.

Why each choice is right or wrong

A - Incorrect: Preinstalling many applications does not establish compatibility with older applications or their supported behavior.

B - Correct: Backward compatibility preserves supported legacy behavior, directly matching the software-compatibility aspect of evolution.

C - Incorrect: Faster execution does not by itself preserve interfaces or behavior required by legacy software.

D - Incorrect: Customizing preferences changes configuration rather than establishing compatibility with older application behavior.

Primary note proof

Study-note section OS01

> Backward compatibility preserves supported older application behavior; it is not a promise that every old binary works.

> Linux is one of popular version of UNIX operating System. It is open source as its source code is freely available. It is free to use. Linux was designed considering UNIX compatibility. Its functionality list is quite similar to that of UNIX.

Operating System module | PDF page 54 | lines 5-17

> Portable - Portability means software can works on different types of hardware in same way. Linux kernel and application programs support their installation on any kind of hardware platform.
> Open Source - Linux source code is freely available and it is community-based development project. Multiple teams work in collaboration to enhance the capability of Linux operating system and it is continuously evolving.
> Multi-User - Linux is a multiuser system means multiple users can access system resources like memory/ ram/ application programs at same time.
> Multiprogramming - Linux is a multiprogramming system means multiple applications can run at same time.
> Hierarchical File System - Linux provides a standard file structure in which system files/ user files are arranged.
> Shell - Linux provides a special interpreter program which can be used to execute

Question sources

Computer Science MCQ practice collection · Question 673

Question 147 | AM0674

What is deadlock in the standard process/resource model?

A. A state in which each member of a blocked set waits for an event or resource that only another blocked member can provide

B. It is a state where a process is terminated abruptly.

C. It is a state where multiple processes are executing concurrently.

D. It is a state where the operating system crashes due to a software bug.

Hint

Trace the resource dependencies and distinguish necessary conditions from evidence of an actual deadlock.

Answer A: A state in which each member of a blocked set waits for an event or resource that only another blocked member can provide

Deadlock describes a blocked set whose members depend on one another for the events or resources required to continue. Because each provider is itself blocked within the same dependency, normal execution cannot resolve the waits. A process being terminated, multiple processes executing, or an OS crash describes a different condition. The revised definition also distinguishes deadlock from starvation caused by unfair repeated bypass.

Why each choice is right or wrong

A - Correct: This states the closed dependency that defines the deadlocked set.

B - Incorrect: Abrupt termination ends execution rather than defining blocked dependencies.

C - Incorrect: Concurrent execution is normal and does not imply deadlock.

D - Incorrect: An OS crash is a different failure; deadlocked processes can exist while the OS remains active.

Primary note proof

Study-note section OS22

> A set is deadlocked when each member waits for an event/resource that only another blocked member can provide. Mere waiting for another holder is normal blocking; indefinite unfair delay can be starvation without a cycle of dependencies.

Study-note section OS06

> New processes are created/admitted; ready means eligible for CPU but not currently running. Running uses a CPU. Waiting/blocked means unable to proceed until an event; terminated means execution has ended.

• Provides a mechanism for process communication.
• Provides a mechanism for deadlock handling.

Operating System module | PDF page 16 | lines 29-39

1. New The process is being created.
2.
Ready The process is waiting to be assigned to a processor. Ready processes are waiting to have the processor allocated to them by the operating system so that they can run.
3.
Running Process instructions are being executed (i.e. The process that is currently being executed).
4.
Waiting The process is waiting for some event to occur (such as the completion of an I/O operation).
5. Terminated The process has finished execution.

Question sources

Computer Science MCQ practice collection · Question 674

Question 148 | AM0675

Which of the following conditions must be present for deadlock to occur?

A. Mutual exclusion, hold and wait, no preemption, and circular wait.

B. Mutual exclusion, hold and wait, preemption, and circular wait.

C. Mutual inclusion, hold and wait, no preemption, and circular wait.

D. Mutual inclusion, hold and wait, preemption, and circular wait.

Hint

Trace the resource dependencies and distinguish necessary conditions from evidence of an actual deadlock.

Answer A: Mutual exclusion, hold-and-wait, no-preemption and circular wait.

OS22 lists the four necessary conditions in the standard reusable-resource model. A preserves the exact set: exclusion, holding while requesting more, no forced resource withdrawal, and a wait cycle. B introduces preemption in place of no-preemption; C and D replace exclusion with inclusion. These are not harmless wording changes because they remove or reverse the relevant restrictions.

Why each choice is right or wrong

A - Correct: This option states all four standard necessary conditions with their correct meanings and polarity.

B - Incorrect: It substitutes preemption for no-preemption, reversing the required resource-withdrawal restriction.

C - Incorrect: It substitutes mutual inclusion for mutual exclusion, losing the nonshareable-resource condition.

D - Incorrect: It reverses both exclusion and no-preemption, so it is not the required condition set.

Primary note proof

Study-note section OS22

> Mutual exclusion allows at most one holder of a nonshareable resource. Hold-and-wait means retaining a resource while requesting another. No resource preemption means release must be voluntary. Circular wait forms a closed chain of such waits.

Study-note section OS22

> All four are necessary in the standard reusable-resource model. Their availability as general system policies does not prove a deadlock exists at this instant; inspect actual allocations/requests.

Question sources

Computer Science MCQ practice collection · Question 675

Question 149 | AM0676

What is mutual exclusion in the context of deadlock?

A. It is the condition where multiple processes can access the same resource simultaneously.

B. It is the condition where a resource can be accessed by only one process at a time.

C. It is the condition where a process holds a resource while waiting for another resource.

D. It is the condition where a process waits indefinitely for a resource.

Hint

Trace the resource dependencies and distinguish necessary conditions from evidence of an actual deadlock.

Answer B: At most one process holds the nonshareable resource at a time.

OS22 defines mutual exclusion as allowing at most one holder of a nonshareable resource. B states that one-at-a-time condition. A describes concurrent sharing, C describes holding while requesting another resource, and D describes indefinite waiting without establishing exclusivity. The definition concerns access safety, not a guarantee that every waiting process eventually obtains the resource.

Why each choice is right or wrong

A - Incorrect: Simultaneous access by several processes contradicts the exclusive-holder condition for a nonshareable resource.

B - Correct: Only one process at a time may hold or use the nonshareable resource.

C - Incorrect: Retaining one resource while requesting another defines hold-and-wait rather than mutual exclusion.

D - Incorrect: Indefinite waiting describes a possible failure outcome and does not define exclusive resource possession.

Primary note proof

Study-note section OS22

> Mere waiting for another holder is normal blocking; indefinite unfair delay can be starvation without a cycle of dependencies. Mutual exclusion allows at most one holder of a nonshareable resource. Hold-and-wait means retaining a resource while requesting another. No resource preemption means release must be voluntary. Circular wait forms a closed chain of such waits.

Question sources

Computer Science MCQ practice collection · Question 676

Question 150 | AM0677

What is hold and wait in the context of deadlock?

A. It is the condition where a process holds a resource while waiting for another resource.

B. It is the condition where a process waits indefinitely for a resource.

C. It is the condition where multiple processes can access the same resource simultaneously.

D. It is the condition where a resource can be accessed by only one process at a time.

Hint

Trace the resource dependencies and distinguish necessary conditions from evidence of an actual deadlock.

Answer A: Retain a resource while waiting for another.

OS22 directly defines hold-and-wait as retaining a resource while requesting another. A contains both parts of that definition. Merely waiting indefinitely does not establish a retained allocation, simultaneous sharing contradicts exclusion, and one-at-a-time access describes mutual exclusion rather than a process holding one resource while requesting more.

Why each choice is right or wrong

A - Correct: The process simultaneously retains an allocated resource and waits to acquire a further one.

B - Incorrect: Indefinite waiting does not establish that the process still holds another resource.

C - Incorrect: Simultaneous shared access is not the retained-allocation-plus-request condition defining hold-and-wait.

D - Incorrect: One process accessing a resource at a time defines mutual exclusion, not hold-and-wait.

Primary note proof

Study-note section OS22

> Mere waiting for another holder is normal blocking; indefinite unfair delay can be starvation without a cycle of dependencies. Mutual exclusion allows at most one holder of a nonshareable resource. Hold-and-wait means retaining a resource while requesting another. No resource preemption means release must be voluntary. Circular wait forms a closed chain of such waits.

Question sources

Computer Science MCQ practice collection · Question 677

Question 151 | AM0678

What is preemption in the context of deadlock prevention?

A. It is the condition where a process holds a resource while waiting for another resource.

B. It is the condition where a process waits indefinitely for a resource.

C. It is the condition where multiple processes can access the same resource simultaneously.

D. It is the condition where a resource can be forcibly taken from a process.

Hint

Identify the resource-request restriction and which necessary condition it removes.

Answer D: A resource may be forcibly taken from its holder.

OS22 defines no-preemption as voluntary release only, while OS24 permits safe withdrawal/restart as a way to attack that restriction. Preemption is the opposite permission: a resource can be forcibly reclaimed. D directly states it. The answer concerns resources that can safely be withdrawn, not a claim that every device or lock can be preempted without corruption.

Why each choice is right or wrong

A - Incorrect: Holding one resource while waiting for another describes hold-and-wait rather than forced resource withdrawal.

B - Incorrect: Indefinite waiting is a possible outcome, not the permission to reclaim a held resource.

C - Incorrect: Concurrent sharing concerns resource shareability rather than withdrawing an existing allocation from its holder.

D - Correct: Forcibly taking a held resource is resource preemption, subject to safe withdrawal/restart support.

Primary note proof

Study-note section OS24

Prevention constrains how requests are made. Share a resource where safe to remove mutual exclusion; request all needed resources before holding any to remove hold-and-wait; permit safe resource withdrawal/restart to attack no-preemption; impose a global acquisition order to remove circular wait. Not every physical resource is shareable or safely preemptable.

Study-note section OS22

Mere waiting for another holder is normal blocking; indefinite unfair delay can be starvation without a cycle of dependencies. Mutual exclusion allows at most one holder of a nonshareable resource. Hold-and-wait means retaining a resource while requesting another. No resource preemption means release must be voluntary. Circular wait forms a closed chain of such waits.

A newly arrived process is put in the ready queue. Processes waits in ready queue for allocating the CPU. Once the CPU is assigned to a process, then that process will execute. While executing the process, any one of the following events can occur.
• The process could issue an I/O request and then it would be placed in an I/O queue.
• The process could create new sub process and will wait for its termination.
• The process could be removed forcibly from the CPU, as a result of interrupt and put back in the ready queue.

Question sources

Computer Science MCQ practice collection · Question 678

Question 152 | AM0679

What is circular wait in the context of deadlock?

A. It is the condition where a process waits indefinitely for a resource.

B. It is the condition where multiple processes can access the same resource simultaneously.

C. It is the condition where a process holds a resource while waiting for another resource.

D. It is the condition where a circular chain of processes exists, each holding a resource requested
by the next process in the chain.

Hint

Trace the resource dependencies and distinguish necessary conditions from evidence of an actual deadlock.

Answer D: A closed chain of resource waits.

OS22 defines circular wait as a closed chain of waits. D specifies that each process holds a resource requested by the next in a circular chain, which returns the dependency to the starting participant. C describes only one hold-and-wait relationship, which need not be cyclic. Indefinite waiting and simultaneous sharing likewise fail to establish a closed chain.

Why each choice is right or wrong

A - Incorrect: Indefinite waiting does not identify a closed cycle of dependencies among resource holders.

B - Incorrect: Simultaneous resource sharing is not a chain of blocked requests and does not define circular wait.

C - Incorrect: One process holding while requesting another establishes hold-and-wait but not necessarily a cycle.

D - Correct: The circular chain of holdings and requests explicitly forms the required closed wait dependency.

Primary note proof

Study-note section OS22

> Mere waiting for another holder is normal blocking; indefinite unfair delay can be starvation without a cycle of dependencies. Mutual exclusion allows at most one holder of a nonshareable resource. Hold-and-wait means retaining a resource while requesting another. No resource preemption means release must be voluntary. Circular wait forms a closed chain of such waits.

Question sources

Computer Science MCQ practice collection · Question 679

Question 153 | AM0680

Which listed policy does not actively prevent an unsafe allocation or detect and recover from an existing deadlock? Interpret “deadlock acceptance” as deliberately ignoring sufficiently rare deadlocks.

A. Deadlock avoidance

B. Deadlock detection and recovery

C. Deadlock prevention

D. Deadlock acceptance

Hint

Separate handling before allocation from actions taken after detection, and consider the cost of checking.

Answer D: Deadlock acceptance

Prevention constrains requests to break a necessary condition; avoidance keeps tentative allocations safe; detection and recovery identifies and resolves an existing deadlock. Deliberate acceptance, as defined here, instead ignores a sufficiently rare problem rather than actively applying those controls. It is still a possible policy choice, but is the only listed one outside the active-control category specified by the revised stem.

Why each choice is right or wrong

A - Incorrect: Avoidance actively restricts grants to preserve a safe state.

B - Incorrect: Detection and recovery actively identifies and resolves deadlock.

C - Incorrect: Prevention actively removes a necessary deadlock condition.

D - Correct: Intentional ignoring is a policy choice but does not actively apply the specified controls.

Primary note proof

Study-note section OS26

> Detection asks whether the current state is deadlocked. Recovery can terminate selected processes or reclaim safely preemptable resources and roll affected work back to a checkpoint. Termination and rollback are both possible recovery tools; choose according to the resource and process conditions.

Study-note section OS26

> Ignoring a sufficiently rare problem is sometimes called the ostrich policy, but real systems still prevent or detect selected deadlocks.

Study-note section OS24

> Prevention constrains how requests are made.

Study-note section OS25

Avoidance allows requests only if the resulting state remains safe.

Question sources

Computer Science MCQ practice collection · Question 680

Question 154 | AM0681

In a resource-allocation graph with one instance of each resource type, which listed roles are valid? Read B as direct resource-to-resource edges and D as showing permission to forcibly withdraw resources. Select all that apply.

A. To represent the allocation of resources to processes.

B. To represent the dependencies between resources.

C. To represent the circular wait condition.

D. To represent the preemption of resources.

Hint

Follow request and assignment arrows and check how many instances each resource has.

Answer A, C: To represent the allocation of resources to processes.; To represent the circular wait condition.

An assignment edge records which process holds a resource instance, and a request edge records what a process is waiting for. Following alternating edges can form a circular wait. In the stated single-instance model a cycle establishes deadlock. The graph does not use direct resource-to-resource dependency edges and does not encode a general permission to preempt resources, so A and C are the valid listed roles.

Why each choice is right or wrong

A - Correct: Assignment edges represent resource holdings by processes.

B - Incorrect: Standard graph edges connect processes and resources, not resources directly to other resources.

C - Correct: A cycle of request and assignment edges represents circular wait.

D - Incorrect: Resource-preemption permission is not encoded by the stated request/assignment edges.

Primary note proof

Study-note section OS23

> In a resource-allocation graph, P→R is a request and an instance R→P is an assignment. Follow these directions to form waits. No cycle implies no deadlock; with one instance of every resource type, a cycle implies deadlock. With multiple instances a cycle alone is insufficient: another instance may permit completion. A wait-for graph replaces single-instance resource nodes with P→Q when P waits for Q.

Question sources

Computer Science MCQ practice collection · Question 681

Question 155 | AM0682

Which resource allocation policy can help prevent deadlock?

A. First-Come, First-Served (FCFS)

B. Round Robin (RR)

C. Shortest Job Next (SJN)

D. Banker's Algorithm

Hint

Compute remaining needs and simulate feasible completions before deciding whether an allocation is safe.

Answer D: Banker’s algorithm, technically an avoidance policy.

OS25 states that Banker grants requests only while preserving a safe state. That can prevent entry into a deadlocked state in the broad everyday sense used by can help prevent, although its technical category is avoidance rather than condition-breaking prevention. FCFS, RR and SJN are CPU scheduling policies and do not themselves test resource-allocation safety.

Why each choice is right or wrong

A - Incorrect: FCFS orders CPU bursts by arrival rather than testing maximum resource claims and safe allocations.

B - Incorrect: RR schedules CPU turns; time slicing does not establish safe allocation of locks or other resources.

C - Incorrect: SJN selects shortest next CPU bursts rather than performing a resource-state safety test.

D - Correct: Banker admits resource requests only when the resulting state is safe; its strict classification is avoidance.

Primary note proof

Study-note section OS25

> Avoidance allows requests only if the resulting state remains safe. Banker requires maximum claims. Compute Need=Max−Allocation.

Study-note section OS14

> Non-preemptive scheduling keeps a running CPU burst until completion, blocking or voluntary yielding. Preemptive scheduling can return running work to ready, usually after a timer quantum or a more urgent arrival. FCFS and non-preemptive SJF are non-preemptive; RR and SRTF are preemptive. Priority can be either, so its name alone cannot decide. Cooperative describes relying on voluntary release.

Question sources

Computer Science MCQ practice collection · Question 682

Question 156 | AM0683

What is the purpose of the Banker's Algorithm in deadlock avoidance?

A. To break the hold and wait condition.

B. To allocate resources in a fair and equitable manner.

C. To detect deadlocked processes and recover from deadlock.

D. To ensure that resource requests will not lead to an unsafe state.

Hint

Compute remaining needs and simulate feasible completions before deciding whether an allocation is safe.

Answer D: Ensure each granted request preserves a safe state.

Banker’s algorithm checks whether a tentative resource grant preserves a safe state. It computes remaining needs and simulates an order in which all processes can finish, granting only requests within the declared need and available resources that pass this safety test. It is an avoidance policy, not a fairness guarantee, an already-deadlocked-state detector, or prevention by eliminating hold-and-wait.

Why each choice is right or wrong

A - Incorrect: Banker does not require removing hold-and-wait; it checks whether tentative allocation remains safe.

B - Incorrect: Its safety criterion is not a guarantee of fair or equal allocation among processes.

C - Incorrect: Detection and recovery address actual deadlock, whereas Banker checks safety before granting a request.

D - Correct: Preserving a safe state after each grant is the purpose of the Banker avoidance test.

Primary note proof

Study-note section OS25

Avoidance allows requests only if the resulting state remains safe. Banker requires maximum claims. Compute Need=Max−Allocation. Set Work=Available and repeatedly find an unfinished process with Need≤Work componentwise; simulate completion by adding its Allocation to Work. Finishing all gives a safe sequence. Tentatively grant a request only if it is within Need and Available and the safety test succeeds. Unsafe does not mean already deadlocked. Banker is avoidance, not CPU scheduling, detection or prevention by breaking a condition.

Study-note section OS24

Prevention constrains how requests are made.

Study-note section OS26

Detection asks whether the current state is deadlocked. Recovery can terminate selected processes or reclaim safely preemptable resources and roll affected work back to a checkpoint.

Question sources

Computer Science MCQ practice collection · Question 683

Question 157 | AM0684

Which of the following is a characteristic of preemptive scheduling?

A. Tasks cannot be interrupted once started.

B. Tasks are allowed to complete their execution.

C. Tasks can be interrupted and rescheduled.

D. Tasks are scheduled based on their arrival time.

Hint

Check whether the running burst can be interrupted before completion or blocking.

Answer C: Tasks can be interrupted and rescheduled.

PDF p25 explicitly preempts a process after its quantum; p19 returns forcibly removed work to the ready queue. C states interrupting and rescheduling that work.

Why each choice is right or wrong

A - Incorrect: Contradicts the explicit forced removal/preemption on pp19,25.

B - Incorrect: Tasks can eventually complete, but permission to finish does not distinguish preemptive scheduling.

C - Correct: Matches the interruption/rescheduling mechanism.

D - Incorrect: Arrival ordering defines FCFS (p23), not preemption.

Primary note proof

Study-note section OS14

> Non-preemptive scheduling keeps a running CPU burst until completion, blocking or voluntary yielding. Preemptive scheduling can return running work to ready, usually after a timer quantum or a more urgent arrival. FCFS and non-preemptive SJF are non-preemptive; RR and SRTF are preemptive. Priority can be either, so its name alone cannot decide. Cooperative describes relying on voluntary release.

Study-note section OS15

> FCFS runs ready bursts in arrival order and ordinarily does not preempt.

Question sources

Computer Science MCQ practice collection · Question 684

Question 158 | AM0685

Which listed scheduling policies are non-preemptive? SJN means non-preemptive shortest-next-burst scheduling; D specifically uses immediate preemption for a higher-priority arrival. Select all that apply.

A. Round Robin

B. First-Come, First-Served (FCFS)

C. Shortest Job Next (SJN)

D. Preemptive Priority Scheduling

Hint

Check whether the running burst can be interrupted before completion or blocking.

Answer B, C: First-Come, First-Served (FCFS); Shortest Job Next (SJN)

FCFS ordinarily serves each ready burst in arrival order without forcibly taking the CPU away. SJN, as explicitly defined, chooses the shortest ready burst and then lets it continue non-preemptively. RR can interrupt a burst at its quantum boundary, while the stated priority variant interrupts for a higher-priority arrival. Thus FCFS and SJN are the two non-preemptive policies in this list.

Why each choice is right or wrong

A - Incorrect: RR uses quantum expiry to preempt unfinished work.

B - Correct: FCFS ordinarily lets the selected burst continue without forced preemption.

C - Correct: SJN is explicitly the non-preemptive shortest-next-burst policy.

D - Incorrect: This option explicitly preempts for a higher-priority arrival.

Primary note proof

Study-note section OS14

> Non-preemptive scheduling keeps a running CPU burst until completion, blocking or voluntary yielding. Preemptive scheduling can return running work to ready, usually after a timer quantum or a more urgent arrival. FCFS and non-preemptive SJF are non-preemptive; RR and SRTF are preemptive. Priority can be either, so its name alone cannot decide. Cooperative describes relying on voluntary release.

Study-note section OS17

> Priority scheduling chooses the highest-priority ready job. Check whether a smaller or larger numeric value means higher priority. State whether a high-priority arrival preempts.

Computer Science MCQ practice collection · Question 685

Question 159 | AM0686

Which scheduling algorithm is based on the priority assigned to each task?

A. Round Robin

B. First-Come, First-Served (FCFS)

C. Shortest Job Next (SJN)

D. Priority Scheduling

Hint

Check priority direction, preemption and whether waiting can change effective rank.

Answer D: Priority Scheduling

PDF p24 assigns a priority to each process and executes the highest priority first. That is D; other policies use quantum, arrival or execution length.

Why each choice is right or wrong

A - Incorrect: RR uses fixed quantum (p25).

B - Incorrect: FCFS follows arrival order (p23).

C - Incorrect: SJN uses job length (p23).

D - Correct: Assigned priority is the explicit selection rule (p24).

Primary note proof

Study-note section OS17

> Priority scheduling chooses the highest-priority ready job.

Study-note section OS18

> RR serves a ready queue cyclically for at most quantum q per turn.

Study-note section OS15

> FCFS runs ready bursts in arrival order and ordinarily does not preempt.

Study-note section OS16

> Non-preemptive SJF/SJN chooses the shortest next burst among currently ready jobs.

Computer Science MCQ practice collection · Question 686

Computer Science MCQ practice collection · Question 697

Question 160 | AM0687

User A has four continuously ready tasks and user B has one. The policy goal is equal aggregate CPU entitlement for each user, independent of task count. Which listed policy directly implements that goal when configured with equal per-user weights?

A. Round Robin

B. First-Come, First-Served (FCFS)

C. Shortest Job Next (SJN)

D. Fair-Share Scheduling

Hint

Identify the allocation entity, entitlement weights and whether the guarantee is probabilistic.

Answer D: Fair-Share Scheduling

Equal-turn RR gives each of the five tasks roughly one fifth of CPU service, so user A receives about 80 percent and B about 20 percent. Equal per-user fair-share instead gives each user half, dividing A’s half among its four tasks. FCFS and SJN do not enforce that user entitlement. The explicitly defined participant scope makes fair-share the unique matching policy.

Why each choice is right or wrong

A - Incorrect: Per-task RR gives A four fifths of service rather than equal per-user shares.

B - Incorrect: FCFS orders bursts by arrival and does not enforce per-user entitlements.

C - Incorrect: SJN favors short bursts and does not allocate equal user shares.

D - Correct: Equal per-user fair-share weights directly implement the stated half-and-half goal.

Primary note proof

Study-note section OS20

Fair-share scheduling allocates according to stated weights, potentially per user/group rather than per process. Equal per-process RR can let a user obtain more aggregate CPU by launching more processes. Proportional shares address that policy choice; fair need not mean equal.

Study-note section OS20

If user A runs four ready tasks and B runs one, plain RR gives A about 80% overall. A policy granting each user half the CPU instead gives A's tasks about 12.5% each and B's task 50%.

Question sources

Computer Science MCQ practice collection · Question 687

Question 161 | AM0688

A ready target has finitely many jobs ahead, all CPU bursts and RR quanta are finite and positive, context overhead is finite, and later arrivals join the tail without bypassing existing peers. Infinitely many later short or high-priority jobs may arrive over time. Which policies prevent that target from being postponed forever by later arrivals? D uses fixed priorities without aging. Select all that apply.

A. Round Robin

B. First-Come, First-Served (FCFS)

C. Shortest Job Next (SJN)

D. Fixed-priority scheduling without aging

Hint

Follow arrival order, include idle periods and distinguish waiting from completion time.

Answer A, B: Round Robin; First-Come, First-Served (FCFS)

RR gives the target a turn after the finite work ahead has received bounded turns. FCFS serves the finite earlier bursts before later arrivals, so the target eventually starts. SJN can repeatedly prefer later short jobs, and fixed priority can repeatedly prefer later high-priority jobs. The assumptions distinguish guaranteed eventual service from policies that permit an endless stream to bypass the target.

Why each choice is right or wrong

A - Correct: RR's finite cyclic turns reach the target without later-arrival bypass.

B - Correct: FCFS drains the finite predecessor work before serving later arrivals.

C - Incorrect: An endless sequence of short arrivals can keep a long target waiting under SJN.

D - Incorrect: An endless sequence of higher-priority arrivals can starve a low-priority target without aging.

Primary note proof

Study-note section OS15

> FCFS runs ready bursts in arrival order and ordinarily does not preempt. If the CPU is idle, jump to the next arrival. Long CPU-bound work can make many short jobs wait: the convoy effect. A finite burst with finitely many jobs ahead eventually starts, but waiting can still be large.

Study-note section OS18

> RR serves a ready queue cyclically for at most quantum q per turn. Unfinished jobs return to the tail; completed/blocked jobs leave.

Study-note section OS17

> Fixed-priority scheduling can starve low-priority jobs under continued high-priority load. SJF can also starve long jobs; starvation is not exclusive to fixed-priority scheduling.

Question sources

Computer Science MCQ practice collection · Question 688

Question 162 | AM0689

Which scheduling algorithm is based on the estimated remaining time required for each task?

A. Round Robin

B. First-Come, First-Served (FCFS)

C. Shortest Job Next (SJN)

D. Shortest Remaining Time First (SRTF)

Hint

Compare the ready jobs using the stated burst or remaining-time rule.

Answer D: Shortest Remaining Time First (SRTF).

OS16 says SRTF reconsiders on arrivals and selects the shortest remaining work. This matches the estimated remaining-time criterion in the stem. SJN chooses the shortest next burst non-preemptively, while RR uses cyclic quanta and FCFS arrival order. The distinction matters after execution has begun: the originally shortest burst need not be the currently shortest remaining job.

Why each choice is right or wrong

A - Incorrect: RR rotates bounded turns rather than selecting the job with the smallest estimated remaining execution.

B - Incorrect: FCFS follows arrival order rather than comparing estimated remaining CPU work.

C - Incorrect: Non-preemptive SJN compares next burst lengths when selecting, not continuously reconsidered remaining work.

D - Correct: SRTF explicitly selects the shortest remaining work and can preempt on a shorter arrival.

Primary note proof

Study-note section OS16

> Non-preemptive SJF/SJN chooses the shortest next burst among currently ready jobs. SRTF reconsiders on arrivals and selects the shortest remaining work; a shorter newcomer can preempt. Future burst lengths normally need estimates.

Study-note section OS16

> Repeated short arrivals can starve a long job. The shortest total original burst is not necessarily the shortest remaining burst after execution has begun.

• Processes with same priority are executed on first come first serve basis.
• Priority can be decided based on memory requirements, time requirements or any other resource requirement.

Question sources

Computer Science MCQ practice collection · Question 689

Question 163 | AM0690

Which policies can starve a ready job through repeated preference for later arrivals? Assume correct implementations, finite bursts, ordinary RR with a positive quantum, FCFS without bypass, non-preemptive SJN, and fixed-priority scheduling without aging. Select all that apply.

A. Round Robin

B. First-Come, First-Served (FCFS)

C. Shortest Job Next (SJN)

D. Priority Scheduling

Hint

Check priority direction, preemption and whether waiting can change effective rank.

Answer C, D: Shortest Job Next (SJN); Priority Scheduling

SJN can continually choose newly arrived short bursts while an older long job remains ready. Fixed priority without aging can likewise keep choosing high-priority arrivals over a low-priority target. Ordinary RR cycles peers, and FCFS does not let later arrivals overtake a finite set of predecessors. Thus the preference rules of SJN and fixed priority create the two stated starvation risks.

Why each choice is right or wrong

A - Incorrect: Ordinary RR returns ready jobs to recurring turns rather than repeatedly bypassing a peer.

B - Incorrect: FCFS preserves arrival order, so later arrivals do not overtake the target.

C - Correct: Repeated short arrivals can starve an older long SJN job.

D - Correct: Continued high-priority arrivals can starve a low-priority job without aging.

Primary note proof

Study-note section OS17

Fixed-priority scheduling can starve low-priority jobs under continued high-priority load. SJF can also starve long jobs; starvation is not exclusive to fixed-priority scheduling.

Study-note section OS15

FCFS runs ready bursts in arrival order and ordinarily does not preempt. If the CPU is idle, jump to the next arrival. Long CPU-bound work can make many short jobs wait: the convoy effect. A finite burst with finitely many jobs ahead eventually starts, but waiting can still be large.

Study-note section OS18

RR serves a ready queue cyclically for at most quantum q per turn. Unfinished jobs return to the tail; completed/blocked jobs leave.

Computer Science MCQ practice collection · Question 690

Question 164 | AM0691

Which scheduling algorithm uses time slices to allocate CPU time to tasks?

A. Round Robin

B. First-Come, First-Served (FCFS)

C. Shortest Job Next (SJN)

D. Priority Scheduling

Hint

Trace bounded turns in ready-queue order and include the stated overhead and arrivals.

Answer A: Round Robin

Each RR process receives a fixed time quantum (PDF p25); it is preempted when that period expires. A is the direct time-slice mechanism.

Why each choice is right or wrong

A - Correct: Exactly the fixed-quantum rule (p25).

B - Incorrect: Arrival-order service does not itself define repeated time slices (p23).

C - Incorrect: SJN bases selection on execution duration (p23).

D - Incorrect: Priority bases selection on assigned rank (p24); it need not use a quantum.

Primary note proof

Study-note section OS18

> RR serves a ready queue cyclically for at most quantum q per turn. Unfinished jobs return to the tail; completed/blocked jobs leave.

Study-note section OS15

> FCFS runs ready bursts in arrival order and ordinarily does not preempt.

Study-note section OS16

> Non-preemptive SJF/SJN chooses the shortest next burst among currently ready jobs.

• Priority can be decided based on memory requirements, time requirements or any other resource requirement.

Question sources

Computer Science MCQ practice collection · Question 691

Question 165 | AM0692

For a fixed finite set of simultaneous ready jobs with known CPU bursts, no I/O and zero switch cost, which listed non-preemptive policy minimizes average waiting over all possible execution orders for arbitrary burst lengths?

A. Round Robin

B. First-Come, First-Served (FCFS)

C. Shortest Job Next (SJN)

D. Shortest Remaining Time First (SRTF)

Hint

Compare the ready jobs using the stated burst or remaining-time rule.

Answer C: Shortest Job Next (SJN)

For the simultaneous known-burst workload, shortest-job order minimizes total waiting. Consider adjacent bursts L>S after an elapsed prefix T. Long then short gives waits T and T+L; short then long gives T and T+S, reducing their sum by L−S. Jobs outside the pair are unaffected. Repeatedly removing inversions gives SJN order. FCFS does not enforce it, while RR and SRTF are preemptive policies.

Why each choice is right or wrong

A - Incorrect: RR is preemptive and is outside the requested non-preemptive policy class.

B - Incorrect: FCFS can tie on favorable orders but does not minimize waiting for arbitrary burst orders.

C - Correct: SJN selects the shortest ready bursts and gives the standard minimum-average-waiting order.

D - Incorrect: SRTF is the preemptive remaining-time policy rather than the requested non-preemptive one.

Primary note proof

Study-note section OS16

> Non-preemptive SJF/SJN chooses the shortest next burst among currently ready jobs. SRTF reconsiders on arrivals and selects the shortest remaining work; a shorter newcomer can preempt. Future burst lengths normally need estimates. SJF minimizes average waiting for the usual fixed simultaneous ready set with known bursts and no preemption/switch cost; that theorem is not a workload-independent comparison against every preemptive policy.

Study-note section OS13

> For arrival A, first start S and completion C, response=S−A and turnaround=C−A. For a single CPU burst B with no I/O, waiting=C−A−B.

Study-note section OS14

> FCFS and non-preemptive SJF are non-preemptive; RR and SRTF are preemptive.

Question sources

Computer Science MCQ practice collection · Question 692

Question 166 | AM0693

Which scheduling algorithm provides better response time for interactive tasks?

A. Round Robin

B. First-Come, First-Served (FCFS)

C. Shortest Job Next (SJN)

D. Priority Scheduling

Hint

Trace bounded turns in ready-queue order and include the stated overhead and arrivals.

Answer A: Round Robin

Time-sharing seeks short response by giving users short CPU bursts (PDF p7). RR implements fixed quantum turns (p25), so A is a well-supported interactive choice with a suitably short quantum.

Why each choice is right or wrong

A - Correct: Repeated short quanta implement the p7 interactive strategy.

B - Incorrect: Arrival-order long work can delay later interactive work (p23).

C - Incorrect: SJN needs duration estimates (p23), not a guaranteed prompt periodic turn.

D - Incorrect: Priority may help selected interactive jobs, but depends on assigned ranks rather than the general time-sharing mechanism.

Primary note proof

Study-note section OS18

> RR serves a ready queue cyclically for at most quantum q per turn. Unfinished jobs return to the tail; completed/blocked jobs leave. Specify how arrivals at a quantum boundary enter the queue. A large quantum approaches FCFS; tiny quanta increase switch overhead. RR gives recurring opportunities, not identical total CPU consumption for jobs of different lengths.

Study-note section OS21

> RR is a conventional interactive choice because turns improve responsiveness, subject to quantum and overhead.

Operating System module | PDF page 7 | lines 20-33

Time sharing is a technique which enables many people, located at various terminals, to use a particular computer system at the same time. Time-sharing or multitasking is a logical extension of multiprogramming. Processor's time which is shared among multiple users simultaneously is termed as time-sharing. The main difference between Multi-programmed Batch Systems and Time-Sharing Systems is that in case of multi-programmed batch systems, objective is to maximize processor use, whereas in Time-Sharing Systems objective is to minimize response time.
Multiple jobs are executed by the CPU by switching between them, but the switches occur so frequently. Thus, the user can receive an immediate response. For example, in a transaction processing, processor execute each user program in a short burst or quantum of computation. That is if n users are present, each user can get time quantum. When the user submits the command, the response time is in few seconds at most.
Operating system uses CPU scheduling and multiprogramming to provide each user with a small portion of a time. Computer systems that were designed primarily as batch systems

Computer Science MCQ practice collection · Question 700

Question 167 | AM0694

Which listed policy is preemptive? SJN denotes non-preemptive shortest-job-next, and D specifically keeps the running burst until completion, blocking or voluntary release.

A. First-Come, First-Served (FCFS)

B. Round Robin

C. Shortest Job Next (SJN)

D. Non-preemptive Priority Scheduling

Hint

Check whether the running burst can be interrupted before completion or blocking.

Answer B: Round Robin

RR limits a turn to a quantum and can return an unfinished runnable job to the ready queue. That is preemption. FCFS and the stated SJN variant keep a selected burst until it ends or blocks. The priority option is explicitly non-preemptive, so a higher-priority arrival does not interrupt its current burst. RR is therefore the unique preemptive policy in this list.

Why each choice is right or wrong

A - Incorrect: FCFS ordinarily does not forcibly interrupt the selected burst.

B - Correct: RR preempts unfinished work at quantum expiry.

C - Incorrect: SJN is explicitly the non-preemptive shortest-job policy.

D - Incorrect: The stated priority variant is explicitly non-preemptive.

Primary note proof

Study-note section OS14

> Non-preemptive scheduling keeps a running CPU burst until completion, blocking or voluntary yielding. Preemptive scheduling can return running work to ready, usually after a timer quantum or a more urgent arrival. FCFS and non-preemptive SJF are non-preemptive; RR and SRTF are preemptive. Priority can be either, so its name alone cannot decide. Cooperative describes relying on voluntary release.

Question sources

Computer Science MCQ practice collection · Question 694

Question 168 | AM0695

Which listed policy allocates CPU according to declared user/group entitlement weights, so fairness can mean unequal proportional shares rather than arrival order?

A. First-Come, First-Served (FCFS)

B. Shortest Job Next (SJN)

C. Priority Scheduling

D. Fair-Share Scheduling

Hint

Identify the allocation entity, entitlement weights and whether the guarantee is probabilistic.

Answer D: Fair-Share Scheduling

Fair-share scheduling allocates service according to stated weights, which may apply to users or groups rather than individual processes. That directly implements proportional entitlement. FCFS respects arrival order, SJN chooses shorter bursts, and priority chooses a ranking; those rules do not themselves specify weighted user/group shares. The revised fairness criterion therefore identifies fair-share without implying every fair policy must use equal shares.

Why each choice is right or wrong

A - Incorrect: FCFS provides arrival ordering rather than declared weighted entitlements.

B - Incorrect: SJN selects by burst length rather than entitlement weights.

C - Incorrect: Priority ranking does not itself implement proportional user/group shares.

D - Correct: Fair-share scheduling allocates according to declared weights and participant scope.

Primary note proof

Study-note section OS20

> Fair-share scheduling allocates according to stated weights, potentially per user/group rather than per process. Equal per-process RR can let a user obtain more aggregate CPU by launching more processes. Proportional shares address that policy choice; fair need not mean equal.

Study-note section OS15

> FCFS runs ready bursts in arrival order and ordinarily does not preempt.

Study-note section OS16

> Non-preemptive SJF/SJN chooses the shortest next burst among currently ready jobs.

Study-note section OS17

> Priority scheduling chooses the highest-priority ready job.

Computer Science MCQ practice collection · Question 695

Question 169 | AM0696

Which algorithm gives priority to the tasks with the shortest burst time?

A. First-Come, First-Served (FCFS)

B. Round Robin

C. Shortest Job Next (SJN)

D. Priority Scheduling

Hint

Compare the ready jobs using the stated burst or remaining-time rule.

Answer C: Shortest Job Next (SJN)

SJF on PDF p23 requires knowing how long a process will take and favors shortest jobs. C uses the synonymous SJN label. Priority can incorporate time requirements, but does not necessarily rank by shortest burst.

Why each choice is right or wrong

A - Incorrect: FCFS chooses order of arrival (p23).

B - Incorrect: RR chooses fixed turns (p25).

C - Correct: Shortest-job selection uses the known execution duration (p23).

D - Incorrect: Assigned priorities can reflect many requirements, not necessarily shortest burst (p24).

Primary note proof

Study-note section OS16

Non-preemptive SJF/SJN chooses the shortest next burst among currently ready jobs.

Study-note section OS15

FCFS runs ready bursts in arrival order and ordinarily does not preempt.

Study-note section OS18

RR serves a ready queue cyclically for at most quantum q per turn.

Study-note section OS17

Priority scheduling chooses the highest-priority ready job.

Question 170 | AM0698

Which scheduling algorithm is most suitable for time-sharing systems?

A. First-Come, First-Served (FCFS)

B. Round Robin

C. Shortest Job Next (SJN)

D. Priority Scheduling

Hint

Compare interaction, CPU sharing and deadline requirements under the stated system model.

Answer B: Round Robin

PDF p7 describes time-sharing as short bursts/quantums for many users, seeking fast response. RR's fixed quantum and preemption (p25) directly implement that pattern, making B the matching policy.

Why each choice is right or wrong

A - Incorrect: A long early FCFS job can delay other users, unlike repeated short turns.

B - Correct: Fixed quantum sharing directly implements p7's time-sharing pattern.

C - Incorrect: SJN requires knowing lengths, not a periodic-turn guarantee.

D - Incorrect: Priority ordering alone does not guarantee each user a quantum.

Primary note proof

Study-note section OS02

> Time-sharing uses rapid scheduling/preemption to support interactive users.

Study-note section OS18

> RR serves a ready queue cyclically for at most quantum q per turn. Unfinished jobs return to the tail; completed/blocked jobs leave.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 7 | lines 20-33

> Time sharing is a technique which enables many people, located at various terminals, to use a particular computer system at the same time. Time-sharing or multitasking is a logical extension of multiprogramming. Processor's time which is shared among multiple users simultaneously is termed as time-sharing. The main difference between Multi-programmed Batch Systems and Time-Sharing Systems is that in case of multi-programmed batch systems, objective is to maximize processor use, whereas in Time-Sharing Systems objective is to minimize response time.
> Multiple jobs are executed by the CPU by switching between them, but the switches occur so frequently. Thus, the user can receive an immediate response. For example, in a transaction

processing, processor execute each user program in a short burst or quantum of computation. That is if n users are present, each user can get time quantum. When the user submits the command, the response time is in few seconds at most.
Operating system uses CPU scheduling and multiprogramming to provide each user with a small portion of a time. Computer systems that were designed primarily as batch systems

Operating System module | PDF page 25 | lines 10-14

7.4 Round Robin Scheduling
• Each process is provided a fix time to execute called quantum.
• Once a process is executed for given time period. Process is preempted and other process executes for given time period.
• Context switching is used to save states of preempted processes.

Operating System module | PDF page 23 | lines 12-17

7.1 First Come First Serve (FCFS)
• Jobs are executed on first come, first serve basis.
• Easy to understand and implement.
• Poor in performance as average wait time is high.
Wait time of each process is following
Process Wait Time: Service Time - Arrival Time

Operating System module | PDF page 23 | lines 23-26

7.2 Shortest Job First (SJF)
• Best approach to minimize waiting time.
• Impossible to implement
• Processer should know in advance how much time process will take.

Operating System module | PDF page 24 | lines 10-15

7.3 Priority Based Scheduling
• Each process is assigned a priority. Process with highest priority is to be executed first and so on.
• Processes with same priority are executed on first come first serve basis.
• Priority can be decided based on memory requirements, time requirements or any other resource requirement.

Question sources

Computer Science MCQ practice collection · Question 698

Question 171 | AM0699

Which correctly implemented policies can still cause starvation under an ongoing stream of preferred arrivals? Assume finite bursts, ordinary RR with tail insertion, FCFS without bypass, non-preemptive SJN, and fixed priority without aging. Select all that apply.

A. First-Come, First-Served (FCFS)

B. Round Robin

C. Shortest Job Next (SJN)

D. Priority Scheduling

Hint

Check priority direction, preemption and whether waiting can change effective rank.

Answer C, D: Shortest Job Next (SJN); Priority Scheduling

Starvation can arise from the policy even when its implementation is correct. SJN repeatedly favors short arrivals over an older long burst, while fixed priority can repeatedly favor high-priority arrivals over low-priority work. FCFS preserves arrival order, and RR provides recurring turns under the stated finite-work assumptions. Thus SJN and fixed priority are the two policies with the specified inherent bypass risk.

Why each choice is right or wrong

A - Incorrect: FCFS later arrivals cannot bypass a target with finite predecessor work.

B - Incorrect: Ordinary RR returns peers to recurring turns rather than favoring newcomers indefinitely.

C - Correct: Repeated shorter arrivals can indefinitely postpone a long SJN job.

D - Correct: Continued higher-priority arrivals can indefinitely postpone low-priority work without aging.

Primary note proof

Study-note section OS17

> Fixed-priority scheduling can starve low-priority jobs under continued high-priority load. SJF can also starve long jobs; starvation is not exclusive to fixed-priority scheduling.

Study-note section OS15

> FCFS runs ready bursts in arrival order and ordinarily does not preempt. If the CPU is idle, jump to the next arrival. Long CPU-bound work can make many short jobs wait: the convoy effect. A finite burst with finitely many jobs ahead eventually starts, but waiting can still be large.

Study-note section OS18

> RR serves a ready queue cyclically for at most quantum q per turn. Unfinished jobs return to the tail; completed/blocked jobs leave.

Computer Science MCQ practice collection · Question 699

Question 172 | AM0701

Which scheduling algorithm has the potential for higher overhead due to frequent context switches?

A. First-Come, First-Served (FCFS)

B. Round Robin

C. Shortest Job Next (SJN)

D. Priority Scheduling

Hint

Trace bounded turns in ready-queue order and include the stated overhead and arrivals.

Answer B: Round Robin

Each RR quantum expiration preempts and saves state (PDF p25). PDF p21 calls context-switch time pure overhead, so frequent short quanta create the overhead risk described.

Why each choice is right or wrong

A - Incorrect: FCFS need not switch after every short quantum.

B - Correct: Repeated quantum expiration creates frequent context saves; p21 identifies their cost.

C - Incorrect: Whole-job SJN does not inherently expire a quantum repeatedly.

D - Incorrect: Priority can preempt frequently under some arrivals, but that is not inherent in its p24 ranking rule.

Primary note proof

Study-note section OS18

> A large quantum approaches FCFS; tiny quanta increase switch overhead.

Study-note section OS05

> A context switch saves one execution context and restores another; useful application work is interrupted by this overhead.

Module passages - related reading

Operating System module | PDF page 25 | lines 10-14

> 7.4 Round Robin Scheduling
> • Each process is provided a fix time to execute called quantum.
> • Once a process is executed for given time period. Process is preempted and other process executes for given time period.
> • Context switching is used to save states of preempted processes.

Operating System module | PDF page 21 | lines 41-50

> A context switch is the mechanism to store and restore the state or context of a CPU in Process Control block so that a process execution can be resumed from the same point at a later time. Using this technique, a context switcher enables multiple processes to share a single CPU. Context switching is an essential part of a multitasking operating system features.
> When the scheduler switches the CPU from executing one process to execute another, the context switcher saves the content of all processor registers for the process being removed from the CPU, in its process descriptor. The context of a process is represented in the process control block of a process. Context switch time is pure overhead. Context switching can significantly affect performance as modern computers have a lot of general

Operating System module | PDF page 23 | lines 12-17

7.1 First Come First Serve (FCFS)
• Jobs are executed on first come, first serve basis.

Question sources

Computer Science MCQ practice collection · Question 701

Question 173 | AM0702

Two continuously ready user groups have declared CPU entitlements of 3:1, independent of how many tasks each launches. Which listed policy is designed to enforce those unequal per-group shares over time?

A. First-Come, First-Served (FCFS)

B. Round Robin

C. Shortest Job Next (SJN)

D. Fair-Share Scheduling

Hint

Identify the allocation entity, entitlement weights and whether the guarantee is probabilistic.

Answer D: Fair-Share Scheduling

A fair-share policy allocates CPU according to declared weights and participant scope. Weights of 3:1 give intended group shares of 75 and 25 percent. Plain RR supplies equal turns to processes and does not implement those unequal group entitlements independently of task count. FCFS and SJN also lack that share rule. The question asks for the policy design rather than a universal finite-time deadline.

Why each choice is right or wrong

A - Incorrect: FCFS orders bursts by arrival rather than enforcing weighted group service.

B - Incorrect: Plain per-task RR does not enforce unequal group weights independent of task count.

C - Incorrect: SJN selects short bursts rather than proportional group entitlements.

D - Correct: Configured fair-share scheduling implements the declared group-weight allocation.

Primary note proof

Study-note section OS20

> Fair-share scheduling allocates according to stated weights, potentially per user/group rather than per process. Equal per-process RR can let a user obtain more aggregate CPU by launching more processes. Proportional shares address that policy choice; fair need not mean equal.

Study-note section OS18

> RR serves a ready queue cyclically for at most quantum q per turn. Unfinished jobs return to the tail; completed/blocked jobs leave.

Study-note section OS15

> FCFS runs ready bursts in arrival order and ordinarily does not preempt.

Study-note section OS16

> Non-preemptive SJF/SJN chooses the shortest next burst among currently ready jobs.

Question sources

Computer Science MCQ practice collection · Question 702

Question 174 | AM0703

Three jobs all arrive at time 0 in listed order P1, P2, P3, with CPU bursts 24, 3, 3 and priorities 2, 1, 3 (smaller number is higher). There is no I/O or overhead. Compare FCFS, RR with quantum 4, non-preemptive SJN, and non-preemptive priority; use listed order for ties. Which has the highest average turnaround for this workload?

A. First-Come, First-Served (FCFS)

B. Round Robin

C. Shortest Job Next (SJN)

D. Priority Scheduling

Hint

Construct a timeline and distinguish completion rates from individual elapsed-time measures.

Answer A: First-Come, First-Served (FCFS)

FCFS completes P1, P2, P3 at 24, 27 and 30, giving average turnaround 27. RR completes them at 30, 7 and 10, averaging 47/3. SJN completes short jobs at 3 and 6, then P1 at 30, averaging 13. Priority runs P2, P1, P3 and averages 20. FCFS is uniquely highest for this specified workload, without a universal worst-policy claim.

Why each choice is right or wrong

A - Correct: FCFS average turnaround is (24+27+30)/3=27, the largest.

B - Incorrect: RR average turnaround is (30+7+10)/3=47/3, below 27.

C - Incorrect: SJN average turnaround is (3+6+30)/3=13.

D - Incorrect: Priority average turnaround is (3+27+30)/3=20.

Primary note proof

Study-note section OS13

For arrival A, first start S and completion C, response=S−A and turnaround=C−A. For a single CPU burst B with no I/O, waiting=C−A−B.

Study-note section OS15

FCFS runs ready bursts in arrival order and ordinarily does not preempt.

Study-note section OS16

Non-preemptive SJF/SJN chooses the shortest next burst among currently ready jobs.

Study-note section OS17

Priority scheduling chooses the highest-priority ready job. Check whether a smaller or larger numeric value means higher priority. State whether a high-priority arrival preempts.

Study-note section OS18

RR serves a ready queue cyclically for at most quantum q per turn. Unfinished jobs return to the tail; completed/blocked jobs leave.

P3 16 - 3 = 13
Average Wait Time: (0+4+6+13)/4 = 5.75

Question sources

Computer Science MCQ practice collection · Question 703

Question 175 | CS0218

Which one of the following is a voluntary termination of a process?

A. Error exit

B. Killed by another process

C. Terminated by another process

D. Fatal exit

Hint

Separate creation, image replacement and termination; classify termination by its cause.

Answer A: Error exit, when the program detects an error and chooses to terminate.

OS07 explicitly classifies program-detected error exits as voluntary. Being killed or terminated by another process is imposed, and a fatal unrecoverable fault is involuntary. The distinction is the termination decision's origin, not whether the run succeeded: a program can voluntarily exit because its input is invalid or it detects another handled error.

Why each choice is right or wrong

A - Correct: A program-detected error exit is a deliberate voluntary termination path, even though execution was unsuccessful.

B - Incorrect: Being killed by another process is imposed externally and is therefore involuntary.

C - Incorrect: Termination by another process is external rather than a voluntary exit chosen by the program.

D - Incorrect: A fatal unrecoverable fault causes involuntary termination rather than a deliberate program error exit.

Primary note proof

Study-note section OS07

Normal completion and a program-detected error exit are voluntary; an unrecoverable fault or being killed is involuntary. exit() terminates normally through the runtime; abort() requests abnormal termination.

Operating System module | PDF page 16 | lines 29-39

1. New The process is being created.
2.
Ready The process is waiting to be assigned to a processor. Ready processes are waiting to have the processor allocated to them by the operating system so that they can run.
3.
Running Process instructions are being executed (i.e. The process that is currently being executed).
4.
Waiting The process is waiting for some event to occur (such as the completion of an I/O operation).
5. Terminated The process has finished execution.

Operating System module | PDF page 19 | lines 20-25

Non-Running Processes that are not running are kept in queue, waiting for their turn to execute. Each entry in the queue is a pointer to a particular process. Queue is implemented by using linked list. Use of dispatcher is as follows. When a process is interrupted, that process is transferred in the waiting queue. If the process has completed or aborted, the process is discarded. In either case, the dispatcher then selects a process from the queue to execute.

Operating System module | PDF page 39 | lines 5-11

Check an internal table for this process, to determine whether the reference was a valid or it was an invalid memory access.
Step 2
If the reference was invalid, terminate the process. If it was valid, but page have not yet brought in, page in the latter.
Step 3 Find a free frame.
Step 4 Schedule a disk operation to read the desired page into the newly allocated frame.

Question sources

Computer Science Exit Exam practice collection · Question 218

Question 176 | CS0219

Which statements are false in a system with one-to-one kernel-supported threads? In A, “children” means a process may create another process and a running thread may invoke a thread-creation operation; it does not require an OS thread-parent hierarchy. In B, “execute sequentially” means threads are required to finish one after another without interleaving. Select all that apply.

A. Both can create children

B. Threads within a process execute sequentially

C. Processes are not independent of one another

D. If one thread is blocked, another thread can run

Hint

Compare per-thread execution context with shared process resources and the stated thread mapping.

Answer B, C: Threads within a process execute sequentially; Processes are not independent of one another

Threads within one process need not finish sequentially; their execution may interleave or run on multiple CPUs. Independent processes can also exist, so C’s universal dependence claim is false. The defined creation operations make A true without imposing a thread-parent hierarchy. Under one-to-one mapping, one blocked thread need not block every other thread, making D a valid possibility rather than a false statement.

Why each choice is right or wrong

A - Incorrect: The defined process and thread creation operations are allowed, so A is true.

B - Correct: Mandatory finish-before-next sequential execution is false; threads can interleave or run in parallel.

C - Correct: Universal process dependence is false because independent processes can exist.

D - Incorrect: One-to-one mapping permits another runnable thread to execute when one blocks, so D is true.

Primary note proof

Study-note section OS08

> A thread has its own PC, registers and stack. Threads in a process share code, address space and usually open-file resources. A process can contain many threads; a thread belongs to one process at a time. Threads are not a group of processes and need not execute sequentially. Independent processes can exist; cooperating ones communicate/share data.

Study-note section OS08

> One-to-one permits another kernel thread to run when one blocks.

Study-note section OS07

Processes arise during initialization, user requests, service requests or a running process's creation call.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Operating System module | PDF page 27 | lines 6-14

A thread is a flow of execution through the process code, with its own program counter, system registers and stack. A thread is also called a light weight process. Threads provide a way to improve application performance through parallelism. Threads represent a software approach to improving performance of operating system by reducing the overhead thread is equivalent to a classical process.
Each thread belongs to exactly one process and no thread can exist outside a process. Each thread represents a separate flow of control. Threads have been successfully used in implementing network servers and web server. They also provide a suitable foundation for parallel execution of applications on shared memory multiprocessors. Following figure shows

Operating System module | PDF page 28 | lines 4-13

In multiple processes each process operates
independently of the others.
One thread can read, write or change
another thread's data.
8.2 Advantages of Thread
• Thread minimizes context switching time.
• Use of threads provides concurrency within a process.
• Efficient communication.
• Economy- It is more economical to create and context switch threads.
• Utilization of multiprocessor architectures to a greater scale and efficiency.

Operating System module | PDF page 29 | lines 4-16

In this case, thread management done by the Kernel. There is no thread management code in the application area. Kernel threads are supported directly by the operating system. Any application can be programmed to be multithreaded. All of the threads within an application are supported within a single process.
The Kernel maintains context information for the process as a whole and for individuals' threads within the process. Scheduling by the Kernel is done on a thread basis. The Kernel performs thread creation, scheduling and management in Kernel space. Kernel threads are generally slower to create and manage than the user threads.
Advantages
• Kernel can simultaneously schedule multiple threads from the same process on multiple processes.
• If one thread in a process is blocked, the Kernel can schedule another thread of the same process.

Operating System module | PDF page 30 | lines 4-7

Many to one model maps many user level threads to one Kernel level thread. Thread management is done in user space. When thread makes a blocking system call, the entire

process will be blocks. Only one thread can access the Kernel at a time, so multiple threads are unable to run in parallel on multiprocessors.

Operating System module | PDF page 19 | lines 6-12

A newly arrived process is put in the ready queue. Processes waits in ready queue for allocating the CPU. Once the CPU is assigned to a process, then that process will execute. While executing the process, any one of the following events can occur.
• The process could issue an I/O request and then it would be placed in an I/O queue.
• The process could create new sub process and will wait for its termination.
• The process could be removed forcibly from the CPU, as a result of interrupt and put back in the ready queue.

Operating System module | PDF page 28 | lines 20-29

In this case, application manages thread management kernel is not aware of the existence of threads. The thread library contains code for creating and destroying threads, for passing message and data between threads, for scheduling thread execution and for saving and restoring thread contexts. The application begins with a single thread and begins running in that thread.
Advantages
• Thread switching does not require Kernel mode privileges.
• User level thread can run on any operating system.
• Scheduling can be application specific in the user level thread.
• User level threads are fast to create and manage.

Computer Science Exit Exam practice collection · Question 219

Question 177 | CS0220

Which statements are false under a classification based on simultaneous users? A single user may run multiple applications, and B means concurrent database accesses by those applications, not by additional users. In C, “at most one” describes the system’s supported capacity. Select all that apply.

A. In single user systems many users can login simultaneously

B. Single user systems can allow concurrent access to the database

C. Multiuser system can allow at most one user at a time

D. In Multiuser system many users can access the system concurrently

Hint

Compare interaction, CPU sharing and deadline requirements under the stated system model.

Answer A, C: In single user systems many users can login simultaneously; Multiuser system can allow at most one user at a time

Single-user and multiuser describe concurrent user access rather than application count. A therefore contradicts single-user status, and C contradicts the supported multiple-user capacity. One user may still run several applications accessing a database concurrently, which is the explicit meaning of B here. D states the multiuser capability correctly. The selected false statements are A and C.

Why each choice is right or wrong

A - Correct: Many simultaneous logged-in users contradict the single-user definition.

B - Incorrect: Concurrent applications belonging to one user do not violate single-user status, so B is true.

C - Correct: A capacity of at most one user contradicts the multiuser definition.

D - Incorrect: Supporting concurrent access by many users is the multiuser capability, so D is true.

Primary note proof

Study-note section OS02

> Single-user and multiuser describe concurrent user access, not the number of applications.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Science Exit Exam practice collection · Question 220

Question 178 | CS0221

When a process executes code that possibly changes the value of shared data, its execution has to be mutually exclusive. Therefore, the process is in:

A. Deadlock

B. Terminated

C. Critical section

D. Blocked

Hint

Identify conflicting shared accesses and the safety or progress property required.

Answer C: Critical section.

OS10 defines a critical section as code accessing shared state that needs protection. The stem describes execution that may change shared data and therefore requires mutual exclusion, directly matching that definition. Deadlock and blocking are waiting states or failures, while termination means execution has ended. None identifies the protected shared-state code currently being executed.

Why each choice is right or wrong

A - Incorrect: Deadlock involves blocked dependencies, whereas the stem describes protected code actively accessing shared data.

B - Incorrect: A terminated process has ended execution, contradicting the stem’s currently executing shared-data operation.

C - Correct: Code that accesses shared data and requires mutual exclusion is a critical section.

D - Incorrect: A blocked process cannot proceed pending an event; the stem instead identifies the code requiring protection.

Primary note proof

Study-note section OS10

A race occurs when results depend on uncoordinated interleaving of conflicting accesses. A critical section is code accessing shared state that needs protection, not the resource itself. A correct exclusion solution requires mutual exclusion, progress and bounded waiting under stated assumptions.

Study-note section OS06

New processes are created/admitted; ready means eligible for CPU but not currently running. Running uses a CPU. Waiting/blocked means unable to proceed until an event; terminated means execution has ended.

Study-note section OS22

A set is deadlocked when each member waits for an event/resource that only another blocked member can provide.

3.
Running Process instructions are being executed (i.e. The process that is currently being executed).
4.
Waiting The process is waiting for some event to occur (such as the completion of an I/O operation).
5. Terminated The process has finished execution.

Computer Science Exit Exam practice collection · Question 221

Question 179 | NS0308

Which one of the following function of operating system is categorized under process management?

A. Allocates the device in the efficient way

B. De-allocates memory when a process releases it.

C. Allocates the memory when the process requests it to do so.

D. Allocates the processor (CPU) to a process

Hint

Decide whether the process is eligible, running or waiting, then identify the responsible queue or scheduling role.

Answer D: Allocate the CPU to a process.

Allocating the CPU to a ready process is the scheduling role within process management. Device allocation belongs to device management. Allocating requested memory and reclaiming memory that has been released belong to memory management. Specifying the resource in the deallocation option removes its former overlap with several managers and leaves processor allocation as the distinct process-management function.

Why each choice is right or wrong

A - Incorrect: Allocating a device is a device-management responsibility.

B - Incorrect: Reclaiming released memory is a memory-management responsibility under the stated resource classification.

C - Incorrect: Allocating requested memory belongs to memory management.

D - Correct: Selecting a ready process to receive the CPU is the process-scheduling responsibility.

Primary note proof

Study-note section OS06

> Long-term scheduling admits jobs; medium-term scheduling suspends/swaps them; short-term scheduling selects ready work. The dispatcher performs the handoff/context restore after selection.

Study-note section OS-S03

> Memory management tracks which primary-memory regions are free or in use, assigns memory to processes and data, and deallocates it when no longer needed or when a process terminates. Allocation and deallocation concern memory ownership; CPU selection belongs to scheduling.

Study-note section OS01

> An OS allocates CPU time, memory, storage, devices and communication resources, and provides services to programs.

Question sources

Computer Science Exit Exam · 2018 · Question 29

Question 180 | NS0316

What is the primary function of an operating system?

A. To connect to the internet

B. To create documents and spreadsheets

C. To design computer hardware

D. To act as an intermediary between users and computer hardware

Hint

Separate broad resource-management goals from individual services or applications.

Answer D: Act as the service/resource intermediary between users/programs and hardware.

OS01 describes the OS allocating hardware resources and providing program services, with convenient interfaces and abstractions. D captures that intermediary role. Internet connectivity and document creation are narrower tasks, and hardware design is not a runtime OS service. The answer combines convenience and resource control rather than reducing the OS to one application or device function.

Why each choice is right or wrong

A - Incorrect: Internet access is one supported communication activity rather than the general purpose of an operating system.

B - Incorrect: Document and spreadsheet creation are application tasks that use OS services rather than define the OS.

C - Incorrect: Designing hardware is not the runtime resource/service function described for an operating system.

D - Correct: The OS provides interfaces and controlled resource services linking users/programs to the underlying hardware.

Primary note proof

Study-note section OS01

> An OS allocates CPU time, memory, storage, devices and communication resources, and provides services to programs. Convenience means making tasks easy through consistent interfaces, files and device abstractions. Efficiency means using resources effectively; it is not synonymous with the fastest response for every process. Application development tools use OS services but application development itself is not a core resource-management function.

Question sources

Computer Science Exit Exam · 2018 · Question 41

Question 181 | NS0323

A user installs a new printer. The OS automatically detects and configures it. This is an example of:

A. Plug-and-play functionality

B. Manual driver installation

C. Manual hardware management

D. Resource allocation

Hint

Separate device hardware, device-specific software and general event or transfer mechanisms.

Answer A: Plug-and-play functionality.

OS34 defines plug-and-play as discovering/configuring compatible new hardware, which directly matches automatic printer setup. A driver may still be needed, so automatic configuration does not imply driver-free operation. Manual driver installation and hardware management contradict the scenario's automatic action. Resource allocation may occur during setup but is broader than the specific feature named.

Why each choice is right or wrong

A - Correct: Automatic detection and configuration of the printer is the note's plug-and-play behavior.

B - Incorrect: The stem specifies automatic setup, not user-performed manual installation of a driver.

C - Incorrect: Manual hardware management does not match the automatic discovery/configuration described in the scenario.

D - Incorrect: Allocation can be part of setup, but it does not specifically name automatic device discovery/configuration.

Primary note proof

Study-note section OS34

> Plug-and-play discovers/configures compatible new hardware but may still require a driver.

Question sources

Computer Science Exit Exam · 2018 · Question 48

Question 182 | NS0330

In a system, resources cannot be forcibly taken from processes; they must be released voluntarily. Which deadlock condition does this represent?

A. No Preemption

B. Hold and Wait

C. Mutual Exclusion

D. Circular Wait

Hint

Trace the resource dependencies and distinguish necessary conditions from evidence of an actual deadlock.

Answer A: No preemption.

OS22 defines no resource preemption as voluntary release by the current holder. The stem repeats that resources cannot be forcibly taken, giving a direct match. Holding while requesting another resource, one-at-a-time ownership and a closed chain of waits are separate conditions and do not by themselves express the withdrawal restriction.

Why each choice is right or wrong

A - Correct: The holder must release voluntarily, so the system cannot forcibly preempt the resource.

B - Incorrect: Hold-and-wait concerns retaining one resource while requesting another rather than whether withdrawal is allowed.

C - Incorrect: Mutual exclusion limits simultaneous ownership, not whether allocated resources can be forcibly reclaimed.

D - Incorrect: Circular wait concerns a closed dependency chain, not the resource-release rule specified here.

Primary note proof

Study-note section OS22

> Mutual exclusion allows at most one holder of a nonshareable resource. Hold-and-wait means retaining a resource while requesting another. No resource preemption means release must be voluntary. Circular wait forms a closed chain of such waits.

Question sources

Computer Science Exit Exam · 2018 · Question 57

Question 183 | NS0359

How does an operating system improve efficiency in a multi-user environment?

A. By allowing only one user to access the system at a time

B. By disabling all background services

C. By using time-sharing and process scheduling to allocate CPU time fairly among users and processes

D. By requiring manual intervention for each task

Hint

Compare interaction, CPU sharing and deadline requirements under the stated system model.

Answer C: Time-sharing and scheduling distribute CPU service among users/processes.

OS02 describes time-sharing as rapid scheduling/preemption supporting interactive users. OS20 explains that fair allocation needs a share policy and may operate per user/group. C describes those relevant mechanisms rather than disabling services or requiring manual intervention. Its fairly should be understood under a specified policy, not as an automatic equality guarantee from time-sharing alone.

Why each choice is right or wrong

A - Incorrect: Restricting access to one user contradicts the multiuser setting rather than explaining its efficient sharing.

B - Incorrect: Disabling every background service is neither required nor the time-sharing/resource-allocation mechanism described.

C - Correct: Scheduling/time-sharing interleave useful work and can allocate service according to the system's fairness policy.

D - Incorrect: Manual intervention for each task adds administration rather than explaining efficient automatic CPU allocation.

Primary note proof

Study-note section OS02

> Multiprogramming keeps several jobs available so another can use the CPU while one waits; it does not require fixed time slices. Time-sharing uses rapid scheduling/preemption to support interactive users. A single CPU interleaves execution; multiple CPUs can execute work truly in parallel.

Study-note section OS20

> Fair-share scheduling allocates according to stated weights, potentially per user/group rather than per process. Equal per-process RR can let a user obtain more aggregate CPU by launching more processes. Proportional shares address that policy choice; fair need not mean equal.

Question sources

Computer Science Exit Exam · 2018 · Question 97

Question 184 | NS0684

What is the primary role of an Operating System?

A. Run application software only

B. Manage hardware and software resources and act as interface between user and hardware

C. Provide internet connectivity

D. Store user files permanently

Hint

Separate broad resource-management goals from individual services or applications.

Answer B: Manage resources and provide interfaces/services.

OS01 defines both allocation of CPU/memory/storage/devices/communications and services to programs, while describing convenient interfaces. B combines those core responsibilities. Running applications only, providing connectivity only or permanently storing files each captures a narrower task and omits the overall system-management role. The primary role is therefore the resource/interface combination, not a single service.

Why each choice is right or wrong

A - Incorrect: Application execution is supported, but only excludes the OS's other essential resource and service duties.

B - Correct: Resource management plus user/program interfaces matches the combined OS role defined here.

C - Incorrect: Internet connectivity is one communication service rather than the complete primary OS role.

D - Incorrect: Permanent file storage is a storage-device/filesystem service and not the complete operating-system purpose.

Primary note proof

Study-note section OS01

> An OS allocates CPU time, memory, storage, devices and communication resources, and provides services to programs. Convenience means making tasks easy through consistent interfaces, files and device abstractions. Efficiency means using resources effectively; it is not synonymous with the fastest response for every process. Application development tools use OS services but application development itself is not a core resource-management function.

Question sources

Operating Systems review questions · Question 1

Question 185 | NS0685

Which type of OS is designed to process large numbers of similar jobs without user interaction during execution?

A. Real-Time OS

B. Time-Sharing OS

C. Batch System

D. Single-User OS

Hint

Compare interaction, CPU sharing and deadline requirements under the stated system model.

Answer C: Batch system.

OS02 defines batch jobs as running with little interaction after submission. That matches processing submitted similar jobs without user interaction during execution. Time-sharing targets interactive users, real-time targets timing correctness, and single-user classifies concurrent access rather than job interaction. The job-processing clue therefore selects batch rather than a user-count or deadline category.

Why each choice is right or wrong

A - Incorrect: Real-time classification concerns meeting deadlines rather than the absence of user interaction during submitted job processing.

B - Incorrect: Time-sharing supports interactive users through rapid scheduling, unlike the noninteractive batch description.

C - Correct: Batch processing runs submitted jobs with little interaction, directly matching the scenario.

D - Incorrect: Single-user describes concurrent user access, not whether a workload is submitted and processed as batches.

Primary note proof

Study-note section OS02

> Batch jobs run with little interaction after submission. Multiprogramming keeps several jobs available so another can use the CPU while one waits; it does not require fixed time slices. Time-sharing uses rapid scheduling/preemption to support interactive users.

Study-note section OS02

> Single-user and multiuser describe concurrent user access, not the number of applications. Network systems expose remote services; distributed systems coordinate work across machines, sometimes hiding location. Real-time correctness includes timing: hard deadlines must be met, while soft deadline misses degrade service.

Question sources

Operating Systems review questions · Question 2

Question 186 | NS0686

In a Process Control Block (PCB), what does the Program Counter store?

A. The process priority level

B. The address of the next instruction to be executed for that process

C. The amount of CPU time used

D. The list of open files

Hint

Distinguish stored instructions, an executing instance and its saved execution state.

Answer B: The saved next-instruction position for resuming the process.

OS05 says the PCB records PC/registers alongside scheduling, memory/accounting and I/O information, and a saved PC identifies where execution resumes. Thus B describes its specific field role. Priority, CPU usage and open files can be other PCB information, but they are not the program-counter value. The question requires distinguishing fields within one record rather than excluding them from the PCB entirely.

Why each choice is right or wrong

A - Incorrect: Priority is scheduling information in the PCB, not the saved next-instruction position held by PC.

B - Correct: The saved PC records the instruction position at which the process will resume execution.

C - Incorrect: CPU time consumed is accounting information rather than the program-counter address.

D - Incorrect: Open files belong to I/O/open-resource state, not to the saved instruction-pointer field.

Primary note proof

Study-note section OS05

> A saved PC identifies where execution resumes.

Question sources

Operating Systems review questions · Question 3

Question 187 | NS0687

Which process state indicates that a process is waiting for an I/O event to complete?

A. Ready

B. Running

C. Waiting

D. Terminated

Hint

Decide whether the process is eligible, running or waiting, then identify the responsible queue or scheduling role.

Answer C: Waiting/blocked.

OS06 defines waiting/blocked as unable to proceed until an event and maps blocking I/O from running to waiting. Therefore a process waiting for I/O completion is in Waiting. It is not ready while the event prevents progress, not running during the wait, and not terminated merely because its request is outstanding. Completion normally makes it ready afterward.

Why each choice is right or wrong

A - Incorrect: Ready means eligible for CPU immediately; the outstanding blocking I/O prevents that eligibility.

B - Incorrect: Running means currently using a CPU, unlike the blocked interval awaiting I/O completion.

C - Correct: Waiting/blocked is the state for a process that cannot proceed until its I/O event completes.

D - Incorrect: Terminated means execution has ended, not temporarily paused pending completion of an I/O request.

Primary note proof

Study-note section OS06

> New processes are created/admitted; ready means eligible for CPU but not currently running. Running uses a CPU. Waiting/blocked means unable to proceed until an event; terminated means execution has ended. Running→ready follows time-slice expiry or another preemption. Running→waiting follows blocking I/O. I/O completion normally gives waiting→ready, not a guaranteed immediate running state.

Question sources

Operating Systems review questions · Question 4

Question 188 | NS0688

What is the primary purpose of a Context Switch?

A. To permanently stop a process

B. To save the state of the current process and restore the state of the next scheduled process

C. To allocate more memory to a process

D. To terminate a low-priority process

Hint

Distinguish stored instructions, an executing instance and its saved execution state.

Answer B: Save one execution context and restore another.

OS05 directly defines a context switch as saving one execution context and restoring another, with overhead interrupting useful application work. B matches. A process may later resume, so switching does not permanently stop or kill it. Allocating memory is another management operation, and a privilege transition alone need not switch processes.

Why each choice is right or wrong

A - Incorrect: The outgoing process can resume later; permanent stopping is termination rather than context switching.

B - Correct: Saving current state and restoring the selected execution context is the defined context-switch purpose.

C - Incorrect: Memory allocation changes resource assignment, not the saved/restored execution context defining a switch.

D - Incorrect: A context switch need not terminate any process, regardless of priority.

Primary note proof

Study-note section OS05

> A context switch saves one execution context and restores another; useful application work is interrupted by this overhead. An interrupt or system call can switch privilege without switching process.

Question sources

Operating Systems review questions · Question 5

Question 189 | NS0689

Which scheduler is responsible for selecting which process from the ready queue should be executed next on the CPU?

A. Long-Term Scheduler

B. Medium-Term Scheduler

C. Short-Term (CPU) Scheduler

D. I/O Scheduler

Hint

Decide whether the process is eligible, running or waiting, then identify the responsible queue or scheduling role.

Answer C: Short-term (CPU) scheduler.

OS06 assigns admission to the long-term scheduler, suspension/swapping to the medium-term scheduler and ready-work selection to the short-term scheduler. The question specifically asks which ready process receives the CPU next, so C is exact. The dispatcher then performs the handoff; that is distinct from selecting the ready process. Device request ordering is not CPU ready-queue selection.

Why each choice is right or wrong

A - Incorrect: The long-term scheduler admits jobs rather than making each immediate ready-queue CPU selection.

B - Incorrect: The medium-term scheduler suspends/swaps work rather than choosing the next CPU-ready process.

C - Correct: The short-term CPU scheduler selects the next eligible process from ready work.

D - Incorrect: An I/O scheduler orders device work rather than selecting the next process for the CPU.

Primary note proof

Study-note section OS06

> The ready queue contains eligible work; device queues hold blocked requests. The broad textbook job queue contains processes in the system, while an admission queue more narrowly holds jobs awaiting memory/admission. Long-term scheduling admits jobs; medium-term scheduling suspends/swaps them; short-term scheduling selects ready work. The dispatcher performs the handoff/context restore after selection.

Question sources

Operating Systems review questions · Question 6

Question 190 | NS0690

What is the role of the Medium-Term Scheduler?

A. Decide which jobs enter the system

B. Pick the next process for the CPU

C. Swap processes between main memory and secondary storage to manage memory

D. Handle device driver requests

Hint

Decide whether the process is eligible, running or waiting, then identify the responsible queue or scheduling role.

Answer C: Suspend/swap processes between resident and backing-store states.

OS06 explicitly assigns suspension/swapping to the medium-term scheduler. OS27 distinguishes traditional whole-process swapping to backing storage from page movement. Thus C is the matching memory/load-control role. Admitting jobs belongs to long-term scheduling, picking the next ready process to short-term scheduling, and servicing drivers to device-management paths.

Why each choice is right or wrong

A - Incorrect: Deciding admission into the system is the long-term scheduler's role in the supplied model.

B - Incorrect: Selecting the next CPU process belongs to the short-term scheduler, not the medium-term one.

C - Correct: Medium-term scheduling suspends/swaps processes to control resident load and memory use.

D - Incorrect: Device-driver requests concern I/O service rather than the scheduler's suspension/swapping function.

Primary note proof

Study-note section OS06

> Long-term scheduling admits jobs; medium-term scheduling suspends/swaps them; short-term scheduling selects ready work.

Study-note section OS27

> Swapping traditionally moves a whole process to backing store; paging moves individual pages.

Study-note section OS34

> A driver converts OS requests into device-specific operations.

Question sources

Operating Systems review questions · Question 7

Question 191 | NS0691

A Race Condition occurs when:

A. Two processes finish execution at the same time

B. Multiple processes access shared resources simultaneously without proper synchronization, causing unpredictable results

C. A high-priority process always runs before a low-priority one

D. A process is preempted by the OS scheduler

Hint

Identify conflicting shared accesses and the safety or progress property required.

Answer B: Uncoordinated conflicting shared accesses make results depend on interleaving.

OS10 defines a race by results depending on uncoordinated interleaving of conflicting accesses. B is the intended match, with shared access understood to include a conflict such as an update; simultaneous read-only access alone is insufficient. Coincident completion, ordinary priority selection and preemption do not by themselves establish a shared-state race.

Why each choice is right or wrong

A - Incorrect: Two completions at the same time need not involve conflicting shared accesses or interleaving-dependent results.

B - Correct: Unsynchronized conflicting shared accesses can make results depend on execution interleaving, which is the race condition.

C - Incorrect: Priority order alone is a scheduling choice and does not establish a conflicting shared-data race.

D - Incorrect: Preemption can expose a race but is not itself sufficient without conflicting unprotected accesses.

Primary note proof

Study-note section OS10

> A race occurs when results depend on uncoordinated interleaving of conflicting accesses.

Study-note section OS10

> Two threads read counter=0, each computes 1 and each stores 1. Two increments produce 1 instead of 2. Protecting the entire read-modify-write with one lock prevents that lost update.

Question sources

Operating Systems review questions · Question 8

Question 192 | NS0692

Which of the following is NOT a necessary condition for deadlock?

A. Mutual Exclusion

B. Hold and Wait

C. Preemption

D. Circular Wait

Hint

Trace the resource dependencies and distinguish necessary conditions from evidence of an actual deadlock.

Answer C: Preemption is not a necessary condition; no-preemption is.

OS22 names mutual exclusion, hold-and-wait, no resource preemption and circular wait as the necessary set. The option Preemption reverses one of those conditions. Therefore C is the exception, while the other three are genuine members. This resource-preemption rule is separate from whether CPU scheduling uses timer preemption.

Why each choice is right or wrong

A - Incorrect: Mutual exclusion is explicitly one of the four necessary conditions in the standard resource model.

B - Incorrect: Hold-and-wait is explicitly necessary: a process retains a resource while requesting another.

C - Correct: The required condition is no-preemption; permitting preemption is not one of the necessary conditions.

D - Incorrect: Circular wait is explicitly a required closed dependency chain in the standard model.

Primary note proof

Study-note section OS22

> Mutual exclusion allows at most one holder of a nonshareable resource. Hold-and-wait means retaining a resource while requesting another. No resource preemption means release must be voluntary. Circular wait forms a closed chain of such waits.

Study-note section OS22

> All four are necessary in the standard reusable-resource model.

Question sources

Operating Systems review questions · Question 9

Question 193 | NS0693

All three processes arrive at time 0 and are ready immediately. Their CPU burst times are P1 = 24 ms, P2 = 3 ms and P3 = 3 ms. Using non-preemptive FCFS with tie order P1, P2, P3, and ignoring context-switch overhead, what is the average waiting time?

A. 3 ms

B. 9 ms

C. 17 ms

D. 27 ms

Hint

Follow arrival order, include idle periods and distinguish waiting from completion time.

Answer C: 17 ms.

FCFS runs P1 from 0 to 24 ms, P2 from 24 to 27 ms, and P3 from 27 to 30 ms. Because every process arrives at 0, their waiting times are 0, 24 and 27 ms. The average is (0+24+27)/3 = 51/3 = 17 ms, so C is correct. The average turnaround is a different quantity: (24+27+30)/3 = 27 ms.

Why each choice is right or wrong

A - Incorrect: 3 ms is the burst time of P2 or P3, not the average ready-queue wait.

B - Incorrect: The three waits total 51 ms, so dividing by three cannot give 9 ms.

C - Correct: The waits 0, 24 and 27 ms average to 17 ms.

D - Incorrect: 27 ms is the average turnaround time in this example, not the average waiting time.

Primary note proof

Study-note section OS15

> FCFS runs ready bursts in arrival order and ordinarily does not preempt.

Study-note section OS15

> All ready at time 0, tie order P1=24,P2=3,P3=3: schedule 0-24 P1,24-27 P2,27-30 P3. Waiting times 0,24,27 average to 17. Turnarounds 24,27,30 average to 27. If arrivals are not simultaneous, recompute using their actual times.

Study-note section OS13

> For arrival A, first start S and completion C, response=S−A and turnaround=C−A. For a single CPU burst B with no I/O, waiting=C−A−B.

Question sources

Operating Systems review questions · Question 10

Question 194 | NS0694

What problem does the 'Aging' technique solve in Priority Scheduling?

A. Deadlock

B. Starvation of low-priority processes

C. Race conditions

D. Memory fragmentation

Hint

Check priority direction, preemption and whether waiting can change effective rank.

Answer B: Starvation of low-priority processes.

OS17 defines aging as increasing waiting jobs' effective priority to reduce indefinite postponement under suitable rules/workloads. Thus B names the problem it addresses. It does not remove a deadlock dependency cycle, coordinate conflicting memory updates or consolidate fragmented memory. The result still depends on the priority/aging policy; naming aging alone does not provide an unconditional deadline guarantee.

Why each choice is right or wrong

A - Incorrect: Aging changes priority rather than breaking the blocked resource dependencies of a deadlock.

B - Correct: Increasing effective priority of waiting low-priority jobs addresses their starvation under sustained higher-priority load.

C - Incorrect: Races require shared-access synchronization; priority aging is not a mutual-exclusion mechanism.

D - Incorrect: Memory fragmentation concerns allocation layout rather than the priority of waiting CPU jobs.

Primary note proof

Study-note section OS17

> Aging increases waiting jobs' effective priority according to a rule, reducing indefinite postponement when the priority scheme and workload permit. It is not a deadlock cure.

Study-note section OS10

> A race occurs when results depend on uncoordinated interleaving of conflicting accesses.

Study-note section OS29

> Internal fragmentation is unused space inside an allocated unit. External fragmentation is sufficient total free space split into holes that cannot satisfy a required contiguous allocation.

Question sources

Operating Systems review questions · Question 11

Question 195 | NS0695

Which scheduling algorithm is known as preemptive SJF?

A. Round Robin

B. FCFS

C. Shortest Remaining Time First (SRTF)

D. Priority Scheduling

Hint

Compare the ready jobs using the stated burst or remaining-time rule.

Answer C: Shortest Remaining Time First.

OS16 distinguishes non-preemptive SJF/SJN from SRTF, which reconsiders at arrivals and can preempt for shorter remaining work. Therefore SRTF is the preemptive SJF variant. RR uses fixed cyclic turns, FCFS arrival order and generic priority an independently defined ranking. The original burst length and the remaining length must not be confused after a job has executed.

Why each choice is right or wrong

A - Incorrect: RR selects cyclic quantum turns rather than the shortest remaining CPU work.

B - Incorrect: FCFS follows arrival order and is ordinarily non-preemptive rather than preemptive shortest-job scheduling.

C - Correct: SRTF chooses minimum remaining work and can interrupt a running job for a shorter arrival.

D - Incorrect: Generic priority scheduling does not specifically rank by remaining burst length and can be either variant.

Primary note proof

Study-note section OS16

> Non-preemptive SJF/SJN chooses the shortest next burst among currently ready jobs. SRTF reconsiders on arrivals and selects the shortest remaining work; a shorter newcomer can preempt. Future burst lengths normally need estimates.

Study-note section OS18

> RR serves a ready queue cyclically for at most quantum q per turn.

Study-note section OS15

> FCFS runs ready bursts in arrival order and ordinarily does not preempt.

Question sources

Operating Systems review questions · Question 12

Question 196 | NS0696

In Round Robin scheduling, what is the key challenge?

A. Managing priority levels

B. Determining the appropriate time quantum length

C. Avoiding deadlocks

D. Allocating memory to processes

Hint

Trace bounded turns in ready-queue order and include the stated overhead and arrivals.

Answer B: Choose an appropriate time quantum.

OS18 says a large RR quantum approaches FCFS, while tiny quanta increase context-switch overhead. Selecting q therefore trades responsiveness against overhead, matching B. Priority management, deadlock policy and memory allocation are separate concerns rather than the defining parameter-selection challenge of ordinary Round Robin. The useful quantum depends on workloads and switching cost.

Why each choice is right or wrong

A - Incorrect: Basic RR uses cyclic ready-queue turns rather than requiring a hierarchy of priority levels.

B - Correct: Quantum length controls responsiveness and switching overhead, creating RR's characteristic tuning tradeoff.

C - Incorrect: Deadlock avoidance concerns resources and dependencies, not the defining RR quantum parameter.

D - Incorrect: Memory allocation is a separate management problem rather than the Round Robin selection rule's main parameter.

Primary note proof

Study-note section OS18

> A large quantum approaches FCFS; tiny quanta increase switch overhead.

Study-note section OS18

> With n continuously ready jobs, no priority bypass and zero overhead, a just-requeued job waits at most (n−1)q for its next turn. This bounds one interval, not total lifetime waiting when arrivals or blocking are unrestricted. Include context-switch costs if given.

Question sources

Operating Systems review questions · Question 13

Question 197 | NS0697

What is a Semaphore?

A. A scheduling algorithm

B. A memory management technique

C. A synchronization variable that controls access to shared resources in a multi-process environment

D. A type of file allocation method

Hint

Track available permits and blocked operations using the stated semaphore model.

Answer C: A synchronization variable with atomic wait and signal operations.

OS11 defines a semaphore through atomic wait/P/down and signal/V/up operations. Tokens control whether participants can proceed with shared resource work, with binary or counting forms. C identifies that synchronization role. Scheduling, memory-management and file-allocation policies solve different resource-selection/layout problems and do not define semaphore semantics.

Why each choice is right or wrong

A - Incorrect: A semaphore synchronizes participants; it is not itself a CPU-selection scheduling algorithm.

B - Incorrect: It controls coordination through permits, rather than choosing memory locations or translation layouts.

C - Correct: Atomic wait/signal on a synchronization variable controls permits for concurrent shared-resource operations.

D - Incorrect: File allocation chooses storage-block layout; that is separate from semaphore synchronization semantics.

Primary note proof

Study-note section OS11

> A semaphore provides atomic wait/P/down and signal/V/up operations. Under the nonnegative-token model, wait consumes one available token or blocks when none is available; signal supplies a token and may wake a waiter. Implementations using negative internal counts encode waiters differently, so state the model. A binary semaphore represents one permit; a counting semaphore tracks several. A mutex normally has ownership rules that a general semaphore lacks.

Study-note section OS15

> FCFS runs ready bursts in arrival order and ordinarily does not preempt.

Study-note section OS28

> A contiguous allocation gives a process one continuous region.

Study-note section OS38

> Contiguous allocation uses consecutive blocks; logical block i is start+i and supports direct access, but growth and external fragmentation are problems.

Question sources

Operating Systems review questions · Question 14

Question 198 | NS0698

What is the difference between a Binary Semaphore and a Counting Semaphore?

A. Binary semaphores are faster

B. Binary semaphores have only two states (0 or 1), while counting semaphores track available resources up to a maximum count

C. Counting semaphores are used only for deadlock prevention

D. There is no difference

Hint

Track available permits and blocked operations using the stated semaphore model.

Answer B: Binary tracks one permit; counting tracks several.

OS11 defines a binary semaphore as one permit and a counting semaphore as several, under the nonnegative-token model. Thus binary availability is 0/1 while a resource pool can have a larger count. B states this logical distinction. Internal negative-waiter encodings are implementation details, not a reason to claim speed guarantees, deadlock-only usage or no difference.

Why each choice is right or wrong

A - Incorrect: The note gives no universal relative-speed guarantee; permit capacity is the defining distinction.

B - Correct: In the nonnegative-token model, binary availability is zero/one while counting semaphores track several available permits.

C - Incorrect: Counting semaphores coordinate resource pools and are not limited to preventing deadlock.

D - Incorrect: The allowed permit count is a substantive difference explicitly stated here.

Primary note proof

Study-note section OS11

> A semaphore provides atomic wait/P/down and signal/V/up operations. Under the nonnegative-token model, wait consumes one available token or blocks when none is available; signal supplies a token and may wake a waiter. Implementations using negative internal counts encode waiters differently, so state the model. A binary semaphore represents one permit; a counting semaphore tracks several. A mutex normally has ownership rules that a general semaphore lacks.

Question sources

Operating Systems review questions · Question 15

Question 199 | NS0699

What must hold simultaneously for a deadlock to occur?

A. Only Mutual Exclusion and Circular Wait

B. Any two of the four conditions

C. All four necessary conditions: Mutual Exclusion, Hold-and-Wait, No Preemption, and Circular Wait

D. Only Circular Wait

Hint

Trace the resource dependencies and distinguish necessary conditions from evidence of an actual deadlock.

Answer C: All four standard necessary conditions.

OS22 says all four conditions are necessary in the standard reusable-resource model. C names that full set. Any two or a cycle alone does not state the complete conjunction. This is a necessary-condition answer, not an assertion that merely allowing all four policies proves a deadlock already exists in a particular allocation state.

Why each choice is right or wrong

A - Incorrect: It omits hold-and-wait and no-preemption, both necessary in the stated standard resource model.

B - Incorrect: An arbitrary pair does not supply all four necessary restrictions for the standard deadlock model.

C - Correct: This option lists mutual exclusion, hold-and-wait, no-preemption and circular wait together.

D - Incorrect: A cycle alone omits other necessary restrictions; it is not the complete standard condition set.

Primary note proof

Study-note section OS22

> Mutual exclusion allows at most one holder of a nonshareable resource. Hold-and-wait means retaining a resource while requesting another. No resource preemption means release must be voluntary. Circular wait forms a closed chain of such waits.

Study-note section OS22

> All four are necessary in the standard reusable-resource model. Their availability as general system policies does not prove a deadlock exists at this instant; inspect actual allocations/requests.

Question sources

Operating Systems review questions · Question 16

Question 200 | NS0700

In a Resource Allocation Graph (RAG), what does a cycle with single-instance resources indicate?

A. Potential deadlock only

B. No deadlock possible

C. Definite deadlock

D. High CPU utilization

Hint

Follow request and assignment arrows and check how many instances each resource has.

Answer C: Definite deadlock under single-instance resource assumptions.

OS23 says a cycle implies deadlock when every resource type has one instance. The stem supplies that decisive assumption, so C follows. With multiple instances a cycle would indicate only a possibility, but importing that different model would ignore the literal question. A graph cycle also says nothing by itself about high CPU utilization.

Why each choice is right or wrong

A - Incorrect: Potential-only applies to the more general multiple-instance caveat, not the supplied single-instance case.

B - Incorrect: A cycle in the stated single-instance model establishes deadlock rather than excluding it.

C - Correct: The note explicitly gives cycle implies deadlock for a graph with one instance per resource type.

D - Incorrect: Resource dependency cycles do not measure CPU busy time or establish high processor utilization.

Primary note proof

Study-note section OS23

> In a resource-allocation graph, P→R is a request and an instance R→P is an assignment. Follow these directions to form waits. No cycle implies no deadlock; with one instance of every resource type, a cycle implies deadlock. With multiple instances a cycle alone is insufficient: another instance may permit completion. A wait-for graph replaces single-instance resource nodes with P→Q when P waits for Q.

Operating Systems review questions · Question 17

Question 201 | NS0701

Which deadlock handling method allows deadlock to occur but then recovers from it?

A. Deadlock Prevention

B. Deadlock Ignorance

C. Deadlock Recovery

D. Deadlock Avoidance

Hint

Separate handling before allocation from actions taken after detection, and consider the cost of checking.

Answer C: Deadlock recovery.

OS26 describes recovery through terminating selected processes or safely reclaiming resources and rolling work back after deadlock is detected. That matches allowing occurrence and then resolving it. Prevention removes a necessary condition, avoidance preserves safety before granting, and ignoring accepts risk without committing to recovery. The complete handling strategy is detection plus recovery; C is the offered recovery component.

Why each choice is right or wrong

A - Incorrect: Prevention constrains requests so the targeted deadlock class cannot arise rather than accepting occurrence first.

B - Incorrect: Ignoring rare deadlock does not define active detection and subsequent recovery.

C - Correct: Recovery acts on an actual detected deadlock using termination, reclamation or rollback as appropriate.

D - Incorrect: Avoidance checks safe states before grants rather than deliberately permitting deadlock and then repairing it.

Primary note proof

Study-note section OS26

> Detection asks whether the current state is deadlocked. Recovery can terminate selected processes or reclaim safely preemptable resources and roll affected work back to a checkpoint. Termination and rollback are both possible recovery tools; choose according to the resource and process conditions.

Study-note section OS24

> Prevention constrains how requests are made.

Study-note section OS25

> Avoidance allows requests only if the resulting state remains safe.

Study-note section OS26

Ignoring a sufficiently rare problem is sometimes called the ostrich policy, but real systems still prevent or detect selected deadlocks.

Operating Systems review questions · Question 18

Question 202 | NS0702

What is Address Binding at 'Load Time'?

A. Addresses are fixed by the compiler before execution

B. Addresses are determined while the program executes

C. Final memory addresses are assigned when the program is loaded into memory (since addresses are unknown at compile time)

D. Addresses are stored on the hard disk

Hint

Track when an address or library reference is resolved and the direction of translation.

Answer C: Relocate addresses when the program is loaded.

OS27 defines load-time binding as relocation when placed into memory. That matches C's final-address assignment at load when placement was unknown at compile time. Fixing absolute addresses during compilation is compile-time binding; translating while running is execution-time binding. Merely storing address bytes on a disk describes neither the placement decision nor its timing.

Why each choice is right or wrong

A - Incorrect: Fixing absolute addresses in the compiler is compile-time binding, not relocation on loading.

B - Incorrect: Translation during execution is execution-time binding rather than assignment during loading.

C - Correct: The loader resolves placement-dependent addresses when placing the program into memory.

D - Incorrect: Storing address information on disk does not define when placement-dependent address binding occurs.

Primary note proof

Study-note section OS27

> Compile-time binding uses absolute addresses if placement is known. Load-time binding relocates when placed into memory. Execution-time binding translates while running and permits movement with hardware support.

Question sources

Operating Systems review questions · Question 19

Question 203 | NS0703

Under basic page-frame allocation and variable-segment allocation, which statement correctly contrasts allocation-unit size and external fragmentation?

A. Paging uses variable-sized blocks; segmentation uses fixed-sized blocks

B. Paging divides memory into fixed-sized pages eliminating external fragmentation; segmentation uses variable-sized logical segments but can cause external fragmentation

C. Segmentation is used only in virtual memory

D. Paging requires no hardware support

Hint

Check the logical region and offset bound before computing its physical location.

Answer B: Fixed-size paging avoids external page-frame fragmentation; variable segments can fragment externally.

Paging maps fixed-size pages into equal-size frames, avoiding external fragmentation of frame allocation, although internal waste can remain. Segmentation uses variable-length logical regions and can leave external holes. This is the unit-size and fragmentation contrast in B. A reverses the sizes. C does not supply that contrast, and D substitutes a hardware-support claim for it; page translation still requires mappings and checks.

Why each choice is right or wrong

A - Incorrect: The sizes are reversed: pages are fixed-size units and segments are variable-length regions.

B - Correct: This gives the required fixed-page versus variable-segment size and external-fragmentation contrast.

C - Incorrect: An exclusive-use statement does not compare allocation-unit sizes or external fragmentation as requested.

D - Incorrect: This does not give the requested size/fragmentation contrast; paging also uses translation mappings and checks.

Primary note proof

Study-note section OS31

> Under the basic models, paging uses fixed units/page tables and can waste space internally; segmentation uses variable logical units/segment tables and can fragment externally. Segments reflect program structure whereas ordinary pages are largely transparent to applications.

Study-note section OS30

> Pages and physical frames have equal fixed size P. Divide virtual address v into page=floor(v/P) and offset=v mod P. The page table maps a page to a frame and protection/status flags. Physical address=frame×P+offset.

Question sources

Operating Systems review questions · Question 20

Question 204 | NS0704

What causes External Fragmentation in memory management?

A. Allocated memory blocks being larger than needed

B. Free memory being scattered in small non-contiguous pieces making it impossible to satisfy large allocation requests

C. Processes using too much CPU time

D. Too many open files in the directory

Hint

Locate unused space relative to an allocated unit and distinguish total free space from contiguous free space.

Answer B: Free capacity is split across holes too small for a required contiguous allocation.

OS29 defines external fragmentation as sufficient total free space split into holes unable to satisfy a contiguous allocation. B matches that definition, with large requests understood to require one continuous region. A instead describes internal fragmentation. CPU time and open-file counts may create other pressures but do not define the spatial fragmentation of free memory.

Why each choice is right or wrong

A - Incorrect: Unused space within an oversized allocated block is internal fragmentation, not external free-hole fragmentation.

B - Correct: Noncontiguous small holes can have enough total capacity yet fail to satisfy one contiguous request.

C - Incorrect: CPU execution time does not define the spatial layout of free memory holes.

D - Incorrect: Open-file count is a resource-use limit rather than the definition of external memory fragmentation.

Primary note proof

Study-note section OS29

> Internal fragmentation is unused space inside an allocated unit. External fragmentation is sufficient total free space split into holes that cannot satisfy a required contiguous allocation.

Question sources

Operating Systems review questions · Question 21

Question 205 | NS0705

What is the purpose of the Page Table in Paging?

A. To allocate CPU time to processes

B. To map logical page numbers to physical frame numbers in memory

C. To store file access permissions

D. To manage disk I/O operations

Hint

Split the address into page and offset, then apply the mapping and access checks.

Answer B: Map virtual/logical pages to physical frames.

OS30 says the page table maps each virtual page to a frame with protection/status flags. B directly states the primary translation role. CPU time allocation belongs to scheduling; file permissions belong to filesystem metadata, despite page tables also having memory-protection bits. Disk I/O may service nonresident pages but does not define the page table's mapping purpose.

Why each choice is right or wrong

A - Incorrect: CPU time allocation is scheduling, not the page-to-frame translation recorded by a page table.

B - Correct: The table identifies the physical frame corresponding to each virtual page and records relevant flags.

C - Incorrect: Memory access-protection flags differ from filesystem file-access permissions; file permissions are not the page table's purpose.

D - Incorrect: Page faults may cause I/O, but general disk-operation management is not the table's translation role.

Primary note proof

Study-note section OS30

> Pages and physical frames have equal fixed size P. Divide virtual address v into page=floor(v/P) and offset=v mod P. The page table maps a page to a frame and protection/status flags.

Study-note section OS36

> A file has content and metadata such as name, size, owner, permissions and timestamps. open obtains an open-file reference, read/write transfer bytes, seek changes an offset, close releases a reference, truncate changes size and unlink removes a name.

Question sources

Operating Systems review questions · Question 22

Question 206 | NS0706

In Segmentation, how is a physical address calculated?

A. Page number x frame size

B. Base address of segment + offset

C. Logical address - limit register

D. Frame number + page offset

Hint

Check the logical region and offset bound before computing its physical location.

Answer B: Physical address = segment base + valid offset.

OS31 gives segment-table base, limit and permissions, then validates (segment,offset) and adds base+offset. B matches, conditional on the offset passing the bound/protection checks. A and D mix in paging components and omit required scaling or displacement, while subtracting a limit is not the segment translation formula. An invalid offset traps rather than spilling into another segment.

Why each choice is right or wrong

A - Incorrect: Page number times frame size is not the segment base-plus-offset translation and omits required mapping.

B - Correct: After segment and bound checks, add the selected segment's physical base to the offset.

C - Incorrect: The limit is a bound for validation, not a number subtracted to form the physical address.

D - Incorrect: Frame terminology belongs to paging, and adding an unscaled frame number is not the segmentation formula.

Primary note proof

Study-note section OS31

> Segmentation uses logical variable-length units such as code, stack and arrays. A segment-table entry provides base, limit and permissions. For (segment,offset), validate the segment and check the bound, then add base+offset. An out-of-range offset traps; it must not spill into the next segment.

Study-note section OS30

> Pages and physical frames have equal fixed size P. Divide virtual address v into page=floor(v/P) and offset=v mod P. The page table maps a page to a frame and protection/status flags. Physical address=frame×P+offset.

Question sources

Operating Systems review questions · Question 23

Question 207 | NS0707

What is Virtual Memory?

A. Extra RAM chips added to a computer

B. A technique using hard disk space as an extension of physical memory, allowing programs larger than physical memory to execute

C. The memory inside the CPU cache

D. Memory used only by the operating system

Hint

Separate a permitted nonresident access from an illegal access and trace the required handling steps.

Answer B: Translated protected address spaces can use backing storage for nonresident portions.

OS32 describes virtual memory as protected translated address spaces with nonresident program portions backed by storage. B gives the disk-backed extension aspect and can allow programs exceeding resident physical memory to execute. It is not a complete definition of virtual memory, nor does it eliminate finite capacity constraints. The other alternatives confuse RAM installation, cache or an OS-only restriction.

Why each choice is right or wrong

A - Incorrect: Installing RAM chips adds physical capacity; virtual-memory translation is a different mechanism.

B - Correct: Backing storage holds nonresident portions, permitting a program's address space to exceed its currently resident physical memory.

C - Incorrect: CPU cache retains copied memory blocks and is not the virtual-address/backing-store mechanism.

D - Incorrect: Processes receive virtual address spaces; virtual memory is not restricted to storage used only by the OS.

Primary note proof

Study-note section OS32

> Virtual memory provides translated, protected address spaces and allows nonresident portions of a program to be backed by storage. It does not add physical RAM or remove all capacity constraints.

Study-note section OS35

> Caching retains copies to accelerate reuse.

Question sources

Operating Systems review questions · Question 24

Question 208 | NS0708

In demand paging, assume the accessed virtual page is valid, permitted and backed by disk, but its contents are not resident and must be read from disk. What event is the page fault in this scenario?

A. A hardware memory error

B. When the CPU tries to access a page not currently in physical memory, requiring the OS to load it from disk

C. An error in the page table

D. When a process exceeds its allocated memory

Hint

Separate a permitted nonresident access from an illegal access and trace the required handling steps.

Answer B: When the CPU tries to access a page not currently in physical memory, requiring the OS to load it from disk

A valid nonresident access traps so the OS can obtain the page contents, update the mapping and restart the access. The specified page is disk-backed and requires a read, making B accurate for this scenario. Page faults in general need not read disk; zero-fill and shared mappings are other cases. Nothing here requires hardware failure, table corruption or exceeding the permitted address range.

Why each choice is right or wrong

A - Incorrect: The trap does not imply damaged memory hardware.

B - Correct: The valid disk-backed page is nonresident, so this access requires the stated page-in.

C - Incorrect: A correct table may intentionally mark a valid page nonresident.

D - Incorrect: The page is explicitly within the valid permitted mapping, so no allocation violation is implied.

Primary note proof

Study-note section OS32

> Demand paging brings a page in when accessed. On a nonresident access: trap, validate mapping/permissions, find a frame or choose a victim, save a dirty victim if needed, obtain contents, update mapping and restart.

Study-note section OS32

> Not every fault reads a disk: some allocate zero-filled pages or establish shared mappings. An illegal access is rejected, not automatically loaded.

Question sources

Operating Systems review questions · Question 25

Question 209 | NS0709

What is Demand Paging?

A. Loading the entire program into memory before execution

B. Loading only the pages that are actually needed during program execution, keeping others on disk until required

C. Allocating memory in fixed partitions

D. Swapping entire processes between memory and disk

Hint

Separate a permitted nonresident access from an illegal access and trace the required handling steps.

Answer B: Bring a page into memory when it is needed/accessed.

OS32 defines demand paging as bringing a page in when accessed. B matches loading only the pages demanded during execution, with disk backing for the described stored portions. Not all pages must literally originate on disk because zero-fill/shared cases exist. Whole-program loading, fixed contiguous partitions and whole-process swapping do not name this per-page demand policy.

Why each choice is right or wrong

A - Incorrect: Loading the entire program before execution is eager loading rather than fetching pages on demand.

B - Correct: Pages are brought in as execution needs them; disk backing is the described common stored-page case.

C - Incorrect: Fixed partitions are a contiguous-allocation arrangement rather than the page-access-triggered loading policy.

D - Incorrect: Moving an entire process is traditional swapping, not the individual-page demand mechanism.

Primary note proof

Study-note section OS32

> Demand paging brings a page in when accessed. On a nonresident access: trap, validate mapping/permissions, find a frame or choose a victim, save a dirty victim if needed, obtain contents, update mapping and restart.

Study-note section OS27

> Swapping traditionally moves a whole process to backing store; paging moves individual pages.

Study-note section OS28

> A contiguous allocation gives a process one continuous region.

Question sources

Operating Systems review questions · Question 26

Question 210 | NS0710

What is the difference between Internal and External Fragmentation?

A. Both are the same type of memory waste

B. Internal fragmentation wastes space inside allocated partitions (allocated > needed); external fragmentation wastes space between allocations

C. External fragmentation occurs in paging systems

D. Internal fragmentation only occurs in virtual memory

Hint

Locate unused space relative to an allocated unit and distinguish total free space from contiguous free space.

Answer B: Internal waste is inside allocations; external holes are between them.

OS29 defines internal fragmentation as unused space inside an allocated unit and external fragmentation as free holes unable to serve a required contiguous request. B states the location distinction. C is not the general definition and needs allocator scope; D adds an unsupported virtual-memory-only restriction. These wastes can arise from allocation geometry rather than the program's CPU behavior.

Why each choice is right or wrong

A - Incorrect: The note explicitly distinguishes internal unused allocation space from external free-hole fragmentation.

B - Correct: Internal space is wasted within an allocation; external waste is free space split between allocations.

C - Incorrect: This does not define the contrast; basic page-frame allocation avoids external fragmentation, though other allocators may differ.

D - Incorrect: Unused space within an allocated unit is not limited by definition to virtual-memory systems.

Primary note proof

Study-note section OS29

> Internal fragmentation is unused space inside an allocated unit. External fragmentation is sufficient total free space split into holes that cannot satisfy a required contiguous allocation.

Study-note section OS29

> Basic fixed-frame paging avoids external fragmentation of page-frame allocation but can waste the final page internally.

Question sources

Operating Systems review questions · Question 27

Question 211 | NS0711

Which memory allocation strategy picks the first hole large enough to accommodate a process?

A. Best-Fit

B. Worst-Fit

C. First-Fit

D. Next-Fit

Hint

Apply the stated hole-selection or base-and-bound rule with its explicit convention.

Answer C: First-fit.

OS28 defines first-fit as selecting the first adequate hole. This is exactly the stem's first hole large enough. Best-fit searches for the smallest adequate hole, worst-fit for the largest, and next-fit resumes from a prior search position. The explicit first-hole condition selects first-fit without any numeric hole trace.

Why each choice is right or wrong

A - Incorrect: Best-fit minimizes adequate hole size rather than stopping at the first adequate hole.

B - Incorrect: Worst-fit selects the largest available hole rather than the first adequate one encountered.

C - Correct: First-fit stops at the first hole that can accommodate the requested allocation.

D - Incorrect: Next-fit continues from the previous search position; the stem gives the ordinary first-fit criterion.

Primary note proof

Study-note section OS28

> First-fit selects the first adequate hole; next-fit continues from the previous search position; best-fit selects the smallest adequate hole; worst-fit selects the largest.

Question sources

Operating Systems review questions · Question 28

Question 212 | NS0712

What is Swapping in OS memory management?

A. Exchanging CPU registers between processes

B. Temporarily moving an entire process from main memory to a backing store (disk) to free memory for other processes

C. Copying files between directories

D. Replacing old CPU instructions with new ones

Hint

Track when an address or library reference is resolved and the direction of translation.

Answer B: Temporarily move a whole process to backing store.

OS27 explicitly distinguishes traditional swapping of a whole process to backing store from paging individual pages and context switching execution state. B describes the whole-process memory-management operation. Saving registers is a context-switch task, file copying is a filesystem operation, and replacing instruction contents does not define swapping's residence change.

Why each choice is right or wrong

A - Incorrect: Saving/restoring CPU register contexts is context switching rather than moving a whole process out of RAM.

B - Correct: Traditional swapping moves a process image to backing storage to free resident memory.

C - Incorrect: Copying files changes directory/storage contents rather than a process image's memory residence.

D - Incorrect: Replacing instruction contents is not the defined transfer of a whole process between RAM and backing store.

Primary note proof

Study-note section OS27

> Swapping traditionally moves a whole process to backing store; paging moves individual pages. These differ from a context switch, which primarily changes execution state.

Study-note section OS05

> A context switch saves one execution context and restores another; useful application work is interrupted by this overhead.

Question sources

Operating Systems review questions · Question 29

Question 213 | NS0713

What is Dynamic Loading?

A. Loading the entire program into memory at startup

B. Loading routines from disk into memory only when they are actually called during execution

C. Dynamically changing the priority of a process

D. Moving pages between RAM and disk automatically

Hint

Track when an address or library reference is resolved and the direction of translation.

Answer B: Load a routine only when needed.

OS27 directly defines dynamic loading as bringing a routine in when needed. B states the routine-on-call form of that rule. Eager startup loading is the opposite, priority changes are scheduling, and automatic page movement is a virtual-memory mechanism at a different granularity. Dynamic loading concerns when code routines become resident, not which process gets CPU priority.

Why each choice is right or wrong

A - Incorrect: Loading all routines at startup is eager loading rather than bringing them in only on demand.

B - Correct: A routine is loaded when execution actually calls or needs it, matching dynamic loading.

C - Incorrect: Changing priority affects scheduling and does not load a routine's code into memory.

D - Incorrect: Paging moves pages by virtual-memory demand, whereas dynamic loading names demand-driven routine loading.

Primary note proof

Study-note section OS27

> Dynamic loading brings a routine in when needed.

Study-note section OS32

> Demand paging brings a page in when accessed.

Study-note section OS17

> Priority scheduling chooses the highest-priority ready job.

Question sources

Operating Systems review questions · Question 30

Question 214 | NS0714

What is the key management-layer distinction between user-level threads and kernel-level threads, without assuming universal speed or reliability advantages?

A. User-level threads are managed by a user-space library; kernel-level threads are known to and managed by the OS

B. Kernel-level threads are always faster

C. User-level threads can access hardware directly

D. There is no practical difference between them

Hint

Compare per-thread execution context with shared process resources and the stated thread mapping.

Answer A: User-level threads are managed by a user-space library; kernel-level threads are known to and managed by the OS

User-level threads are managed by a library, while kernel threads are execution contexts known to the OS. Their mapping affects blocking behavior and use of multiple CPUs. The management layer alone does not guarantee faster creation, faster execution or greater stability; those depend on implementation. It also does not grant user code privileged hardware access. The option keeps the supported management distinction.

Why each choice is right or wrong

A - Correct: This states library management versus OS-known kernel threads.

B - Incorrect: No management layer guarantees that kernel threads are always faster.

C - Incorrect: User-level thread management does not grant direct privileged hardware access.

D - Incorrect: Blocking and CPU-use differences show that the distinction has practical effects.

Primary note proof

Study-note section OS08

> User-level threads are managed by a library; kernel threads are known to the OS. In many-to-one mapping, a blocking kernel call can block all user threads and one kernel execution context cannot use multiple CPUs simultaneously. One-to-one permits another kernel thread to run when one blocks. Many-to-many multiplexes user threads over several kernel threads. Speed and reliability depend on implementation; the management layer alone guarantees neither. Application names such as browser or Excel do not prove a particular version’s threading model.

Study-note section OS-S02

> Being scheduled or managed by the kernel does not give application thread code kernel privilege. Ordinary applications and supporting utilities execute in restricted user mode and request protected services through libraries and system calls. Kernel component code executes in privileged kernel mode and performs permitted low-level hardware operations.

Question sources

Operating Systems review questions · Question 31

Question 215 | NS0715

What is IPC (Inter-Process Communication)?

A. A CPU scheduling algorithm

B. Mechanisms allowing processes to exchange information, synchronize, and coordinate activities

C. A method for allocating memory between processes

D. A file system operation

Hint

Identify how data moves, which participant waits and what event allows the operation to continue.

Answer B: Mechanisms for exchanging information and coordinating processes.

OS09 describes shared-memory communication, send/receive, pipes, queues, sockets and RPC, including synchronization for conflicting updates. B summarizes the exchange and coordination role. IPC is not a CPU selection algorithm or a particular memory-allocation/file operation, even though shared memory and file-based mechanisms may be used to implement it.

Why each choice is right or wrong

A - Incorrect: CPU scheduling selects execution opportunities, rather than defining communication and coordination among processes.

B - Correct: Exchanging information with appropriate synchronization/coordination captures the IPC mechanisms described here.

C - Incorrect: Shared memory can implement IPC, but memory allocation alone does not define interprocess communication.

D - Incorrect: Files can participate in communication, but IPC is not restricted to one filesystem operation.

Primary note proof

Study-note section OS09

> Shared memory lets processes access a common region and requires synchronization for conflicting updates. Message passing exchanges data through send/receive operations. Pipes provide streams; message queues preserve messages; sockets connect endpoints; RPC requests a remote operation. HTTP is an application protocol over a communication mechanism and can carry interprocess communication, so it is not universally “not IPC.”

Study-note section OS09

File locks coordinate access rather than transfer arbitrary payloads, though locking is synchronization within IPC.

Question sources

Operating Systems review questions · Question 32

Question 216 | NS0716

What is the Critical Section problem concerned with?

A. Preventing processes from using too much CPU

B. Ensuring that no two processes are executing their critical sections (code accessing shared resources) simultaneously

C. Managing disk I/O operations

D. Scheduling processes in real-time systems

Hint

Identify conflicting shared accesses and the safety or progress property required.

Answer B: Mutually exclude conflicting critical-region execution.

OS10 defines a critical section as code accessing shared state needing protection and lists mutual exclusion, progress and bounded waiting as requirements. B states the exclusion aspect for critical sections protecting the same conflicting resource. The problem also includes progress/fair-waiting requirements, so exclusion is not its entire specification. CPU quotas, disk management and real-time scheduling are different topics.

Why each choice is right or wrong

A - Incorrect: CPU consumption limits are not the shared-access exclusion problem defining critical sections.

B - Correct: Conflicting critical regions must not execute simultaneously; this is the mutual-exclusion part of the correctness requirements.

C - Incorrect: Disk I/O can involve shared state, but managing it generally is not the critical-section problem definition.

D - Incorrect: Real-time selection addresses timing/scheduling, not the core shared-state exclusion requirement requested.

Primary note proof

Study-note section OS10

A race occurs when results depend on uncoordinated interleaving of conflicting accesses. A critical section is code accessing shared state that needs protection, not the resource itself. A correct exclusion solution requires mutual exclusion, progress and bounded waiting under stated assumptions. Mutual exclusion is a desired safety property; races, starvation and deadlock are possible failures.

Study-note section OS10

Keep critical regions small and ensure every conflicting access uses the same protection. A barrier waits until a defined set of participants reaches a point; a monitor encapsulates protected operations with condition synchronization. Locking can itself introduce deadlock if acquisition order is inconsistent.

Question sources

Operating Systems review questions · Question 33

Question 217 | NS0717

For a general process that may perform I/O, which formula defines turnaround time from event timestamps? Waiting means time in the ready queue; burst means total CPU service. The formula must remain valid for nonzero arrival times and blocked intervals.

A. Burst Time - Waiting Time

B. Completion Time - Arrival Time

C. Start Time + Burst Time

D. Waiting Time + Burst Time

Hint

Construct a timeline and distinguish completion rates from individual elapsed-time measures.

Answer B: Completion Time - Arrival Time

Turnaround is completion time minus arrival time, including CPU execution, ready-queue waiting and blocked intervals. Ready waiting plus CPU service omits blocked time when I/O occurs. Start plus burst may resemble a completion timestamp for uninterrupted work, but it is not elapsed turnaround and does not subtract arrival. Burst minus waiting has no general elapsed-time interpretation. Only B remains valid in the full stated model.

Why each choice is right or wrong

A - Incorrect: Subtracting ready waiting from CPU service is not turnaround.

B - Correct: Completion minus arrival includes the entire elapsed lifetime.

C - Incorrect: Start plus burst is not generally completion with I/O and does not subtract arrival.

D - Incorrect: Ready waiting plus CPU service omits blocked intervals.

Primary note proof

Study-note section OS13

> For arrival A, first start S and completion C, response=S−A and turnaround=C−A. For a single CPU burst B with no I/O, waiting=C−A−B. With I/O, subtract all CPU and blocked time to isolate ready-queue waiting.

Question sources

Operating Systems review questions · Question 34

Question 218 | NS0718

What is the Convoy Effect in FCFS scheduling?

A. High-priority processes always complete first

B. All processes receive equal CPU time

C. Short processes get stuck waiting behind one very long process, causing high average waiting times

D. Multiple processes share the same memory space

Hint

Follow arrival order, include idle periods and distinguish waiting from completion time.

Answer C: Short jobs wait behind a long FCFS burst.

OS15 describes the convoy effect as long CPU-bound work making many short jobs wait under non-preemptive FCFS. C directly states that queueing effect and its high waiting-time consequence. FCFS does not use priority order or grant equal total CPU, and shared address space is unrelated to the arrival-order delay. The effect depends on a long burst preceding shorter ones.

Why each choice is right or wrong

A - Incorrect: Priority order does not define FCFS, which follows arrival order rather than high-priority completion.

B - Incorrect: FCFS serves entire bursts of possibly different lengths rather than enforcing equal CPU shares.

C - Correct: Short jobs are delayed behind the long non-preempted burst, producing the FCFS convoy effect.

D - Incorrect: Shared memory concerns address-space organization rather than the scheduling delay called a convoy.

Primary note proof

Study-note section OS15

> FCFS runs ready bursts in arrival order and ordinarily does not preempt. If the CPU is idle, jump to the next arrival. Long CPU-bound work can make many short jobs wait: the convoy effect.

Study-note section OS18

> RR gives recurring opportunities, not identical total CPU consumption for jobs of different lengths.

Study-note section OS08

> A thread has its own PC, registers and stack. Threads in a process share code, address space and usually open-file resources.

Question sources

Operating Systems review questions · Question 35

Question 219 | NS0719

What is Cooperative (Non-Preemptive) vs Preemptive Scheduling?

A. They are the same thing

B. Non-preemptive: process runs until it voluntarily releases CPU; Preemptive: OS can forcibly take CPU from a running process for another

C. Preemptive scheduling never interrupts processes

D. Non-preemptive scheduling always gives better performance

Hint

Check whether the running burst can be interrupted before completion or blocking.

Answer B: Voluntary release versus possible forced CPU preemption.

OS14 says non-preemptive scheduling retains the CPU until completion, blocking or voluntary yielding, while preemptive scheduling may return running work to ready. B captures the voluntary-versus-forced distinction, with completion/blocking included among natural release events. C contradicts preemption, D claims an unsupported universal performance ranking, and A erases the defining difference.

Why each choice is right or wrong

A - Incorrect: The policies differ in whether a running CPU burst can be forcibly interrupted for another process.

B - Correct: Non-preemptive work releases naturally/voluntarily; preemptive policy may forcibly reassign CPU execution time.

C - Incorrect: Forcibly interrupting running work is exactly what preemptive scheduling permits.

D - Incorrect: No policy universally performs better for all workloads and objectives, so the absolute performance claim fails.

Primary note proof

Study-note section OS14

> Non-preemptive scheduling keeps a running CPU burst until completion, blocking or voluntary yielding. Preemptive scheduling can return running work to ready, usually after a timer quantum or a more urgent arrival. FCFS and non-preemptive SJF are non-preemptive; RR and SRTF are preemptive. Priority can be either, so its name alone cannot decide. Cooperative describes relying on voluntary release.

Study-note section OS21

> There is no universally best policy for response, waiting, fairness and throughput simultaneously.

Question sources

Operating Systems review questions · Question 36

Question 220 | NS0720

Which scheduling criterion measures the number of processes completed per unit of time?

A. CPU Utilization

B. Response Time

C. Throughput

D. Turnaround Time

Hint

Construct a timeline and distinguish completion rates from individual elapsed-time measures.

Answer C: Throughput.

OS13 defines throughput as completed jobs divided by elapsed time. That exactly matches the stem's process-completion rate. CPU utilization is busy-time fraction; response measures delay to first start, and turnaround delay to completion. The units therefore distinguish throughput from the other criteria without requiring a scheduling example.

Why each choice is right or wrong

A - Incorrect: CPU utilization measures busy-time fraction, not how many processes finish per unit time.

B - Incorrect: Response measures first-service delay for a process rather than a completion-count rate.

C - Correct: Throughput is explicitly the number of completed jobs divided by elapsed time.

D - Incorrect: Turnaround measures arrival-to-completion elapsed duration rather than completed jobs per time.

Primary note proof

Study-note section OS13

> For arrival A, first start S and completion C, response=S−A and turnaround=C−A. For a single CPU burst B with no I/O, waiting=C−A−B. With I/O, subtract all CPU and blocked time to isolate ready-queue waiting. Throughput=completed jobs/elapsed time; CPU utilization=busy time/elapsed time. Minimize response/turnaround/waiting under the selected goal and maximize useful throughput/utilization.

Question sources

Operating Systems review questions · Question 37

Question 221 | NS0721

What does the Job Queue contain?

A. Only processes currently running on the CPU

B. All processes currently in the system, including those not yet admitted to memory

C. Only processes waiting for I/O devices

D. Processes that have already terminated

Hint

Decide whether the process is eligible, running or waiting, then identify the responsible queue or scheduling role.

Answer B: All processes in the broad textbook system/job-queue sense.

OS06 explicitly defines the broad textbook job queue as processes in the system and distinguishes a narrower admission queue awaiting memory. B matches that broad usage, including not-yet-admitted jobs. Ready/running or I/O-blocked work are subsets, not the whole category; already-ended processes are not the intended current job population. The answer retains the note's terminology qualification.

Why each choice is right or wrong

A - Incorrect: Currently running work is only a subset, not the broad population represented by the textbook job queue.

B - Correct: The broad textbook usage includes system processes/jobs, including those awaiting memory admission.

C - Incorrect: I/O waiting belongs to device queues and does not exhaust the broad job-queue population.

D - Incorrect: Already-terminated work is not the current job population intended here's broad system queue.

Primary note proof

Study-note section OS06

> The ready queue contains eligible work; device queues hold blocked requests. The broad textbook job queue contains processes in the system, while an admission queue more narrowly holds jobs awaiting memory/admission. Long-term scheduling admits jobs; medium-term scheduling suspends/swaps them; short-term scheduling selects ready work.

Study-note section OS06

> New processes are created/admitted; ready means eligible for CPU but not currently running. Running uses a CPU. Waiting/blocked means unable to proceed until an event; terminated means execution has ended. Running→ready follows time-slice expiry or another preemption. Running→waiting follows blocking I/O. I/O completion normally gives waiting→ready, not a guaranteed immediate running state.

Question sources

Operating Systems review questions · Question 38

Question 222 | NS0722

In an open seekable file’s state, what does its current file-offset field (the file-position pointer, rather than the descriptor handle) track?

A. The physical location of the file on disk

B. The current position within an open file for the next read or write operation

C. The owner's access permissions

D. The file's creation timestamp

Hint

Distinguish a file operation, a resource handle, an offset and file metadata.

Answer B: The current position within an open file for the next read or write operation

The current offset records the logical position used for the next read or write on a seekable open file. A descriptor is instead a process-local integer handle referring to open-file state. Physical disk-block locations, permissions and creation timestamps describe other mapping or metadata information. By asking specifically about the position field, the revised stem makes B precise without conflating a descriptor with an offset.

Why each choice is right or wrong

A - Incorrect: Physical disk location is separate from the current logical I/O offset.

B - Correct: The file-offset field records the position for the next read or write.

C - Incorrect: Owner permissions are access-control metadata rather than the current position.

D - Incorrect: Creation time is metadata rather than the current I/O offset.

Primary note proof

Study-note section OS36

> A file has content and metadata such as name, size, owner, permissions and timestamps. open obtains an open-file reference, read/write transfer bytes, seek changes an offset, close releases a reference, truncate changes size and unlink removes a name. A file descriptor is a process-local integer handle; the associated open-file state contains the current offset and access mode. Descriptor and offset are not synonyms.

Study-note section OS36

> Read advances the offset on seekable files and may return fewer bytes than requested; zero normally indicates end-of-file.

Question sources

Operating Systems review questions · Question 39

Question 223 | NS0723

What is the purpose of an Access Control List (ACL) in file protection?

A. To track disk space usage

B. To specify exactly which users/groups have which types of access (read, write, execute) to each file

C. To manage disk fragmentation

D. To schedule file I/O operations

Hint

Distinguish identity checks, permission checks and the particular security property at issue.

Answer B: Specify principals and permitted access rights.

OS39 defines an ACL as listing principals and rights. B states that users/groups can receive different read/write/execute permissions for a file. Authentication verifies identity first; authorization uses these permitted operations. Space accounting, fragmentation and I/O ordering do not define an access-control list. The answer does not assume universal default rights or that every filesystem uses exactly the same permission model.

Why each choice is right or wrong

A - Incorrect: Disk-space usage is storage accounting, not the list of principals and allowed operations.

B - Correct: An ACL associates users/groups or other principals with specified access rights on the resource.

C - Incorrect: Fragmentation concerns block placement and free-space layout rather than authorization entries.

D - Incorrect: Scheduling I/O requests controls service order, not which principal is authorized to access a file.

Primary note proof

Study-note section OS39

> Authentication verifies identity; authorization checks permitted operations. An ACL lists principals and rights; owner/group/other bits are a simpler policy model, not universal defaults granting all owners full access or everyone read. Read, write, execute, append and delete are different rights, with filesystem-specific rules.

Study-note section OS29

> Internal fragmentation is unused space inside an allocated unit. External fragmentation is sufficient total free space split into holes that cannot satisfy a required contiguous allocation.

Study-note section OS06

> The ready queue contains eligible work; device queues hold blocked requests.

Question sources

Operating Systems review questions · Question 40

Question 224 | NS0724

What is Contiguous Allocation of disk space?

A. Files are stored in scattered blocks linked by pointers

B. Each file occupies a continuous set of consecutive disk blocks, enabling fast sequential and direct access

C. Files are indexed using a separate index block

D. Files are allocated in fixed-size frames

Hint

Trace how logical file blocks reach physical blocks and account for pointer metadata.

Answer B: A file occupies consecutive disk blocks.

OS38 defines contiguous allocation through consecutive blocks, with logical block i at start+i. This permits sequential and direct access without following a chain. B matches. Scattered pointers describe linked allocation, a separate index describes indexed allocation, and fixed physical memory frames belong to paging rather than file-contiguity organization. Growth and external fragmentation remain drawbacks.

Why each choice is right or wrong

A - Incorrect: Scattered blocks linked by pointers describe linked allocation rather than one consecutive run.

B - Correct: A consecutive block run supports start-plus-index lookup and sequential/direct file access.

C - Incorrect: A separate block-pointer index describes indexed allocation, not contiguous placement itself.

D - Incorrect: Physical memory frames are paging units rather than the disk-block contiguity rule for a file.

Primary note proof

Study-note section OS38

> Contiguous allocation uses consecutive blocks; logical block i is start+i and supports direct access, but growth and external fragmentation are problems. Extents allow several contiguous runs. Linked allocation chains blocks and supports growth without reserving a complete contiguous file; locating block i requires traversing preceding links. FAT stores chains in a table; caching that table does not change the chain into a direct arithmetic mapping.

Study-note section OS38

> Indexed allocation uses a per-file array/tree of block pointers and supports direct lookup with metadata overhead.

Study-note section OS30

> Pages and physical frames have equal fixed size P.

Question sources

Operating Systems review questions · Question 41

Question 225 | NS0725

What problem does Linked Allocation solve compared to Contiguous Allocation?

A. It speeds up random access

B. It eliminates external fragmentation and pre-known file size requirements since blocks can be scattered and linked anywhere

C. It reduces internal fragmentation

D. It requires less memory for storing file metadata

Hint

Trace how logical file blocks reach physical blocks and account for pointer metadata.

Answer B: Linked blocks permit growth without reserving a full contiguous run.

OS38 says linked allocation supports growth without reserving a complete contiguous file. Since successive blocks can occupy separate free locations, it removes the external-contiguity problem and the need to reserve the final length beforehand. B captures that advantage. Random access still requires traversing earlier links, internal last-block waste may remain, and no universal smaller-metadata claim follows.

Why each choice is right or wrong

A - Incorrect: Locating a later linked block requires traversal, so faster random access is not its general advantage.

B - Correct: Separate linked blocks allow incremental growth without a single reserved contiguous region or preknown final length.

C - Incorrect: A partially used final block can still waste space internally; linking does not specifically remove that waste.

D - Incorrect: Pointers add metadata, and the note gives no universal less-memory guarantee over contiguous allocation.

Primary note proof

Study-note section OS38

> Contiguous allocation uses consecutive blocks; logical block i is start+i and supports direct access, but growth and external fragmentation are problems. Extents allow several contiguous runs.

Linked allocation chains blocks and supports growth without reserving a complete contiguous file; locating block i requires traversing preceding links. FAT stores chains in a table; caching that table does not change the chain into a direct arithmetic mapping.

Study-note section OS29

Internal fragmentation is unused space inside an allocated unit. External fragmentation is sufficient total free space split into holes that cannot satisfy a required contiguous allocation.

Question sources

Operating Systems review questions · Question 42

Question 226 | NS0726

In Indexed Allocation, what is the Index Block?

A. A pointer stored in each data block to the next block

B. A dedicated block containing all the disk-block addresses (pointers to data blocks) for a specific file

C. A table stored at the beginning of the disk for all files

D. A block that stores file metadata like size and timestamps

Hint

Trace how logical file blocks reach physical blocks and account for pointer metadata.

Answer B: A per-file block of data-block pointers in the simple indexed model.

OS38 defines indexed allocation through a per-file array/tree of block pointers and gives an index-block capacity example. B describes the simple single-index-block form. Large files may need multiple index levels, so all addresses in one block is model-dependent rather than universal. A is linked allocation, C a global-table description, and D ordinary metadata without the defining data-block pointers.

Why each choice is right or wrong

A - Incorrect: A next pointer in each data block describes linked allocation rather than a separate per-file index.

B - Correct: In the simple indexed model, a dedicated per-file index contains pointers to the file's data blocks.

C - Incorrect: A global table for all files is not the per-file index block described by indexed allocation.

D - Incorrect: Size/timestamps alone do not provide the data-block address index that defines this allocation structure.

Primary note proof

Study-note section OS38

Indexed allocation uses a per-file array/tree of block pointers and supports direct lookup with metadata overhead. A Unix inode can combine direct pointers with indirect levels. Check pointer size, block size, index capacity and whether metadata reads are cached.

Study-note section OS38

A 1024-byte index block with 4-byte pointers holds 256 block addresses. With 1024-byte data blocks, one such index level addresses 256 KiB of file data, excluding metadata and any reserved entries.

Study-note section OS38

FAT stores chains in a table; caching that table does not change the chain into a direct arithmetic mapping.

Question sources

Operating Systems review questions · Question 43

Question 227 | NS0727

What is the difference between Sequential Access and Direct Access for files?

A. They are identical access methods

B. Sequential access reads/writes records in order; direct access allows jumping to any block/record position by specifying its block number

C. Direct access is only possible for text files

D. Sequential access requires more disk space

Hint

Trace how logical file blocks reach physical blocks and account for pointer metadata.

Answer B: Sequential access proceeds in order; direct access selects a position.

OS38 contrasts linked traversal of preceding blocks with contiguous start+i and indexed direct lookup. These illustrate the access distinction in B: sequential progression versus selecting a numbered position without reading every preceding record. Nothing restricts direct access to text or requires sequential files to occupy more disk space merely because of their access method.

Why each choice is right or wrong

A - Incorrect: Order-dependent traversal and direct selection are different access behaviors, not identical methods.

B - Correct: Sequential access advances through records; direct access identifies a chosen block/position for access.

C - Incorrect: The direct block-lookup rule does not impose a text-file-only restriction.

D - Incorrect: Access order alone does not determine a greater storage-space requirement for sequential files.

Primary note proof

Study-note section OS38

> Contiguous allocation uses consecutive blocks; logical block i is start+i and supports direct access, but growth and external fragmentation are problems. Extents allow several contiguous runs. Linked allocation chains blocks and supports growth without reserving a complete contiguous file; locating block i requires traversing preceding links. FAT stores chains in a table; caching that table does not change the chain into a direct arithmetic mapping.

Study-note section OS38

> Indexed allocation uses a per-file array/tree of block pointers and supports direct lookup with metadata overhead.

Question sources

Operating Systems review questions · Question 44

Question 228 | NS0728

What is a Tree-Structured Directory?

A. A directory where all files are in one flat list

B. A hierarchical directory organization with a root directory from which subdirectories and files branch out, each file having a unique path

C. A directory shared among multiple users

D. A temporary directory deleted on reboot

Hint

Follow namespace structure and distinguish names, underlying files and mounted filesystems.

Answer B: A rooted hierarchy of nested directories and files.

OS37 says a tree allows nested directories and absolute/relative paths. In the pure tree model, each entry has a path from the root, matching B. Flat lists instead describe single-level organization; sharing among users and deletion at reboot do not define tree structure. Links can add graph relationships, but that is an extension beyond the pure tree premise.

Why each choice is right or wrong

A - Incorrect: One flat file list is single-level organization rather than nested branches from a root.

B - Correct: A root with nested subdirectories and paths is the tree hierarchy described here.

C - Incorrect: Multiple users sharing a directory does not by itself define its structural hierarchy.

D - Incorrect: Deletion on reboot is a lifetime policy rather than the rooted directory-tree organization.

Primary note proof

Study-note section OS37

> A single-level directory requires unique names in one namespace. Two-level directories separate users. A tree allows nested directories and absolute/relative paths; links can create shared graphs. Modern general-purpose systems commonly present hierarchical namespaces, but a feature name alone does not prove that every system excludes simpler arrangements.

Question sources

Operating Systems review questions · Question 45

Question 229 | NS0729

What is the difference between Hard Links and Symbolic Links in file systems?

A. Hard links can span different file systems; symbolic links cannot

B. Hard links create multiple directory entries pointing to the same file's data blocks; symbolic links are special files containing the path to another file

C. Symbolic links cannot be deleted

D. Hard links are only supported in Windows

Hint

Follow namespace structure and distinguish names, underlying files and mounted filesystems.

Answer B: Hard links name one file object; symbolic links store a pathname.

A hard link supplies another name for the same underlying file object; a symbolic link stores a pathname. Symbolic links can cross filesystems and may dangle, whereas ordinary hard links stay within a filesystem. Linux's link operation supplies a direct counterexample to the Windows-only claim. unlink can remove a symbolic-link name, so the link is not undeletable. B states the correct distinction.

Why each choice is right or wrong

A - Incorrect: The boundary is reversed: symbolic links may cross filesystems, while ordinary hard links remain within one.

B - Correct: Both hard-link names identify the same underlying file; a symbolic link contains a pathname to resolve.

C - Incorrect: A symbolic-link name can be removed with unlink; removing it does not erase the target's contents.

D - Incorrect: Linux provides hard links through link(), so they are not supported only in Windows.

Primary note proof

Study-note section OS37

> A hard link is another name for the same underlying file object, usually within one filesystem; a symbolic link stores a pathname and can point across filesystems or become dangling. Removing one hard link does not erase content while other names/open references retain it.

Study-note section OS-S06

> Linux provides link() to create another hard-link name for an existing file. The old and new names identify the same file, so hard links are not a Windows-only facility. unlink() removes a filesystem name; when that name is a symbolic link, it removes the link itself. Removing a name and erasing the target's contents are different operations.

Question sources

Operating Systems review questions · Question 46

Question 230 | NS0730

What is File System Mounting?

A. Creating a new file system

B. The process of attaching a file system to a specific location in the existing directory tree, making it accessible

C. Deleting old files to free disk space

D. Formatting a disk partition

Hint

Follow namespace structure and distinguish names, underlying files and mounted filesystems.

Answer B: Attach a filesystem at a mount point.

OS37 explicitly defines mounting as attaching a filesystem at a mount point and distinguishes it from formatting. B states that integration into the existing namespace. Creation/formatting establish a filesystem's on-device structure; deleting files frees content space. None of those is the namespace attachment operation requested by mounting.

Why each choice is right or wrong

A - Incorrect: Creating a new filesystem establishes storage structure rather than attaching it to an existing namespace.

B - Correct: Mounting makes a filesystem accessible at a chosen point in the directory hierarchy.

C - Incorrect: Deleting files changes contents/free space rather than attaching a filesystem to the namespace.

D - Incorrect: Formatting is explicitly distinguished from mounting in the supplied note.

Primary note proof

Study-note section OS37

> NFS provides remote filesystem access; FTP transfers files rather than itself mounting a local filesystem.

Study-note section OS35

> Disk initialization/filesystem creation is OS/tool work, firmware begins boot, and drive firmware may remap bad sectors.

Question sources

Operating Systems review questions · Question 47

Question 231 | NS0731

In the context of deadlock recovery, what is 'Rollback'?

A. Restarting the entire operating system

B. Returning a preempted process to a safe previous state after resources are taken back from it during deadlock resolution

C. Deleting all processes involved in a deadlock

D. Rebooting the computer to free all resources

Hint

Separate handling before allocation from actions taken after detection, and consider the cost of checking.

Answer B: Restore an affected process to a prior checkpoint after reclaiming resources.

OS26 describes reclaiming safely preemptable resources and rolling affected work back to a checkpoint. B states that restoration to a safe prior state after resources are withdrawn. Restarting the entire OS/computer and killing all involved processes are different coarse recovery actions, not the meaning of rollback. Safe checkpoints/restart semantics are required to make withdrawal and restoration coherent.

Why each choice is right or wrong

A - Incorrect: Restarting the whole OS is not the checkpoint restoration of affected work that defines rollback.

B - Correct: Rollback restores an affected process to a previous recoverable state after safe resource reclamation.

C - Incorrect: Terminating processes is a separate recovery tool rather than restoring their earlier execution state.

D - Incorrect: Rebooting frees broad machine state but is not the process-checkpoint restoration definition of rollback.

Primary note proof

Study-note section OS26

> Detection asks whether the current state is deadlocked. Recovery can terminate selected processes or reclaim safely preemptable resources and roll affected work back to a checkpoint. Termination and rollback are both possible recovery tools; choose according to the resource and process conditions.

Question sources

Operating Systems review questions · Question 48

Question 232 | NS0732

What is the purpose of relocation/base and limit registers in the standard contiguous single-process-region memory model? The limit denotes the permitted region length.

A. They speed up CPU scheduling decisions

B. The relocation register stores the process's physical base and the limit its permitted length; hardware checks the logical offset before adding the base

C. They track file system locations on disk

D. They manage virtual memory page tables

Hint

Apply the stated hole-selection or base-and-bound rule with its explicit convention.

Answer B: The relocation register stores the process's physical base and the limit its permitted length; hardware checks the logical offset before adding the base

In the standard base/limit model, the base identifies the process's physical starting address and the limit gives its permitted length. Hardware checks that the logical offset is nonnegative and smaller than the limit, then computes base plus offset. This protects accesses to the assigned region. The registers do not describe the OS base and size, schedule CPU work, track disk files or manage page tables.

Why each choice is right or wrong

A - Incorrect: These registers check memory accesses rather than schedule CPU work.

B - Correct: The option states the process base, length bound and checked translation.

C - Incorrect: Disk-block locations are not the purpose of RAM base/limit registers.

D - Incorrect: Simple contiguous base/limit translation does not manage page-table mappings.

Primary note proof

Study-note section OS28

> A contiguous allocation gives a process one continuous region. In the standard base/limit model, base is that process's physical starting address and limit is its permitted length. Check 0≤logical_offset<limit, then physical=base+offset. The relocation register does not normally hold the OS base.

Study-note section OS30

> Pages and physical frames have equal fixed size P. Divide virtual address v into page=floor(v/P) and offset=v mod P. The page table maps a page to a frame and protection/status flags.

Question sources

Operating Systems review questions · Question 49

Question 233 | NS0733

In Dynamic Linking, what is a key advantage over Static Linking?

A. Programs run faster with dynamic linking

B. Multiple programs share one copy of library code in memory rather than each program embedding its own copy, saving memory

C. Dynamic linking eliminates the need for a page table

D. Dynamically linked programs cannot have bugs

Hint

Track when an address or library reference is resolved and the direction of translation.

Answer B: Share suitable library code pages across programs.

OS27 says dynamic linking resolves external-library references at load/runtime and allows suitable library code pages to be shared, whereas static linking copies selected code into the executable. B captures the potential memory saving. It is not an unconditional speed guarantee, does not remove address translation/page tables and cannot eliminate programming bugs. Only shareable code/pages are implied, not arbitrary writable library state.

Why each choice is right or wrong

A - Incorrect: Dynamic resolution/sharing does not guarantee faster execution for every program or workload.

B - Correct: Several processes can share suitable library code pages rather than each embedding a separate static copy.

C - Incorrect: Library linking does not remove virtual-address translation or its page-table requirements.

D - Incorrect: Choosing dynamic rather than static linking cannot guarantee the absence of programming errors.

Primary note proof

Study-note section OS27

> Dynamic linking resolves references to external libraries at load/runtime, allowing suitable library code pages to be shared; static linking copies selected code into the executable.

Study-note section OS30

> Pages and physical frames have equal fixed size P. Divide virtual address v into page=floor(v/P) and offset=v mod P. The page table maps a page to a frame and protection/status flags.

Question sources

Operating Systems review questions · Question 50

Software Engineering

Questions & Worked Answers

278 questions

Question 1 | Q00003

A company delivers registration first, then adds payments and reporting, each as a usable delivery. Which model specifically names this addition-of-functionality strategy, independent of whether earlier features are also refined?

A. Waterfall

B. Incremental

C. Spiral

D. Evolutionary

Hint

Identify whether the scenario prioritizes delivery, learning, adaptation or risk reduction. Several processes can share individual practices, so compare their defining emphasis.

Answer B: Incremental

The delivery strategy adds usable capabilities in stages so that end users receive a valuable subset before the complete product is ready. Incremental development names that addition of functionality. Evolutionary development broadly emphasizes refinement and can overlap with increments, but does not specifically name the stated delivery distinction. Spiral is organized around risk-reduction cycles, and classical waterfall normally delays usable delivery until its planned development phases are complete.

Why each choice is right or wrong

A - Incorrect: Classical waterfall organizes sequential phases rather than prioritizing staged usable subsets.

B - Correct: Incremental development adds usable capability in successive deliveries.

C - Incorrect: Spiral names risk-driven cycles; those may contain increments without defining this delivery strategy.

D - Incorrect: Evolutionary refinement can overlap with increments, but the question asks the specific name for adding usable functionality.

Primary note proof

Study-note section SE04

> Choose incremental delivery when prioritized partial capability must reach users early. Smaller changes can be easier to debug and permit feedback, though architecture and integration still require planning. Iteration need not rebuild the whole system every time, and increments need

not be perfectly independent modules. Broad descriptions of early working software can fit prototypes, iterative or Agile processes; identify the purpose of that early version.

Study-note section SE06

Spiral development is risk driven. Each cycle identifies objectives and alternatives, assesses and reduces important risks, develops/verifies an appropriate next result, and plans further commitment. A prototype may test a risky technology before a large investment. The amount and type of work depend on the risks.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 22 | lines 8-12

This model delivers software in small but usable pieces, called —increments. In general, each increment builds on those that have already been delivered. The model is iterative in nature and focuses on the delivery of an operational product with each increment. Early increments are stripped down versions of the final product, but they do provide capability that serves the user and
also provide a platform for evaluation by the user.

Software Engineering module | PDF page 20 | lines 18-22

the development plan. Its major problem is the inflexible partitioning of the project into distinct stages. Commitments must be made at an early stage in the process, which makes it difficult to respond to changing customer requirements.
In principle, the waterfall model should only be used when the requirements are well understood
and unlikely to change radically during system development. However, the waterfall model

Question sources

MOE Computer Science Exit Exam · 2016 · Question 3

Question 2 | Q00010

If you want to test individual sub-systems of software, which phase of software testing is appropriate?

A. Integration testing

B. Unit testing

C. System testing

D. Acceptance testing

Hint

Separate testing scope, technique and purpose. Use the stated workload, observable result or coverage target rather than a universal ranking.

Answer B: Unit testing

Unit testing tests isolated building blocks, including objects and subsystems; integration begins when individually tested components are combined.

Why each choice is right or wrong

A - Incorrect: Combines components rather than isolating a subsystem. See PDF p. 148, 144.

B - Correct: Directly tests an individual object or subsystem. See PDF p. 148, 144.

C - Incorrect: Tests components together as one system. See PDF p. 148, 144.

D - Incorrect: Checks the delivered system against the client agreement. See PDF p. 148, 144.

Primary note proof

Study-note section SE35

> Acceptance testing supports the customer/user's acceptance decision against agreed needs and criteria. Alpha typically happens in a controlled developer setting with selected users; beta uses external users in their environments. None of these levels is universally the longest. Unit is a level, while white-box is a technique; a unit can be tested using black-box cases too.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 148 | lines 19-26

> Unit testing focuses on the building blocks of the software system, that is, objects and subsystems.
> There are three motivations behind focusing on components. First, unit testing reduces the complexity of the overall test activities, allowing us to focus on smaller units of the system. Second, unit testing makes it easier to pinpoint and correct faults, given that few components are involved in the test. Third, unit testing allows parallelism in the testing activities; that is, each component can be tested independently of one another.
> The specific candidates for unit testing are chosen from the object model and the system decomposition of the system. In principle, all the objects developed during the development

Software Engineering module | PDF page 144 | lines 17-32

> Figure 6.2 depicts an overview of the testing activities:
> • Unit testing tries to find faults in participating objects and/or subsystems with respect to the use cases from the use case model
> • Integration testing is the activity of finding faults when testing the individually tested components together, for example, subsystems described in the subsystem decomposition, while executing the use cases and scenarios from the RAD.
> o The system structure testing is the culmination of integration testing involving all components of the system. Integration tests and structure tests exploit knowledge from the SDD using an integration strategy described in the Test Plan (TP).
> • System testing tests all the components together, seen as a single system to identify errors with respect to the scenarios from the problem statement and the requirements and design goals identified in the analysis and system design, respectively:

o Functional testing tests the requirements from the RAD and, if available, from the user manual.
o Performance testing checks the nonfunctional requirements and additional design goals from the SDD. Note that functional and performance testing are both done by

Question sources

MOE Computer Science Exit Exam · 2016 · Question 10

Question 3 | Q00019

Which characteristic of requirements specifies that the requirement should be phrased so that there is one and only one interpretation for it?

A. Unambiguous

B. Correct

C. Feasible

D. Verifiable

Hint

Distinguish observable services, measurable qualities and implementation constraints. Check scope, stakeholder meaning and the requested level of specificity.

Answer A: Unambiguous

A single interpretation is the unambiguous property. Correctness, feasibility and verifiability answer different questions.

Why each choice is right or wrong

A - Correct: Rules out two or more interpretations. See PDF p. 68, 70.

B - Incorrect: Accuracy to the client's view does not guarantee a unique reading. See PDF p. 68, 70.

C - Incorrect: Realism concerns implementation within constraints. See PDF p. 68, 70.

D - Incorrect: Requires a repeatable test, not a unique interpretation alone. See PDF p. 68, 70.

Primary note proof

Study-note section SE11

Correct requirements reflect actual stakeholder needs. Complete requirements address the agreed scope, normal and exceptional behavior. Consistency excludes contradictions. Clarity/unambiguity gives one intended interpretation; feasibility/realism means achievable within constraints. Verifiability means objective evidence can check fulfillment. Replace “fast for most users” with a defined metric, workload and threshold.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 68 | lines 18-26

system specification. Requirement validation involves checking if the specification is correct, complete, consistent, unambiguous, and realistic. A specification is correct if it represents the client's view of the system (i.e., everything in the requirements model accurately represents an aspect of the system). It is complete if all possible scenarios through the system are described, including exceptional behavior (i.e., all aspects of the system are represented in the requirements
model). The system specification is consistent if it does not contradict itself. The system specification is unambiguous if exactly one system is defined (i.e., it is not possible to interpret the specification two or more different ways). Finally, it is realistic if the system can be implemented within constraints. These properties are illustrated with UML instance diagrams in

Software Engineering module | PDF page 70 | lines 3-16

3.2.5. Verifiability and Traceability
Two more desirable properties of a system specification are that it be verifiable and traceable. The
specification is verifiable if, once the system is built; a repeatable test can be designed to demonstrate that the system fulfills the requirement. For example, a mean time to failure of a hundred years for SatWatch would be difficult to achieve (assuming it is realistic in the first place).
The following requirements are additional examples of non-verifiable requirements:
• The product shall have a good user interface (good is not defined).
• The product shall be error free (requires large amount of resources to establish).
• The product shall respond to the user with 1 second for most cases ("most cases" is not defined).
A system specification is traceable if each system function can be traced to its corresponding set of requirements. Traceability is not a constraint on the content of the specification, but rather, on its organization. Traceability facilitates the development of tests and the systematic validation of the design against the requirements.

MOE Computer Science Exit Exam · 2016 · Question 19

Computer Science Exit Exam practice collection · Question 12

Question 4 | Q00082

Which option most completely summarizes the listed observable behaviors that functional requirements may specify?

A. specifies the tasks the program must complete

B. Specifies observable tasks the program must not perform

C. Specifies required observable responses to invalid input

D. All of the mentioned

Hint

Distinguish observable services, measurable qualities and implementation constraints. Check scope, stakeholder meaning and the requested level of specificity.

Answer D: All of the mentioned

Functional requirements describe observable services and behavior, including what must happen, what is prohibited and how the system responds to errors. Each individual choice gives one of these forms. The all-of-the-mentioned option is therefore the complete summary. Selecting only A, B or C would omit other valid functional obligations; negative wording alone does not make a requirement nonfunctional.

Why each choice is right or wrong

A - Incorrect: Required tasks are functional, but A alone omits the other listed forms.

B - Incorrect: Prohibited tasks can be functional, but B alone is incomplete.

C - Incorrect: Required error responses are functional, but C alone is incomplete.

D - Correct: All three listed observable behavior forms can be functional requirements.

Primary note proof

Study-note section SE09

> A functional requirement states an observable service or behavior, including reactions to inputs, errors and forbidden actions. “When the sensor detects intrusion, send an alert” is functional. “Only a manager may approve refunds” also specifies permitted/prohibited behavior. A negative statement is not automatically nonfunctional.

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 65 | lines 19-23

> 3.2.1. Functional Requirements
> Functional requirements describe the interactions between the system and its environment independent of its implementation. The environment includes the user and any other external system with which the system interacts. For example, the following is an example of functional requirements for SatWatch, a watch that resets itself without user intervention:

Question sources

MOE Computer Science Exit Exam · 2016 · Question 82

Question 5 | Q00083

A team has little experience with a project's unfamiliar technology. Major feasibility risks must be evaluated before each further commitment, and experienced risk-analysis support is available. Which lifecycle is selected specifically by that risk-driven criterion?

A. Iterative Enhancement Model

B. RAD

C. Spiral

D. Waterfall

Hint

Identify whether the scenario prioritizes delivery, learning, adaptation or risk reduction. Several processes can share individual practices, so compare their defining emphasis.

Answer C: Spiral

Spiral organizes each cycle around objectives, alternatives, risk assessment and reduction before further commitment. That directly addresses the specified major feasibility risks and supported risk-analysis capability. Iterative enhancement can aid learning but does not make risk assessment its defining organizer; RAD needs rapid construction and skilled support. Classical waterfall fits stable requirements and familiar technology, which the scenario does not supply.

Why each choice is right or wrong

A - Incorrect: Iteration supports feedback but is not defined by risk-driven commitments.

B - Incorrect: RAD emphasizes rapid construction rather than the specified risk cycle.

C - Correct: Spiral explicitly organizes commitment around major risk reduction.

D - Incorrect: Unfamiliar technology and unresolved risks do not fit the stated classical waterfall rationale.

Primary note proof

Study-note section SE02

> Select a process using requirement stability, technical risk, delivery urgency, stakeholder availability, team skills and assurance needs. "Team has little experience" alone does not uniquely identify a process. A risk-driven cycle, prototype or carefully planned staged process may each help, depending on the actual uncertainty. No process eliminates the need for testing or documentation.

Study-note section SE06

> Spiral development is risk driven. Each cycle identifies objectives and alternatives, assesses and reduces important risks, develops/verifies an appropriate next result, and plans further commitment. A prototype may test a risky technology before a large investment. The amount and type of work depend on the risks.

Software Engineering module | PDF page 20 | lines 18-22

> the development plan. Its major problem is the inflexible partitioning of the project into distinct stages. Commitments must be made at an early stage in the process, which makes it difficult to respond to changing customer requirements.
> In principle, the waterfall model should only be used when the requirements are well understood
> and unlikely to change radically during system development. However, the waterfall model

Software Engineering module | PDF page 13 | lines 22-27

> Sometimes, software processes are categorized as either plan-driven or agile processes. Plan-driven processes are processes where all of the process activities are planned in advance and progress is measured against this plan. In agile processes planning is incremental and it is easier to change the process to reflect changing customer requirements. There is no hard and fast rules to
> follow but each approach is suitable for different types of software. Generally, you need to find a balance between plan-driven and agile processes.

Question sources

MOE Computer Science Exit Exam · 2016 · Question 83

MOE Computer Science Exit Exam · 2016 · Question 95

Question 6 | Q00084

In which step of SDLC actual programming of software code is done?

A. Development and Documentation

B. Maintenance and Evaluation

C. Design

D. Analysis

Hint

Identify whether the scenario prioritizes delivery, learning, adaptation or risk reduction. Several processes can share individual practices, so compare their defining emphasis.

Answer A: Development and Documentation

Programming translates the design into source code in implementation. A corresponds to the development stage of implementation and unit testing.

Why each choice is right or wrong

A - Correct: Development is the option corresponding to producing source code; documentation accompanies the process. See PDF p. 18, 18, 19.

B - Incorrect: Maintenance modifies an operational product. See PDF p. 18, 18, 19.

C - Incorrect: Design derives implementation structure rather than source code. See PDF p. 18, 18, 19.

D - Incorrect: Analysis establishes and organizes requirements. See PDF p. 18, 18, 19.

Primary note proof

Study-note section SE02

A common lifecycle names requirements, design, implementation, testing, deployment and maintenance. Analysis clarifies the problem; system design chooses architecture; object/detail design specifies interfaces and algorithms; implementation writes code; testing evaluates behavior; deployment puts it into service. These activities may overlap and repeat.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 18 | lines 28-32

3. Implementation and unit testing: During this stage, the software design is realized as a set of programs or program units. Unit testing involves verifying that each unit meets its specification. The purpose of the coding phase (sometimes called the implementation phase) of software development is to translate the software design into source code. Each component of the design is
implemented as a program module. The end-product of this phase is a set of program modules that

Software Engineering module | PDF page 18 | lines 13-20

System and software design: The systems design process allocates the requirements to either hardware or software systems by establishing an overall system architecture.
Software design involves identifying and describing the fundamental software system abstractions
and their relationships. The goal of the design phase is to transform the requirements specified in
the SRS document into a structure that is suitable for implementation in some programming language. In technical terms, during the design phase the software architecture is derived from the
SRS document. Two distinctly different approaches are available: the traditional design approach
and the object-oriented design approach.

Software Engineering module | PDF page 19 | lines 24-29

5. Operation and maintenance: Normally (although not necessarily), this is the longest life cycle phase. Maintenance of a typical software product requires much more than the effort necessary to
develop the product itself. The system is installed and put into practical use. Maintenance involves
correcting errors which were not discovered in earlier stages of the life cycle, improving the

implementation of system units and enhancing the system ‘s services as new requirements are discovered.

Question sources

MOE Computer Science Exit Exam · 2016 · Question 84

MOE Computer Science Exit Exam · 2016 · Question 96

Question 7 | Q00094

Which offered requirement is nonfunctional, specifying a measurable quality rather than required or prohibited observable tasks?

A. specifies the tasks the program must complete

B. Specifies observable tasks the program must not perform

C. Specifies the required error response to invalid input

D. Search shall respond within two seconds under 100 concurrent users.

Hint

Distinguish observable services, measurable qualities and implementation constraints. Check scope, stakeholder meaning and the requested level of specificity.

Answer D: Search shall respond within two seconds under 100 concurrent users.

The response-time limit under a defined concurrent-user workload is a measurable performance requirement, a nonfunctional quality constraint. Required services, prohibited actions and specified error responses are all forms of observable functional behavior. Their positive or negative wording does not determine the category. D instead constrains how well the search service must perform, making it the unique nonfunctional example.

Why each choice is right or wrong

A - Incorrect: Required observable tasks are functional.

B - Incorrect: Prohibited observable tasks can be functional.

C - Incorrect: An observable error response specifies functional behavior.

D - Correct: The time threshold and workload constrain performance quality.

Primary note proof

Study-note section SE09

A functional requirement states an observable service or behavior, including reactions to inputs, errors and forbidden actions. “When the sensor detects intrusion, send an alert” is functional. “Only a manager may approve refunds” also specifies permitted/prohibited behavior. A negative statement is not automatically nonfunctional.

Study-note section SE10

"Search responds within two seconds under 100 concurrent users" is measurable performance. "New users finish checkout within one minute without help" is usability. "Use Java" is a technology/pseudo-requirement, often separately classified as a system constraint. Dependability includes reliability, safety and robustness; portability is not its usual central category. Performance degradation at peak load primarily concerns performance, not automatically reliability.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 65 | lines 19-23

3.2.1. Functional Requirements
Functional requirements describe the interactions between the system and its environment independent of its implementation. The environment includes the user and any other external system with which the system interacts. For example, the following is an example of functional requirements for SatWatch, a watch that resets itself without user intervention:

Question sources

MOE Computer Science Exit Exam · 2016 · Question 94

Question 8 | Q00098

Which of the following is the understanding of software product limitations, learning system related problems or changes to be done in existing systems beforehand, identifying and addressing the impact of project on organization and personnel etc.?

A. Software Design

B. Feasibility Study

C. Requirement Gathering

D. System Analysis

Hint

Distinguish observable services, measurable qualities and implementation constraints. Check scope, stakeholder meaning and the requested level of specificity.

Answer B: Feasibility study.

SE08 asks whether a proposal is worth doing and deliverable, considering existing limitations, impacts on organization and personnel, benefits, costs, skills and integration risk. That matches the stem's preliminary impact and constraint investigation. System analysis studies the detailed problem and behavior and informs feasibility, but the broad early viability assessment is the more specific match here.

Why each choice is right or wrong

A - Incorrect: Design chooses solution structures rather than primarily assessing preliminary viability and organizational impacts.

B - Correct: Feasibility investigates existing limitations, impacts and whether the proposal is worthwhile and deliverable.

C - Incorrect: Gathering needs is useful input but does not by itself cover the full viability assessment.

D - Incorrect: System analysis examines detailed problem behavior; feasibility is the more specific preliminary impact/viability activity.

Primary note proof

Study-note section SE08

> Feasibility asks whether a proposal is worth doing and can be delivered within technical, economic, operational and schedule constraints. Examine existing limitations, organizational impacts, benefits, cost, available skills and integration risk. System analysis studies the problem and needed behavior in more detail; the activities inform each other.

Module passages - related reading

Software Engineering module | PDF page 25 | lines 15-18

> There are four main activities in the requirements engineering process:
> 1. Feasibility study: Feasibility shows viability and practicality of a software, project or idea. An estimate is made of whether the identified user needs may be satisfied using current software and hardware technologies. The study considers whether the proposed system will be cost-

Software Engineering module | PDF page 26 | lines 3-5

> effective from a business point of view and if it can be developed within existing budgetary constraints. A feasibility study should be relatively cheap and quick. The result should inform the decision of whether or not to go ahead with a more detailed analysis.

Software Engineering module | PDF page 100 | lines 11-24

> Analysis focuses on producing a model of the system, called the analysis model, which is correct, complete, consistent, and verifiable. Analysis is different from requirements elicitation in that developers focus on structuring and formalizing the requirements elicited from users
> Figure 4.1 Products of requirements elicitation and analysis (UML activity diagram).
> Althoughtheanalysismodelmaynotbeunderstandabletotheusersandtheclient, it helps developers verify the system specification produced during requirements elicitation. There is a natural tendency for users and developers to postpone difficult decisions until later in the project. A decision may be difficult because of lack of domain knowledge, lack of technological knowledge, or simply because of disagreements among users and developers. Postponing decisions enables the
> project to move on smoothly and avoid confrontation with reality or peers. Unfortunately, difficult
> decisions will eventually need to be made, often at higher cost when intrinsic problems are discovered during testing, or worse, during user evaluation. Translating a system specification in to a formal or semi-formal model forces developers to identify and resolve difficult issues early

in
the development.

Question sources

MOE Computer Science Exit Exam · 2016 · Question 98

Question 9 | Q00120

For a software product developed to meet a client’s requirements, which choice most completely describes its scope?

A. Software product refers any software created to meet the client's requirements.

B. Software product includes design and test documentation.

C. Software product includes requirement specifications, and user manuals.

D. All of the above

Hint

Identify whether the scenario prioritizes delivery, learning, adaptation or risk reduction. Several processes can share individual practices, so compare their defining emphasis.

Answer D: All of the above

SE01 explicitly includes executable code plus requirements, designs, test assets, configuration and user documentation in a software product. A describes the implemented software, while B and C name relevant accompanying artifacts. All three descriptions are therefore compatible; none limits the product to code alone. D is the inclusive answer among these options.

Why each choice is right or wrong

A - Incorrect: True as one component, but incomplete as the requested full selection. Software built to meet client requirements forms part of the product.

B - Incorrect: True as one component, but incomplete as the requested full selection. Relevant design and testing documentation are included product artifacts.

C - Incorrect: True as one component, but incomplete as the requested full selection. Requirements specifications and user manuals are relevant product documentation.

D - Correct: All three descriptions are compatible with the complete software-product scope.

Primary note proof

Study-note section SE01

Software engineering applies systematic methods to development, operation and maintenance. A software product includes executable code and relevant requirements, designs, test assets, configuration and user documentation. A process defines activities, ordering, roles, products and entry/exit conditions. Its four broad activities are specification, design/implementation, validation and evolution.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 89 | lines 17-24

> Assigning a role to a participant usually translates into assigning the responsibility of a specific work product. A work product is an artifact that is produced during the development, such as an internal document for other project participants or a deliverable to the customer.
> An analyst is responsible for a section of the RAD describing the functionality of the system. A system architect is responsible for the SDD describing the system's high-level architecture. A project manager is responsible for the SPMP describing the development processes. Finally, the system and its accompanying documentation also constitute a set of work products that are delivered to the client.

Software Engineering module | PDF page 83 | lines 12-25

> 3.4.4. Documenting Requirements Elicitation
> The results of the requirements elicitation activity and the analysis activity are documented in the
> Requirements Analysis Document (RAD). This document completely describes the system in terms of functional and nonfunctional requirements and serves as a contractual basis between the
> client and the developers. The audience for the RAD includes the client, the users, the project management, the system analysts (i.e., the developers who participate in the requirements), and the system designers (i.e., the developers who participate in the system design). The first part of the document, including use cases and nonfunctional requirements, is written during requirements
> elicitation. The formalization of the specification in terms of object models is written during analysis.
> The first section of the RAD is an Introduction. Its purpose is to provide a brief overview of the function of the system and the reasons for its development, its scope, and references to the development context (e.g., related problem statement, references to existing systems, feasibility studies). The introduction also includes the objectives and success criteria of the project.

Software Engineering module | PDF page 130 | lines 3-11

> 6.3. DOCUMENTING SYSTEM DESIGN
> System design is documented in the System Design Document (SDD). It describes design goals set by the project, the subsystem decomposition (with UML class diagrams), the hardware/software mapping (with UML deployment diagrams), the data management, the access control, control flow mechanisms, and boundary conditions. The SDD is used to define interfaces between teams of developers and as reference when architecture-level decisions need to be revisited. The audience for the SDD includes the project management, the system architects (i.e., the developers who participate in the system design), and the developers who design and implement each subsystem. The following is an example template for a SDD:

Question sources

Addis Ababa University mock exam · Question 22

Question 10 | Q00121

One of the followings is type of requirements associated with quality features of a software.

A. Business requirements

B. Functional requirements requirements

C. Non-functional

D. User requirements

Hint

Distinguish observable services, measurable qualities and implementation constraints. Check scope, stakeholder meaning and the requested level of specificity.

Answer C: Non-functional

Quality and user-visible constraints beyond functional behavior are nonfunctional requirements; user and business are viewpoints rather than this quality classification.

Why each choice is right or wrong

A - Incorrect: Business objectives do not identify the stated quality category. See PDF p. 66, 78.

B - Incorrect: Specifies provided interactions and services. See PDF p. 66, 78.

C - Correct: Matches nonfunctional quality constraints. See PDF p. 66, 78.

D - Incorrect: User requirements can contain several types, so this is broader than quality features. See PDF p. 66, 78.

Primary note proof

Study-note section SE10

> Nonfunctional requirements include quality attributes and constraints. Performance concerns response time, throughput and resource use; reliability concerns failure-free service; availability concerns being ready for use; usability concerns task success and ease of learning. Security concerns protection; compatibility concerns cooperating environments; portability concerns moving environments; maintainability/supportability concern change, diagnosis and evolution.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 66 | lines 14-18

> 3.2.2. Non-Functional and Pseudo-Requirements
> Nonfunctional requirements describe user-visible aspects of the system that are not directly related with the functional behavior of the system. Nonfunctional requirements include quantitative constraints, such as response time (i.e., how fast the system reacts to user commands)
> or accuracy (i.e., how precise are the system’s numerical answers). The following are the

Software Engineering module | PDF page 78 | lines 12-30

3.3.7. Identifying Non-Functional Requirements
Nonfunctional requirements describe user-visible aspects of the system that are not directly related
to the functional behavior of the system. Nonfunctional requirements span a number of issues, from user interface look and feel to response time requirements to security issues. Nonfunctional
requirements are defined at the same time as functional requirements are, because they have as much impact on the development and cost of the system.
For example, consider a mosaic display that an air traffic controller uses to track planes. A mosaic
display system complies data from a series of radar and databases (hence the term “mosaic”) into
a summary display indicating all aircraft in a certain area, including their identification, speed, and
altitude. The number of aircraft such a system can display constrains the performance of the air traffic controller and the cost of the system. If the system can only handle a few aircraft simultaneously, the system cannot be used at busy airports. On the other hand, a system able to handle a large number of aircraft is more costly and more complex to build.
Nonfunctional requirements can be elicited by investigating the following issues.
• User interface and human factors. What kind of interface should the system provide? What is the level of expertise of the users?
• Documentation. What level of document is required? Should only user documentation be provided? Should there be technical documentation for maintainers? Should the development process be documented?

Question sources

Addis Ababa University mock exam · Question 23

Question 11 | Q00122

A type of requirement that describes why the software project is needed and used to define the objective of the software is .

A. Business requirements

B. Functional requirements

C. Non-functional requirements

D. User requirements

Hint

Distinguish observable services, measurable qualities and implementation constraints. Check scope, stakeholder meaning and the requested level of specificity.

Answer A: Business requirements.

SE08 distinguishes the business reason and objectives of a project from user needs and detailed system obligations. The question asks why the project is needed and what objectives it serves, so business requirements match directly. Functional requirements describe behavior, while nonfunctional requirements describe qualities or constraints; neither primarily states the project's business justification.

Why each choice is right or wrong

A - Correct: Business requirements state the project's purpose, justification and intended organizational goals.

B - Incorrect: Functional requirements specify observable system services rather than the overall business reason for the project.

C - Incorrect: Nonfunctional requirements specify qualities or constraints rather than why the project exists.

D - Incorrect: User requirements describe stakeholder needs at a high level rather than the project's business justification.

Primary note proof

Study-note section SE08

> Business requirements explain why the project exists and its goals. User requirements describe stakeholder needs at a useful high level; system requirements specify detailed services and constraints. The Software Requirements Specification (SRS) organizes the agreed requirements. A natural-language specification communicates with clients while analysis models formalize it for technical discussion; real specifications can also contain diagrams.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 83 | lines 12-25

> 3.4.4. Documenting Requirements Elicitation
> The results of the requirements elicitation activity and the analysis activity are documented in the
> Requirements Analysis Document (RAD). This document completely describes the system in terms of functional and nonfunctional requirements and serves as a contractual basis between the
> client and the developers. The audience for the RAD includes the client, the users, the project management, the system analysts (i.e., the developers who participate in the requirements), and the system designers (i.e., the developers who participate in the system design). The first part of the document, including use cases and nonfunctional requirements, is written during requirements
> elicitation. The formalization of the specification in terms of object models is written during analysis.
> The first section of the RAD is an Introduction. Its purpose is to provide a brief overview of the function of the system and the reasons for its development, its scope, and references to the

development context (e.g., related problem statement, references to existing systems, feasibility studies). The introduction also includes the objectives and success criteria of the project.

Software Engineering module | PDF page 26 | lines 10-17

3. Requirement's specification: Requirements specification is the activity of translating the information gathered during the analysis activity in to a document that defines a set of requirements. Two types of requirements may be included in this document. User requirements are
abstract statements of the system requirements for the customer and end-user of the system; system
requirements are a more detailed description of the functionality to be provided.
4. Requirement's validation: This activity checks the requirements for realism, consistency, and completeness. During this process, errors in the requirements document are inevitably discovered.
It must then be modified to correct these problems.

Question sources

Addis Ababa University mock exam · Question 24

Question 12 | Q00123

Which of the following is used to model the functionality of software?

A. Use case diagram

B. Class diagram

C. E-R diagram

D. Deployment diagram

Hint

Match the information to be represented with each model's purpose. Read relationship direction, boundary and ownership conditions before classifying it.

Answer A: Use case diagram

Use-case diagrams model external roles and their goals or interactions with the system. This is the functional view requested. Class diagrams instead emphasize static classes, features and relationships. Entity-relationship diagrams organize entity types, attributes and data relationships. Deployment diagrams map software artifacts to execution nodes. Each can contribute to understanding a system, but only the use-case view directly presents the actor-goal functionality in this comparison.

Why each choice is right or wrong

A - Correct: Use-case diagrams show external actors and the system goals they use.

B - Incorrect: Class diagrams describe static types and their relationships.

C - Incorrect: ER diagrams describe entity types, attributes and data relationships.

D - Incorrect: Deployment diagrams map software artifacts onto execution nodes.

Primary note proof

Study-note section SE14

> Draw actors outside the system boundary rectangle and use-case ovals inside. Name a goal with a verb and noun. The diagram shows roles, goals and relationships, not the full detailed algorithm or UI layout. Being an internal component is different from being an external actor; the chosen boundary determines which role applies.

Study-note section SE-S03

> An entity-relationship diagram models entity types, their attributes and the relationships between them, commonly for data design. Its focus differs from a use-case diagram of external roles and goals, a class diagram of classes and their features, or a deployment diagram mapping artifacts to execution nodes.

Study-note section SE24

> A component diagram shows components/interfaces/dependencies; a deployment diagram places software artifacts on nodes.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 47 | lines 30-39

> Actors are external entities that interact with the system. Examples of actors include a user role (e.g., a system administrator, a bank customer, a bank teller) or another system (e.g., a central database, a fabrication line). Actors have unique names and descriptions.
> Use cases describe the behavior of the system as seen from an actor’s point of view. Behavior described by the use case model is also called external behavior. A use case describes a function provided by the system as a set of events that yields a visible result for the actors. Actors initiate a
> use case to access the system functionality. The use case can then initiate other use cases and gather
> more information from the actors. When actors and use cases exchange information, they are said
> to communicate. We will see later that we represent these exchanges with communication relationships.

Software Engineering module | PDF page 51 | lines 14-24

> 2.3.2. Class Diagrams
> Classes and objects
> Class diagrams describe the structure of the system in terms of classes and objects. Classes are abstractions that specify the attributes and behavior of a set of objects. Objects are entities that encapsulate state and behavior. Each object has an identity: It can be referred individually and is distinguishable from other objects.
> In UML, classes and objects are depicted by boxes including three compartments. The top

compartment displays the name of the class or object. The center compartment displays its attributes, and the bottom compartment displays its operations. The attribute and operation compartment can be omitted for clarity. Object names are underlined to indicate that they are instances. By convention, class names start with an uppercase letter. Objects in object diagrams

Software Engineering module | PDF page 130 | lines 3-11

6.3. DOCUMENTING SYSTEM DESIGN
System design is documented in the System Design Document (SDD). It describes design goals set by the project, the subsystem decomposition (with UML class diagrams), the hardware/software mapping (with UML deployment diagrams), the data management, the access control, control flow mechanisms, and boundary conditions. The SDD is used to define interfaces between teams of developers and as reference when architecture-level decisions need to be revisited. The audience for the SDD includes the project management, the system architects (i.e., the developers who participate in the system design), and the developers who design and implement each subsystem. The following is an example template for a SDD:

Question sources

Addis Ababa University mock exam · Question 25

Question 13 | Q00124

Which of the following refers to the deployment platform? i

A. Use case

B. Tier

C. Layer

D. Component

Hint

Separate responsibilities inside a component from dependencies across boundaries. Evaluate the stated structure, change and reuse goals without assuming guaranteed benefits.

Answer B: Tier.

SE23 explicitly separates logical abstraction from deployment separation. A layer organizes responsibilities logically, whereas a tier describes their deployment separation or platform arrangement. A use case models an actor goal, and a component is a software building block. Neither is the term for the deployment distinction asked for here.

Why each choice is right or wrong

A - Incorrect: A use case models a goal or interaction rather than the deployment platform separation.

B - Correct: A tier identifies deployment separation, contrasting with logical layering.

C - Incorrect: A layer is a logical abstraction level and need not occupy a distinct deployment platform.

D - Incorrect: A component is a software element and does not itself denote a deployment tier.

Primary note proof

Study-note section SE23

A layer is a logical abstraction level; a tier is a deployment separation. A closed layered architecture permits calls only to the immediately lower layer; an open one permits approved skipping. For top-to-bottom A,B,C,D, A→B obeys closed layering, A→C skips, and lower-to-upper calls violate the simple dependency rule unless explicitly mediated by a defined mechanism.

Software Engineering module | PDF page 130 | lines 3-11

6.3. DOCUMENTING SYSTEM DESIGN
System design is documented in the System Design Document (SDD). It describes design goals set by the project, the subsystem decomposition (with UML class diagrams), the hardware/software mapping (with UML deployment diagrams), the data management, the access control, control flow mechanisms, and boundary conditions. The SDD is used to define interfaces between teams of developers and as reference when architecture-level decisions need to be revisited. The audience for the SDD includes the project management, the system architects (i.e., the developers who participate in the system design), and the developers who design and implement each subsystem. The following is an example template for a SDD:

Software Engineering module | PDF page 67 | lines 3-8

Pseudo-requirements are requirements imposed by the client that restrict the implementation of the system. Typical pseudo-requirements are the implementation language and the platform on which the system is to be implemented. For life-critical developments, pseudo-requirements often
include process and documentation requirements (e.g., the use of a formal specification method, the complete release of all work products). Pseudo-requirements have usually no direct effect on the users' view of the system. The following are the pseudo functional requirements for SatWatch:

Question sources

Addis Ababa University mock exam · Question 26

Question 14 | Q00125

When requirements will change substantially and frequent early feedback is needed, which classical process organization is least accommodating among these choices?

A. Waterfall

B. Scrum

C. RAD

D. Agile

Hint

Identify whether the scenario prioritizes delivery, learning, adaptation or risk reduction. Several processes can share individual practices, so compare their defining emphasis.

Answer A: Waterfall

Classical waterfall commits to planned phases and reviewed deliverables, making late feedback and changed requirements costly. Agile and Scrum plan and inspect work incrementally, allowing later content to adapt. RAD also uses rapid construction and user participation to obtain feedback. The comparison therefore favors waterfall as the least accommodating under the stated conditions, without claiming that a waterfall project is physically unable to authorize any change.

Why each choice is right or wrong

A - Correct: Late feedback and phase commitments make major requirement changes costly in classical waterfall.

B - Incorrect: Scrum inspects usable increments and adapts later work within its planning framework.

C - Incorrect: RAD uses rapid construction and user participation to obtain feedback.

D - Incorrect: Agile explicitly values responding to changing needs.

Primary note proof

Study-note section SE03

> Classical waterfall separates planned phases with reviewed deliverables. It fits well-understood, stable requirements and familiar technology; late feedback makes changes costly. It does not make change physically impossible: real projects revisit work under control, and modified waterfall explicitly includes feedback. Rigidity offers milestone visibility but can freeze incorrect assumptions.

Study-note section SE05

> Agile favors people collaborating, useful working results, customer participation and adaptation over rigid adherence to procedures, exhaustive documents, contracts or fixed plans. The latter still have value. Agile does not mean no planning or no documentation. A user story states a small user need and value, supported by acceptance criteria; an epic groups broader work.

Study-note section SE07

A prototype explores requirements, usability or technical feasibility. A throwaway prototype is discarded after learning; an evolutionary prototype is deliberately refined toward production. A quick prototype may omit robustness, security or architecture, so do not deploy it unchanged without evaluation. Coding may occur during prototyping even if a diagram labels that activity construction rather than coding.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 20 | lines 18-22

the development plan. Its major problem is the inflexible partitioning of the project into distinct stages. Commitments must be made at an early stage in the process, which makes it difficult to respond to changing customer requirements.
In principle, the waterfall model should only be used when the requirements are well understood
and unlikely to change radically during system development. However, the waterfall model

Software Engineering module | PDF page 13 | lines 22-27

Sometimes, software processes are categorized as either plan-driven or agile processes. Plan-driven processes are processes where all of the process activities are planned in advance and progress is measured against this plan. In agile processes planning is incremental and it is easier to change the process to reflect changing customer requirements. There is no hard and fast rules to
follow but each approach is suitable for different types of software. Generally, you need to find a balance between plan-driven and agile processes.

Question sources

Addis Ababa University mock exam · Question 27

Question 15 | Q00126

Which of the following aims to find errors?

A. Requirement Analysis

B. Design

C. Testing

D. None of the above

Hint

Distinguish process assurance from product evaluation, and compare specified obligations with actual stakeholder needs.

Answer C: Testing

Testing systematically attempts to expose errors in the implementation; the other named activities primarily construct specifications and designs.

Why each choice is right or wrong

A - Incorrect: Structures requirements, although validation may reveal requirement defects. See PDF p. 140, 100, 18.

B - Incorrect: Constructs the solution design. See PDF p. 140, 100, 18.

C - Correct: Explicit planned fault detection activity. See PDF p. 140, 100, 18.

D - Incorrect: Testing is present, so none is false. See PDF p. 140, 100, 18.

Primary note proof

Study-note section SE34

A fault/defect is an underlying problem; an error may be an incorrect internal state; a failure is an externally observed departure from required service. Reliability is a product quality attribute; low cost or short development time are project outcomes. Tests increase confidence and reveal defects but cannot generally guarantee correctness over every possible input.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 140 | lines 27-32

7.1 OVERVIEW OF SOFTWARE QUALITY ASSURANCE
We define testing as the systematic attempt to find errors in a planned way in the implemented software. Contrast this definition with another commonly used definition that says that “testing is
the process of demonstrating that errors are not present.” The distinction between these two definitions is important. Our definition does not mean we simply demonstrate that the program does what it is intended to do. The explicit goal of testing is to demonstrate the presence of faults.

Software Engineering module | PDF page 100 | lines 11-24

Analysis focuses on producing a model of the system, called the analysis model, which is correct, complete, consistent, and verifiable. Analysis is different from requirements elicitation in that developers focus on structuring and formalizing the requirements elicited from users
Figure 4.1 Products of requirements elicitation and analysis (UML activity diagram).
Althoughtheanalysismodelmaynotbeunderstandabletotheusersandtheclient, it helps developers verify the system specification produced during requirements elicitation. There is a natural tendency for users and developers to postpone difficult decisions until later in the project. A decision may be difficult because of lack of domain knowledge, lack of technological knowledge, or simply because of disagreements among users and developers. Postponing decisions enables the
project to move on smoothly and avoid confrontation with reality or peers. Unfortunately, difficult
decisions will eventually need to be made, often at higher cost when intrinsic problems are discovered during testing, or worse, during user evaluation. Translating a system specification in to a formal or semi-formal model forces developers to identify and resolve difficult issues early in
the development.

Software Engineering module | PDF page 18 | lines 13-20

System and software design: The systems design process allocates the requirements to either hardware or software systems by establishing an overall system architecture.
Software design involves identifying and describing the fundamental software system abstractions
and their relationships. The goal of the design phase is to transform the requirements specified in
the SRS document into a structure that is suitable for implementation in some programming language. In technical terms, during the design phase the software architecture is derived from the
SRS document. Two distinctly different approaches are available: the traditional design approach
and the object-oriented design approach.

Question sources

Addis Ababa University mock exam · Question 28

Question 16 | Q00239

Which among the following focuses on the way the elements interact with each other at runtime during architectural design?

A. All choices are correct

B. Component-and-connector (C&C) structures

C. Allocation structures

D. Module decomposition structure

Hint

Separate responsibilities inside a component from dependencies across boundaries. Evaluate the stated structure, change and reuse goals without assuming guaranteed benefits.

Answer B: Component-and-connector structures.

The runtime interaction of software elements is the subject of component-and-connector structures in SE23. Module structures instead organize the code, while allocation structures relate software to hardware, teams or environments. These are different architectural views, so the inclusive choice fails: only the C&C option specifically answers the runtime-interaction focus.

Why each choice is right or wrong

A - Incorrect: The alternatives address different architectural concerns, so not every choice focuses on runtime interaction.

B - Correct: C&C structures show runtime elements and the connectors through which they interact.

C - Incorrect: Allocation structures map software to hardware, teams or environments rather than primarily describing runtime exchanges.

D - Incorrect: Module decomposition shows code organization rather than the runtime interactions emphasized by the stem.

Primary note proof

Study-note section SE23

A structure is the elements/relations themselves; a view represents selected aspects. Module structures show code organization, component-and-connector structures runtime interaction, and allocation structures map software to hardware, teams or environment. Processes/threads belong in concurrency views. Evaluate architectures against quality attributes and scenarios; processor allocation, decomposition and style selection can all be architectural concerns.

Software Engineering module | PDF page 121 | lines 6-15

6.1.4. Software architecture
As the complexity of systems increases, the specification of the system decomposition is critical. It is difficult to modify or correct a weak decomposition once development has started, as most subsystem interfaces have to change. In recognition of the importance of this problem, the concept
of software architecture has emerged. A software architecture includes the system decomposition, the global control flow, error-handling policies and inter subsystem communication protocols.
In this section, we describe a few sample architectures that can be used for different systems. This
is by no means a systematic or thorough exposition of the subject. Rather, we aim to provide a few
representative examples and refer the reader to the literature for more details.

Question sources

Mock exam 4 · Question 41

Question 17 | Q00240

Which option combines both explicitly specified testability mechanisms among A, C and D? Treat refactoring alone as behavior-preserving restructuring with no stated testability improvement.

A. Sand box

B. A and D

C. Refactoring

D. Limiting structural complexity

Hint

Separate responsibilities inside a component from dependencies across boundaries. Evaluate the stated structure, change and reuse goals without assuming guaranteed benefits.

Answer B: A and D

A sandbox can isolate execution, giving control over the test environment. Limiting structural complexity also supports testability by making behavior easier to control and observe. Refactoring preserves behavior while changing structure, but without a stated improvement it does not automatically supply either testability effect. The combination A and D therefore includes both explicitly supported mechanisms; the individual choices each give only one.

Why each choice is right or wrong

A - Incorrect: Sandbox isolation is valid but only one of the two mechanisms.

B - Correct: A and D include both explicitly supported mechanisms.

C - Incorrect: Unspecified refactoring need not improve testability.

D - Incorrect: Limited structural complexity is valid but only one of the two mechanisms.

Primary note proof

Study-note section SE27

> Variability can use selectable features, omission/inclusion and extension points; overloading supplies alternate signatures in code but is not every variability mechanism. Testability improves with controllable inputs, observable outputs, replaceable dependencies and limited structural complexity. A sandbox can isolate execution. Assess each design claim independently before evaluating a combined statement.

Study-note section SE22

> Logical cohesion groups similar-category operations, often selected by a flag; temporal cohesion groups operations done at the same time; functional cohesion focuses on one task. Splitting an unrelated three-purpose component improves modularity. If behavior is preserved, the restructuring is refactoring; the words are not mutually exclusive answers. Smaller modules can aid understanding, independent work, reuse and maintenance, but too many interfaces also create complexity.

Software Engineering module | PDF page 127 | lines 10-28

> 6.2.1. Identifying design goals
> The definition of design goals is the first step of system design. It identifies the qualities that our system should focus on. Many design goals can be inferred from the nonfunctional requirements or from the application domain. Others will have to be elicited from the client. It is, however, necessary to state them explicitly such that every important design decision can be made consistently following the same set of criteria.
> For example, in the light of the nonfunctional requirements for MyTrip, we identify reliability and
> fault tolerance to connectivity loss as design goals. We then identify security as a design goal, as numerous drivers will have access to the same trip planning server. We add modifiability as a design goal, as we want to provide the ability for drivers to select a trip planning service of their

choice. The following box summarizes the design goals we identified.
In general, we can select design goals from a long list of highly desirable qualities. Tables 5-1-5-5 list a number of possible design criteria. These criteria are organized into five groups: performance, dependability, cost, maintenance, and end user criteria. Performance, dependability,
and end user criteria are usually specified in the requirements or inferred from the application domain. Cost and maintenance criteria are dictated by the customer and the supplier.
Performance criteria (Table 5-1) include the speed and space requirements imposed on the system. Should the system be responsive or should it accomplish a maximum number of tasks? Is memory space available for speed optimizations or should memory be used sparingly?

Software Engineering module | PDF page 133 | lines 3-15

transformation on subsets of a particular model. Typical activities include transforming n-ary associations into binary associations, implementing binary associations as references, merging two similar classes from two different subsystems into a single class, collapsing classes with no significant behavior into attributes, splitting complex classes into simpler ones, rearranging classes and operations to increase the inheritance and packaging. During restructuring, we address design goals such as maintainability, readability, and understandability of the system model.
• Optimization. Optimization activities address performance requirements of the system model. This includes changing algorithms to respond to speed or memory requirements, reducing multiplicities in associations to speed up queries, adding redundant associations for efficiency, rearranging execution orders, adding derived attributes to improve the access time to objects and opening up the architecture, that is, adding access to lower layers because of performance requirements.

Question sources

Mock exam 4 · Question 42

Question 18 | Q00241

Which choices explicitly provide architectural variability through selectable elements or defined extension interfaces? Select all that apply. Treat overloading as alternate code signatures only.

A. Overloading

B. Omission or inclusion of elements

C. Extension point

D. All of the above

Hint

Separate responsibilities inside a component from dependencies across boundaries. Evaluate the stated structure, change and reuse goals without assuming guaranteed benefits.

Answer B, C: Omission or inclusion of elements; Extension point

Omitting or including selected elements permits configured architectural variation, and extension points define places where additional behavior can be supplied. Overloading by itself supplies alternate code signatures and does not establish either architectural mechanism. Thus B and C meet the specified architectural scope. The all-of-the-above choice includes that insufficient code-level case and therefore cannot be selected as a correct aggregate.

Why each choice is right or wrong

A - Incorrect: Alternate signatures alone do not define the specified architectural variability.

B - Correct: Selectable omission or inclusion changes architectural configuration.

C - Correct: Extension points explicitly support variation at defined boundaries.

D - Incorrect: It incorrectly includes overloading alone as an architectural mechanism.

Primary note proof

Study-note section SE27

> Variability can use selectable features, omission/inclusion and extension points; overloading supplies alternate signatures in code but is not every variability mechanism. Testability improves with controllable inputs, observable outputs, replaceable dependencies and limited structural complexity. A sandbox can isolate execution. Assess each design claim independently before evaluating a combined statement.

> 5.1.4. Generalization
> Generalization enables us to organize concepts in to hierarchies. There may be any number of intermediate levels in between, covering more-or-less generalized concepts (e.g., Low Priority Incident, Emergency, Disaster). Such hierarchies allow us to refer to many concepts precisely.

When
we use the term Incident, we mean all instances of all types of Incidents. When we use the term Emergency, we only refer to an Incident that requires an immediate response. This view of generalization stems from modeling.
In an object-oriented programming language, inheritance is a reusability technique. If a class Child
inherits from a class Parent, all the attributes and methods available on Parent are automatically available on Child. The class Child may add additional methods or override inherited methods, thus refining the class Parent. As in the case of generalization, the class at the top of the hierarchy
tends to be the most general one, whereas the leaves tend to be the most specialized.

Question sources

Mock exam 4 · Question 43

Question 19 | Q00242

Which choice most completely describes the stated advantages of the Factory Method pattern?

A. Allows the sub-classes to choose the type of objects to create

B. Promotes loose coupling

C. A and B

D. None of the above

Hint

Separate responsibilities inside a component from dependencies across boundaries. Evaluate the stated structure, change and reuse goals without assuming guaranteed benefits.

Answer C: A and B

SE27 describes Factory Method as letting subclasses choose a concrete product through a creation operation, reducing dependence on concrete constructors. Those are exactly the two benefits in A and B, so C is the inclusive answer. The reference is to Factory Method; a simple factory is related but does not necessarily delegate product choice to subclasses.

Why each choice is right or wrong

A - Incorrect: True as one component, but incomplete as the requested full selection. Factory Method lets subclasses select the concrete product through the creation operation.

B - Incorrect: True as one component, but incomplete as the requested full selection. Depending on the creation abstraction reduces coupling to concrete product constructors.

C - Correct: Both listed benefits hold for Factory Method, making this the inclusive answer.

D - Incorrect: The note explicitly supports both benefits, so none is false.

Primary note proof

Study-note section SE27

Factory Method lets subclasses choose a concrete product through a creation operation, reducing coupling to concrete constructors. A simple factory centralizes creation but is not identical to Factory Method. Singleton controls access to one instance; Observer notifies subscribers; Memento stores/restores state while hiding representation; Iterator traverses; Decorator adds behavior through wrapping. The pattern name is Memento, not Momento.

Software Engineering module | PDF page 120 | lines 6-12

6.1.3. Coupling and coherence
Coupling is the strength of dependencies between two subsystems. If two subsystems are loosely coupled, they are relatively independent, and thus, modifications to one of the subsystems will have little impact on the other. If two subsystems are strongly coupled, modifications to one subsystem is likely to have impact on the other. A desirable property of a subsystem decomposition
is that subsystems are as loosely coupled as possible. This minimizes the impact that errors or future changes have on the correct operation of the system.

Software Engineering module | PDF page 104 | lines 6-17

5.1.4. Generalization
Generalization enables us to organize concepts in to hierarchies. There may be any number of intermediate levels in between, covering more-or-less generalized concepts (e.g., Low Priority Incident, Emergency, Disaster). Such hierarchies allow us to refer to many concepts precisely. When
we use the term Incident, we mean all instances of all types of Incidents. When we use the term Emergency, we only refer to an Incident that requires an immediate response. This view of generalization stems from modeling.
In an object-oriented programming language, inheritance is a reusability technique. If a class Child
inherits from a class Parent, all the attributes and methods available on Parent are automatically available on Child. The class Child may add additional methods or override inherited methods, thus refining the class Parent. As in the case of generalization, the class at the top of the hierarchy
tends to be the most general one, whereas the leaves tend to be the most specialized.

Mock exam 4 · Question 44

Question 20 | Q00243

Which statements correctly distinguish architectural structures and views? Select all that apply.

A. B and D only

B. Views design structures whereas architects document the structures.

C. A structure is the set of elements and their relations as they exist in software or hardware.

D. A view is a representation of a structure

Hint

Separate responsibilities inside a component from dependencies across boundaries. Evaluate the stated structure, change and reuse goals without assuming guaranteed benefits.

Answer C, D: A structure is the set of elements and their relations as they exist in software or hardware.; A view is a representation of a structure

An architectural structure consists of elements and their relations in the modeled software or hardware. A view represents selected aspects of a structure for a particular purpose. Both C and D therefore express compatible definitions. Views are representations, not agents that design structures, so B is false. The aggregate A includes that false statement and incorrectly excludes the true structure definition.

Why each choice is right or wrong

A - Incorrect: The B-and-D-only combination includes false B and excludes true C.

B - Incorrect: Views represent structures rather than acting as their designers.

C - Correct: A structure is the underlying set of elements and relations.

D - Correct: A view represents selected aspects of a structure.

Primary note proof

Study-note section SE23

> A structure is the elements/relations themselves; a view represents selected aspects. Module structures show code organization, component-and-connector structures runtime interaction, and allocation structures map software to hardware, teams or environment. Processes/threads belong in concurrency views. Evaluate architectures against quality attributes and scenarios; processor allocation, decomposition and style selection can all be architectural concerns.

Question sources

Mock exam 4 · Question 45

Question 21 | Q00244

Which testing level isolates one function or class, using stubs or mocks for called dependencies, so its internal branches can be tested directly?

A. System testing

B. Integration testing

C. System and integration testing together

D. Unit testing

Hint

Separate testing scope, technique and purpose. Use the stated workload, observable result or coverage target rather than a universal ranking.

Answer D: Unit testing

Unit testing isolates a function, class or small component and may replace dependencies with stubs or mocks. That matches the stated test scope. White-box cases can then target its internal branches, but white-box is a technique rather than a testing level. Integration and system tests cover combined interactions or the full system, so neither matches the isolation specified here.

Why each choice is right or wrong

A - Incorrect: System testing evaluates the complete integrated system.

B - Incorrect: Integration testing targets interactions among combined parts.

C - Incorrect: Combining system and integration levels does not give isolated unit scope.

D - Correct: Unit testing isolates the function or class with replaceable dependencies.

Primary note proof

Study-note section SE35

> Unit testing isolates a function, class or small component, often replacing dependencies with stubs/mocks; a driver invokes the unit and a stub substitutes a called dependency. Integration testing exercises interfaces and interactions among combined parts. System testing checks the complete integrated system against functional and nonfunctional requirements in a representative environment.

Study-note section SE36

> Functional tests check required behavior against the SRS and acceptance criteria. Performance tests assess speed, throughput and resources under a specified workload; load uses expected demands and stress exceeds normal limits. Usability, security, compatibility and reliability tests target their respective qualities. “Normal operating conditions” alone does not distinguish functional from performance testing.

> Path testing
> Path testing is a white box testing technique that identifies faults in the implementation of the component. The assumption behind path testing is that, by exercising all possible paths through the code at least once, most faults will trigger failures. The identification of paths requires knowledge of the source code and data structures.
> The starting point for path testing is the flow graph. A flow graph consists of nodes representing

Software Engineering module | PDF page 148 | lines 19-26

> Unit testing focuses on the building blocks of the software system, that is, objects and subsystems.
> There are three motivations behind focusing on components. First, unit testing reduces the complexity of the overall test activities, allowing us to focus on smaller units of the system. Second, unit testing makes it easier to pinpoint and correct faults, given that few components are involved in the test. Third, unit testing allows parallelism in the testing activities; that is, each component can be tested independently of one another.
> The specific candidates for unit testing are chosen from the object model and the system decomposition of the system. In principle, all the objects developed during the development

Question sources

Mock exam 4 · Question 46

Question 22 | Q00245

Which offered UML diagram models external behavioral goals and actor interactions at a high level, rather than detailed message timing or state evolution?

A. Component diagram

B. Use case diagram

C. Deployment diagram

D. Class Diagram

Hint

Match the information to be represented with each model's purpose. Read relationship direction, boundary and ownership conditions before classifying it.

Answer B: Use case diagram

A use-case diagram presents external roles, their goals and relationships within a chosen system boundary. It therefore matches the specified high-level behavioral scope. Component, deployment and class diagrams describe structural organization, allocation or static types. Sequence, activity and state diagrams would be appropriate for detailed interactions, workflows or state changes, but those finer-grained dynamic questions are explicitly outside this stem.

Why each choice is right or wrong

A - Incorrect: Component diagrams describe components and interfaces.

B - Correct: Use-case diagrams show actor roles and high-level goals.

C - Incorrect: Deployment diagrams allocate artifacts to nodes.

D - Incorrect: Class diagrams show static types and relationships.

Primary note proof

Study-note section SE20

> An activity diagram models workflow: filled circle start, rounded actions, guarded decision diamond, thick fork/join bars and partitions/swimlanes for responsibility. A diamond can also merge alternative flows; a join synchronizes concurrent flows. A state machine models states and transitions triggered by events, often with guards/actions, for one object's lifecycle.

Study-note section SE14

> Draw actors outside the system boundary rectangle and use-case ovals inside. Name a goal with a verb and noun. The diagram shows roles, goals and relationships, not the full detailed algorithm or UI layout. Being an internal component is different from being an external actor; the chosen boundary determines which role applies.

> Actors are external entities that interact with the system. Examples of actors include a user role (e.g., a system administrator, a bank customer, a bank teller) or another system (e.g., a central database, a fabrication line). Actors have unique names and descriptions.
> Use cases describe the behavior of the system as seen from an actor's point of view. Behavior described by the use case model is also called external behavior. A use case describes a function provided by the system as a set of events that yields a visible result for the actors. Actors initiate a
> use case to access the system functionality. The use case can then initiate other use cases and gather
> more information from the actors. When actors and use cases exchange information, they are said
> to communicate. We will see later that we represent these exchanges with communication relationships.

Question sources

Mock exam 4 · Question 47

Question 23 | Q00246

Which choice most completely identifies the listed reasons requirements elicitation can be difficult?

A. All choices are correct

B. Problem of scope

C. Problem of understanding

D. Problem of volatility

Hint

Distinguish observable services, measurable qualities and implementation constraints. Check scope, stakeholder meaning and the requested level of specificity.

Answer A: All choices are correct

SE11 identifies scope, understanding and volatility as distinct elicitation difficulties. Scope concerns agreeing what belongs in the system; understanding concerns discovering and interpreting actual needs; volatility concerns needs changing as the project progresses. Since all three listed problems are valid, the inclusive answer is appropriate rather than choosing just one source of difficulty.

Why each choice is right or wrong

A - Correct: All three listed difficulties are explicitly recognized in the complete note.

B - Incorrect: True as one component, but incomplete as the requested full selection. Unclear system boundaries make agreeing on included and excluded requirements difficult.

C - Incorrect: True as one component, but incomplete as the requested full selection. Different interpretations and tacit stakeholder needs complicate accurate understanding.

D - Incorrect: True as one component, but incomplete as the requested full selection. Changing needs make elicitation an ongoing activity rather than a one-time capture.

Primary note proof

Study-note section SE11

> Correct requirements reflect actual stakeholder needs. Complete requirements address the agreed scope, normal and exceptional behavior. Consistency excludes contradictions. Clarity/unambiguity gives one intended interpretation; feasibility/realism means achievable within constraints. Verifiability means objective evidence can check fulfillment. Replace “fast for most users” with a defined metric, workload and threshold.

Study-note section SE11

> Trace each requirement backward to its source/rationale and forward to design, code and tests. Record dependencies among requirements. A traceability matrix links these artifacts and helps impact analysis; it is not just a cost/schedule ledger. Stakeholders must negotiate conflicting requirements rather than independently approving incompatible demands. Scope, understanding and volatility are distinct elicitation difficulties.

Study-note section SE-S01

> Elicitation difficulties have several distinct sources. Scope problems concern agreeing on system boundaries and the appropriate level of detail. Understanding problems arise when stakeholders and analysts have different domain knowledge, omit tacit needs or communicate conflicting interpretations. Volatility means that requirements change as circumstances and understanding develop.

Study-note section SE-S01

> These difficulties call for repeated communication, explicit boundaries, negotiated meanings and controlled revision. They can occur together; resolving one does not automatically remove the others.

> 2. Requirement’s elicitation and analysis: This is the process of deriving the system requirements through observation of existing systems, discussions with potential users and procurers, task analysis, and so on. This may involve the development of one or more system models and prototypes. These help you understand the system to be specified.

Software Engineering module | PDF page 68 | lines 18-26

system specification. Requirement validation involves checking if the specification is correct, complete, consistent, unambiguous, and realistic. A specification is correct if it represents the client's view of the system (i.e., everything in the requirements model accurately represents an aspect of the system). It is complete if all possible scenarios through the system are described, including exceptional behavior (i.e., all aspects of the system are represented in the requirements
model). The system specification is consistent if it does not contradict itself. The system specification is unambiguous if exactly one system is defined (i.e., it is not possible to interpret the specification two or more different ways). Finally, it is realistic if the system can be implemented within constraints. These properties are illustrated with UML instance diagrams in

Software Engineering module | PDF page 41 | lines 16-17

✓ Software evolution takes place when you change existing software systems to meet new requirements. Changes are continuous and the software must evolve to remain useful.

Mock exam 4 · Question 48

Question 24 | Q00247

Which development activity primarily recognizes and clarifies the problem, required behavior and related constraints before choosing the solution architecture or algorithms?

A. Implementation

B. Testing

C. Analysis

D. Design

Hint

Identify whether the scenario prioritizes delivery, learning, adaptation or risk reduction. Several processes can share individual practices, so compare their defining emphasis.

Answer C: Analysis

Analysis clarifies the problem, required behavior and constraints. Design then chooses architecture, interfaces and algorithms for a solution; implementation writes it, and testing evaluates its behavior. The revised scope keeps these responsibilities distinct instead of mixing problem recognition with selecting methods to overcome it. Creativity can occur in several activities, so the activity's purpose, rather than that adjective, determines the answer.

Why each choice is right or wrong

A - Incorrect: Implementation writes the selected solution.

B - Incorrect: Testing evaluates behavior.

C - Correct: Analysis clarifies the problem and constraints.

D - Incorrect: Design selects the solution architecture and mechanisms.

Primary note proof

Study-note section SE02

A common lifecycle names requirements, design, implementation, testing, deployment and maintenance. Analysis clarifies the problem; system design chooses architecture; object/detail design specifies interfaces and algorithms; implementation writes code; testing evaluates behavior; deployment puts it into service. These activities may overlap and repeat.

Software Engineering module | PDF page 100 | lines 11-24

Analysis focuses on producing a model of the system, called the analysis model, which is correct, complete, consistent, and verifiable. Analysis is different from requirements elicitation in that developers focus on structuring and formalizing the requirements elicited from users
Figure 4.1 Products of requirements elicitation and analysis (UML activity diagram).
Althoughtheanalysismodelmaynotbeunderstandabletotheusersandtheclient, it helps developers verify the system specification produced during requirements elicitation. There is a natural tendency for users and developers to postpone difficult decisions until later in the project. A decision may be difficult because of lack of domain knowledge, lack of technological knowledge, or simply because of disagreements among users and developers. Postponing decisions enables the
project to move on smoothly and avoid confrontation with reality or peers. Unfortunately, difficult
decisions will eventually need to be made, often at higher cost when intrinsic problems are discovered during testing, or worse, during user evaluation. Translating a system specification in to a formal or semi-formal model forces developers to identify and resolve difficult issues early in
the development.

Software Engineering module | PDF page 18 | lines 13-20

System and software design: The systems design process allocates the requirements to either hardware or software systems by establishing an overall system architecture.
Software design involves identifying and describing the fundamental software system abstractions
and their relationships. The goal of the design phase is to transform the requirements specified in
the SRS document into a structure that is suitable for implementation in some programming language. In technical terms, during the design phase the software architecture is derived from the
SRS document. Two distinctly different approaches are available: the traditional design approach
and the object-oriented design approach.

Mock exam 4 · Question 49

Question 25 | Q00248

_____ is a set of notations and conventions used to describe and model an application.

A. All choices are correct

B. Unified approach (UA)

C. Unified modeling language (UML)

D. Jacobson's use case

Hint

Match the information to be represented with each model's purpose. Read relationship direction, boundary and ownership conditions before classifying it.

Answer C: Unified modeling language (UML)

UML provides modeling notations and conventions; it is distinct from a development methodology.

Why each choice is right or wrong

A - Incorrect: UA and use cases are not both equivalent to the language. See PDF p. 32.

B - Incorrect: UA specifies steps for development. See PDF p. 32.

C - Correct: The exact defined modeling notation language. See PDF p. 32.

D - Incorrect: A use case is an interaction model inside the approach. See PDF p. 32.

Primary note proof

Study-note section SE17

A class box lists name, attributes and operations; + public, - private, # protected and ~ package indicate visibility. A class diagram shows static types and relationships, while an object diagram shows particular instances/links. UML is maintained and standardized by OMG; it is a modeling language, not a lifecycle process. Structural things describe conceptual or physical structural elements.

1.3.2. Overview of the unified approach.
The unified modeling language (UML) is a set of notations and conventions used to describe and model an application. But, the UML does not specify a methodology or what steps to follow to develop an application; that would be the task of the UA. Figure 1.2 depicts the essence of the unified approach. The heart of the UA is Jacobson's use case. The use case represents a typical interaction between a user and a computer system to capture the users' goals and needs. The main

Mock exam 4 · Question 50

Question 26 | Q00249

Which structural risk can arise when repeated software changes are made without coherent design or refactoring?

A. Reduced user engagement

B. Increased software complexity

C. Increased automation

D. Elimination of maintenance costs

Hint

Classify the motive for the change before its implementation: repair, environment, useful capability or reduced future risk.

Answer B: Increased software complexity

Repeated changes without coherent boundaries can accumulate dependencies and make the evolving system harder to understand. Refactoring and good subsystem design help control that structural complexity while maintenance still requires impact analysis and regression checks. User engagement is a product-use outcome rather than the structural risk asked for. Automation is an execution technique, not itself structural deterioration, and ongoing evolution does not eliminate maintenance costs.

Why each choice is right or wrong

A - Incorrect: Engagement concerns user behavior rather than the internal structural deterioration asked for.

B - Correct: Accumulated poorly coordinated changes can increase structural complexity.

C - Incorrect: Automation does not itself describe deterioration of responsibilities or dependency structure.

D - Incorrect: Changing software still requires maintenance and regression work.

Primary note proof

Study-note section SE01

> Software engineering applies systematic methods to development, operation and maintenance. A software product includes executable code and relevant requirements, designs, test assets, configuration and user documentation. A process defines activities, ordering, roles, products and entry/exit conditions. Its four broad activities are specification, design/implementation, validation and evolution.

Study-note section SE40

Corrective maintenance fixes faults; adaptive maintenance responds to environment changes; perfective maintenance improves useful capability/performance; preventive maintenance reduces future risk, such as restructuring fragile code. Motive determines category; refactoring can support preventive or perfective work. Maintenance often lasts years and includes understanding legacy code and regression effort, so it may dominate lifecycle cost.

Study-note section SE22

Cohesion measures how well elements inside a module serve a related purpose; coupling measures dependency between modules. Seek high cohesion and low coupling. Shared mutable data and knowledge of another module's internal representation increase coupling. Information hiding exposes stable operations while concealing changeable decisions.

Study-note section SE01

poor object design can still be complex.

Study-note section SE43

Refactor to preserve behavior while improving structure; optimize only against measured needs; record rationale and update traceability and regression evidence after change.

Software Engineering module | PDF page 19 | lines 24-29

5. Operation and maintenance: Normally (although not necessarily), this is the longest life cycle phase. Maintenance of a typical software product requires much more than the effort necessary to
develop the product itself. The system is installed and put into practical use. Maintenance involves
correcting errors which were not discovered in earlier stages of the life cycle, improving the implementation of system units and enhancing the system ‘s services as new requirements are discovered.

Software Engineering module | PDF page 120 | lines 6-12

6.1.3. Coupling and coherence
Coupling is the strength of dependencies between two subsystems. If two subsystems are loosely coupled, they are relatively independent, and thus, modifications to one of the subsystems will have little impact on the other. If two subsystems are strongly coupled, modifications to one subsystem is likely to have impact on the other. A desirable property of a subsystem decomposition
is that subsystems are as loosely coupled as possible. This minimizes the impact that errors or future changes have on the correct operation of the system.

Mock exam 4 · Question 51

Question 27 | Q00250

Which of the following best describes the difference between CPM and PERT?

A. CPM focuses on minimizing cost, while PERT focuses on minimizing time.

B. CPM is used for projects with uncertain activity durations, while PERT is used for projects with known activity durations.

C. PERT is used for projects with uncertain activity durations, while CPM is used for projects with known activity durations.

D. PERT is deterministic, whereas CPM is probabilistic.

Hint

Write out the supplied quantities and dependency constraints. Compute and compare values under the stated metric, finish condition and assumptions.

Answer C: PERT models uncertain durations; traditional CPM uses point durations.

SE30 gives traditional CPM point estimates and PERT optimistic, most-likely and pessimistic duration estimates. PERT therefore represents duration uncertainty, whereas the traditional CPM calculation uses known or fixed activity durations. The cost-versus-time contrast is not the defining distinction here, and the other two choices reverse the described treatment of uncertainty.

Why each choice is right or wrong

A - Incorrect: The note's defining contrast concerns duration uncertainty rather than assigning cost exclusively to CPM.

B - Incorrect: This reverses the models: PERT explicitly represents uncertain activity durations.

C - Correct: PERT uses uncertain three-point estimates, while traditional CPM uses fixed point durations.

D - Incorrect: The probabilistic/deterministic characterization is reversed relative to the note.

Primary note proof

Study-note section SE30

> Traditional CPM uses point durations; PERT models uncertainty with optimistic a, most-likely m and pessimistic b. The classic estimate is TE=(a+4m+b)/6 and variance=((b-a)/6)^2. For 3,6,15 days, TE=42/6=7 days and variance=4 days^2. Do not replace the weighted estimate by a simple average. These formulas are approximations, not guaranteed actual completion times.

4.6. Scheduling, Organization and Team Structures
Project-task scheduling is an important project planning activity. It involves deciding which tasks would
be taken up when. In order to schedule the project activities, a software project manager needs to do
the following:
• Identify all the tasks needed to complete the project and Break down large tasks into small activities.
• Determine the dependency among different activities and Establish the most likely estimates for the time durations necessary to complete the activities and Allocate resources to activities.
• Plan the starting and ending dates for various activities and Determine the critical path. A critical path is the chain of activities that determines the duration of the project.

Question sources

Mock exam 4 · Question 52

Question 28 | Q00251

A key benefit of using a project management tool in software development is:

A. Automatic bug detection and fixing.

B. Replacing the need for human project managers.

C. Improved communication and collaboration within the team.

D. Increased coding efficiency for developers.

Hint

Distinguish the planning or organization goal from the tool or structure used to support it. Apply the stated project conditions.

Answer C: Improved team communication and collaboration.

SE28 says planning tools coordinate ownership, dependencies and progress while leaving judgment to people. That coordination supports communication and collaboration. The tool does not automatically detect and repair code faults, replace project managers or directly guarantee faster coding. Those benefits would require other capabilities and evidence beyond project-management tooling itself.

Why each choice is right or wrong

A - Incorrect: Project-management tools do not automatically detect and repair software defects.

B - Incorrect: They support planning and coordination while human managers still supply judgment.

C - Correct: Shared ownership, dependency and progress information helps the team communicate and collaborate.
