Question 111 | Q00518

Which modifier lists can legally prefix int X = 1; when it is declared as a field in a Java interface? Missing public/static/final modifiers are supplied implicitly. Treat each choice independently. Select all that apply.

A. public static

B. private final

C. public final

D. static final

Hint

Identify the interface contract, effective modifiers and permitted implementation forms.

Answer A, C, D: public static; public final; static final

Every interface field is implicitly public static final. A can omit final, C can omit static, and D can omit public because the language supplies each missing modifier. The initializer int X=1 satisfies the constant field's initialization requirement. Private conflicts with the field's public visibility and is therefore forbidden. The three legal partial modifier lists all produce the same effective field modifiers.

Why each choice is right or wrong

A - Correct: public static is legal because final is implicit.

B - Incorrect: private conflicts with an interface field's implicit public visibility.

C - Correct: public final is legal because static is implicit.

D - Correct: static final is legal because public is implicit.

Primary note proof

Study-note section OOP19

> No interface instance fields or constructors exist; fields are implicitly public static final.

Question 112 | Q00519

In Java 17, which option most completely describes the permitted method contents of an interface? Here “declaration” means an abstract method declaration without a body and “definition” means a permitted method with a body; it does not ask what every interface must contain.

A. Method definition

B. Method declaration

C. Method declaration and definition

D. Method name

Hint

Identify the interface contract, effective modifiers and permitted implementation forms.

Answer C: Method declaration and definition

Modern Java interfaces can contain abstract method declarations and method bodies of permitted kinds, including default and static methods and private helpers. They need not contain every kind, but both declarations and definitions are allowed. A and B each describe only part of that capability. C is the most complete category, while a bare method name does not constitute the required declaration or definition.

Why each choice is right or wrong

A - Incorrect: Permitted method bodies are part of the answer, but this omits abstract declarations.

B - Incorrect: Abstract declarations are allowed, but this omits permitted method bodies.

C - Correct: Both abstract declarations and permitted method definitions can appear in Java 17 interfaces.

D - Incorrect: A name alone is not a complete method declaration or definition.

Primary note proof

Study-note section OOP19

> A method declaration without private, default or static is implicitly public abstract. Modern interfaces may also have default/static method bodies, and Java 9+ private helper methods.

Question 114 | Q00521

When does Exceptions in Java arises in code sequence?

A. Run Time

B. Can Occur Any Time

C. Compilation Time

D. None of the mentioned

Hint

Separate source errors from runtime exceptions and determine the hierarchy and checked obligation.

Answer A: Exceptions are thrown at runtime; checked obligations are checked at compile time.

OOP29 explains that checked does not mean an exception occurs during compilation. The compiler verifies catch-or-declare obligations; an actual exception throw occurs during program execution. Therefore Run Time is the correct occurrence answer. Compile-time syntax or name errors are a different category and do not make Java exceptions occur at any arbitrary stage.

Why each choice is right or wrong

A - Correct: An actual exception throw occurs during execution, as OOP29 explicitly states.

B - Incorrect: Any time conflates runtime throwing with compile-time checking and source errors.

C - Incorrect: Compilation checks obligations or reports source errors; it is not when the described program throws an exception.

D - Incorrect: Run Time is offered and is the supported occurrence stage, so none is false.

Primary note proof

Study-note section OOP29

A missing semicolon or undeclared variable is a compile-time source error, not a checked exception.

Study-note section OOP29

Checked does not mean the exception occurs at compile time: the compiler checks an obligation to catch or declare it, while an actual throw occurs at runtime.

Which of these keywords is not a part of exception handling?

A. finally

B. thrown

C. catch

D. try

Hint

Check the thrown type and catch order before tracing propagation or handler output.

Answer B: thrown

try, catch and finally are Java exception-handling keywords; thrown is an English word in compiler diagnostics, rather than a Java keyword.

Why each choice is right or wrong

A - Incorrect: Present in the example's cleanup block

B - Correct: Not a keyword used to declare or handle exceptions; distinguish the word thrown in diagnostics

C - Incorrect: Present as the handler clause

D - Incorrect: Present as the monitored block

Primary note proof

Study-note section OOP30

Which of these keywords must be used to handle the exception thrown by try block in some rational manner?

A. finally

B. throw

C. catch

D. try

Hint

Check the thrown type and catch order before tracing propagation or handler output.

Answer C: catch

The catch clause contains the handler for its exception type. finally is separate cleanup, and try surrounds the monitored operation.

Why each choice is right or wrong

A - Incorrect: Runs final code rather than the type-specific handler

B - Incorrect: Would signal an exception rather than handle one

C - Correct: The explicit exception handler clause

D - Incorrect: Marks monitored code, not the handler

Question 117 | Q00526

Which of these is a super class of all errors and exceptions in the Java language?

A. Catchable

B. Throwable

C. RunTimeExceptions

D. None of the above

Hint

Separate source errors from runtime exceptions and determine the hierarchy and checked obligation.

Answer B: Throwable.

OOP29 places Exception and Error under the common root Throwable. Therefore Throwable is the superclass covering all errors and exceptions in the question. RuntimeException is only a sub-branch and cannot be the root of Error or checked exceptions. Catchable is not the root type named in the provided hierarchy.

Why each choice is right or wrong

A - Incorrect: Catchable is not the root class specified here’s throwable hierarchy.

B - Correct: Throwable is explicitly the shared root above both Exception and Error.

C - Incorrect: RuntimeException is an unchecked exception branch, not the common superclass of all errors and exceptions.

D - Incorrect: Throwable is offered and is the hierarchy root, so none of the above is false.

Primary note proof

Study-note section OOP29

> Throwable is the root of throwable values, with Exception and Error branches. RuntimeException and Error subclasses are unchecked; other throwable classes are checked.

Question 118 | Q00527

In which of the following package Exception class exist?

A. java.file

B. java.lang

C. java.io

D. java.util

Hint

Read the cited conceptual rules, state the model, and apply them before comparing the alternatives.

Answer B: java.lang.Exception belongs to java.lang.

The base Exception class belongs to java.lang, which is implicitly imported. Its place in the Throwable hierarchy does not determine the package of every subclass: I/O-specific subclasses may belong to java.io while the base remains java.lang.Exception. java.util contains utility types, and java.file is not the package of this class. Thus B supplies the correct package.

Why each choice is right or wrong

A - Incorrect: The official API places Exception in java.lang, not the proposed java.file package.

B - Correct: The official Java SE17 API explicitly identifies Exception as a java.lang class.

C - Incorrect: Specific I/O exceptions do not relocate the Exception base class from java.lang into java.io.

D - Incorrect: java.util provides utility types, while the authoritative API places Exception in java.lang.

Primary note proof

Study-note section OOP-S04

The base Exception class is java.lang.Exception. It does not belong to java.io merely because some subclasses represent I/O failures. Package membership and position in an inheritance hierarchy are separate facts.

Study-note section OOP29

Throwable is the root of throwable values, with Exception and Error branches.

Study-note section OOP28

java.lang is implicitly imported; java.util supplies utilities; java.io supplies I/O; java.awt includes Button and Checkbox.

Question 119 | Q00528

Applets are designed to be embedded within an _____.

A. Javascript

B. Css

C. HTML

D. SQL

Hint

Use the historical host lifecycle and distinguish activation, suspension, drawing and unloading.

Answer C: An HTML document, in the historical applet model.

OOP34 explicitly says historical applet code was embedded in an HTML document and executed by a compatible JVM host/plugin or applet viewer. HTML is therefore the requested embedding format. The answer concerns legacy applets; it does not imply modern browsers execute applets or that JavaScript, CSS or SQL provides the described host document.

Why each choice is right or wrong

A - Incorrect: JavaScript is not the embedding document format identified for historical applets in OOP34.

B - Incorrect: CSS specifies styling rather than the HTML document into which the historical applet is embedded.

C - Correct: HTML is the document format explicitly named as the historical applet embedding context.

D - Incorrect: SQL is not the document format that hosts the historical applet in OOP34.

Which of the following is required to view an applet?

A. JCM

B. JDM

C. JVM

D. Java class

Hint

Use the historical host lifecycle and distinguish activation, suspension, drawing and unloading.

Answer C: A JVM, together with a compatible historical host or applet viewer.

OOP34 says applets execute through a compatible JVM host/plugin or applet viewer. JVM is therefore the necessary component among the named options, although a JVM alone is not the entire browser embedding environment. This is a historical requirement rather than a statement that current browsers provide applet support.

Why each choice is right or wrong

A - Incorrect: JCM is not the JVM execution component specified by OOP34 for historical applet viewing.

B - Incorrect: JDM is not the JVM host or applet-viewer component identified here.

C - Correct: A compatible JVM is necessary to execute the applet, together with an appropriate historical host/viewer.

D - Incorrect: A Java class supplies code but does not itself provide the required JVM execution environment.

Question 121 | Q00530

Which method is automatically called after the browser calls the init method?

A. start

B. stop

C. destroy

D. paint

Hint

Use the historical host lifecycle and distinguish activation, suspension, drawing and unloading.

Answer A: start.

OOP34 says init initializes once and start follows initialization and resumes activity. Thus start is the lifecycle method called after init under the historical host model. stop suspends activity, destroy cleans up before unloading, and paint draws content; none states the next lifecycle stage after initialization.

Why each choice is right or wrong

A - Correct: start follows initialization and resumes applet activity, exactly matching the requested lifecycle point.

B - Incorrect: stop suspends activity when deactivated; it is not the post-init startup callback.

C - Incorrect: destroy performs cleanup before unloading, rather than starting activity immediately after initialization.

D - Incorrect: paint draws content and is not the lifecycle startup callback that follows init.

Primary note proof

Study-note section OOP34

> init initializes once; start follows initialization and resumes activity; stop suspends activity when the host deactivates it; destroy performs final cleanup before unloading. paint draws content and is not a constructor.

Question 122 | Q00531

In the historical Java applet lifecycle, which callback performs final cleanup when a compatible host normally unloads the applet?

A. start

B. stop

C. destroy

D. paint

Hint

Use the historical host lifecycle and distinguish activation, suspension, drawing and unloading.

Answer C: destroy

The applet lifecycle assigns final cleanup before unloading to destroy. start begins or resumes activity, stop handles host deactivation, and paint draws content. A normal browser shutdown may cause an unload, but unloading can also occur without shutting the browser down. The revised stem therefore asks for the cleanup callback directly and does not make an incorrect exclusive shutdown claim or promise cleanup after an abrupt crash.

Why each choice is right or wrong

A - Incorrect: start begins or resumes activity rather than performing final cleanup.

B - Incorrect: stop suspends activity on host deactivation, not final unloading.

C - Correct: destroy performs final cleanup before normal applet unloading.

D - Incorrect: paint draws content rather than handling final cleanup.

Primary note proof

Study-note section OOP34

> init initializes once; start follows initialization and resumes activity; stop suspends activity when the host deactivates it; destroy performs final cleanup before unloading. paint draws content and is not a constructor.

Study-note section OOP34

> destroy is not defined exclusively as “browser shuts down”: the host may destroy an applet on unloading, and abrupt process termination does not guarantee cleanup.

Question 123 | Q00566

What are non-static Java fields declared directly in a class, outside methods, constructors and initializer-block local scopes, called?

A. Instance variables

B. Local variables

C. Class variables

D. Static variables

Hint

Locate the declaration scope and check default initialization versus definite assignment.

Answer A: Instance variables

Fields belong to a class declaration, but non-static fields hold separate state for each object and are called instance variables. Static fields are class variables shared by instances, so merely being outside a method would not distinguish them. The stem now explicitly excludes static and block-local declarations. Local variables belong to method, constructor or block scopes rather than to each object's field state.

Why each choice is right or wrong

A - Correct: Non-static object fields are instance variables.

B - Incorrect: Locals belong to executable scopes rather than the class's object state.

C - Incorrect: Class variables are static fields, excluded by the question.

D - Incorrect: Static variables are shared class fields, excluded by the question.

Primary note proof

Study-note section OOP05

> The introductory three-way grouping is local, instance and class/static variables. Locals occur in methods, constructors or blocks; they must be definitely assigned before use and cannot have public/private/protected modifiers. Fields occur in a class outside method bodies; non-static fields belong to each instance, while static fields belong to the class. Declaration location alone does not distinguish instance and static fields.

C. Class/Static variables
• Are declared with the static keyword in a class, but outside a method, constructor or a block.
• There would only be one copy of each class variable per class, regardless of how many objects are created from it.
• Are rarely used other than being declared as constants. (public static final)
• Are stored in the static memory.
• Static variables are created when the program starts and destroyed when the program stops.
• Visibility is similar to instance variables. However, most static variables are declared public
• Default values are same as instance variables.
• Static variables can be accessed by calling with the class name ClassName.VariableName.

A. obj.add

B. obj.add.obj

C. obj.add()

D. obj.add().obj

Hint

Question 125 | Q00576

The process of binding both attributes and methods together within a class is?

A. Inheritance

B. Encapsulation

C. Polymorphism

D. Overriding

Hint

Identify whether the emphasis is grouping state, hiding implementation, exposing essentials or varying behavior.

Answer B: Encapsulation

Binding attributes and methods into one class is encapsulation.

Why each choice is right or wrong

A - Incorrect: Transfers properties across classes

B - Correct: Groups data and the operations on that data

C - Incorrect: Allows an operation to take different forms

D - Incorrect: Replaces an inherited method implementation

Primary note proof

Study-note section OOP02

Encapsulation groups related state and operations and controls access. Information hiding keeps implementation decisions behind a stable interface.

Study-note section OOP02

Inheritance forms a subtype relationship and may reuse implementation. Polymorphism lets code using a common type invoke behavior appropriate to different concrete objects. Prefer a precise mechanism over a vague slogan: wrapping fields and methods points to encapsulation; showing what an operation does while hiding how points to abstraction.

Study-note section OOP14

A subclass overrides an eligible inherited instance method with the same signature and a compatible return type; a covariant reference return may be a subtype.

Question 126 | Q00587

A keyword used to have only a single piece of storage for a particular field is?

A. this

B. object

C. Final

D. Static

Hint

Decide whether a member belongs to a class or an object, then check initialization and final restrictions.

Answer D: Static

Only one copy of each class variable exists per class regardless of object count, and static is the declaration modifier for that property.

Why each choice is right or wrong

A - Incorrect: this does not provide shared storage

B - Incorrect: object does not declare the shared field category

C - Incorrect: final prevents modification rather than determining one copy

D - Correct: Static denotes the intended static modifier, though the literal Java spelling is lowercase static

Primary note proof

Study-note section OOP07

> static gives one field per loaded class, shared by its instances. If count starts at zero and every constructor increments it, three creations leave count=3. Prefer ClassName.count and ClassName.utility().

Study-note section OOP07

> final prevents reassignment of a variable, overriding of a method or extension of a class. A final reference may still refer to a mutable object.

What represents the concept that data can only be manipulated in known, well-defined ways

A. Inheritance

B. Information hiding

C. Polymorphism

D. overloading

Hint

Identify whether the emphasis is grouping state, hiding implementation, exposing essentials or varying behavior.

Answer B: Information hiding

Encapsulation hides class data and controls access through the class's methods. This is the information-hiding control over how data is manipulated.

Why each choice is right or wrong

A - Incorrect: Does not restrict manipulation paths

B - Correct: Describes control through the hidden-data/method boundary

C - Incorrect: Concerns multiple forms rather than restricting access

D - Incorrect: Concerns same-name methods with differing parameters

Primary note proof

Study-note section OOP02

> Encapsulation groups related state and operations and controls access. Information hiding keeps implementation decisions behind a stable interface. Abstraction presents the essential operations while omitting details irrelevant to the caller.

Question 128 | Q00599

Which one of the following is incorrect about inheritance

A. Subclass inherits members of superclass

B. Constructors are not members

C. Constructors of superclass can be invoked from subclass

D. Constructors of superclass inherited by subclass

Hint

Read the cited conceptual rules, state the model, and apply them before comparing the alternatives.

Answer D: Constructors of superclass inherited by subclass

Java constructors are not members and are not inherited, but a subclass can invoke its superclass constructor using super.

Why each choice is right or wrong

A - Incorrect: Subclass membership inheritance is the general mechanism

B - Incorrect: Constructors are not members.

C - Incorrect: Explicitly demonstrated with super(arg-list)

D - Correct: Contradicts the noninheritance rule

Primary note proof

Study-note section OOP-S05

In Java’s class-declaration terminology, constructors are not members and are not inherited. A subclass can invoke superclass construction; this does not turn the superclass constructor into an inherited subclass method.

Study-note section OOP10

Under Java 17 rules, an explicit this(args) or super(args) invocation must be the first constructor statement. this invokes another constructor in the same class; super invokes the immediate superclass constructor. A constructor cannot explicitly invoke both. If there is no explicit delegation, an implicit super() is inserted; a matching accessible no-argument parent constructor must exist.

Types of inheritance
1. Simple/single inheritance: is damn easy to understand. When a class extends another one class only.
2. Multi-Level inheritance: One can inherit from a derived class, thereby making this derived class the base class for the new class.
3. Hierarchical inheritance: One class is inherited by many sub classes.
• Java does not support the inheritance of multiple super classes into a single subclass. (Multiple & Hybrid inheritances)
• No class can be a superclass of itself
• Superclass can be used by itself.
• The superclass has no knowledge of what a subclass adds to it.

Question 129 | Q00605

Consider an abstract Java class that explicitly declares an abstract method. Which statement is incorrect about that class? In C, constructing objects means directly instantiating this abstract class.

A. It is a class containing abstract method

B. Abstract method is incomplete

C. Used to construct objects

D. None of the above

Hint

Check whether a class is concrete and whether every inherited abstract contract has an implementation.

Answer C: Used to construct objects

The given class contains an abstract method by assumption, and that method has no implementation body. An abstract class may include constructors and concrete methods, but it cannot itself be directly instantiated. C is therefore the false statement in the stated sense. A describes the given class rather than imposing a requirement on every abstract class, and None is false because C is incorrect.

Why each choice is right or wrong

A - Incorrect: This is true of the particular class because the stem explicitly says it declares an abstract method.

B - Incorrect: An abstract method has no implementation body, which is the intended meaning of incomplete.

C - Correct: Direct instantiation of the abstract class is prohibited, so this is the incorrect statement.

D - Incorrect: C is an incorrect statement, so None of the above cannot be selected.

Primary note proof

Study-note section OOP18

An abstract class cannot be directly instantiated but can define fields, constructors, abstract methods and concrete methods. It need not contain an abstract method. An abstract method has

no body; abstract and final conflict because an operation cannot require overriding while forbidding it.

Study-note section OOP18

A concrete subclass must provide or inherit implementations of all required abstract methods; otherwise it must itself be abstract.

Question 130 | Q00608

Which statement correctly describes imports in an ordinary Java source compilation unit?

A. A Java source file may contain zero or more import statements before its top-level type declarations

B. Import statement appears after the class declaration

C. Import statement appears before package statement

D. All of the above

Hint

Check declaration order, exact case, package boundaries and the compile-versus-launch stage.

Answer A: A Java source file may contain zero or more import statements before its top-level type declarations

An optional package declaration comes first, followed by any import declarations, then the top-level type declarations. A source file can have no imports or multiple imports in that position. B places imports after a class, and C places them before the package declaration, reversing the ordering rules. D includes those false statements. These ordering rules apply to Java source files, rather than compiled .class contents.

Why each choice is right or wrong

A - Correct: This places zero or more source imports before the top-level types.

B - Incorrect: Imports precede top-level class declarations rather than following them.

C - Incorrect: The package declaration, when present, precedes imports.

D - Incorrect: B and C reverse the required ordering, so all is incorrect.

Which one of the following is correct about narrowing casting?

A. Done by the programmer

B. It is automatic

C. Done by the compiler

D. All

Hint

Identify the primitive category, width and conversion rule before evaluating a declaration or expression.

Answer A: Done by the programmer

Narrowing is explicit and must be done programmatically using a cast; the automatic conversion section instead describes widening.

Why each choice is right or wrong

A - Correct: Matches explicit programmatic narrowing

B - Incorrect: Confuses narrowing with widening

C - Incorrect: The compiler does not insert the narrowing cast described here

D - Incorrect: B and C do not match explicit narrowing

Primary note proof

Study-note section OOP06

> A compatible widening conversion often needs no cast; narrowing usually needs an explicit cast and may lose information. Widening an int to float can lose precision, so “widening never loses information” is false.

Which one of the following is incorrect about method overriding?

A. A method declared final cannot be overridden

B. Similar argument list is required

C. Constructors cannot be overridden

D. None

Hint

Check inheritance, signature compatibility, visibility and eligibility for an override.

Answer D: None

final methods cannot be overridden, argument types and order must match, and constructors are not inherited methods. Hence none of A-C is incorrect under the intended exact-match reading.

Why each choice is right or wrong

A - Incorrect: Explicitly prohibited by overriding rules

B - Incorrect: Here, “similar argument list” must mean the same argument types in the same order.

C - Incorrect: Constructors are not inherited methods and have the class's own name

D - Correct: None of A-C contradicts these rules

Primary note proof

Study-note section OOP14

> A subclass overrides an eligible inherited instance method with the same signature and a compatible return type; a covariant reference return may be a subtype. Question 133 | Q00641

Which listed cases are not checked exceptions in Java? Interpret “array index out of bounds” as ArrayIndexOutOfBoundsException and “file required not found” as FileNotFoundException. Select all that apply.

A. Missing semicolons

B. Array index out of bounds

C. Usage of undeclared variables

D. File required not found

Hint

Separate source errors from runtime exceptions and determine the hierarchy and checked obligation.

Answer A, B, C: Missing semicolons; Array index out of bounds; Usage of undeclared variables

A missing semicolon and an undeclared variable are source errors rejected during compilation; neither is a checked exception. ArrayIndexOutOfBoundsException is a runtime exception and is unchecked. FileNotFoundException is a checked exception, so its catch-or-declare obligation is checked by the compiler even though an actual throw occurs at runtime. The revised multiple-selection question accepts all three cases outside the checked-exception category.

Why each choice is right or wrong

A - Correct: A missing semicolon is a compile-time source error, not a checked exception.

B - Correct: ArrayIndexOutOfBoundsException is unchecked.

C - Correct: An undeclared variable is a compile-time source error, not a checked exception.

D - Incorrect: FileNotFoundException is checked and therefore is not selected.

Primary note proof

Study-note section OOP29

IOException, FileNotFoundException and SQLException are standard checked examples. ArithmeticException, NullPointerException, ClassCastException and array bounds exceptions are unchecked. A missing semicolon or undeclared variable is a compile-time source error, not a checked exception.

Study-note section OOP29

Checked does not mean the exception occurs at compile time: the compiler checks an obligation to catch or declare it, while an actual throw occurs at runtime.

Which of the following is not valid variable in java?

A. A$_2

B. By2

C. Java

D. A@2$

Hint

Check the lexical category and whether the notation names a value, a declaration or non-executed source text.

Answer D: A@2$ is invalid.

OOP28 explicitly allows $ in Java identifiers but rejects @ as an identifier character. D contains @, so it cannot be the requested variable name. A's dollar sign and underscore do not create that defect. By2 and Java also contain ordinary letters and a permitted trailing digit where present.

Why each choice is right or wrong

A - Incorrect: A$_2 uses a letter first and permitted dollar sign, underscore and digit thereafter.

B - Incorrect: By2 starts with a letter and has an allowed digit after the letters.

C - Incorrect: Java is a case-sensitive ordinary identifier, not the prohibited @ pattern identified in the note.

D - Correct: A@2$ contains @, which OOP28 explicitly prohibits within a Java identifier.

Primary note proof

A. Inheritance

B. Polymorphism

C. Encapsulation

D. Abstract Classes

Hint

Answer A: Inheritance

Generalization groups specialized classes under a general superclass; a subclass specializes its superclass, and inheritance implements that hierarchy.

Question 140 | Q00747

Choose the incorrect statement in terms of Objects.

A. Objects are abstractions of real-world

B. Objects can't manage themselves

C. Objects encapsulate state and representation information

D. All of the mentioned

Hint

Distinguish an object’s stored state, operations, identity and class definition.

Answer B: “Objects cannot manage themselves” is the incorrect generalization.

OOP01 says objects hold state and behavior, control responsibilities, communicate through method calls and can delegate. It expressly calls the claim that objects cannot manage their own state misleading. Therefore B is the false generalization. A is a conventional modeling description, and C describes encapsulated state, so all statements cannot be incorrect.

Why each choice is right or wrong

A - Incorrect: Objects can model abstractions of real-world entities; this conventional modeling description is not the identified false generalization.

B - Correct: Objects can control their state through behavior and delegate responsibilities, contradicting this categorical claim.

C - Incorrect: Encapsulation of state and related representation is consistent with the note’s object model.

D - Incorrect: The supported abstraction and encapsulation descriptions prevent treating every supplied statement as incorrect.

Primary note proof

Study-note section OOP01

> An object has identity, state and behavior. State is stored in fields; behavior is provided by methods. A Rectangle object may hold width and height and answer getArea() or getPerimeter(). Two objects can have equal fields and still be distinct objects. A class defines their common structure and behavior; an object is a particular instance.

Study-note section OOP01

> Choose classes around responsibilities: an account controls its own balance, a transaction records a payment, and a service coordinates them. Objects send messages through method calls such as obj.add(). They can delegate work to other objects; saying that objects cannot manage their own state is misleading. Procedural and object oriented designs both support reuse; global shared data is not compulsory in procedural programming.

Study-note section OOP02

Encapsulation groups related state and operations and controls access. Information hiding keeps implementation decisions behind a stable interface. Abstraction presents the essential operations while omitting details irrelevant to the caller.

Question 141 | Q00748

Which OOP concept describes one operation in a class hierarchy producing different behavior for different runtime object types?

A. Aggregation

B. Polymorphism

C. Inheritance

Hint

Check what compiles from the declared type, then select behavior from the actual runtime class.

Answer B: Polymorphism

Polymorphism lets code using a common type invoke behavior appropriate to each concrete object. Eligible overriding supplies this effect at runtime: the same inherited operation may dispatch to a different subclass implementation. Inheritance establishes the relationship that permits those related types, but does not alone name the varying behavior. Aggregation instead models a whole grouping parts, rather than method dispatch.

Why each choice is right or wrong

A - Incorrect: Aggregation describes whole-part object relationships, not varying operation behavior.

B - Correct: Polymorphism names behavior selected appropriately for different concrete object types through a common operation.

C - Incorrect: Inheritance establishes the subtype hierarchy; polymorphism names the differing behavior through that hierarchy.

Primary note proof

> For an eligible overridden sound(), a.sound() invokes Dog.sound() at runtime.

Study-note section OOP-S05

> Aggregation models one instance grouping other instances as a whole with parts. It is an object-relationship concept, not a method-dispatch rule. Inheritance instead relates a specialized class to a general class; overridden operations can then provide polymorphic behavior.

Question 142 | Q00896

Which statement correctly describes the implicit object argument in an ordinary C++17 member-function call?

A. The this pointer is supplied as the implicit object argument to ordinary non-static member functions

B. The this pointer is supplied as a hidden argument to static member variables

C. The this pointer is supplied as a hidden argument to static member functions

D. The this pointer is supplied as a hidden argument to every member function, including static functions

Hint

Use the stated language rules and identify whether a member call has an implicit current object.

Answer A: The this pointer is supplied as the implicit object argument to ordinary non-static member functions

In ordinary C++17 non-static member functions, this points to the object on which the function is invoked and can be understood as the implicit object argument. Member variables do not receive call arguments. Static member functions have no current instance and no this pointer, so a claim about every member function is also too broad. Correcting variables to functions in A restores the intended distinction.

Why each choice is right or wrong

A - Correct: Ordinary non-static member functions have the implicit object represented by this.

B - Incorrect: Variables are not calls and do not receive hidden object arguments.

C - Incorrect: Static member functions have no this pointer.

D - Incorrect: Including static functions makes the universal claim false.

Primary note proof

Study-note section OOP17

> In ordinary C++17 non-static member functions, this is a pointer to the object on which the function is called; this->field selects a member. It is often explained as an implicit object argument to a member function call. It is not an argument passed to member variables, and a static member function has no this pointer.

What does this Java program print?
public class Calculation {
public static void main(String[] args) {
int sum = 0;
for (int j = 1; j <= 10; j++) {
sum = sum + j;
}
System.out.println(+sum);
}
}

A. 55

B. 44

C. 33

D. 66

Hint

Trace condition tests, control transfers and printing as separate steps.

Answer A: 55

The loop adds each integer from 1 through 10 exactly once. Their sum is 10×11/2=55, and unary plus does not change that integer before printing. The malformed trailing token is replaced by the required closing braces, leaving the loop itself unchanged. Forty-four and thirty-three are not the inclusive sum, while sixty-six would correspond to additionally summing 11, beyond the bound.

Why each choice is right or wrong

A - Correct: The inclusive sum 1+2+...+10 is 55.

B - Incorrect: 44 is not the sum of the ten loop values.

C - Incorrect: 33 is not the sum produced by the inclusive loop.

D - Incorrect: 66 would include an extra 11 beyond the stated upper bound.

Question 144 | Q00905

Which exact case-sensitive Java keyword declares a subclass relationship to a superclass?

A. Inherits

B. Superclass

C. extends

D. Implements

Hint

Identify the subtype or ownership relationship and distinguish class inheritance from interface contracts.

Answer C: extends

A Java class declares its superclass with extends, as in class Dog extends Animal. The lowercase spelling is required because Java identifiers and keywords are case sensitive. implements is used for interface contracts rather than the superclass relationship, while Inherits and Superclass are not the required keyword. Correcting the option's initial letter makes the subclass-declaration question exact without changing its concept.

Why each choice is right or wrong

A - Incorrect: Inherits is not the Java subclass-declaration keyword.

B - Incorrect: Superclass names the relationship but is not its declaration keyword.

C - Correct: extends is the exact keyword used between subclass and superclass names.

D - Incorrect: implements concerns interfaces, and the printed capitalized word is not the required keyword.

Primary note proof

Question 145 | Q00930

A BankAccount keeps its balance and deposit operation together. Clients cannot assign balance directly and must use validated operations. Which principle specifically names this bundling of state with operations and control of access to that state?

A. Abstraction

B. Inheritance

C. Polymorphism

D. Encapsulation

Hint

Identify whether the emphasis is grouping state, hiding implementation, exposing essentials or varying behavior.

Answer D: Encapsulation controls which information of an object is exposed.

The question specifically asks for the mechanism that groups an object's state with its operations and controls access to that state. That is encapsulation. Abstraction also matters in the account's public view, but it names the essential operations presented to callers rather than the requested state-and-operation boundary. Inheritance and polymorphism concern subtype relationships and behavior through common types, respectively.

Why each choice is right or wrong

A - Incorrect: Abstraction emphasizes the essential caller-facing view; it does not specifically name the requested grouping and state-access boundary.

B - Incorrect: Inheritance forms a subtype relationship rather than the requested state-and-operation boundary.

C - Incorrect: Polymorphism selects behavior through a common type rather than grouping and controlling this state.

D - Correct: Encapsulation specifically groups the balance with its operations and controls direct access.

Primary note proof

Study-note section OOP02

> Encapsulation groups related state and operations and controls access. Information hiding keeps implementation decisions behind a stable interface. Abstraction presents the essential operations while omitting details irrelevant to the caller. These ideas overlap: a private balance plus deposit(amount) can demonstrate all three, depending on what the question emphasizes.

Consider the following code snippet
class Animal { void sound() { System.out.printIn("Animal sound"); } }
class Dog extends Animal { void sound() { System.out.printIn("Bark!"); } }
Which OOP concept is illustrated when Dog provides its own version of sound?

A. Method overriding

B. Method overloading

C. Abstraction

D. Encapsulation

Hint

Check inheritance, signature compatibility, visibility and eligibility for an override.

Answer A: Method overriding

Dog repeats sound() from Animal with its own body: that is a subclass method with the same name/signature as its superclass method. Literal printIn is a typo, but does not change the declaration relationship.

Why each choice is right or wrong

A - Correct: Matches the same-signature subclass relationship

B - Incorrect: No changed parameter list is shown

C - Incorrect: No abstract declaration or essential-interface example is needed

D - Incorrect: The example emphasizes replacement behavior, not grouping hidden data

Primary note proof

Study-note section OOP14

A subclass overrides an eligible inherited instance method with the same signature and a compatible return type; a covariant reference return may be a subtype.

Study-note section OOP12

Overloaded methods share a name but have different parameter types, counts or type order.

Question 147 | Q00956

Which most restrictive Java member-access category admits unrelated classes in the same package and qualified subclass access in other packages, while excluding unrelated classes in other packages?

A. Public

B. Default

C. Private

D. Protected

Hint

Locate the accessing code, declaring type, package and receiver before applying visibility rules.

Answer D: Protected, subject to cross-package receiver restrictions.

Protected combines same-package access with qualified subclass access across packages. It therefore reaches both required contexts while excluding unrelated other-package clients. Public is broader and violates that exclusion. Package/default access does not reach the other-package subclass, while private is narrower than the required same-package access. Cross-package instance access must still use the inherited context or an appropriate subclass-typed receiver.

Why each choice is right or wrong

A - Incorrect: Public also admits unrelated classes in other packages, violating the explicit exclusion.

B - Incorrect: Package/default access does not admit the required subclass access across packages.

C - Incorrect: Private does not grant access to unrelated same-package classes.

D - Correct: Protected grants the required same-package and qualified cross-package subclass access without granting universal access.

Primary note proof

Study-note section OOP08

> For ordinary members: private restricts access to the declaring class/nest; no modifier grants package access; protected grants same-package access plus qualified subclass access; public is widest, provided the declaring type itself is accessible. Top-level classes/interfaces may be public or package-private, not protected/private. Member types have additional visibility possibilities.

Question 148 | Q00965

In abstract class Employee, calculateTax must remain a public concrete instance method while explicitly forbidding subclasses from overriding it. Which declaration achieves that requirement?

A. public abstract double calculateTax();

B. public final double calculateTax(){ return 0.0; }

C. private double calculateTax(){ return 0.0; }

D. public static double calculateTax(){ return 0.0; }

Hint

Decide whether a member belongs to a class or an object, then check initialization and final restrictions.

Answer B: public final double calculateTax(){ return 0.0; }

final explicitly prohibits overriding an instance method while allowing it to remain public and concrete. abstract instead requires an implementation and supplies no body. private would remove public access and create independent child declarations rather than preserve the required public contract. static changes the method into a class operation whose same-signature child method hides it. Only the public final instance declaration satisfies all stated requirements.

Why each choice is right or wrong

A - Incorrect: abstract removes the concrete implementation and permits or requires overriding.

B - Correct: public final retains public concrete instance behavior and prohibits overriding.

C - Incorrect: private violates the required public accessibility.

D - Incorrect: static violates the requirement to remain an instance method.

Primary note proof

Study-note section OOP07

final prevents reassignment of a variable, overriding of a method or extension of a class.

Study-note section OOP14

A subclass overrides an eligible inherited instance method with the same signature and a compatible return type; a covariant reference return may be a subtype. Visibility cannot become more restrictive, and checked exceptions cannot be broadened incompatibly. @Override

Study-note section OOP18

An abstract method has no body; abstract and final conflict because an operation cannot require overriding while forbidding it.

What will be the output for the Java expression: 8 - 2 * 5 * (3 + 9 / 3) + 6 / 3

A. -150

B. -30

C. -50

D. 50

Hint

Respect operator grouping and operand types, then trace each operation in evaluation order.

Answer C: -50.

Inside the parentheses, 9/3=3, so the group is 3+3=6. The multiplication gives 2*5*6=60, and the remaining integer division gives 6/3=2. The result is 8-60+2=-50, matching OOP23's explicit example. The negative sign follows from subtracting the larger product.

Why each choice is right or wrong

A - Incorrect: -150 does not follow the parenthesized value 6 and product 60 obtained from the stated operands.

B - Incorrect: -30 miscalculates the product or remaining terms; 8-60+2 is -50.

C - Correct: The grouped arithmetic gives 8-60+2, which equals -50.

D - Incorrect: The product is subtracted, so changing -50 to positive 50 loses the required sign.

Primary note proof

In which character method returns the uppercase form of the specified char value.

A. a | toUpperCase()

B. i? | toLowerCase()

C. @) toString()

D. | isDigit()

Hint

Read the cited conceptual rules, state the model, and apply them before comparing the alternatives.

Answer A: Character.toUpperCase(ch).

OOP22 names Character.toUpperCase(ch) as the operation that converts a character to uppercase. A supplies the correct method name, with its argument abbreviated away. Lowercase conversion, string representation and a digit test have different purposes.

Why each choice is right or wrong

A - Correct: toUpperCase is the named conversion; an actual Character call supplies the char argument.

B - Incorrect: toLowerCase names the opposite letter-case conversion rather than producing uppercase.

C - Incorrect: toString names textual representation rather than uppercase conversion of the supplied character.

D - Incorrect: isDigit names a predicate about a character, not an uppercase conversion operation.

Primary note proof

Study-note section OOP-S04

In which parameter is the regular expression to which this string is to be matched?

A. a | regul x

B. Q « x

C. |@| regex v

D. | None of the above x

Hint

Separate identity, content equality, immutable values and references that may be reassigned.

Answer C: regex, in the documented Java String.matches(String regex) signature.

In the Java String-matching API, matches(String regex) names its regular-expression parameter regex. This answers the API-signature question; it does not make regex a mandatory parameter name in arbitrary programmer-defined methods.

Why each choice is right or wrong

A - Incorrect: The image recovers regul, which is not the parameter name in OOP22's documented matches signature.

B - Incorrect: The image recovers reg; the documented String.matches parameter is named regex, not reg.

C - Correct: The image places regex at C, matching the regular-expression parameter named in OOP22.

D - Incorrect: The documented parameter name is present at C, so none of the above is false.

Question 153 | Q01212

Which one of the following is not the purpose of the super keyword?

A. Refer to the current object

B. Call superclass constructor

C. Access hidden variables

D. Invoke superclass method with the same name as the subclass method

Hint

Distinguish the current instance, parent context, hidden fields and static dispatch.

Answer A: Refer to the current object

super refers to the immediate superclass and can access its members or constructor. It is distinguished from this, which refers to the current instance.

Why each choice is right or wrong

A - Correct: Current-object role belongs to this, not the superclass qualifier

B - Incorrect: Explicit superclass-constructor use

C - Incorrect: super.member can resolve hidden variables

D - Incorrect: Explicit superclass-method access use

Primary note proof

Study-note section OOP16

> Java this denotes the current object; this.name=name distinguishes a field from a parameter. super.name selects a hidden superclass field; super.sound() directly requests the parent implementation. It does not create a second parent object. An unqualified instance call may dispatch dynamically; an explicit super call is different.

Study-note section OOP10

> Under Java 17 rules, an explicit this(args) or super(args) invocation must be the first constructor statement. this invokes another constructor in the same class; super invokes the immediate superclass constructor. A constructor cannot explicitly invoke both.

Question 154 | Q01219

Which one of the following has the same name as the class name?

A. Method

B. Variable

C. Constructor

D. Package name

Hint

Check the class name, return-type absence and the constructors actually declared.

Answer C: Constructor

Constructors have the same name as their class and no return type; a regular method need not have that name.

Why each choice is right or wrong

A - Incorrect: No requirement for ordinary methods to match the class name

B - Incorrect: Variables have their own identifiers

C - Correct: This naming rule applies to constructors

D - Incorrect: Packages are organizational names, not constructor names

Primary note proof

Study-note section OOP09

A constructor has the class's exact name and no return type, not even void. It initializes the new object and can be overloaded or private.

Study-note section OOP28

Packages organize names and control access; hierarchical spelling does not grant special access between a package and its subpackages.

Question 155 | Q01227

Which statement is true about the class concept?

A. The role of a class is to define the attributes and methods.

B. Class is used to distinguish one type of object from another.

C. A set of objects that share common methods, structure, and behavior.

D. All of the above

Hint

Distinguish an object’s stored state, operations, identity and class definition.

Answer D: All of the above

A class defines the common data/method shape of its objects and is itself a reference type. That supports attributes/methods, a distinct type, and a collection of similar objects.

Why each choice is right or wrong

A - Incorrect: Class consists of data and methods

B - Incorrect: Class defines a reference type and its objects' shape

C - Incorrect: Matches the definition of a set of similar objects

D - Correct: Combines the three supported descriptions

Primary note proof

Question 156 | Q01233

Which one is used to achieve the encapsulation concept in Java?

A. Declare the variables of a class as private.

B. Provide public setter and getter methods to modify and view the variable's values.

C. By using an Interface.

D. A & B

Hint

Identify whether the emphasis is grouping state, hiding implementation, exposing essentials or varying behavior.

Answer D: A & B

Hidden private fields plus accessible methods provide controlled access to class data. A alone hides data; B supplies the permitted interaction boundary.

Why each choice is right or wrong

A - Incorrect: Provides class-only data visibility

B - Incorrect: Provides the methods through which hidden data can be accessed

C - Incorrect: An interface alone does not hide a class's data fields

D - Correct: Combines hiding and controlled method access

Primary note proof

Study-note section OOP02

> Encapsulation groups related state and operations and controls access. Information hiding keeps implementation decisions behind a stable interface.

Study-note section OOP08

Which one of the following is the collection of statements that performs a specific operation?

A. Class

B. Package

C. Variable

D. Method

Hint

Separate parameters from arguments and operations that read state from operations that change it.

Answer D: Method

Methods are class members that perform operations and contain executable bodies.

Why each choice is right or wrong

A - Incorrect: A class groups fields and methods, not just one operation's statements

B - Incorrect: Package groups classes/interfaces

C - Incorrect: Variable stores data rather than an operation body

D - Correct: Matches an operation implemented by a statement body

Primary note proof

Question 158 | Q01255

For this valid Java instance method inside a class, which input/output statement is correct?

```
public void test(boolean a, boolean b) {
if (a) {
System.out.println("A");
} else if (a && b) {
System.out.println("A && B");
} else {
if (!b) {
System.out.println("!B");
} else {
System.out.println("None");
}
}
}
```

A. If a and b are both true, the output is "A && B".

B. If a is true and b is false, the output is "!B".

C. If a is false and b is true, the output is "None".

D. If a and b are both false, the output is "None".

Hint

Trace condition tests, control transfers and printing as separate steps.

Answer C: a=false and b=true prints None.

If a is true, the first branch prints A regardless of b. If a is false, the else-if condition a && b is necessarily false, so execution enters the final else. There !b selects !B when b is false and None when b is true. Only C pairs its input values with the resulting output.

Why each choice is right or wrong

A - Incorrect: When a is true the first branch prints A, not the unreachable A && B branch.

B - Incorrect: a=true selects A immediately regardless of b, so !B does not print.

C - Correct: a=false bypasses both earlier tests and b=true makes !b false, selecting None.

D - Incorrect: With both false, the final !b test is true and prints !B rather than None.

Primary note proof

Study-note section OOP25

Which one of the following methods can be overriding?

A. Abstract method

B. Final Method

C. Private method

D. Static method

Hint

Check inheritance, signature compatibility, visibility and eligibility for an override.

Answer A: Abstract method

Subclasses provide implementations of inherited abstract methods; the overriding rules explicitly exclude private, static and final methods.

B - Incorrect: Explicitly prohibited

C - Incorrect: Explicitly prohibited

Considering the following program, Which one of the following statements gives syntax error?

```
class Shape {
double x;
void area() { ... }
}
class Circle extends Shape {
double PI = 3.14;
void display() { ... }
}
```

A. Shape s = new Circle(); s.area();

B. Shape s = new Shape(); s.area();

C. Shape s = new Circle(); s.display();

D. Circle c = new Circle(); c.area();

Hint

Check what compiles from the declared type, then select behavior from the actual runtime class.

Answer C: Shape s = new Circle(); s.display();

A superclass reference can refer to a child object, but only exposes members available through its declared type. An Animal reference cannot directly access the Dog-specific field breed. Shape has no display(), so s.display() is the analogous compile-time member error.

Why each choice is right or wrong

A - Incorrect: Shape reference can call its declared area; runtime dispatch applies

B - Incorrect: Shape object and its declared area are consistent

C - Correct: display is only declared in Circle, not the reference type Shape

D - Incorrect: Circle inherits area from Shape

Primary note proof

Study-note section OOP15

> For Animal a=new Dog(), Animal is the declared type and Dog the actual type. The declared type determines which member operations compile. If fetch() exists only in Dog, a.fetch() fails compilation. For an eligible overridden sound(), a.sound() invokes Dog.sound() at runtime.

• Dynamic method dispatch is the mechanism by which a call to an overridden method is resolved at run time, rather than compile time.
• Dynamic method dispatch is important because this is how Java implements run-time polymorphism
• When an overridden method is called through a superclass reference, Java determines which version of that method to execute based upon the type of the object being referred to at the time the call occurs.
• Thus, this determination is made at run time.
• Method Overriding is an example of runtime polymorphism.

One of the following does not describe an object

A. Delegates responsibilities to other objects

B. It receives and sends message from/to other objects

C. It is an instance of a class

D. It is an abstract description of the state and behavior of a collection of similar objects

Hint

Distinguish an object's stored state, operations, identity and class definition.

Answer D: It is an abstract description of the state and behavior of a collection of similar objects

An object is a concrete runtime instance with state and behavior, whereas the abstract description of similar objects is the class blueprint.

Why each choice is right or wrong

A - Incorrect: Can describe collaborating operations, though delegation is not separately defined

B - Incorrect: Method communication is consistent with the class operations description

C - Incorrect: Explicit object definition

D - Correct: Describes the class template rather than one instance

Question 162 | Q01505

Which statements about Java 17 constructors are false? Select all that apply.

A. A constructor can be overloaded

B. It has the same name as the class

C. can be invoked within any method without object instantiation.

D. the first line of the constructor must be a call on another constructor in the same class

E. Has no return statement

Hint

Check the class name, return-type absence and the constructors actually declared.

Answer C, D, E: can be invoked within any method without object instantiation.; the first line of the constructor must be a call on another constructor in the same class; Has no return statement

Constructors can be overloaded and must use the class's exact name, so A and B are true. They are not ordinary methods that can be called anywhere without construction. A same-class this(...) call is not mandatory; delegation may use super(...) or implicit super(). Constructors also allow bare return; even though they have no return type and cannot return an expression. Therefore C, D and E are false.

Why each choice is right or wrong

A - Incorrect: Overloading constructors is permitted, so this statement is true.

B - Incorrect: A constructor has the exact class name, so this statement is true.

C - Correct: Constructors are not ordinary methods callable from any method without construction.

D - Correct: An explicit same-class constructor call is not mandatory.

E - Correct: A bare return; is allowed, so the claim of no return statement is false.

Primary note proof

Study-note section OOP09

> A constructor has the class's exact name and no return type, not even void. It initializes the new object and can be overloaded or private. A private constructor can support a factory or controlled singleton creation; it does not mean the class can never create an object internally.

Study-note section OOP09

> Constructors are not inherited or overridden. They may contain return; but cannot return an expression. Fields get their default values before ordinary constructor initialization, rather than receiving defaults only because a default constructor was generated.

Study-note section OOP10

Under Java 17 rules, an explicit this(args) or super(args) invocation must be the first constructor statement. this invokes another constructor in the same class; super invokes the immediate superclass constructor. A constructor cannot explicitly invoke both. If there is no explicit delegation, an implicit super() is inserted; a matching accessible no-argument parent constructor must exist.

}
public class Casting {
public static void main(String []args){

d.brake();
}
}
class Ferrari extends Car {
void drive() {
System.out.print("drive:");
}
void brake() {
System.out.println("brake hard:");
}
}
```

A. Generic noise: brake hard

B. drive: brake hard

C. generic nose: drive: brake hard

D. Compiler Error

E. Run time Error

Hint

Separate compile-time cast compatibility from the object’s actual runtime type.

Answer E: Runtime ClassCastException before any drive or brake output.

a refers to an actual Car created with new Car(), not to a Ferrari. The cast is type-checkable because Ferrari is a subclass, but it fails at runtime as OOP21 states. Execution stops at the cast with ClassCastException, before a.drive() or d.brake() can print any of their messages.

Why each choice is right or wrong

A - Incorrect: The failing cast occurs before either drive or brake, so neither listed message prints.

B - Incorrect: No Ferrari object exists here; the cast throws before any dynamic drive or brake call.

C - Incorrect: The program never reaches any of the three proposed messages because the cast fails first.

D - Incorrect: The related-class cast can pass compile-time checking; the actual object type causes a runtime failure.

E - Correct: Casting a plain Car object to Ferrari throws ClassCastException at runtime before any method output.

Primary note proof

Study-note section OOP21

> Upcasting a subclass reference to a superclass is implicit and does not change the object. A downcast may pass compile-time type checks yet fail at runtime. Car a=new Car(); Ferrari f=(Ferrari)a; throws ClassCastException before subsequent drive() or brake() calls. It does not turn a plain Car into a Ferrari.

Question 164 | Q01624

Which Java local declarations are valid when considered independently? Assume no type named x exists and the references are not read before assignment. Select all that apply.

A. None of the choices is correct

B. int [ ] x, y = new int[5];

C. int x[ ] = new x[5];

D. int [ ] x = new int[4];

E. int x = {5, 4, 9};

Hint

Check declared dimensions, initializer shape, fixed length and zero-based index bounds.

Answer B, D: int [ ] x, y = new int[5];; int [ ] x = new int[4];

In B, int[] is the shared type of both x and y. Only y receives a new five-element array, which is a legal declaration as long as unassigned x is not read. D separately creates a four-element int array. C cannot use the variable-like name x as an allocation type under the stated scope, and E declares a scalar int with an array initializer. Thus B and D are valid.

Why each choice is right or wrong

A - Incorrect: B and D are valid declarations, so none is incorrect.

B - Correct: Both references have type int[]; initializing only y is legal.

C - Incorrect: No type x exists, so new x[5] is not a valid allocation here.

D - Correct: This is a valid int[] declaration and allocation.

E - Incorrect: A scalar int cannot be initialized with a multi-element brace array initializer.

Primary note proof

Study-note section OOP26

> int[] a=new int[5]; and int a[]={1,2,3}; are valid. int[] a={}; creates a zero-length array; explicit new is unnecessary in a declaration initializer. int a[],b; makes only a an array; int[] c,d; makes both arrays. Array objects have fixed length after creation, although the reference may be reassigned.

Study-note section OOP05

> Locals occur in methods, constructors or blocks; they must be definitely assigned before use and cannot have public/private/protected modifiers.

Java has two basic data types
1. Primitive Data Types: are 8 in java (byte, short, int, long, float, double, char & Boolean)
2. Reference types: Arrays, classes, and interfaces, String)
• Note: Boolean type has a value true or false (there is no conversion b/n Boolean and other types).
• All non-primitive types are reference types, so all class types are reference types.
• All integers in Java are signed, Java doesn‟t support unsigned integers.

Question 165 | Q01625

What is a Java static initializer block?

A. A block that initializes class-level state during class initialization, before that class's first relevant active use, including its main invocation

B. None of the choices is correct.

C. There is no such block.

D. It is used to create synchronized code.

Hint

Decide whether a member belongs to a class or an object, then check initialization and final restrictions.

Answer A: A block that initializes class-level state during class initialization, before that class's first relevant active use, including its main invocation

A static initializer executes during class initialization and can initialize static state. It runs before the class's first relevant active use, including invoking its main method, rather than simply whenever a class file is loaded. It is a real Java construct, so none and the denial option are false. Synchronization is a different concern and does not define a static initializer's purpose.

Why each choice is right or wrong

A - Correct: This states the class-state initialization purpose and correct initialization timing.

B - Incorrect: A correctly describes a real construct, so none is incorrect.

C - Incorrect: Static initializer blocks exist in Java.

D - Incorrect: Creating synchronized code is not the defining role of a static initializer.

Primary note proof

Study-note section OOP07

A static initializer runs during class initialization, before the class's first relevant active use, not simply whenever a file is loaded.

C. Class/Static variables
• Are declared with the static keyword in a class, but outside a method, constructor or a block.
• There would only be one copy of each class variable per class, regardless of how many objects are created from it.
• Are rarely used other than being declared as constants. (public static final)
• Are stored in the static memory.
• Static variables are created when the program starts and destroyed when the program stops.
• Visibility is similar to instance variables. However, most static variables are declared public
• Default values are same as instance variables.
• Static variables can be accessed by calling with the class name ClassName.VariableName.

Object Oriented Programming module | PDF page 14 | lines 2-19

Static methods and Final Variables
• A static method can access only static data.
• A static method can call only other static data (Static methods & variables), but can not call a non-static data from it.
• Static method is belongs to the class and not to the object.
• A static method can be accessed directly by the class name and doesn‟t need any object.

• i.e ClassName.methodName(args)
• A static method cannot refer to "this" or "super" keywords in anyway
• But can be overloaded since they are resolved using static binding by compiler at compile time.

Question 166 | Q01626

What is the output of the below given Java code? Assume every necessary components of the program are included.

```
int i;
for (i = 0; i < 5; i++) {
if (i % 2 == 0)
System.out.print ( i + " ");
System.out.print ( i + 1);
}
```

A. 0 12 34 5

B. None of the choices is correct

C. 0 2 4 6

D. 0 122 344 5

Hint

Trace condition tests, control transfers and printing as separate steps.

Answer D: 0 122 344 5.

Only the first print is controlled by if. At i=0,2,4 it prints the even value followed by a space; every iteration then prints i+1 without a separator. The contributions are "0 1", "2", "2 3", "4", "4 5". Joining them produces "0 122 344 5", exactly as OOP25 records.

Why each choice is right or wrong

A - Incorrect: This omits digits from the unconditional i+1 prints on odd and even iterations.

B - Incorrect: D supplies the exact concatenated output, so none of the choices is false.

C - Incorrect: The unconditional print runs five times; the output is not just an even-number sequence.

D - Correct: Joining every conditional and unconditional print yields the exact string 0 122 344 5.

Primary note proof

Study-note section OOP25

Count executions independently from printing. For i=0..4, if(i%2==0) print(i+" "); followed unconditionally by print(i+1); produces "0 122 344 5".

Study-note section OOP-S02

A print call emits its value without inserting a separator or ending the line. A println call emits its value followed by a line terminator. Spaces must come from the supplied text or explicit output operations; adjacent calls do not automatically separate their values.

_____ is a way of saying: This object is a type of that object.

A. IS-A

B. HAS-A

C. ARE-A

D. HAD-A

Hint

Identify the subtype or ownership relationship and distinguish class inheritance from interface contracts.

Answer A: IS-A

IS-A describes type membership: an object belongs to a type or one of its subtypes.

Why each choice is right or wrong

A - Correct: Matches the named IS-A relationship

B - Incorrect: HAS-A would describe composition/containment rather than type membership

C - Incorrect: Not the named relationship

D - Incorrect: Not the named relationship

Primary note proof

Study-note section OOP13

> Use inheritance when a subtype can satisfy the parent's contract: Dog is an Animal. For shared Pet.name and speak(), put common state/contract in Pet, specialized fetch() in Dog, and appropriate speak() implementations in Dog and Cat. Composition represents has-a, such as Car containing Engine. Reuse alone does not justify an invalid is-a relationship.

Question 168 | SM0012

Which Java member access modifier permits subclasses in other packages to access inherited members through their own inherited context, while excluding unrelated clients in those other packages? Same-package access is allowed.

A. protected

B. private

C. default

D. public

Hint

Locate the accessing code, declaring type, package and receiver before applying visibility rules.

Answer A: protected

protected includes same-package access and also permits qualified subclass access across packages. That matches the revised boundary, which excludes unrelated clients in other packages while allowing same-package clients. private does not generally expose inherited members to separately declared subclasses, package access does not reach other packages, and public allows unrelated external clients. The question no longer demands an impossible universal subclasses-only rule.

Why each choice is right or wrong

A - Correct: protected provides same-package access plus the specified qualified cross-package subclass access.

B - Incorrect: private does not grant the requested general cross-package subclass access.

C - Incorrect: Package/default access does not extend to subclasses in another package.

D - Incorrect: public also permits unrelated accessible external clients, violating the boundary.

Primary note proof

Study-note section OOP08

> For ordinary members: private restricts access to the declaring class/nest; no modifier grants package access; protected grants same-package access plus qualified subclass access; public is widest, provided the declaring type itself is accessible.

Study-note section OOP08

> Across packages, a subclass accessing a protected instance member must do so through its own inherited context or an appropriate subclass-typed receiver, not any arbitrary superclass object. protected therefore does not mean “subclasses only”: unrelated classes in the same package also have access.

Access Specifiers
Access level modifiers determine whether other classes can use a particular field or invoke a particular method.
Their are four types access levels:
1. No Modifier(Default): Visible to the package(source file), and it is called package-private
2. Private: Visible to the class only.
3. Public: Visible to the world.
4. Protected: Visible to the package and all subclasses.

Which one of the following is the correct way of creating a String object?

A. String m = 'Computer Science';

B. String m = new String('Technology');

C. String m = 'H', 'e', 'l', 'l', 'o';

D. String m = new String("Exit Exam");

Hint

Read the cited conceptual rules, state the model, and apply them before comparing the alternatives.

Answer D: String m = new String("Exit Exam");

A String literal uses double quotes, while a character literal supplies one char in single quotes. D passes a valid String literal to the String constructor and assigns the resulting object reference. A and B instead use invalid multi-character character literals. C is not one valid String initializer: separate comma-delimited character literals do not form a String expression or a character-array constructor argument.

Why each choice is right or wrong

A - Incorrect: The multi-character text in single quotes is not a valid Java character literal or String expression.

B - Incorrect: new String does not make its invalid single-quoted multi-character argument legal.

C - Incorrect: The comma-separated character literals do not form one String initializer or a supplied char-array value.

D - Correct: A double-quoted String argument matches the String constructor and initializes the String reference.

Primary note proof

Study-note section OOP-S04

> A double-quoted string literal denotes a String object. new String(existingString) creates a String with the same text; new String(charArray) copies the array's characters into an immutable String. Question 170 | SM0069

Which one of the following is false about String in Java?

A. In Java a string is treated as object

B. We can create a String object using String literal

C. We can create a String object using array of characters

D. Content of a string can be changed once the string is created

Hint

Read the cited conceptual rules, state the model, and apply them before comparing the alternatives.

Answer D: A created String's content cannot be changed.

OOP22 explicitly states that Java String objects are immutable. A variable can later reference a new String result, but the existing object's content does not change. D therefore contradicts the rule. The other choices describe String objects or ways of supplying initial content, which do not assert mutation of an already-created String.

Why each choice is right or wrong

A - Incorrect: String is an object type in the note; this is not the false mutability claim.

B - Incorrect: A String literal supplies String content; it does not imply the resulting object can later mutate.

C - Incorrect: Supplying initial character content creates a String; it does not change an existing String's immutable content.

D - Correct: This is false: Java String objects are immutable after creation, even if a variable is rebound.

Primary note proof

Study-note section OOP-S04

A double-quoted string literal denotes a String object. new String(existingString) creates a String with the same text; new String(charArray) copies the array's characters into an immutable String. A single-quoted literal denotes one char, so several characters enclosed together in single quotes cannot supply a String.

Study-note section OOP22

Java String objects are immutable. text += " World" assigns a reference to a new concatenated result and can print Hello World without mutating the original String object. final class String prevents subclassing; final alone does not make arbitrary objects immutable.

Question 171 | SM0074

Which concept refers to extending specialized classes from generalized classes in object-oriented programming?

A. Inheritance

B. Overriding

C. Overloading

D. Data field Encapsulation

Hint

Identify the subtype or ownership relationship and distinguish class inheritance from interface contracts.

Answer A: Inheritance

A subclass is a specialized version of a superclass, and inheritance creates that relation.

Why each choice is right or wrong

A - Correct: Matches specialized-from-general hierarchy

B - Incorrect: Replaces an inherited method, not the class relationship

C - Incorrect: Adds same-name methods with changed parameters

D - Incorrect: Groups/controls data, not class specialization

B. The derived class (subclass) is allowed to add methods or redefine them

C. A feature that allows us to derive a class from another class

D. Allows programmers to customize without actually modifying the original class (superclass)

Hint

Answer A: The subclass can add variables, but cannot redefine them

B declares its own i, hiding A.i, and adds its own methods. Thus subclass fields can be declared with an ancestor's name; A's cannot claim is false in the intended hiding sense.

Why each choice is right or wrong

A - Correct: Contradicted by B's int i hiding A.i

B - Incorrect: Subclass can add methods and override inherited ones

C - Incorrect: Matches the inheritance definition

D - Incorrect: Subclass extension permits customization without changing the parent

Which OOP concept allows objects of different classes to be treated as objects of a common superclass?

A. Polymorphism

B. Inheritance

C. Abstraction

D. Encapsulation

Hint

Check what compiles from the declared type, then select behavior from the actual runtime class.

Answer A: Polymorphism

A parent-class reference referring to child objects is a common use of polymorphism. Inheritance establishes the relation, while polymorphism is the treatment through the common type.

Why each choice is right or wrong

A - Correct: Names the common-superclass many-forms treatment

B - Incorrect: Prerequisite relationship but not the treatment asked for

C - Incorrect: Hides background details

D - Incorrect: Groups data and methods

Question 174 | SM0243

Which purposes apply to a Java interface viewed as a capability contract? “Blueprint” means an operation contract for implementing classes, and “multiple inheritance” means multiple type inheritance rather than multiple superclass state inheritance. Select all that apply.

A. To define a blueprint for a class

B. To allow multiple inheritance

C. To create objects directly

D. To hide internal implementation details

Hint

Identify the interface contract, effective modifiers and permitted implementation forms.

Answer A, B, D: To define a blueprint for a class; To allow multiple inheritance; To hide internal implementation details

An interface specifies an operation contract that implementing classes satisfy, so the qualified blueprint description is valid. A class can implement multiple interfaces, gaining multiple type inheritance. Clients can use the contract without depending on a particular implementation’s internals, supporting abstraction. Interfaces are not directly instantiated, so creating objects directly is not their purpose. The multi-select form therefore accepts A, B and D.

Why each choice is right or wrong

A - Correct: An operation blueprint is the contract that implementations must satisfy.

B - Correct: Implementing multiple interfaces supports multiple type inheritance.

C - Incorrect: An interface cannot be instantiated directly.

D - Correct: The public contract lets callers use capabilities without depending on internal implementation details.

Extending multiple Interface
Multiple inheritance in Java by interface
• If a class implements multiple interfaces, or an interface extends multiple interfaces i.e. known as multiple inheritance.
Extending multiple Interface
• A single interface can extend multiple interfaces, below is a simple example.

Variant 1 | Alternative version 1

Which purposes apply to Java interfaces as capability contracts, rather than complete per-instance state definitions? “Blueprint” means an operation contract, and “multiple inheritance” means multiple type inheritance. Select all that apply.

A. To create multiple constructors for a class

B. To define the state and behavior of an object

C. To define a blueprint of a class

D. To achieve multiple inheritance

Answer C, D: Interfaces define capability contracts and support multiple type inheritance.

This variant places the contract/blueprint purpose at C and multiple type inheritance at D. Both are valid: implementing objects satisfy the public operation contract, and a class may implement several interfaces. Interfaces have no constructors or per-instance fields, so they do not create class constructors or define an object’s complete state and implementation. Its selected labels therefore differ from the primary option set.

Why each choice is right or wrong

A - Incorrect: Interfaces have no constructors, so creating multiple constructors is not their purpose.

B - Incorrect: An interface specifies capabilities rather than complete per-instance state and implementation.

C - Correct: The defined blueprint is an operation contract for implementing classes.

D - Correct: Several interface types provide multiple type inheritance.

Primary note proof

Study-note section OOP19

> interface Payable{double getPaymentAmount();} declares an abstract public operation. class Invoice implements Payable must provide public double getPaymentAmount(), perhaps returning getQuantity()*getPricePerItem(). A class can extend a superclass and implement zero or more interfaces. An interface can extend several interfaces. No interface instance fields or constructors exist; fields are implicitly public static final.

Question 175 | SM0245

Which OOP relationship is formed when a Java class implements several interface contracts? Choose the relationship concept, rather than the language construct declaring each contract.

A. Polymorphism

B. Encapsulation

C. Inheritance

D. Interface

Hint

Identify the interface contract, effective modifiers and permitted implementation forms.

Answer C: Inheritance, specifically multiple interface/type inheritance.

Implementing several interfaces gives the class several interface types and forms multiple type inheritance. Inheritance is therefore the relationship concept requested. Interface names a construct used to declare a contract, rather than the relationship itself. Polymorphism can use the resulting common types to select behavior, while encapsulation groups state and controls access. Neither names the requested multiple-type relationship.

Why each choice is right or wrong

A - Incorrect: Polymorphism uses common types for appropriate behavior; the question asks for the type relationship itself.

B - Incorrect: Encapsulation groups state and controls access rather than forming the specified type relationship.

C - Correct: The class acquires multiple interface types, which is multiple type inheritance.

D - Incorrect: Interface is the construct defining a contract, not the requested relationship concept.

Extending multiple Interface
Multiple inheritance in Java by interface
• If a class implements multiple interfaces, or an interface extends multiple interfaces i.e. known as multiple inheritance.
Extending multiple Interface
• A single interface can extend multiple interfaces, below is a simple example.

Object Oriented Programming module | PDF page 31 | lines 9-30

• It provides total abstraction;
• Means all the methods in interface are declared with empty body and are public and all fields are public, static and final by default.
• A class that implement interface must implement all the methods declared in the interface.
• If a class implements an interface and does not provide method bodies for all functions specified in the interface, then class must be declared abstract.
Rules of Interface
• Variables declared in an interface are public, static & final by default.
• Java does not allow you to extend more than one class, However you can implement more than one interfaces in your class.
• class implements interface but an interface extends another interfaces.

Question 176 | SM0283

Which of the following concepts in OOP allows a class to inherit attributes and methods from another class?

A. Inheritance

B. Abstraction

C. Encapsulation

D. Polymorphism

Hint

Identify the subtype or ownership relationship and distinguish class inheritance from interface contracts.

Answer A: Inheritance

Acquiring another class's methods and fields defines inheritance.

Why each choice is right or wrong

A - Correct: Matches acquisition from another class

B - Incorrect: Essential information exposure

C - Incorrect: Wrapping data/methods together

D - Incorrect: Many forms of behavior, rather than the transfer relation

Primary note proof

Study-note section OOP13

> class Dog extends Animal declares a subclass/derived/child of a superclass/base/parent.

Study-note section OOP02

> Encapsulation groups related state and operations and controls access. Information hiding keeps implementation decisions behind a stable interface. Abstraction presents the essential operations while omitting details irrelevant to the caller.

Study-note section OOP02

> Inheritance forms a subtype relationship and may reuse implementation. Polymorphism lets code using a common type invoke behavior appropriate to different concrete objects.

> What is Inheritance?
> • Inheritance is one of the cornerstones of

object-oriented programming because it allows the creation of hierarchical classifications.
• Inheritance is the process where one class acquires the properties (methods and fields) of another.
• A class that is inherited is called a superclass.
• The class that does the inheriting is called a subclass.
• OR: The class which inherits the properties of other is known as subclass (derived class, child class) and
• The class whose properties are inherited is known as superclass (base class, parent class).
• Therefore, a subclass is a specialized version of a superclass.
• It inherits all of the instance variables and methods defined by the superclass and add its own, unique elements.
• The extends keyword: is the keyword used to inherit the properties of a class. Below given is the syntax of extends keyword.

According to the introductory module's language-characteristics list, which description contradicts its characterization of Java?

A. Java is Object-Oriented

B. Java is Platform Independent

C. Java is difficult to learn

D. Java is architecture neutral

Hint

Read the cited conceptual rules, state the model, and apply them before comparing the alternatives.

Answer C: Java is difficult to learn

Java is commonly characterized as object oriented, platform independent and simple. Architecture-neutral bytecode is executed by a compatible platform-specific JVM. Difficult to learn conflicts with the module's intended simple characterization, making C the requested mismatch. This is a question about the module's description, not an objective claim that every learner finds Java easy or that every program runs unchanged in every environment.

Why each choice is right or wrong

A - Incorrect: Object orientation is part of the stated introductory characterization.

B - Incorrect: Platform independence is part of the stated characterization, subject to a compatible JVM and environment.

C - Correct: Difficult to learn conflicts with the module's intended simple characterization.

D - Incorrect: Architecture-neutral bytecode supports this characteristic within the specified compatible-runtime model.

Primary note proof

Study-note section OOP-S06

> Java is commonly characterized as object oriented, platform independent and simple. Its architecture-neutral bytecode is executed by a compatible platform-specific JVM. "Simple" is a teaching characterization relative to language design, not a promise that every learner finds every Java program easy.

Question 178 | SS094

Which statement about Java interfaces is false? In A, “interface instance” means an object made by directly instantiating the interface itself, without an implementation. C means interfaces may include abstract methods.

A. An interface can be instantiated directly without supplying an implementation, and its abstract methods can then be invoked

B. Like a class, an interface is a reference data type

C. Interface includes abstract methods

D. One class can implement multiple interfaces

Hint

Identify the interface contract, effective modifiers and permitted implementation forms.

Answer A: An interface can be instantiated directly without supplying an implementation, and its abstract methods can then be invoked

An interface cannot be instantiated directly without an implementation. An interface reference can instead hold an implementing object and invoke its contract methods. Interfaces are reference types, can declare abstract operations, and can be implemented alongside other interfaces by one class. Clarifying A’s construction meaning isolates the false statement without incorrectly rejecting ordinary calls through interface-typed references.

Why each choice is right or wrong

A - Correct: Direct interface instantiation without an implementation is forbidden, so A is false.

B - Incorrect: An interface is a reference type usable for implementation references, so B is true.

C - Incorrect: An interface may declare abstract methods, so C is true.

D - Incorrect: One class can implement multiple interfaces, so D is true.

Primary note proof

Study-note section OOP19

interface Payable{double getPaymentAmount();} declares an abstract public operation. class Invoice implements Payable must provide public double getPaymentAmount(), perhaps

returning getQuantity()*getPricePerItem(). A class can extend a superclass and implement zero or more interfaces. An interface can extend several interfaces.

Study-note section OOP19

Interfaces cannot be instantiated directly, but references may hold implementing objects, anonymous implementations or suitable functional-interface lambdas.

Chapter - Five: Java Interface
• An interface in java is a blueprint of a class.
• It has static constants and abstract methods.
• The interface in java is a mechanism to achieve abstraction.
• There can be only abstract methods in the java interface not method body (contain only signature, not body).
• It is used to achieve abstraction and multiple inheritance in Java.
• Java Interface also represents IS-A relationship.
• It cannot be instantiated just like abstract class.
• There are mainly three reasons to use interface.
• It is used to achieve abstraction.
• By interface, we can support the functionality of multiple inheritance.

Question 179 | SS097

The following UML design shows Student class. Assume that the attributes have declared as private and the methods as public. The get methods
return the value of the attributes and the calculateAge() returns the Student age. Which of the following would not raise an error when you run this
program?

A. Student st1 = new Student ("John","CS","0913222222","25");

B. Student st1 = new Student ("John","SE","0913222222",20);

C. st1 Student = new Student ("John","CS","02085332455", 23);

D. Student st1 = new Student ("John","IT","2000");

Hint

Read the notation and distinguish a class description from a particular instance.

Answer B: Student st1 = new Student ("John","SE","0913222222",20);

The UML specifies Student parameters of types String, String, String and int, in that order. B supplies exactly those four argument types. Distinct String and int primitives/reference types rule out the quoted age in A.

Why each choice is right or wrong

A - Incorrect: Fourth argument is String 25 rather than int

B - Correct: Three String arguments and an int age match the UML

C - Incorrect: Reverses the required type/name declaration order

D - Incorrect: Only three String arguments; missing the required int age

Primary note proof

Study-note section OOP04

A UML class box normally contains name, attributes and operations. Visibility uses + public, - private and # protected. A field can be written name:String and an operation getName():String. A constructor Student(String,String,String,int) requires three strings and an integer, so an age argument "25" has the wrong type.

Study-note section OOP03

What we use to pass the data between activities in Android?

A. Broadcast receiver

B. PostgreSQL Database

C. Intent

D. Content Provider

Hint

Distinguish an interactive entry point, a requested action and attached data.

Answer C: An Intent, with extras.

OOP35 says an Intent describes an action or target and extras carry values between activities. Its putExtra("id",17) example supplies a concrete transfer. A broadcast receiver handles broadcasts and a content provider shares structured data; neither is the ordinary activity-start-with-parameters mechanism. A PostgreSQL database is not the inter-activity carrier described here.

Why each choice is right or wrong

A - Incorrect: A broadcast receiver handles broadcasts rather than serving as the ordinary activity-to-activity parameter carrier.

B - Incorrect: A database can store data but is not the Intent-and-extras transfer mechanism specified in OOP35.

C - Correct: An Intent selects the action/target and carries values between activities using extras.

D - Incorrect: A content provider shares structured data, rather than being the ordinary parameterized activity-start mechanism.

Primary note proof

Study-note section OOP35

> An Intent describes a requested action or explicit target; extras carry values between activities. For example, putExtra("id",17) attaches an ID for the destination to read. A content provider shares structured data, while a broadcast receiver handles broadcast messages; neither is the ordinary mechanism for starting an activity with parameters.

What Is Manifest.xml in android?

A. It has the information about activities in an application

B. It has all the information about an application

C. Itis an executable file of the application

D. It has information about layout in an application

Hint

Separate application declarations, view containers and installation packaging.

Answer A: The manifest declares essential metadata, including application activities.

OOP36 says AndroidManifest.xml declares essential metadata such as components, permissions and intent filters. Activities are components, so A states a supported part of its contents. B overstates the scope by claiming all application information, which the note explicitly rejects. The image's reordered highlighted all-information choice cannot override that rule or the main option labels.

Why each choice is right or wrong

A - Correct: Activities are application components whose declarations form part of the manifest's essential metadata.

B - Incorrect: All information is too broad; the manifest does not contain all source code or layout details.

C - Incorrect: The manifest declares metadata and is explicitly not executable application code.

D - Incorrect: Layout resources describe views; the manifest does not contain the layout details asserted here.

Primary note proof

Question 182 | SS109

Assume you have an interface called Payable as follows:
public interface Payable {
double getPaymentAmount();
}
If you have another class Invoice that implements this interface and getQuantity() and getPricePerItem() methods that return quantity and price per item, which options correctly implement the Payable contract? Treat each option as an independent class skeleton with accessible getQuantity() and getPricePerItem() methods supplied and compatible with multiplication returning double. An abstract class may supply a concrete implementation. Select all that apply.

A. public abstract class Invoice implements Payable {
public double getPaymentAmount() {
return getQuantity() * getPricePerItem();
}
}

B. public class Invoice implements Payable {
public double getPaymentAmount() {
return getQuantity() * getPricePerItem();
}
}

C. public class Invoice implements Payable {
public getPaymentAmount() {
return getQuantity() * getPricePerItem();
}
}

D. public class Invoice extends Payable {
public double getPaymentAmount() {
return getQuantity() * getPricePerItem();
}
}

Hint

Identify the interface contract, effective modifiers and permitted implementation forms.

**Answer A, B: public abstract class Invoice implements Payable {
public double getPaymentAmount() {
return getQuantity() * getPricePerItem();
}
}; public class Invoice implements Payable {
public double getPaymentAmount() {
return getQuantity() * getPricePerItem();
}
}**

Both A and B provide public double getPaymentAmount() with the required quantity-times-unit-price result. Declaring A abstract does not prevent it from implementing the interface method concretely; it only prevents direct construction of Invoice itself. The assumed helper methods make both skeletons complete for this comparison. C omits the return type, while D incorrectly uses extends for the interface relationship. Thus A and B satisfy the contract.

Why each choice is right or wrong

A - Correct: An abstract class may still provide this concrete public double implementation.

B - Correct: The concrete class provides the required public double implementation.

C - Incorrect: The method lacks a return type and is not a valid implementation declaration.

D - Incorrect: A class implements Payable; it cannot extend that interface as a superclass.

Primary note proof

Study-note section OOP19

> interface Payable{double getPaymentAmount();} declares an abstract public operation. class Invoice implements Payable must provide public double getPaymentAmount(), perhaps returning getQuantity()*getPricePerItem(). A class can extend a superclass and implement zero or more interfaces.

Question 183 | SS117

Which statement is wrong about a Java try-catch construct? Assume any exception considered has a matching catch, and no earlier control transfer prevents reaching it.

A. The execution control is moved to catch block after exception occur in try block

B. When exception occurs, the execution of try block is interrupted

C. The catch block is executed once regardless of exceptions in try block

D. The catch block is used to handle exceptions that occur in try block

Hint

Check the thrown type and catch order before tracing propagation or handler output.

Answer C: The catch block is executed once regardless of exceptions in try block

If the try block completes normally, its catch does not execute. If an exception occurs, normal execution of the try is interrupted and the matching handler runs. Thus the claim that catch runs once regardless of exceptions is false. Catch is conditional handling, whereas finally normally provides cleanup after the try and any selected handler. The matching-handler assumption makes the other transfer statements precise.

Why each choice is right or wrong

A - Incorrect: With the stated matching-handler assumption, an exception transfers control to that catch.

B - Incorrect: The exception interrupts normal execution and skips the remaining try body.

C - Correct: This is false: normal completion of try does not execute catch.

D - Incorrect: The matching catch handles the exception thrown during try.

Primary note proof

Study-note section OOP30

> try encloses guarded operations; a matching catch handles the thrown type or a subtype. Execution skips the remainder of the try when a throw occurs.

Study-note section OOP31

> finally normally executes after try and any selected catch, including when leaving by return or propagating an exception.

Question 184 | SS118

An accessible abstract Class_A declares public abstract String welcome(); and has an accessible no-argument constructor. Which independent concrete definition of Class_B compiles? Each public class is in its own correctly named source file. These options restore the complete A-D code blocks from the source images.

A.
```
public class Class_B extends Class_A {
  public String whatObjectAmI() { return "I am a class B object"; }
  }
```

B.
```
public class Class_B extends Class_A {
  public int welcome() { int x = 10; return x; }
  }
```

C.
```
public class Class_B extends Class_A {
  public String whatObjectAmI() { return "I am a class D object"; }
  public String welcome() { return "I am a class C object"; }
  public int welcome(int y) { int x = 2 * y; return x; }
  }
```

D.
```
public class Class_B extends Class_A {
  public void welcome(String str) { }
  }
```

Hint

Check whether a class is concrete and whether every inherited abstract contract has an implementation.

Answer C: public class Class_B extends Class_A {
public String whatObjectAmI() { return "I am a class D object"; }
public String welcome() { return "I am a class C object"; }
public int welcome(int y) { int x = 2 * y; return x; }
}

The required inherited method has no parameters and returns String. C supplies that exact public implementation and may additionally overload welcome with an int parameter. A has no welcome implementation, B returns an incompatible int, and D supplies only a different-parameter overload. Those concrete subclasses leave the abstract contract unsatisfied or violate return compatibility.

Why each choice is right or wrong

A - Incorrect: whatObjectAmI() does not implement the required welcome() contract.

B - Incorrect: int is incompatible with the required String return for the same signature.

C - Correct: The exact public String welcome() implementation is present; welcome(int) is an allowed overload.

D - Incorrect: welcome(String) is an overload and does not implement no-argument welcome().

Primary note proof

Study-note section OOP18

> A concrete subclass must provide or inherit implementations of all required abstract methods; otherwise it must itself be abstract. If parent declares abstract String welcome(), a String welcome() implementation is required; int welcome() is incompatible, and welcome(int) merely adds an overload. A valid class can contain both the required implementation and an unrelated overload.

For traditional Android View-based layout containers, which class is their common container superclass?

A. android.view.Layout

B. android.view.RelativeLayout

C. android.view.ViewGroup

D. android.view.Widget

Hint

Separate application declarations, view containers and installation packaging.

Answer C: android.view.ViewGroup, for traditional view-based layout containers.

Traditional Android View-based layout containers, including LinearLayout and RelativeLayout, derive from android.view.ViewGroup. ViewGroup contains child views, matching the container role. RelativeLayout is one particular container rather than the common superclass, and the other supplied names do not identify that superclass. The View-system scope avoids extending this claim to every modern Android layout abstraction.

Why each choice is right or wrong

A - Incorrect: This is not the named View-system container superclass.

B - Incorrect: RelativeLayout is a particular layout container, not the common superclass of the layout containers.

C - Correct: android.view.ViewGroup is the child-view container superclass for this traditional View-system scope.

D - Incorrect: This does not name the View-system container superclass.

Primary note proof

> Traditional view-based layout containers such as LinearLayout and RelativeLayout derive from android.view.ViewGroup, which contains child views.

Which statements about a Java abstract class are true? Select all that apply.

A. Cannot be instantiated directly

B. Must contain at least one abstract method

C. Can contain both abstract and non-abstract methods

D. Cannot be inherited

Hint

Check whether a class is concrete and whether every inherited abstract contract has an implementation.

Answer A, C: Cannot be instantiated directly; Can contain both abstract and non-abstract methods

An abstract class cannot be constructed directly, but it can contain both abstract and concrete methods. It can also be abstract without declaring any abstract method, so B is false. Abstract classes may be inherited; a concrete subclass must fulfill outstanding abstract method contracts. Cleaning the source marking noise and replacing the vague encapsulation slogan leaves two precise true properties at A and C.

Why each choice is right or wrong

A - Correct: Direct instantiation of an abstract class is prohibited.

B - Incorrect: An abstract class need not declare any abstract method.

C - Correct: Abstract and concrete methods may coexist in an abstract class.

D - Incorrect: Abstract classes can be inherited; concrete subclasses must fulfill their contracts.

Primary note proof

Study-note section OOP18

An abstract class cannot be directly instantiated but can define fields, constructors, abstract methods and concrete methods. It need not contain an abstract method. An abstract method has no body; abstract and final conflict because an operation cannot require overriding while forbidding it.

Study-note section OOP18

A concrete subclass must provide or inherit implementations of all required abstract methods; otherwise it must itself be abstract.

Question 187 | SS129

What is an activity in android?

A. A single screen in an application with supporting java code

B. android class used to configure the android application

C. Itis an intent

D. android package file holding all the packages used

Hint

Distinguish an interactive entry point, a requested action and attached data.

Answer A: An Activity is a user-interaction entry component, often a screen.

An Android Activity is a component providing an entry point for user interaction, often corresponding to a screen. A is the introductory screen-and-code description that best matches this definition, though a one-to-one screen mapping is not universal. Configuration, Intents and package archives are separate concepts.

Why each choice is right or wrong

A - Correct: The screen with supporting code is the introductory description closest to the note's interaction-entry component.

B - Incorrect: Configuring the application describes a different responsibility than providing the Activity's user-interaction entry point.

C - Incorrect: An Intent describes a requested action or target; it is not itself an Activity.

D - Incorrect: An Android package archive is installation/runtime packaging, rather than a user-interaction component.

Primary note proof

Study-note section OOP35

> An Android Activity is a component providing an entry point for user interaction, often corresponding to a screen. An Intent describes a requested action or explicit target; extras carry values between activities. For example, putExtra("id",17) attaches an ID for the destination to read. A content provider shares structured data, while a broadcast receiver handles broadcast messages; neither is the ordinary mechanism for starting an activity with parameters.

Question 188 | SS140

Assume that there is a Pet family from which Pets like Dog and Cat share behavior from.Every Pet family has a name. However, the pet families have
some specific behaviors that are exhibited by only particular Pets. For instance, only Dogs can fetch something while both cats and dogs can speak.
Which of the following object oriented designprinciple would be suitable for this case?

A. Polymorphism

B. Encapsulation

C. Inheritance

D. _ Information hiding

Hint

Identify the subtype or ownership relationship and distinguish class inheritance from interface contracts.

Answer C: Inheritance

A shared Pet superclass can hold name and common speak behavior; Dog and Cat specialize it, with fetch only in Dog. This directly uses inheritance. Overriding speak could also yield polymorphism but is not required by the stem.

Why each choice is right or wrong

A - Incorrect: Would apply if speak were dispatched to different overrides, which is not stated

B - Incorrect: Groups data/methods but does not establish shared family specialization

C - Correct: Models shared parent features plus subclass-specific behavior

D - Incorrect: Hides details rather than defining the family hierarchy

Primary note proof

Study-note section OOP13

Use inheritance when a subtype can satisfy the parent's contract: Dog is an Animal. For shared Pet.name and speak(), put common state/contract in Pet, specialized fetch() in Dog, and appropriate speak() implementations in Dog and Cat. Composition represents has-a, such as Car containing Engine. Reuse alone does not justify an invalid is-a relationship.

Study-note section OOP02

Encapsulation groups related state and operations and controls access. Information hiding keeps implementation decisions behind a stable interface. Abstraction presents the essential operations while omitting details irrelevant to the caller.

What is Inheritance?
• Inheritance is one of the cornerstones of object-oriented programming because it allows the creation of hierarchical classifications.
• Inheritance is the process where one class acquires the properties (methods and fields) of another.
• A class that is inherited is called a superclass.
• The class that does the inheriting is called a subclass.
• OR: The class which inherits the properties of other is known as subclass (derived class, child class) and
• The class whose properties are inherited is known as superclass (base class, parent class).
• Therefore, a subclass is a specialized version of a superclass.
• It inherits all of the instance variables and methods defined by the superclass and add its own, unique elements.
• The extends keyword: is the keyword used to inherit the properties of a class. Below given is the syntax of extends keyword.
• Sytax:
class Super{

.....}
class Sub extends Super{ }

Object Oriented Programming module | PDF page 16 | lines 51-70

Types of inheritance
1. Simple/single inheritance: is damn easy to understand. When a class extends another one class only.
2. Multi-Level inheritance: One can inherit from a derived class, thereby making this derived class the base class for the new class.
3. Hierarchical inheritance: One class is inherited by many sub classes.
• Java does not support the inheritance of multiple super classes into a single subclass. (Multiple & Hybrid inheritances)
• No class can be a superclass of itself
• Superclass can be used by itself.
• The superclass has no knowledge of what a subclass adds to it.
• Constructors are not members, so they are not inherited by subclasses.

Object Oriented Programming module | PDF page 3 | lines 58-64

2. Polymorphism:
• The word polymorphism means the ability to take more than one form.
• In terms of the OOP, this means that a particular operation may behave differently for different sub-classes of the same class.

Question 189 | SS165

Which method has the same name as that of its class?

A. constructor

B. class

C. delete

D. finalize

Hint

Check the class name, return-type absence and the constructors actually declared.

Answer A: constructor

The constructor naming rule requires the same name as its class. The term method is used informally in the question; constructors have no return type.

Why each choice is right or wrong

A - Correct: Matches the constructor naming rule

B - Incorrect: class is a declaration keyword, not this routine category

C - Incorrect: delete is not the constructor category

D - Incorrect: finalize has its own name rather than the class name

Primary note proof

APK stands for:

A. Android Phone Kit

B. Android Page Kit

C. Android Platform Kit

D. Android Package Kit

Hint

Separate application declarations, view containers and installation packaging.

Answer D: Android Package Kit is the common exam expansion.

Android Package Kit is a common exam expansion of APK; the artifact is an Android package archive. Thus D is appropriate under this expansion convention. None of the Phone, Page or Platform alternatives describes this package archive.

Why each choice is right or wrong

A - Incorrect: Phone Kit does not match the common expansion or the package-archive meaning given in OOP36.

B - Incorrect: Page Kit does not describe the installation package archive identified here.

C - Incorrect: Platform Kit is not the bank expansion explicitly documented in OOP36.

D - Correct: Package Kit is the common exam expansion expressly stated, with Android package as the official artifact terminology.

Primary note proof

Question 191 | AM0304

Which option specifically describes encapsulation’s bundling of related state and operations, rather than focusing on hiding implementation decisions behind an interface?

A. Combining data and methods into a single entity.

B. Hiding implementation details and providing a public interface.

C. Creating multiple instances of a class.

D. Inheriting properties and behavior from a base class.

Hint

Identify whether the emphasis is grouping state, hiding implementation, exposing essentials or varying behavior.

Answer A: Combining data and methods into a single entity.

Encapsulation groups related state and operations and controls access to them. A directly describes the grouping or bundling aspect requested here. B describes information hiding and can accompany encapsulation, but the stem deliberately asks for the grouping emphasis. Creating instances is object construction, while inheriting base properties is inheritance. This specific emphasis makes A the unique answer without denying the overlap of the broader principles.

Why each choice is right or wrong

A - Correct: Combining data and methods directly describes the requested bundling aspect.

B - Incorrect: This emphasizes information hiding rather than the specific grouping mechanism asked for.

C - Incorrect: Creating instances is object construction rather than encapsulation’s grouping.

D - Incorrect: Reusing base-class properties describes inheritance.

Primary note proof

Study-note section OOP02

Encapsulation groups related state and operations and controls access. Information hiding keeps implementation decisions behind a stable interface. Abstraction presents the essential operations while omitting details irrelevant to the caller. These ideas overlap: a private balance plus deposit(amount) can demonstrate all three, depending on what the question emphasizes.

What is inheritance in Java?

A. The process of creating objects from classes.

B. The ability of a class to inherit properties and behavior from another class.

C. Creating multiple instances of a class.

D. The ability to access variables and methods of a different class.

Hint

Identify the subtype or ownership relationship and distinguish class inheritance from interface contracts.

Answer B: The ability of a class to inherit properties and behavior from another class.

Inheritance means acquiring another class's fields and methods, matching the properties-and-behavior description.

Why each choice is right or wrong

A - Incorrect: Instantiation rather than inheritance

B - Correct: Matches acquisition from a parent class

C - Incorrect: Instance creation rather than inheritance

D - Incorrect: Too broad: arbitrary access to another class is not inheritance

What is the concept of polymorphism in Java?

A. The ability to create multiple objects from a single class.

B. The ability to hide implementation details.

C. The ability to override methods in a subclass.

D. The ability of an object to take many forms and be treated as an instance of its superclass.

Hint

Identify whether the emphasis is grouping state, hiding implementation, exposing essentials or varying behavior.

Answer D: The ability of an object to take many forms and be treated as an instance of its superclass.

Polymorphism means many forms and can be illustrated by a parent reference to a child object. Overriding is one mechanism, not the full concept.

Why each choice is right or wrong

A - Incorrect: Creating several same-class objects does not imply many type forms

B - Incorrect: Hiding details describes abstraction

C - Incorrect: Overriding supports runtime polymorphism but is a narrower mechanism

D - Correct: Matches both many forms and common-superclass treatment

Primary note proof

Study-note section OOP02

> Inheritance forms a subtype relationship and may reuse implementation. Polymorphism lets code using a common type invoke behavior appropriate to different concrete objects.

Study-note section OOP15

> For Animal a=new Dog(), Animal is the declared type and Dog the actual type. The declared type determines which member operations compile. If fetch() exists only in Dog, a.fetch() fails compilation. For an eligible overridden sound(), a.sound() invokes Dog.sound() at runtime.

Question 194 | AM0307

What is the purpose of the super keyword in Java?

A. To access the superclass of a derived class.

B. To instantiate a new object.

C. To access the current object.

D. To define a method within a class.

Hint

Distinguish the current instance, parent context, hidden fields and static dispatch.

Answer A: To access the superclass of a derived class.

super selects the superclass context for member access and can request a superclass implementation. A hidden parent field can be selected with super.name, and super.sound() directly calls the parent version. It does not allocate a separate parent object or name the current instance; this is the current-object reference. Method definitions use declarations, so A is the valid purpose among the primary choices.

Why each choice is right or wrong

A - Correct: This describes selecting the superclass context and its members.

B - Incorrect: super does not allocate a separate object.

C - Incorrect: this denotes the current object; super selects parent context.

D - Incorrect: A method declaration defines a method; super does not do that.

Primary note proof

Study-note section OOP16

> Java this denotes the current object; this.name=name distinguishes a field from a parameter. super.name selects a hidden superclass field; super.sound() directly requests the parent implementation. It does not create a second parent object. An unqualified instance call may dispatch dynamically; an explicit super call is different.

> • super( ) must always be the first statement executed inside a subclass‟ constructor.

Variant 1 | Alternative version 1

Inside an instance method declared in the current subclass, which descriptions correctly identify the parent-class context selected by Java super? Select all that apply.

A. It refers to the current object instance.

B. It refers to the superclass of the current class.

C. It refers to the class that contains the current method.

D. It refers to the class from which the current class is derived.

Answer B, D: Both B and D describe the superclass context selected by super.

The superclass of the current class and the class from which the current class derives name the same parent relationship, so B and D both apply. super selects that parent context for member access or explicit parent implementation calls. A instead describes this, while C identifies the current subclass containing the declared method. The variant therefore needs multiple selection even though the primary choices have one correct answer.

Why each choice is right or wrong

A - Incorrect: The current object instance is denoted by this, not the parent-context selector super.

B - Correct: The superclass is the parent context selected by super.

C - Incorrect: The method is declared in the current subclass, whereas super selects its parent context.

D - Correct: The class from which the current class derives is its superclass, equivalent to B.

Primary note proof

Question 195 | AM0308

What is the difference between an abstract class and an interface in Java?

A. An abstract class can have concrete methods, while an interface cannot.

B. An interface can have static methods, while an abstract class cannot.

C. An abstract class can be instantiated, while an interface cannot.

D. An interface can extend multiple interfaces, while an abstract class cannot.

Hint

Identify the interface contract, effective modifiers and permitted implementation forms.

Answer D: Interfaces can extend multiple interfaces; an abstract class instead implements interfaces and extends one class.

OOP19 permits an interface to extend several interfaces and a class to extend one superclass while implementing multiple interfaces. Thus D is correct when extend retains its Java declaration meaning. It must not be paraphrased as abstract classes cannot implement multiple interfaces. A is outdated for modern interfaces, B wrongly excludes class static methods, and C wrongly permits abstract instantiation.

Why each choice is right or wrong

A - Incorrect: Modern interfaces can contain default/static bodies, so concrete behavior is not exclusive to abstract classes.

B - Incorrect: Abstract classes can have static methods; their abstract modifier does not prohibit class-level methods.

C - Incorrect: An abstract class cannot be directly instantiated, so the first half of this distinction is false.

D - Correct: An interface extends multiple interfaces; a class implements them instead and has one direct superclass.

Primary note proof

Study-note section OOP19

> A class can extend a superclass and implement zero or more interfaces. An interface can extend several interfaces.

Study-note section OOP19

> A method declaration without private, default or static is implicitly public abstract. Modern interfaces may also have default/static method bodies, and Java 9+ private helper methods.

Study-note section OOP18

Question 197 | AM0310

What is the purpose of the this keyword in Java?

A. To refer to the superclass of a class.

B. To instantiate a new object.

C. To access the current object's variables and methods.

D. To define a method within a class.

Hint

Distinguish the current instance, parent context, hidden fields and static dispatch.

Answer C: Access the current object's variables and methods.

OOP16 says this denotes the current object and demonstrates this.name=name to distinguish a field from a parameter. That makes C the requested purpose. super selects parent context, new creates an object, and method declarations define methods. this neither creates a new instance nor denotes the superclass or the class itself.

Why each choice is right or wrong

A - Incorrect: Superclass context is selected using super, whereas this denotes the current object.

B - Incorrect: Object instantiation uses new and constructor invocation, not the this current-object reference.

C - Correct: this refers to the current object, enabling its instance fields and methods to be selected.

D - Incorrect: A method is defined by a declaration and body; this is an expression referring to the current object.

Primary note proof

Which keyword is used to explicitly indicate that a method does not return any value in Java?

A. void

B. null

C. final

D. static

Hint

Answer A: void

The general method pattern returns a value only if type is not void, and test() is shown as void without a value return.

Question 199 | AM0312

What is method overloading in Java?

A. Defining multiple methods with the same name but different parameters in the same class.

B. Defining a method within another method.

C. Invoking a method from within itself.

D. Creating multiple instances of a class.

Hint

Compare names and parameter signatures before considering return types or access modifiers.

Answer A: Defining multiple methods with the same name but different parameters in the same class.

The definition retains one method name while differentiating parameter lists. Return type alone is insufficient, so signature differences must be in parameters.

Why each choice is right or wrong

A - Correct: Matches same name and different parameters

B - Incorrect: Nested method definition is not overloading

C - Incorrect: Self-invocation is recursion

D - Incorrect: Multiple objects are instantiation, not overloaded methods

Primary note proof

Study-note section OOP12

Overloaded methods share a name but have different parameter types, counts or type order. Return type alone is insufficient in Java and C++. Overloads can also arise through inherited methods; “same class only” is a teaching simplification. f(int), f(double) and f(int,int) are distinct, but changing a parameter name does not create an overload.

Method Overloading
• Is a process of having the same name for different methods as long as their parameter list or data types in the parameter list is different?
• The return type alone is insufficient to distinguish two versions of a method.
• Parameters are key identifiers of OM.
• Is one of the ways that Java supports polymorphism

Variant 1 | Alternative version 1

What is method overloading in Java?

A. Creating multiple methods with the same name but different return types.

B. Creating multiple methods with the same name but different parameter lists.

C. Creating multiple methods with the same name and parameter list but different return types.

D. Creating multiple methods with the same name and parameter list but different access modifiers.

Answer B: Creating multiple methods with the same name but different parameter lists.

Apply the same study-note rule to this alternative source set; the choice contrasts below show the derivation.

Why each choice is right or wrong

A - Incorrect: Same-name/different-return methods are not necessarily overloads; return type alone is explicitly insufficient

B - Correct: Same name with different parameter lists is the exact overloading definition

C - Incorrect: Same parameter list prevents return-type-only overloading

D - Incorrect: Access-modifier differences do not supply the required parameter difference

Primary note proof

Question 200 | AM0313

What is the purpose of the new keyword in Java?

A. To instantiate a new object.

B. To invoke a method.

C. To define a variable.

D. To define a class.

Hint

Separate a reference declaration, object allocation, reference copying and changes to the shared object.

Answer A: To instantiate a new object.

A reference declaration is distinct from new Dog(), which creates the actual instance and triggers initialization.

Why each choice is right or wrong

A - Correct: Matches object creation

B - Incorrect: An ordinary method call does not by itself state the new allocation

C - Incorrect: A variable declaration can exist without an object

D - Incorrect: class declares the blueprint, not its instance

Primary note proof

Study-note section OOP03

> Student s; declares a reference variable; it creates no Student object. Student s=new Student(); allocates and initializes an instance.

Question 201 | AM0314

What is the output of the following Java code snippet?

```
class MyClass {
public static void main(String[] args) {
int x = 5;
System.out.println(x++);
System.out.println(++x);
}
}
```

A. 5, 6

B. 5, 7

C. 6, 6

D. 6, 7

Hint

Track the old and updated values separately and distinguish a character operand from a string.

Answer B: 5, then 7, on separate lines.

OOP24 gives this exact sequence: postfix x++ supplies the old value 5 and then stores 6; prefix ++x then stores and supplies 7. The two println calls print those values on separate lines. The commas in the choices describe the sequence rather than literal commas emitted by the program.

Why each choice is right or wrong

A - Incorrect: The second prefix increment advances the stored 6 to 7 before printing, so the second value is not 6.

B - Correct: Postfix prints the old 5, then prefix increments the stored 6 and prints 7.

C - Incorrect: The first postfix expression supplies 5 rather than the incremented 6.

D - Incorrect: The second value is 7, but the first remains 5 because its increment is postfix.

Primary note proof

Study-note section OOP24

> Starting x=5, printing x++ then ++x gives 5 then 7.

Question 202 | AM0315

Which Java keyword directly exits the enclosing loop prematurely while allowing execution to continue after that loop in the same method?

A. break

B. continue

C. return

D. exit

Hint

Trace condition tests, control transfers and printing as separate steps.

Answer A: break

break exits the enclosing loop and transfers control to the statement after it. continue skips the remaining body of the current iteration and may begin another iteration. return leaves the entire method, so it does not satisfy the stated requirement to continue after the loop in that same method. exit is not a Java loop-control keyword. The narrower control-flow target makes break unique.

Why each choice is right or wrong

A - Correct: break exits the loop and resumes after it within the method.

B - Incorrect: continue proceeds toward another iteration rather than exiting the loop.

C - Incorrect: return exits the entire method, contrary to the required continuation.

D - Incorrect: exit is not a Java loop-control keyword.

Primary note proof

Study-note section OOP25

> break exits the loop; continue skips its remaining body and then runs a for update.

Study-note section OOP-S03

> An unlabeled break leaves the innermost enclosing loop or switch. continue moves to the next iteration step, while return leaves the current method and may supply a return value. These transfers have different destinations; return is not merely a loop exit.

What is the purpose of the try-catch block in Java?

A. To handle exceptions and prevent program crashes.

B. To define a custom class.

C. To declare variables with restricted access.

D. To instantiate objects.

Hint

Check the thrown type and catch order before tracing propagation or handler output.

Answer A: To handle exceptions and prevent program crashes.

An exception disrupts execution, and try/catch monitors code and supplies a handler, as shown for an input mismatch. It can handle matched exceptions, not guarantee prevention of every crash.

Why each choice is right or wrong

A - Correct: Matches exception handling, with no universal recovery guarantee

B - Incorrect: Class definition is a different construct

C - Incorrect: Visibility modifiers govern access

D - Incorrect: new and constructors instantiate objects

Primary note proof

Study-note section OOP30

> try encloses guarded operations; a matching catch handles the thrown type or a subtype. Execution skips the remainder of the try when a throw occurs.

Question 204 | AM0317

Which independent Java declarations correctly create an int array? Select all that apply.

A. int[] numbers = {1, 2, 3};

B. int numbers[] = new int[3];

C. int numbers = new int[]{1, 2, 3};

D. int numbers[] = {1, 2, 3};

Hint

Check declared dimensions, initializer shape, fixed length and zero-based index bounds.

Answer A, B, D: int[] numbers = {1, 2, 3};; int numbers[] = new int[3];; int numbers[] = {1, 2, 3};

A and D use legal bracket placements with a brace initializer to create arrays containing 1, 2 and 3. B also declares an int array and allocates three elements, initially zero. C instead declares numbers as a scalar int but supplies an int-array value, producing a type mismatch. Both bracket placement styles and both allocation forms are allowed, so A, B and D are selected.

Why each choice is right or wrong

A - Correct: The int[] type and brace initializer create a three-element int array.

B - Correct: Brackets after the variable name and new int[3] are valid.

C - Incorrect: The scalar int variable cannot hold the int[] initializer value.

D - Correct: The name[] form with a brace initializer is valid.

Primary note proof

Study-note section OOP26

> int[] a=new int[5]; and int a[]={1,2,3}; are valid. int[] a={}; creates a zero-length array; explicit new is unnecessary in a declaration initializer. int a[],b; makes only a an array; int[] c,d; makes both arrays. Array objects have fixed length after creation, although the reference may be reassigned.

What is the role of the super keyword in Java?

A. To refer to the current object instance.

B. To invoke a method from the superclass.

C. To define a class as final.

D. To allocate memory for an object.

Hint

Distinguish the current instance, parent context, hidden fields and static dispatch.

Answer B: To invoke a method from the superclass.

super.member may name a method or instance variable of the immediate superclass. This directly covers invoking a superclass method.

Why each choice is right or wrong

A - Incorrect: Current-object role is this rather than super

B - Correct: Matches superclass method access

C - Incorrect: final is the separate class modifier

D - Incorrect: new is the allocation operation

Primary note proof

Study-note section OOP16

> Java this denotes the current object; this.name=name distinguishes a field from a parameter. super.name selects a hidden superclass field; super.sound() directly requests the parent implementation. It does not create a second parent object.

Question 207 | AM0320

What does the static keyword mean in Java?

A. It denotes that a variable or method belongs to the superclass.

B. It indicates that a variable or method can only be accessed within the same class.

C. It allows a variable or method to be accessed without creating an instance of the class.

D. It specifies that a variable or method cannot be modified.

Hint

Decide whether a member belongs to a class or an object, then check initialization and final restrictions.

Answer C: It allows a variable or method to be accessed without creating an instance of the class.

Static members belong to the class, and the static method is accessible by class name without an object. Visibility and immutability are separate properties.

Why each choice is right or wrong

A - Incorrect: Class membership does not mean belonging to the superclass

B - Incorrect: Private is the visibility restriction

C - Correct: Matches class access without creating an instance

D - Incorrect: final, not static, prevents modification

Primary note proof

Study-note section OOP07

static gives one field per loaded class, shared by its instances. If count starts at zero and every constructor increments it, three creations leave count=3. Prefer ClassName.count and ClassName.utility(). A static method has no current instance, but can still use instance members through an explicit object reference.

Study-note section OOP07

final prevents reassignment of a variable, overriding of a method or extension of a class.

Static methods and Final Variables
• A static method can access only static data.
• A static method can call only other static data (Static methods & variables), but can not call a non-static data from it.
• Static method is belongs to the class and not to the object.
• A static method can be accessed directly by the class name and doesn‟t need any object.
• i.e ClassName.methodName(args)
• A static method cannot refer to "this" or "super" keywords in anyway
• But can be overloaded since they are resolved using static binding by compiler at compile time.

Object Oriented Programming module | PDF page 5 | lines 39-61

C. Class/Static variables
• Are declared with the static keyword in a class, but outside a method, constructor or a block.
• There would only be one copy of each class variable per class, regardless of how many objects are created from it.
• Are rarely used other than being declared as constants. (public static final)
• Are stored in the static memory.
• Static variables are created when the program starts and destroyed when the program stops.
• Visibility is similar to instance

variables. However, most static variables are declared public
• Default values are same as instance variables.
• Static variables can be accessed by calling with the class name ClassName.VariableName.

What is the output of the following Java code snippet?

```
class MyClass {
public static void main(String[] args) {
String text = "Hello";
text += " World";
System.out.println(text);
}
}
```

A. Hello

B. World

C. Hello World

D. Compile error

Hint

Separate identity, content equality, immutable values and references that may be reassigned.

Answer C: Hello World.

OOP22 directly explains that text += " World" assigns a reference to a new concatenated result rather than mutating the original String. The variable therefore refers to "Hello World" before printing. String immutability does not prevent rebinding a non-final variable, so the code is valid and prints the combined text with its space.

Why each choice is right or wrong

A - Incorrect: The variable is rebound to the concatenated result, so it no longer prints only its initial text.

B - Incorrect: Concatenation retains Hello and appends the space and World; it does not replace the entire content with World.

C - Correct: The new concatenated String contains Hello, a space and World, and text refers to that result.

D - Incorrect: String immutability permits this reference reassignment; the code does not attempt to mutate the original String.

Primary note proof

Study-note section OOP22

> Java String objects are immutable. text += " World" assigns a reference to a new concatenated result and can print Hello World without mutating the original String object. final class String prevents subclassing; final alone does not make arbitrary objects immutable.

Which access modifier allows a class member to be accessible only within the same package?

A. public

B. private

C. protected

D. Default (no modifier specified)

Hint

Locate the accessing code, declaring type, package and receiver before applying visibility rules.

Answer D: Default (no modifier specified)

No modifier/default is explicitly package-private. Other modifiers are narrower or wider than the package-only requirement.

Why each choice is right or wrong

A - Incorrect: World-visible, too broad

B - Incorrect: Class-only, too narrow

C - Incorrect: Also includes out-of-package subclasses

D - Correct: Exactly the package-private scope

Primary note proof

For ordinary members: private restricts access to the declaring class/nest; no modifier grants package access; protected grants same-package access plus qualified subclass access; public is widest, provided the declaring type itself is accessible.

Study-note section OOP08

Across packages, a subclass accessing a protected instance member must do so through its own inherited context or an appropriate subclass-typed receiver, not any arbitrary superclass object. protected therefore does not mean “subclasses only”: unrelated classes in the same package also have access.

A. 5

B. 10

C. Compile error

D. Runtime exception

Hint

Locate the accessing code, declaring type, package and receiver before applying visibility rules.

Answer B: 10

The write to obj.x is inside MyClass itself, even though main is static; private is class-based, not object-based. obj.x=10 updates the instance, and getX returns that field.

Why each choice is right or wrong

A - Incorrect: Old initializer is replaced by the assignment

B - Correct: Getter returns the updated field value 10

C - Incorrect: Same-class code may access private fields through obj

D - Incorrect: No exceptional operation is indicated by these class-local accesses

What is the purpose of the toString() method in Java?

A. To convert an object to a string representation.

B. To compare two objects for equality.

C. To perform arithmetic calculations.

D. To access the superclass methods.

Hint

Separate identity, content equality, immutable values and references that may be reassigned.

Answer A: Return an object’s textual representation.

OOP22 defines toString as giving a textual representation and distinguishes it from an equality test. A states that purpose. Comparing objects is the role of equals under the class’s policy, while arithmetic and superclass method access are separate operations. The representation need not create a new copy of the original object.

Why each choice is right or wrong

A - Correct: A textual String representation of an object is the purpose explicitly assigned to toString in OOP22.

B - Incorrect: Object equality is handled by equals under the class’s equality policy, not by toString.

C - Incorrect: Arithmetic calculations are not the defining contract of an object’s textual representation method.

D - Incorrect: Superclass access uses super; it is not the purpose of toString.

Question 212 | AM0325

What is the purpose of the equals() method in Java?

A. To convert an object to a string representation.

B. To compare two objects for equality.

C. To perform arithmetic calculations.

D. To access the superclass methods.

Hint

Separate identity, content equality, immutable values and references that may be reassigned.

Answer B: Compare objects according to the class's equality policy.

OOP22 says equals invokes a class's equality policy; Object.equals uses identity unless overridden, while String.equals compares content. B is therefore correct without assuming every class implements value equality. The other choices describe textual representation, arithmetic or superclass access, none of which is equals' comparison purpose.

Why each choice is right or wrong

A - Incorrect: Textual representation is the purpose of toString, rather than equals.

B - Correct: equals compares objects using the class's policy, which may be identity or an overridden value/content policy.

C - Incorrect: equals supplies an equality result rather than being an arithmetic calculation mechanism.

D - Incorrect: Superclass access uses super and is distinct from the equality comparison performed by equals.

Primary note proof

Question 213 | AM0326

What is the correct way to create an instance of a class in Java?

A. MyClass obj = new MyClass();

B. MyClass obj = MyClass();

C. MyClass obj = create MyClass();

D. MyClass obj = instance MyClass();

Hint

Separate a reference declaration, object allocation, reference copying and changes to the shared object.

Answer A: MyClass obj = new MyClass();

Dog myDog = new Dog(); includes a declaration, new allocation, constructor parentheses and assignment. A follows precisely that form.

Why each choice is right or wrong

A - Correct: Matches the demonstrated object construction

B - Incorrect: Omission of new does not match construction syntax

C - Incorrect: create is not Java's allocation keyword

D - Incorrect: instance is not Java's allocation keyword

Primary note proof

Question 214 | AM0327

What is the purpose of the static keyword for a method in Java?

A. It indicates that the method can be overridden.

B. It allows the method to be accessed without creating an instance of the class.

C. It denotes that the method can only be called by the class itself.

D. It specifies that the method cannot be modified.

Hint

Decide whether a member belongs to a class or an object, then check initialization and final restrictions.

Answer B: It allows the method to be accessed without creating an instance of the class.

Static methods can be called directly by class name without an object and cannot be overridden; a subclass declaration can hide them.

Why each choice is right or wrong

A - Incorrect: Contradicts the static non-overriding rule

B - Correct: Matches object-free class access

C - Incorrect: Visibility depends on access modifiers, not static alone

D - Incorrect: Immutability/non-overriding is not the same as prohibition on modifying the method

Primary note proof

Study-note section OOP07

static gives one field per loaded class, shared by its instances. If count starts at zero and every constructor increments it, three creations leave count=3. Prefer ClassName.count and ClassName.utility(). A static method has no current instance, but can still use instance members through an explicit object reference.

Study-note section OOP14

Constructors, final methods, static methods and private parent methods are not overridden.

Study-note section OOP08

For ordinary members: private restricts access to the declaring class/nest; no modifier grants package access; protected grants same-package access plus qualified subclass access; public is widest, provided the declaring type itself is accessible.

Static methods and Final Variables
• A static method can access only static data.
• A static method can call only other static data (Static methods & variables), but can not call a non-static data from it.
• Static method is belongs to the class and not to the object.
• A static method can be accessed directly by the class name and doesn‟t need any object.
• i.e ClassName.methodName(args)
• A static method cannot refer to "this" or "super" keywords in anyway
• But can be overloaded since they are resolved using static binding by compiler at compile time.

Question 215 | AM0328

What is the role of the this keyword in Java?

A. It refers to the current object instance.

B. It refers to the superclass of the current class.

C. It refers to the class that contains the current method.

D. It refers to the class from which the current class is derived.

Hint

Distinguish the current instance, parent context, hidden fields and static dispatch.

Answer A: this refers to the current object instance.

OOP16 defines this as the current object. In the main options that statement is A; it denotes an instance rather than its class, subclass or superclass. The source variant moves the same correct statement to C, so its labels must be reviewed separately. super is the distinct parent-context mechanism.

Why each choice is right or wrong

A - Correct: The current object instance is exactly what Java this denotes in ordinary instance context.

B - Incorrect: Superclass context is selected by super, not by the current-object reference this.

C - Incorrect: this refers to an instance, not to the class declaration containing a method.

D - Incorrect: The class from which the current class derives is its superclass, not the meaning of this.

Primary note proof

Study-note section OOP16

> Java this denotes the current object; this.name=name distinguishes a field from a parameter. super.name selects a hidden superclass field; super.sound() directly requests the parent implementation. It does not create a second parent object.

The super keyword
• Since encapsulation is a primary attribute of OOP, Whenever a subclass needs to refer to its immediate superclass, it can do so by use of the keyword super.
• Super has two general forms.
1. Used to access parent class instance members.
2. Used to access parent class constructor.
1. Used to access parent class instance members.
• super acts somewhat like this, except that it always refers to the superclass of the subclass in which it is used.
• Super has the form: super.member Here, member can be either a method or an instance variable.
• Super is most applicable to resolve member hiding.
• super( ) must always be the first statement executed inside a subclass‟ constructor.

Variant 1 | Alternative version 1

What is the role of the this keyword in Java?

A. It refers to the superclass of the current class.

B. It refers to the subclass of the current class.

C. It refers to the current object instance.

D. It refers to the class that contains the current method.

Answer C: this refers to the current object instance.

OOP16 defines this as the current object. This source variant places that definition at C, rather than main-option A. The superclass and subclass alternatives name type relationships, and the containing-class alternative denotes a type rather than the current instance.

Why each choice is right or wrong

A - Incorrect: Superclass context is associated with super, rather than the current-instance reference this.

B - Incorrect: A subclass is a type relationship; this denotes the current object, not a subclass.

C - Correct: This variant places the exact current-object-instance definition from OOP16 at label C.

D - Incorrect: The containing class is a type; this refers to the current object instance of a class.

Primary note proof

What is a constructor in Java?

A. A method that returns a value.

B. A method used for exception handling.

C. A special method used to initialize objects.

D. A method used to override a superclass method.

Hint

Check the class name, return-type absence and the constructors actually declared.

Answer C: A special method used to initialize objects.

Constructors automatically initialize objects, have the same name as their class and have no return type.

Why each choice is right or wrong

A - Incorrect: Contradicts the no-return-type rule

B - Incorrect: Exception handling uses try/catch

C - Correct: Matches automatic initialization of new objects

D - Incorrect: Constructors are not inherited overriding methods

Question 217 | AM0331

Assume an accessible inherited instance method is non-final, the subclass supplies the same name and parameter list with a compatible return type, and visibility is not reduced. Which descriptions fit the resulting method overriding? Select all that apply.

A. Creating multiple methods with the same name but different return types.

B. Creating multiple methods with the same name but different parameter lists.

C. Creating a new method with the same name and parameter list in the subclass.

D. Redefining a method in the subclass that already exists in the superclass.

Hint

Check inheritance, signature compatibility, visibility and eligibility for an override.

Answer C, D: Creating a new method with the same name and parameter list in the subclass.; Redefining a method in the subclass that already exists in the superclass.

Under the stated eligibility, signature, return and visibility conditions, the subclass method overrides the inherited method. C describes the same name and parameters, and D describes redefining the inherited superclass operation, so both describe this case. Different parameter lists denote overloading instead. Merely changing return types does not define overriding or a valid overload. The assumptions make the two overlapping valid descriptions explicit.

Why each choice is right or wrong

A - Incorrect: Different return types alone do not define overriding or distinguish valid overloads.

B - Incorrect: Different parameter lists describe overloading rather than this same-signature override.

C - Correct: The same-name, same-parameter subclass declaration is an override under the supplied conditions.

D - Correct: It redefines the eligible inherited superclass operation under the supplied conditions.

Primary note proof

Study-note section OOP14

> A subclass overrides an eligible inherited instance method with the same signature and a compatible return type; a covariant reference return may be a subtype. Visibility cannot become more restrictive, and checked exceptions cannot be broadened incompatibly.

What is polymorphism in Java?

A. The ability to create multiple objects of the same class.

B. The process of converting an object to a string representation.

C. The ability of an object to take on many forms through inheritance.

D. The process of comparing two objects for equality.

Hint

Identify whether the emphasis is grouping state, hiding implementation, exposing essentials or varying behavior.

Answer C: The ability of an object to take on many forms through inheritance.

Polymorphism means many forms, typically illustrated by a superclass reference pointing at child objects; inheritance supplies those related forms.

Why each choice is right or wrong

A - Incorrect: Several objects of the same class is multiplicity of instances

B - Incorrect: Object-to-string conversion is unrelated

C - Correct: Matches many forms through a hierarchy

D - Incorrect: Equality comparison is unrelated

Which object-oriented principle promotes the concept of reusing code and creating relationships between classes?

A. Encapsulation

B. Inheritance

C. Polymorphism

D. Abstraction

Hint

Identify whether the emphasis is grouping state, hiding implementation, exposing essentials or varying behavior.

Answer B: Inheritance

The inheritance section explicitly links reuse to creating a new class that inherits Person without changing Person, forming the parent/child relationship.

Why each choice is right or wrong

A - Incorrect: Wraps and hides data rather than deriving related classes

B - Correct: Directly supplies reuse through inherited relationships

C - Incorrect: Uses varying behavior through types rather than creating the reuse relationship

D - Incorrect: Suppresses details rather than acquiring reusable members

Primary note proof

Study-note section OOP02

What is the purpose of encapsulation in object-oriented programming?

A. To create relationships between classes

B. To allow classes to inherit properties and behaviors

C. To hide internal implementation details and expose a public interface

D. To provide different implementations of a method based on the object's type

Hint

Identify whether the emphasis is grouping state, hiding implementation, exposing essentials or varying behavior.

Answer C: To hide internal implementation details and expose a public interface

The hidden-data part of encapsulation exposes access through methods, which is the public interaction boundary described by C. A/B describe inheritance and D describes polymorphic overriding.

Question 223 | AM0338

Which Java keyword declares that one class inherits from another class?

A. super

B. extends

C. implements

D. this

Hint

Identify the subtype or ownership relationship and distinguish class inheritance from interface contracts.

Answer B: extends

A class declaration uses extends to name its direct superclass, as in class Dog extends Animal. A class implements interface contracts using implements, which is a different declaration relationship. super selects parent context inside a class, while this denotes the current instance. Restricting the question to class-to-class inheritance makes extends the unique keyword among these choices.

Why each choice is right or wrong

A - Incorrect: Refers to superclass members/constructor

B - Correct: Matches class Sub extends Super

C - Incorrect: Used for interface implementation instead

D - Incorrect: Refers to current-instance context, not an inheritance declaration

Primary note proof

Question 224 | AM0339

Which Java annotation requests compiler checking that a method overrides or implements an inherited method contract?

A. super

B. extends

C. implements

D. @Override

Hint

Check inheritance, signature compatibility, visibility and eligibility for an override.

Answer D: @Override

@Override asks the compiler to verify that a declaration satisfies overriding rules. Java does not have an override keyword, and the annotation does not create an override by itself; the declaration must still meet the inherited-contract conditions. super selects parent context, extends declares class inheritance, and implements declares interface relationships. Correcting the requested construct to an annotation preserves the intended override-checking concept.

Why each choice is right or wrong

A - Incorrect: super selects parent members or construction rather than checking a declaration's override status.

B - Incorrect: extends establishes class inheritance rather than annotating a method.

C - Incorrect: implements establishes an interface relationship rather than checking one method declaration.

D - Correct: @Override requests compiler verification of the overriding/implementation relationship.

Primary note proof

Study-note section OOP14

> A subclass overrides an eligible inherited instance method with the same signature and a compatible return type; a covariant reference return may be a subtype. What is Inheritance?
• Inheritance is one of the cornerstones of object-oriented programming because it allows the creation of hierarchical classifications.
• Inheritance is the process where one class acquires the properties (methods and fields) of another.
• A class that is inherited is called a superclass.
• The class that does the inheriting is called a subclass.
• OR: The class which inherits the properties of other is known as subclass (derived class, child class) and
• The class whose properties are inherited is known as superclass (base class, parent class).
• Therefore, a subclass is a specialized version of a superclass.
• It inherits all of the instance variables and methods defined by the superclass and add its own, unique elements.
• The extends keyword: is the keyword used to inherit the properties of a class. Below given is the syntax of extends keyword.
• Sytax:
class Super{

Rules of method overriding in Java..
• Argument list: The argument list of overriding (method of subclass) and Overridden (method of super class) method must be similar.
• The data types of the arguments and

their sequence should exactly match.
• Method names: must be similar.
• private, static and final methods cannot be overridden as they are local to the class.
• Access Modifier of the overriding method cannot be more restrictive than the overridden method of parent class.

Question 225 | AM0341

Which object-oriented principle promotes the concept of grouping related properties and behaviors into a single unit?

A. Encapsulation

B. Inheritance

C. Polymorphism

D. Abstraction

Hint

Identify whether the emphasis is grouping state, hiding implementation, exposing essentials or varying behavior.

Answer A: Encapsulation

The stem repeats the definition of grouping data and methods into a single class unit.

Why each choice is right or wrong

A - Correct: Direct wrapping-up/grouping principle

B - Incorrect: Acquires another class's members

C - Incorrect: Many behavior forms

D - Incorrect: Essential-information view rather than grouping

Primary note proof

Study-note section OOP02

Encapsulation groups related state and operations and controls access. Information hiding keeps implementation decisions behind a stable interface. Abstraction presents the essential operations while omitting details irrelevant to the caller. These ideas overlap: a private balance plus deposit(amount) can demonstrate all three, depending on what the question emphasizes.

Study-note section OOP02

Inheritance forms a subtype relationship and may reuse implementation. Polymorphism lets code using a common type invoke behavior appropriate to different concrete objects.

Which object-oriented concept is used to create objects based on a predefined blueprint or class?

A. Polymorphism

B. Inheritance

C. Encapsulation

D. Instantiation

Hint

Separate a reference declaration, object allocation, reference copying and changes to the shared object.

Answer D: Instantiation

A class is the template and an object its instance; new creates that actual object. Instantiation names creating the instance from the template.

Why each choice is right or wrong

A - Incorrect: Many forms rather than creation from a blueprint

B - Incorrect: Deriving classes rather than objects

C - Incorrect: Grouping data/methods rather than object creation

D - Correct: Matches creating the actual instance from a class template

Which one of the following is true regarding constructors in Java?

A. Constructors are invoked to create objects without using the new operator

B. Constructors can have a return type

C. A constructor can have a different name from its class name

D. Constructors play the role of initializing objects

Hint

Check the class name, return-type absence and the constructors actually declared.

Answer D: Constructors play the role of initializing objects

Constructors initialize objects automatically during new, share the class name and have no return type.

Why each choice is right or wrong

A - Incorrect: Contradicts the described new/constructor creation sequence for ordinary construction

B - Incorrect: Contradicts no return type, not even void

C - Incorrect: Contradicts same-class-name rule

D - Correct: Matches automatic initialization

Question 229 | CS0102

Which one of the following is NOT correct about function overloading in C++?

A. Two or more overloaded functions may differ in their number of parameters

B. Two or more overloaded functions may differ in data types of their parameters

C. Two or more overloaded functions should have the same function name

D. Two or more overloaded functions may differ only in their return types

Hint

Compare names and parameter signatures before considering return types or access modifiers.

Answer D: Return type alone cannot distinguish C++ overloads.

OOP12 states that overloaded methods/functions share a name and differ in parameter types, counts or order. It expressly rejects return type alone as sufficient in Java and C++. D is therefore the incorrect overloading claim. A, B and C describe valid differences or the shared-name requirement rather than violating the overload rule.

Why each choice is right or wrong

A - Incorrect: Different parameter counts can distinguish overloads, so this is a correct overloading statement.

B - Incorrect: Different parameter data types can distinguish overloads, so this is a correct overloading statement.

C - Incorrect: Overloads share a function name, so this statement correctly describes their naming requirement.

D - Correct: This is the false claim: return type alone cannot distinguish C++ overloads with otherwise identical signatures.

Question 230 | NS0219

Which purposes apply to Java interfaces? “Blueprint” means an operation contract, “state and behavior” in B means complete per-instance state and implementation, and “multiple inheritance” means type inheritance. Select all that apply.

A. To create multiple constructors for a class

B. To define the state and behavior of an object

C. To define a blueprint of a class

D. To achieve multiple inheritance

Hint

Identify the interface contract, effective modifiers and permitted implementation forms.

Answer C, D: To define a blueprint of a class; To achieve multiple inheritance

An interface gives implementing classes an operation contract, so the defined blueprint purpose is valid. A class can implement multiple interfaces, supporting multiple type inheritance. Interfaces have no constructors or per-instance fields, so they do not create a class’s constructors or define an object’s complete state and implementation. With those meanings explicit, C and D are valid purposes and the other two are excluded.

Why each choice is right or wrong

A - Incorrect: Interfaces have no constructors and do not create class constructors.

B - Incorrect: The complete per-instance state and implementation belong to classes, not interface capability contracts.

C - Correct: The blueprint is an operation contract for implementing classes.

D - Correct: Multiple implemented interfaces provide multiple type inheritance.

Primary note proof

Study-note section OOP19

> interface Payable{double getPaymentAmount();} declares an abstract public operation. class Invoice implements Payable must provide public double getPaymentAmount(), perhaps returning getQuantity()*getPricePerItem(). A class can extend a superclass and implement zero or more interfaces. An interface can extend several interfaces. No interface instance fields or constructors exist; fields are implicitly public static final.

Question 231 | NS0292

Consider this C++17 class and statements inside a valid main function:
struct Meter {
int reading = 0;
void set(int reading) { this->reading = reading; }
static int twice(int x) { return 2 * x; }
};
Meter first, second;
first.set(4);
second.set(9);
int doubled = Meter::twice(3);
Which statement correctly describes the implicit object context during second.set(9) and the call to twice?

A. In set, this points to second; twice has no this pointer.

B. In set, this points to first; twice has no this pointer.

C. In set, this points to second; twice reuses second as its implicit object.

D. The hidden object argument is passed to the reading data member rather than to set.

Hint

Use the stated language rules and identify whether a member call has an implicit current object.

Answer A: In set, this points to second; twice has no this pointer.

Each non-static set call has an implicit object: first for first.set(4) and second for second.set(9). During the latter call, this therefore points to second, and this->reading selects that object's field. The static twice function has no current object or this pointer, regardless of which instance method ran most recently. Data members themselves do not receive hidden call arguments.

Why each choice is right or wrong

A - Correct: second is the receiver of second.set(9); the static twice call has no implicit object.

B - Incorrect: The earlier call on first does not make first the receiver of the later call on second.

C - Incorrect: twice is static and does not acquire a this pointer from the most recent instance call.

D - Incorrect: The implicit object belongs to the non-static function call; the reading data member does not receive a hidden argument.

Primary note proof

Study-note section OOP17

> In ordinary C++17 non-static member functions, this is a pointer to the object on which the function is called; this->field selects a member. It is often explained as an implicit object argument to a member function call. It is not an argument passed to member variables, and a static member function has no this pointer.

What will be the output of the following program segment?
public class Calculation {

public static void main(String[] args) {
int sum = 0;
for(int j = 1; j<=10; j++) {
sum = sum + j;
}
System.out.println(+sum);
}

A. 55

B. 44

C. 33

D. 66

Hint

Trace condition tests, control transfers and printing as separate steps.

Answer A: 55 for the shown program segment.

The shown program segment initializes sum to zero and adds j for all values 1 through 10 inclusive. Its numerical result is 55. The unary plus in println(+sum) preserves that value. This is a program segment; a complete compilation unit also requires the outer class's closing brace.

Why each choice is right or wrong

A - Correct: The ten inclusive additions produce 55; unary plus leaves that integer unchanged.

B - Incorrect: 44 is not the sum of the stated inclusive sequence 1 through 10.

C - Incorrect: 33 does not match all ten additions performed by the shown loop.

D - Incorrect: 66 would correspond to including an additional 11, which this condition excludes.

Question 233 | NS0318

Which OOP principle specifically defines the boundary that groups an object's state with its methods and controls clients' access to that state?

A. Abstraction

B. Inheritance

C. Polymorphism

D. Encapsulation

Hint

Identify whether the emphasis is grouping state, hiding implementation, exposing essentials or varying behavior.

Answer D: Encapsulation.

Encapsulation groups related state and operations and controls access to them. That grouping and access boundary is the mechanism requested. Abstraction emphasizes the essential public view while omitting irrelevant details; it can coexist with encapsulation but does not name this specific boundary. Inheritance forms subtype relationships, and polymorphism supplies appropriate behavior through a common type.

Why each choice is right or wrong

A - Incorrect: Abstraction concerns the essential view presented to callers, rather than the specific grouping/access boundary requested.

B - Incorrect: Inheritance forms a subtype relationship rather than a state-access boundary.

C - Incorrect: Polymorphism provides behavior through common types rather than defining this grouping and access control.

D - Correct: Encapsulation specifically groups state with operations and controls client access.

Consider the following code snippet
class Animal { void sound() { System.out.println("Animal sound"); } }
class Dog extends Animal { void sound() { System.out.println("Bark!"); } }
Which OOP concept is illustrated when Dog provides its own version of sound?

A. Method overriding

B. Method overloading

C. Abstraction

D. Encapsulation

Hint

Check inheritance, signature compatibility, visibility and eligibility for an override.

Answer A: Method overriding.

Dog extends Animal and declares its own sound() with the same name, no parameters and the same void result. Neither method is static, private or final in the shown code. Dog therefore overrides the inherited instance method, providing subtype-specific behavior. No changed parameter list exists to make this an overload.

Why each choice is right or wrong

A - Correct: Dog supplies the same eligible inherited sound() signature with its own behavior, which is overriding.

B - Incorrect: Overloading requires a different parameter list; both sound methods have the same no-argument signature.

C - Incorrect: Abstraction is broader essential-interface design, not the specific same-signature subclass mechanism shown.

D - Incorrect: Encapsulation concerns grouped state/access control rather than this replacement of inherited method behavior.

Primary note proof

Study-note section OOP14

> A subclass overrides an eligible inherited instance method with the same signature and a compatible return type; a covariant reference return may be a subtype. Question 235 | NS0338

A member declared in package p must be usable by an unrelated helper in p and by a subclass in package q through its inherited context. Unrelated classes outside p must be excluded. Which access category fits these requirements?

A. Public

B. Default

C. Private

D. Protected

Hint

Locate the accessing code, declaring type, package and receiver before applying visibility rules.

Answer D: Protected, with qualified subclass access across packages.

Protected permits same-package access, including an unrelated helper, and qualified subclass access from another package. It does not grant access to unrelated clients in other packages. Public violates that exclusion, package/default access cannot reach the other-package subclass, and private cannot admit the unrelated same-package helper. For an instance member, the cross-package receiver restriction remains part of the protected rule.

Why each choice is right or wrong

A - Incorrect: Public would also admit the unrelated other-package clients that the stem excludes.

B - Incorrect: Default/package access would exclude the subclass in q.

C - Incorrect: Private would exclude the unrelated helper in p.

D - Correct: Protected provides both requested contexts while retaining the stated other-package exclusion.

Primary note proof

Study-note section OOP08

> For ordinary members: private restricts access to the declaring class/nest; no modifier grants package access; protected grants same-package access plus qualified subclass access; public is widest, provided the declaring type itself is accessible.

Study-note section OOP08

> Across packages, a subclass accessing a protected instance member must do so through its own inherited context or an appropriate subclass-typed receiver, not any arbitrary superclass object. protected therefore does not mean “subclasses only”: unrelated classes in the same package also have access.

Question 236 | NS0345

Consider these Java 17 classes:
class Employee {
public final double calculateTax() { return 100.0; }
}
class Manager extends Employee {
// Insert exactly one candidate declaration here.
}
Which candidate fails compilation because it attempts to override the inherited final method? Evaluate each candidate independently.

A. public double calculateTax(double income) { return income * 0.1; }

B. public double calculateTax() { return 200.0; }

C. private double calculateTax(int category) { return category * 10.0; }

D. public static double calculateTax(String band) { return 0.0; }

Hint

Check inheritance, signature compatibility, visibility and eligibility for an override.

Answer B: public double calculateTax() { return 200.0; }

Employee's no-argument calculateTax method is final, so Manager cannot provide another instance method with that same signature. B attempts exactly that override and fails compilation. A and C have different parameter types and therefore declare overloads. D also has a different parameter list; its static declaration is a separate overload, not a replacement for the inherited no-argument instance method. The final restriction does not prohibit every reuse of the name.

Why each choice is right or wrong

A - Incorrect: The double parameter creates a different signature, so this overload does not override the final no-argument method.

B - Correct: This has the inherited no-argument signature and attempts to override the final method.

C - Incorrect: The int parameter creates an independent overload; its private access does not reduce the inherited method's visibility.

D - Incorrect: The String parameter creates a distinct static overload and leaves the inherited no-argument method unchanged.

Primary note proof

Study-note section OOP14

> Constructors, final methods, static methods and private parent methods are not overridden.

Study-note section OOP12

> Overloaded methods share a name but have different parameter types, counts or type order. Return type alone is insufficient in Java and C++.

Study-note section OOP07

Question 237 | NS0632

A class has a constructor: public Circle(double r) { this.radius = r; }. What happens when you write: Circle c = new Circle(); ?

Hint

Check the class name, return-type absence and the constructors actually declared.

Answer: Compilation fails unless Circle also declares an accessible no-argument constructor.

Declaring Circle(double r) prevents Java from supplying the implicit default constructor. new Circle() requests a no-argument constructor, not the existing one-argument signature. OOP09 therefore predicts a compilation error unless another accessible no-argument constructor has been provided. Passing a double argument would instead target the shown constructor.

Primary note proof

Study-note section OOP09

> If a class declares no constructor, Java supplies a default constructor. If Circle(double r) is declared, new Circle() fails unless a no-argument constructor is also declared.

Question 238 | NS0633

Which of the following is TRUE about instance variables that are not explicitly initialized?

Hint

Locate the declaration scope and check default initialization versus definite assignment.

Answer: Uninitialized instance fields receive type defaults: numeric zero, false, null, or the zero char.

Instance variables are fields, so OOP05 gives them automatic defaults before explicit initialization. Numeric fields receive zero, boolean fields false, references null and char the zero code unit. This does not authorize reading an unassigned local variable: locals obey a separate definite-assignment requirement rather than receiving these field defaults.

Primary note proof

Study-note section OOP05

> Java fields and array elements receive defaults: numeric zero, char '\u0000', boolean false and references null. A local int t; followed by printing t is a compilation error.

Question 239 | NS0634

What is the output of: static int count = 0; in a class, after creating 3 objects each incrementing count++ in their constructor?

Hint

Decide whether a member belongs to a class or an object, then check initialization and final restrictions.

Answer: The shared count becomes 3; printing it would output 3.

static makes count a single field shared by the instances, not three independent counters. Starting at zero, each of the three constructor increments adds one to that same field, leaving three. The declaration itself prints nothing; 3 is the stored value and the result if the question's output means subsequently printing count.

Primary note proof

Study-note section OOP07

> static gives one field per loaded class, shared by its instances. If count starts at zero and every constructor increments it, three creations leave count=3. Prefer ClassName.count and ClassName.utility().

Question 240 | NS0635

You declare: int number; inside a method and try to print it without assigning a value. What happens?

Hint

Locate the declaration scope and check default initialization versus definite assignment.

Answer: Compilation fails because the local variable has not been definitely assigned.

number is declared inside a method, making it a local rather than an instance or static field. OOP05 requires a local to be definitely assigned before use. Printing it is a read, so the compiler rejects that read. Java does not substitute field-style zero or permit an arbitrary garbage output for the local.

> Locals occur in methods, constructors or blocks; they must be definitely assigned before use and cannot have public/private/protected modifiers.

In UML class diagrams, how is an instance shown differently from a class?

Hint

Read the notation and distinguish a class description from a particular instance.

Answer: An instance uses an underlined instanceName:ClassName label, often with slot values.

OOP04 gives an underlined label such as sara:Student for one particular object. A class box describes the common type with its name, attributes and operations; an instance notation can show actual slot values. Underlining static class features is a separate UML convention, so the full instanceName:ClassName pattern identifies the object here.

Primary note proof

Study-note section OOP04

> A UML class box normally contains name, attributes and operations. Visibility uses + public, - private and # protected. A field can be written name:String and an operation getName():String.

Study-note section OOP04

> An instance is conventionally labeled with an underlined instanceName:ClassName, such as sara:Student. Class notation describes a type; instance notation describes one particular object and may show its slot values. Underlining static class features has a different purpose; read the whole notation rather than assuming every underline means the same thing.

Under Java 17, what is the key restriction on an explicit this(...) invocation inside a constructor?

Hint

Trace constructor delegation and initialization in the specified Java version.

Answer: It must be the first constructor statement and delegates to another constructor in the same class.

Under Java 17, an explicit this(...) invocation must be the first constructor statement and delegates to another constructor of the same class. The constructor cannot also explicitly invoke super(...); the delegation chain reaches superclass construction through another constructor. The version qualification matters because later Java versions permit a restricted prologue, so the Java 17 rule should not be presented as timeless.

Primary note proof

Study-note section OOP10

> Under Java 17 rules, an explicit this(args) or super(args) invocation must be the first constructor statement. this invokes another constructor in the same class; super invokes the immediate superclass constructor. A constructor cannot explicitly invoke both. If there is no explicit delegation, an implicit super() is inserted; a matching accessible no-argument parent constructor must exist.

Study-note section OOP10

> Java 25 permits restricted statements before explicit constructor invocation; the older first-statement rule must be version qualified.

Question 243 | NS0638

A class has: public static final int MAX = 100; Can a subclass change this value?

Hint

Decide whether a member belongs to a class or an object, then check initialization and final restrictions.

Answer: No. final prevents assigning a new value to that MAX field.

MAX is one static field whose initialized value is 100. final prevents a subclass or other client from assigning a replacement value to that field. A subclass could declare a separate same-name hidden field, but that would not change the inherited constant. Public controls accessibility, not permission to reassign a final field.

Primary note proof

Study-note section OOP16

> Fields are hidden rather than dynamically overridden, and same-signature static methods hide rather than override.

Question 244 | NS0639

Which access modifier allows access ONLY within the same package (not even subclasses in other packages)?

Hint

Locate the accessing code, declaring type, package and receiver before applying visibility rules.

Answer: Package-private/default access: omit an access modifier.

OOP08 says an ordinary member with no access modifier grants package access. This admits other code in the same package but does not admit an other-package subclass merely through inheritance. protected would be broader because it adds qualified cross-package subclass access; private would be narrower. The answer is omission, not a default keyword modifier.

Primary note proof

Study-note section OOP08

> For ordinary members: private restricts access to the declaring class/nest; no modifier grants package access; protected grants same-package access plus qualified subclass access; public is widest, provided the declaring type itself is accessible.

Study-note section OOP08

> Across packages, a subclass accessing a protected instance member must do so through its own inherited context or an appropriate subclass-typed receiver, not any arbitrary superclass object. protected therefore does not mean “subclasses only”: unrelated classes in the same package also have access.

Question 245 | NS0640

Can a constructor be declared private? What is a use case?

Hint

Check the class name, return-type absence and the constructors actually declared.

Answer: Yes. A private constructor can support a factory or controlled singleton creation.

OOP09 explicitly permits private constructors. Restricting constructor access prevents arbitrary outside callers from directly constructing the class, while its own permitted code can still instantiate it. A factory can control creation, or a singleton arrangement can expose a controlled instance. Private construction does not mean the class can never create any object internally.

Primary note proof

Study-note section OOP09

> It initializes the new object and can be overloaded or private. A private constructor can support a factory or controlled singleton creation; it does not mean the class can never create an object internally.

Question 246 | NS0641

What is the difference between a.equals(b) and a == b when comparing objects?

Hint

Separate identity, content equality, immutable values and references that may be reassigned.

Answer: == compares reference identity; equals uses the class's equality policy.

For object references, == asks whether they denote the same object. equals invokes a method whose policy may compare content or value; Object.equals remains identity-based unless overridden. String.equals compares character content. Therefore equals does not automatically mean value equality for every class, and two distinct objects may be equal under an appropriate override.

Primary note proof

Study-note section OOP22

> For object references, == tests identity; equals invokes the class's equality policy. Object.equals uses identity unless overridden; String.equals compares character content. Equal objects must have equal hashCode values when that contract is implemented. toString gives a textual representation, not an equality test.

Question 247 | NS0642

In Java, a class extends two classes simultaneously: public class Dog extends Animal, Mammal {}. What is the result?

Hint

Identify the subtype or ownership relationship and distinguish class inheritance from interface contracts.

Answer: Compilation fails: a Java class cannot extend two direct superclasses.

OOP13 explicitly prohibits class Dog extends Animal,Mammal. Java class inheritance permits one direct superclass, so the comma-separated extends clause is invalid rather than a runtime ambiguity to resolve. A class can instead implement multiple interfaces for multiple type contracts, and composition can combine separately held collaborators where multiple state/implementation sources are needed.

Primary note proof

Study-note section OOP13

> class Dog extends Animal declares a subclass/derived/child of a superclass/base/parent. A class extends one direct class and can implement multiple interfaces. Single, multilevel and hierarchical inheritance mean one parent, a chain, and several children of one parent. Java does not permit class Dog extends Animal,Mammal.

Study-note section OOP13

> Composition represents has-a, such as Car containing Engine.

Question 248 | NS0643

A private method in a superclass is 'overridden' in a subclass with the same name and signature. What actually happens?

Hint

Check inheritance, signature compatibility, visibility and eligibility for an override.

Answer: The child declaration is independent; it does not override the private parent method.

OOP14 expressly treats a same-signature child method matching a private parent method as an independent declaration. The parent's private method is not an eligible inherited method for runtime overriding. Thus equal spelling and parameters alone do not establish polymorphic replacement, and this is not ordinary static-method hiding either. Calls must follow each declaration's own accessibility and context.

Primary note proof

Study-note section OOP14

> A same-signature child method matching a private parent method is an independent declaration, not runtime overriding and not ordinary static-method hiding.

Study-note section OOP14

> Constructors, final methods, static methods and private parent methods are not overridden.

Question 249 | NS0644

Animal a = new Dog(); - What is the declared type and actual type?

Hint

Check what compiles from the declared type, then select behavior from the actual runtime class.

Answer: Declared type: Animal. Actual/runtime type: Dog.

Animal is the variable’s declared compile-time type, determining which member operations may be selected by source checking. new Dog() creates the object, making Dog its actual runtime class. Assignment to the Animal reference does not turn that object into an Animal-only instance. Eligible overridden calls still use the runtime Dog implementation.

Primary note proof

Study-note section OOP15

> For Animal a=new Dog(), Animal is the declared type and Dog the actual type. The declared type determines which member operations compile. If fetch() exists only in Dog, a.fetch() fails compilation. For an eligible overridden sound(), a.sound() invokes Dog.sound() at runtime.

Question 250 | NS0645

You have Animal a = new Dog(); and Dog has a method fetch() not in Animal. What happens when you call a.fetch()?

Hint

Check what compiles from the declared type, then select behavior from the actual runtime class.

Answer: Compilation fails because fetch() is absent from the declared Animal type.

Although the object is a Dog, the reference a has declared type Animal. OOP15 checks member availability using that declared type before considering runtime overriding. Because fetch() exists only in Dog, a.fetch() is rejected. A checked/safe narrowing to a suitable Dog reference could expose Dog-specific members, but the original expression does not perform that narrowing.

Primary note proof

Study-note section OOP15

> For Animal a=new Dog(), Animal is the declared type and Dog the actual type. The declared type determines which member operations compile. If fetch() exists only in Dog, a.fetch() fails compilation. For an eligible overridden sound(), a.sound() invokes Dog.sound() at runtime.

Question 251 | NS0646

What is dynamic binding (late binding) in Java?

Hint

Check what compiles from the declared type, then select behavior from the actual runtime class.

Answer: Eligible overridden instance methods are selected at runtime from the actual object class.

The compiler first verifies accessible members and selects the method signature from declared types. Runtime dispatch then selects the most specific eligible override in the object's actual class. For Animal a=new Dog(), a.sound() can therefore invoke Dog.sound(). This rule does not make Dog-only methods compile through Animal, and static methods/fields follow different selection rules.

Primary note proof

Study-note section OOP15

> For Animal a=new Dog(), Animal is the declared type and Dog the actual type. The declared type determines which member operations compile. If fetch() exists only in Dog, a.fetch() fails compilation. For an eligible overridden sound(), a.sound() invokes Dog.sound() at runtime.

Study-note section OOP15

> To solve dispatch questions: check the declaration and visibility, determine the compile-time signature, then identify the object's runtime class and its most specific override.

Study-note section OOP16

> Fields are hidden rather than dynamically overridden, and same-signature static methods hide rather than override. With Animal a=new Dog(), a.staticMethod() resolves using Animal's compile-time type. Prefer Animal.staticMethod() for clarity.

Question 252 | NS0647

An abstract class has 3 abstract methods. A subclass implements only 2. What is the result?

Hint

Check whether a class is concrete and whether every inherited abstract contract has an implementation.

Answer: The subclass must remain abstract unless it provides or inherits the third implementation; a concrete incomplete subclass fails compilation.

Implementing only two of three required methods leaves an abstract obligation. OOP18 requires a concrete subclass to provide or inherit implementations for every required method. If the third is still unimplemented, declaring the subclass abstract is permitted; declaring it concrete is not. Merely implementing a majority of the methods does not satisfy the parent contract.

Primary note proof

Study-note section OOP18

> A concrete subclass must provide or inherit implementations of all required abstract methods; otherwise it must itself be abstract.

Object-Oriented Programming review questions · Question 16

Question 253 | NS0648

Can an abstract class have a constructor? Can it be instantiated?

Hint

Check whether a class is concrete and whether every inherited abstract contract has an implementation.

Answer: Yes, it can have constructors; no, it cannot be directly instantiated.

OOP18 allows an abstract class to define constructors alongside fields and concrete/abstract methods. Its constructor participates in initializing the inherited part of a concrete subclass object. That initialization role does not permit new of the abstract class itself. Direct instantiation remains prohibited even if the abstract class happens to contain no abstract methods.

Primary note proof

Study-note section OOP18

> An abstract class cannot be directly instantiated but can define fields, constructors, abstract methods and concrete methods. It need not contain an abstract method.

Study-note section OOP10

> Under Java 17 rules, an explicit this(args) or super(args) invocation must be the first constructor statement. this invokes another constructor in the same class; super invokes the immediate superclass constructor. A constructor cannot explicitly invoke both.

Question 254 | NS0649

What is the difference between implementing an interface and extending a class?

Hint

Identify the subtype or ownership relationship and distinguish class inheritance from interface contracts.

Answer: extends forms a single superclass relationship; implements fulfills one or more interface contracts.

A class can extend one superclass, gaining a subtype relationship and appropriate inherited implementation/state. It can also implement multiple interfaces, satisfying their required public operations through provided or inherited methods. Interfaces supply capability contracts rather than per-instance fields or constructors. Modern default/static interface methods mean the distinction cannot simply be summarized as interfaces never contain bodies.

Primary note proof

Study-note section OOP13

> class Dog extends Animal declares a subclass/derived/child of a superclass/base/parent. A class extends one direct class and can implement multiple interfaces.

Study-note section OOP19

> A class can extend a superclass and implement zero or more interfaces. An interface can extend several interfaces. No interface instance fields or constructors exist; fields are implicitly public static final.

Study-note section OOP19

> A method declaration without private, default or static is implicitly public abstract. Modern interfaces may also have default/static method bodies, and Java 9+ private helper methods. Not every interface method must lack a body in modern Java. Implementations must satisfy all inherited abstract contracts; they may inherit suitable public implementations.

Question 255 | NS0650

For an ordinary bodyless Java interface method declaration with no private, default or static modifier, which two method modifiers are implicit?

Hint

Identify the interface contract, effective modifiers and permitted implementation forms.

Answer: public and abstract.

The specified bodyless interface method is implicitly public and abstract. An implementing concrete class must satisfy the public contract without reducing its visibility. This scoped rule does not describe every modern interface method: default and static methods may have bodies, and Java 9 and later allow private helper methods. Those forms are explicitly outside the declaration being classified.

Primary note proof

Study-note section OOP19

> A method declaration without private, default or static is implicitly public abstract. Modern interfaces may also have default/static method bodies, and Java 9+ private helper methods.

Question 256 | NS0651

Can an interface have instance fields (instance variables)?

Hint

Identify the interface contract, effective modifiers and permitted implementation forms.

Answer: No. Interface fields are implicitly public static final, not per-instance variables.

OOP19 explicitly excludes interface instance fields. Any field declared in an interface is a public static final class-level constant under the note's rule, even when some modifiers are not written. Implementing classes may define their own instance fields, but those belong to the implementing objects rather than being instance state supplied by the interface.

Primary note proof

Study-note section OOP19

> No interface instance fields or constructors exist; fields are implicitly public static final.

Question 257 | NS0652

What is the output? Animal a = new Cat(); a.makeNoise(); - Cat overrides makeNoise() to print 'Meow'

Hint

Check what compiles from the declared type, then select behavior from the actual runtime class.

Answer: Meow, from Cat.makeNoise(), assuming the inherited method is accessible and eligible for overriding.

The declared Animal type allows the makeNoise call under the stated override relationship. The actual object is a Cat, so runtime dispatch selects Cat's overriding implementation and prints Meow. Assignment to a superclass reference does not suppress subclass behavior. The question does not specify an exact print API, so no additional punctuation or newline is invented.

Primary note proof

Study-note section OOP15

> For Animal a=new Dog(), Animal is the declared type and Dog the actual type. The declared type determines which member operations compile. If fetch() exists only in Dog, a.fetch() fails compilation. For an eligible overridden sound(), a.sound() invokes Dog.sound() at runtime.

Question 258 | NS0653

When is downcasting (Dog dog = (Dog) animal;) safe to use?

Hint

Separate compile-time cast compatibility from the object's actual runtime type.

Answer: For a non-null value, when the actual object is Dog or a subtype; test instanceof when uncertain.

An Animal reference may denote a Dog, another subtype or a plain Animal. Downcasting succeeds for an actual Dog-compatible object and otherwise throws ClassCastException. OOP21 recommends instanceof before narrowing when uncertain. Casting null also succeeds and yields null, but using it as an object afterward fails; therefore successful casting and safe dereferencing are distinct questions.

Primary note proof

Study-note section OOP21

> Upcasting a subclass reference to a superclass is implicit and does not change the object. A downcast may pass compile-time type checks yet fail at runtime. Car a=new Car(); Ferrari f=(Ferrari)a; throws ClassCastException before subsequent drive() or brake() calls. It does not turn a plain Car into a Ferrari.

Study-note section OOP21

> Use if(a instanceof Ferrari) before narrowing when the dynamic type is uncertain. null instanceof Ferrari is false; casting null yields null, although dereferencing it fails.

Question 259 | NS0654

What does the final keyword prevent when applied to a class like: final class String {}?

Hint

Decide whether a member belongs to a class or an object, then check initialization and final restrictions.

Answer: It prevents subclasses from extending that class.

OOP07 says final on a class prohibits extension. Developers therefore cannot declare a subclass of String. This differs from final on a variable, which prevents reassignment, and final on a method, which prevents overriding. A final class is not automatically immutable merely because subclassing is prohibited; String's immutability is an additional property discussed in OOP22.

Primary note proof

Study-note section OOP07

> final prevents reassignment of a variable, overriding of a method or extension of a class. A final reference may still refer to a mutable object.

Study-note section OOP22

> final class String prevents subclassing; final alone does not make arbitrary objects immutable.

Question 260 | NS0655

Can a static method be overridden in Java?

Hint

Distinguish the current instance, parent context, hidden fields and static dispatch.

Answer: No. A same-signature subclass static method hides the parent static method.

OOP16 states that static methods hide rather than override. Selecting a static method through a reference uses the compile-time type, unlike eligible instance-method dispatch based on the object's runtime class. Thus Animal a=new Dog(); a.staticMethod() selects Animal's static declaration. ClassName.method() is the clearer recommended spelling and makes that selection explicit.

Primary note proof

Study-note section OOP16

> Fields are hidden rather than dynamically overridden, and same-signature static methods hide rather than override. With Animal a=new Dog(), a.staticMethod() resolves using Animal's compile-time type. Prefer Animal.staticMethod() for clarity. Java this and super are unavailable as current-instance references in static context.

Question 261 | NS0656

What is the 'is-a' relationship and how does it relate to inheritance?

Hint

Identify the subtype or ownership relationship and distinguish class inheritance from interface contracts.

Answer: A subtype is a valid instance of its parent contract: Dog is an Animal.

OOP13 recommends inheritance when a subtype can satisfy its parent's contract, as Dog satisfies Animal. That is the is-a relationship rather than mere code reuse. Car containing Engine is instead has-a composition. Reusing fields or methods alone does not justify declaring a subclass if its behavior cannot honor the parent's promised operations.

Primary note proof

Study-note section OOP13

> Use inheritance when a subtype can satisfy the parent's contract: Dog is an Animal. For shared Pet.name and speak(), put common state/contract in Pet, specialized fetch() in Dog, and appropriate speak() implementations in Dog and Cat. Composition represents has-a, such as Car containing Engine. Reuse alone does not justify an invalid is-a relationship.

Question 262 | NS0657

You call super() in a subclass constructor but the superclass has no no-arg constructor. What happens?

Hint

Trace constructor delegation and initialization in the specified Java version.

Answer: Compilation fails unless an accessible matching no-argument superclass constructor exists.

An explicit super() requests the immediate superclass's no-argument constructor. OOP10 requires a matching accessible parent constructor, so a superclass with only parameterized constructors cannot satisfy that invocation. The subclass must instead call an appropriate super(arguments) or the superclass must provide an accessible no-argument constructor. Java does not synthesize one after another constructor has been declared.

Primary note proof

Study-note section OOP10

> this invokes another constructor in the same class; super invokes the immediate superclass constructor. A constructor cannot explicitly invoke both. If there is no explicit delegation, an implicit super() is inserted; a matching accessible no-argument parent constructor must exist.

Study-note section OOP09

> If a class declares no constructor, Java supplies a default constructor. If Circle(double r) is declared, new Circle() fails unless a no-argument constructor is also declared.

Question 263 | NS0658

What is the purpose of the protected access modifier specifically for inheritance?

Hint

Locate the accessing code, declaring type, package and receiver before applying visibility rules.

Answer: It permits inherited access in subclasses across packages, and also same-package access.

protected supports subclass use of a parent member without making it universally public. OOP08 also grants access to unrelated code in the same package, so it is not subclasses-only. Across packages an instance member must be accessed in the inherited context or through an appropriate subclass-typed receiver, rather than any arbitrary superclass object.

Primary note proof

Study-note section OOP08

> For ordinary members: private restricts access to the declaring class/nest; no modifier grants package access; protected grants same-package access plus qualified subclass access; public is widest, provided the declaring type itself is accessible.

Study-note section OOP08

> Across packages, a subclass accessing a protected instance member must do so through its own inherited context or an appropriate subclass-typed receiver, not any arbitrary superclass object. protected therefore does not mean “subclasses only”: unrelated classes in the same package also have access.

Question 264 | NS0659

An interface Drawable extends both Shape and Colorable interfaces. A class Circle implements Drawable. What must Circle implement?

Hint

Identify the interface contract, effective modifiers and permitted implementation forms.

Answer: A concrete Circle must satisfy all inherited abstract operations from Drawable, Shape and Colorable.

Drawable can extend both interfaces, combining their contracts. Circle implements Drawable and must therefore provide or inherit suitable public implementations of every remaining abstract operation from the full hierarchy. One compatible implementation can satisfy a shared signature; inherited defaults may supply implementations where applicable. If obligations remain unresolved, Circle must be abstract rather than an incomplete concrete class.

Primary note proof

Study-note section OOP19

> A class can extend a superclass and implement zero or more interfaces. An interface can extend several interfaces.

Study-note section OOP19

> Implementations must satisfy all inherited abstract contracts; they may inherit suitable public implementations.

Study-note section OOP20

> If two compatible interfaces merely declare the same abstract signature, one public implementation can satisfy both. If return types or other contracts conflict, additional declarations may still be impossible.

Study-note section OOP18

> A concrete subclass must provide or inherit implementations of all required abstract methods; otherwise it must itself be abstract.

Question 265 | NS0660

What happens if you declare the same method in both an abstract class and the interface it implements?

Hint

Check the kind of inherited method and whether competing contracts require an explicit resolution.

Answer: Compatible declarations can coexist; implementation obligations depend on abstract, concrete and default status.

OOP20 says a concrete inherited class method takes precedence over an interface default. An abstract class declaration can instead leave an implementation obligation for a concrete subclass. A compatible public implementation may satisfy the interface contract, but incompatible signatures/return types may be impossible. Without declaration details, these conditional rules are the answer rather than one unconditional outcome.

Primary note proof

Study-note section OOP20

> A concrete inherited class method takes precedence over an interface default. An inherited abstract class declaration can require a concrete subclass to implement the operation rather than silently adopting a default.

Study-note section OOP20

> Unrelated interfaces providing conflicting defaults require an explicit resolution; interfaces do not remove every diamond ambiguity. If two compatible interfaces merely declare the same abstract signature, one public implementation can satisfy both. If return types or other contracts conflict, additional declarations may still be impossible. The answer to “same method in abstract class and interface” depends on whether each is abstract or implemented and whether their signatures are compatible.

Question 266 | NS0661

Can you instantiate an interface? If not, how do you use it?

Hint

Identify the interface contract, effective modifiers and permitted implementation forms.

Answer: Not directly. Use an interface reference holding an implementing object, anonymous implementation or suitable lambda.

OOP19 prohibits direct interface instantiation while allowing a reference of interface type to hold an implementing object. Calls then use the interface contract with the object's implementation. Anonymous class syntax still creates an implementing class instance, and a compatible functional-interface lambda supplies an implementation; neither means constructing a bare interface with no implementation.

Primary note proof

Study-note section OOP19

> Implementations must satisfy all inherited abstract contracts; they may inherit suitable public implementations. Interfaces cannot be instantiated directly, but references may hold implementing objects, anonymous implementations or suitable functional-interface lambdas.

Question 267 | NS0662

What is the difference between throw and throws in Java?

Hint

Check the thrown type and catch order before tracing propagation or handler output.

Answer: throw actively raises an exception value; throws declares a method's possible checked-exception obligation.

OOP30 contrasts throw new IOException("message") with throws IOException in a method signature. The first performs an action in control flow, skipping the remaining try body; the second declares an obligation that callers must handle or propagate. A throws clause does not itself throw anything, and throwing a checked exception still requires handling or declaration.

Primary note proof

Study-note section OOP30

> throw new IOException("message") actively throws a value; throws IOException in a signature declares a possible checked exception. A caller must handle or propagate checked obligations. try encloses guarded operations; a matching catch handles the thrown type or a subtype. Execution skips the remainder of the try when a throw occurs.

Question 268 | NS0663

What happens if an exception occurs in a try block and there is no matching catch block?

Hint

Check the thrown type and catch order before tracing propagation or handler output.

Answer: It propagates outward to a matching enclosing handler; if uncaught, its thread terminates.

Without a matching local catch, the exception is not ignored and execution does not resume with the next ordinary statement in the try. OOP30 sends it outward through enclosing calls/handlers. Relevant finally blocks normally execute during that exit under OOP31's limits. If no handler catches it, the uncaught exception terminates its thread, not necessarily every JVM thread.

Primary note proof

Study-note section OOP30

> Execution skips the remainder of the try when a throw occurs.

Study-note section OOP30

> If no catch matches, the exception propagates outward and an uncaught exception terminates its thread.

Study-note section OOP31

Question 269 | NS0664

Is it mandatory to handle an ArithmeticException?

Hint

Separate source errors from runtime exceptions and determine the hierarchy and checked obligation.

Answer: No catch-or-declare obligation applies: ArithmeticException is unchecked.

OOP29 lists ArithmeticException among unchecked exceptions, so Java does not require a surrounding catch or throws declaration merely because it may occur. A program can still catch it when that provides useful recovery. Unchecked means no mandatory compile-time handling obligation, not harmless behavior: an uncaught occurrence propagates and may terminate its thread.

Primary note proof

Study-note section OOP29

> RuntimeException and Error subclasses are unchecked; other throwable classes are checked. IOException, FileNotFoundException and SQLException are standard checked examples. ArithmeticException, NullPointerException, ClassCastException and array bounds exceptions are unchecked.

Study-note section OOP29

> Checked does not mean the exception occurs at compile time: the compiler checks an obligation to catch or declare it, while an actual throw occurs at runtime.

Study-note section OOP30

> If no catch matches, the exception propagates outward and an uncaught exception terminates its thread.

What is the order of execution in: try { ... } catch(E e) { ... } finally { ... }?

Hint

Check the thrown type and catch order before tracing propagation or handler output.

Answer: Run try, then a matching catch if thrown, then normally finally.

If try completes normally, no catch executes and finally follows. If an exception is thrown, the remaining try body is skipped, a matching catch runs if available, and finally normally executes before continuation or outward propagation. finally also normally runs on return. Process/JVM exit, a crash or control never leaving try prevents an unconditional always claim.

You catch a general Exception before a specific IOException. What is the result?

Hint

Check the thrown type and catch order before tracing propagation or handler output.

Answer: Compilation fails because the IOException catch after Exception is unreachable.

Exception already catches IOException values because IOException is a subtype. The later subtype handler can never be selected, and OOP30 says this ordering prevents compilation rather than merely causing the general handler to win at runtime. Place the specific IOException catch before Exception if both handlers are needed.

Primary note proof

Question 272 | NS0667

What does e.printStackTrace() actually print?

Hint

Track pending returns or exceptions and distinguish normal cleanup from process termination.

Answer: Exception information plus recorded call-stack frames for diagnosis.

OOP31 distinguishes getMessage, toString and printStackTrace. The stack trace reports exception information together with recorded call frames, helping locate the call path associated with the failure. It is more diagnostic context than the message alone and does not repair or handle the error by itself. Exact text depends on the exception and recorded frames.

Primary note proof

Study-note section OOP31

> getMessage returns the message, toString normally includes type and message, and printStackTrace shows exception information and recorded call frames for diagnosis. Tests should cover expected success, caught failures and propagation. Exception handling does not replace validation or correct an algorithm’s logic automatically.

Question 273 | NS0668

Can a finally block change the return value of a try block?

Hint

Track pending returns or exceptions and distinguish normal cleanup from process termination.

Answer: Yes. A return from finally overrides the pending try/catch return; avoid it.

A try return expression is evaluated before finally runs. A return statement inside finally can replace that pending return and can even suppress an exception, which OOP31 warns against. Merely changing a local after a primitive return expression was evaluated does not automatically recompute that earlier result. The explicit finally return is the clear override mechanism.

Primary note proof

Study-note section OOP31

> A return expression is evaluated before finally; a finally return overrides the pending return and can suppress an exception, so avoid that pattern.

Question 274 | NS0669

What is the difference between Error and Exception in Java?

Hint

Separate source errors from runtime exceptions and determine the hierarchy and checked obligation.

Answer: They are Throwable branches: Error usually denotes serious conditions; Exception contains checked and unchecked application exceptions.

OOP29 places Error and Exception below Throwable. Error normally signals serious conditions for which routine recovery is inappropriate and its subclasses are unchecked. Exception includes unchecked RuntimeException subclasses and other checked exceptions requiring catch-or-declare handling. It is technically possible to catch Error, so the distinction must not be stated as errors can never be caught.

Primary note proof

Study-note section OOP29

> Throwable is the root of throwable values, with Exception and Error branches. RuntimeException and Error subclasses are unchecked; other throwable classes are checked.

Study-note section OOP29

> Checked does not mean the exception occurs at compile time: the compiler checks an obligation to catch or declare it, while an actual throw occurs at runtime. A custom exception can extend Exception or RuntimeException. Error normally signals serious conditions for which routine recovery is inappropriate; it is not technically impossible to catch an Error.

Question 275 | NS0670

FileNotFoundException is a subclass of IOException. Which catch block executes: catch(IOException e) or catch(FileNotFoundException e)?

Hint

Check the thrown type and catch order before tracing propagation or handler output.

Answer: For FileNotFoundException, the first applicable catch wins; put it before IOException.

Both handler types can match a FileNotFoundException, so catch order matters. If FileNotFoundException is first, that specific block executes. If IOException is placed first with FileNotFoundException afterward, the latter is unreachable and compilation fails. If only IOException is present, it can handle the subclass. The prompt omits order, so these cases must be distinguished.

Primary note proof

Study-note section OOP30

> Execution skips the remainder of the try when a throw occurs.

Study-note section OOP30

> Catch blocks are considered in source order. Place FileNotFoundException before IOException and IOException before Exception; a general catch before a subtype catch makes that later handler unreachable and prevents compilation. Question 276 | NS0671

What does ClassCastException indicate?

Hint

Separate compile-time cast compatibility from the object's actual runtime type.

Answer: An attempted reference cast is incompatible with the actual object type.

A cast can be syntactically and type-checkably permitted between related reference types while still fail at runtime. OOP21's plain Car cannot become a Ferrari merely by casting, so ClassCastException occurs before subsequent method calls. The exception reports an incompatible dynamic type, not object transformation, allocation or a numeric conversion failure.

Primary note proof

Study-note section OOP21

> Upcasting a subclass reference to a superclass is implicit and does not change the object. A downcast may pass compile-time type checks yet fail at runtime. Car a=new Car(); Ferrari f=(Ferrari)a; throws ClassCastException before subsequent drive() or brake() calls. It does not turn a plain Car into a Ferrari.

Study-note section OOP21

> For Object obj="Hello", (String)obj succeeds and (Integer)obj throws ClassCastException.

Question 277 | NS0672

Can you use multiple catch blocks for one try block? Can one catch block catch multiple exceptions?

Hint

Check the thrown type and catch order before tracing propagation or handler output.

Answer: Yes to both: use ordered catches or a multi-catch such as catch(IOException | SQLException e).

One try can have several catch blocks; source order and specific-before-general reachability still apply. A single multi-catch can also handle alternative exception types. OOP30 prohibits alternatives related by subclassing, so IOException and FileNotFoundException cannot be paired in one union catch. Their hierarchy instead calls for an appropriate common catch or ordered handlers.

Primary note proof

Study-note section OOP30

> Catch blocks are considered in source order. Place FileNotFoundException before IOException and IOException before Exception; a general catch before a subtype catch makes that later handler unreachable and prevents compilation. If no catch matches, the exception propagates outward and an uncaught exception terminates its thread. Multiple catch blocks are allowed; catch(IOException | SQLException e) handles alternatives, which must not be related by subclassing.

Question 278 | NS0673

What is the output? int x = 5; int y = ++x * x--; System.out.println(x + ' ' + y);

Hint

Track the old and updated values separately and distinguish a character operand from a string.

Answer: 73. The expression leaves x=5 and y=36, then adds the space character's value 32.

Java evaluates ++x first, changing 5 to 6 and supplying 6. x-- then supplies 6 and restores x to 5, so y=36. In x + ' ' + y the space is char, not String, and numeric promotion gives 5+32+36=73. Replacing it with a double-quoted space would instead concatenate separated values.

Primary note proof

Study-note section OOP24

> Starting x=5, printing x++ then ++x gives 5 then 7. For int y=++x*x--, Java uses 6*6=36 and leaves x=5. System.out.println(x + ' ' + y) then adds char space's numeric value 32, so it prints 73. To print separated values, use x + " " + y instead.

Study-note section OOP06

> Arithmetic promotes char, byte and short to int in many expressions.

Question 279 | NS0674

Circle and Sphere are separately declared top-level Java classes. Circle declares private double radius; and Sphere extends Circle. What happens if an instance method of Sphere attempts this.radius = 5.0;?

Hint

Separate parameters from arguments and operations that read state from operations that change it.

Answer: Compilation fails for an ordinary separately declared Sphere: the inherited radius field is private.

The direct field access fails compilation. Circle's private field is not accessible from a separately declared top-level subclass, and this only identifies the current object; it does not relax visibility. Sphere must use an accessible operation supplied by Circle if it needs to request a radius change. Declaring the classes separately removes the shared-nest exception from the scenario.

Primary note proof

Study-note section OOP11

> A private field cannot normally be accessed directly by a separately declared subclass, even with this.field; use a permitted parent operation.

Study-note section OOP08

> For ordinary members: private restricts access to the declaring class/nest; no modifier grants package access; protected grants same-package access plus qualified subclass access; public is widest, provided the declaring type itself is accessible.

Study-note section OOP16

> Java this denotes the current object; this.name=name distinguishes a field from a parameter.

Question 280 | NS0675

What is the difference between a concrete class and an abstract class?

Hint

Check whether a class is concrete and whether every inherited abstract contract has an implementation.

Answer: A concrete class can be instantiated and must satisfy abstract obligations; an abstract class cannot be directly instantiated.

An abstract class can hold state, constructors, concrete methods and abstract methods, and need not contain an abstract method. A concrete subclass must provide or inherit implementations of every required abstract operation before it can serve as an instantiable class. Abstract is therefore a class-level instantiation/contract restriction, not a prohibition on implemented behavior.

Primary note proof

Study-note section OOP18

> An abstract class cannot be directly instantiated but can define fields, constructors, abstract methods and concrete methods. It need not contain an abstract method.

Study-note section OOP18

> A concrete subclass must provide or inherit implementations of all required abstract methods; otherwise it must itself be abstract.

Question 281 | NS0676

String is declared as a final class. What does this mean for developers?

Hint

Decide whether a member belongs to a class or an object, then check initialization and final restrictions.

Answer: Developers cannot subclass String; final prohibits extension.

Applying final to String prevents any class from extending String. It does not prevent constructing or referencing String instances, nor does the class modifier alone explain immutability of arbitrary objects. OOP22 treats String's immutable content as a distinct property. Developers should use existing String operations rather than attempting a String subclass.

Primary note proof

Study-note section OOP07

> final prevents reassignment of a variable, overriding of a method or extension of a class. A final reference may still refer to a mutable object.

Study-note section OOP22

> Java String objects are immutable. text += " World" assigns a reference to a new concatenated result and can print Hello World without mutating the original String object. final class String prevents subclassing; final alone does not make arbitrary objects immutable.

Question 282 | NS0677

What is method hiding in Java and how does it differ from overriding?

Hint

Distinguish the current instance, parent context, hidden fields and static dispatch.

Answer: A subclass static method hides a same-signature parent static method; overriding is runtime instance dispatch.

For static hiding, the selected declaration follows the compile-time type used to qualify the call. For eligible overridden instance methods, the object's runtime class determines the implementation. OOP16's Animal a=new Dog() static call therefore resolves to Animal, unlike a virtual instance sound call that could invoke Dog. Class qualification makes static selection clearer.

Primary note proof

Study-note section OOP16

> Fields are hidden rather than dynamically overridden, and same-signature static methods hide rather than override. With Animal a=new Dog(), a.staticMethod() resolves using Animal's compile-time type. Prefer Animal.staticMethod() for clarity.

Study-note section OOP15

> For Animal a=new Dog(), Animal is the declared type and Dog the actual type. The declared type determines which member operations compile. If fetch() exists only in Dog, a.fetch() fails compilation. For an eligible overridden sound(), a.sound() invokes Dog.sound() at runtime.

Question 283 | NS0678

Given: interface A { void m1(); } interface B { void m2(); } class C implements A, B {} - What must C define?

Hint

Identify the interface contract, effective modifiers and permitted implementation forms.

Answer: C must provide public void m1() and public void m2(), or inherit suitable implementations.

Both unmodified interface declarations are implicitly public abstract. A concrete C implementing A and B must satisfy both signatures, not merely one. In the shown class with no suitable superclass implementation, define public void m1() and public void m2(). Package-private implementations would narrow the public contract; otherwise C must be declared abstract instead of concrete.

Primary note proof

Study-note section OOP19

> A method declaration without private, default or static is implicitly public abstract. Modern interfaces may also have default/static method bodies, and Java 9+ private helper methods. Not every interface method must lack a body in modern Java. Implementations must satisfy all inherited abstract contracts; they may inherit suitable public implementations.

Study-note section OOP14

> Visibility cannot become more restrictive, and checked exceptions cannot be broadened incompatibly.

Question 284 | NS0679

What is the significance of the java.lang.Throwable class?

Hint

Separate source errors from runtime exceptions and determine the hierarchy and checked obligation.

Answer: Throwable is the common root of Java's throwable Error and Exception hierarchy.

OOP29 places both Error and Exception under Throwable, establishing the common type for Java throwable values. The distinction between checked and unchecked branches controls catch-or-declare obligations, not whether an exception happens during compilation. Throwable therefore unifies the hierarchy without implying that every subclass is an ordinary recoverable application exception.

Primary note proof

Study-note section OOP29

> Throwable is the root of throwable values, with Exception and Error branches. RuntimeException and Error subclasses are unchecked; other throwable classes are checked.

Study-note section OOP29

> Checked does not mean the exception occurs at compile time: the compiler checks an obligation to catch or declare it, while an actual throw occurs at runtime. A custom exception can extend Exception or RuntimeException. Error normally signals serious conditions for which routine recovery is inappropriate; it is not technically impossible to catch an Error.

Question 285 | NS0680

A method throws a checked exception but neither catches it nor declares throws. What happens?

Hint

Check the thrown type and catch order before tracing propagation or handler output.

Answer: Compilation fails because the checked exception is neither handled nor declared.

OOP30 requires callers and methods to handle or propagate checked obligations. A method that may throw a checked exception but neither catches it nor declares it in throws violates that compile-time requirement. The failure is not that checked exceptions occur during compilation: the compiler is checking a possible future runtime throw.

Primary note proof

Study-note section OOP30

> throw new IOException("message") actively throws a value; throws IOException in a signature declares a possible checked exception. A caller must handle or propagate checked obligations. try encloses guarded operations; a matching catch handles the thrown type or a subtype.

Study-note section OOP29

> Checked does not mean the exception occurs at compile time: the compiler checks an obligation to catch or declare it, while an actual throw occurs at runtime.

Question 286 | NS0681

What does 'extensibility' mean in the context of polymorphism?

Hint

Check what compiles from the declared type, then select behavior from the actual runtime class.

Answer: New subtypes can supply behavior while existing common-type client code remains reusable.

OOP15 describes a common Animal array loop invoking speak on Dog and Cat objects. Adding another conforming Animal subtype can supply its own override without rewriting that generic loop. That ability is extensibility through polymorphism: clients depend on the shared contract, while runtime dispatch supplies subtype behavior. The new subtype must still satisfy that contract.

Primary note proof

Study-note section OOP15

> To solve dispatch questions: check the declaration and visibility, determine the compile-time signature, then identify the object's runtime class and its most specific override. An array Animal[]{new Dog(),new Cat()} can call speak() on each using one loop. New subclasses can supply behavior without rewriting this generic loop, which is the practical meaning of extensibility.

Question 287 | NS0682

You have: Object obj = 'Hello'; String s = (String) obj; Is this valid? What about Integer i = (Integer) obj;?

Hint

Separate compile-time cast compatibility from the object's actual runtime type.

Answer: Literal single-quoted Hello is invalid. With "Hello", the String cast succeeds and the Integer cast throws ClassCastException.

A Java character literal cannot contain the multi-character text 'Hello', so the printed declaration fails before either cast executes. OOP21 explicitly separates that defect from the intended double-quoted version. After changing it to a String literal, obj refers to a String: narrowing back to String succeeds, but narrowing it to Integer fails at runtime.

Primary note proof

Study-note section OOP21

> For Object obj="Hello", (String)obj succeeds and (Integer)obj throws ClassCastException. A literal 'Hello' is invalid Java syntax; use double quotes for a string literal before tracing the program.

Study-note section OOP-S04

> A double-quoted string literal denotes a String object. new String(existingString) creates a String with the same text; new String(charArray) copies the array's characters into an immutable String. A single-quoted literal denotes one char, so several characters enclosed together in single quotes cannot supply a String.

Question 288 | NS0683

If a subclass constructor doesn't explicitly call super(), what does Java do?

Hint

Trace constructor delegation and initialization in the specified Java version.

Answer: If no explicit this(...) or super(...) delegation exists, Java inserts super(); this(...) instead delegates within the class.

Omitting explicit super() alone is insufficient to determine what happens. A constructor may explicitly call this(...), delegating to another same-class constructor that eventually reaches superclass construction. Only when there is no explicit constructor delegation does OOP10 insert super(), requiring an accessible matching parent no-argument constructor. Otherwise the program fails to compile.

Primary note proof

Study-note section OOP10

> Under Java 17 rules, an explicit this(args) or super(args) invocation must be the first constructor statement. this invokes another constructor in the same class; super invokes the immediate superclass constructor. A constructor cannot explicitly invoke both. If there is no explicit delegation, an implicit super() is inserted; a matching accessible no-argument parent constructor must exist.

Question 289 | NS0734

What is the difference between a class and an object? Use a concrete example.

Hint

Distinguish an object’s stored state, operations, identity and class definition.

Answer: A class defines common structure/behavior; an object is one instance, such as a particular Rectangle with width and height.

Rectangle can define width, height, getArea and getPerimeter for every rectangle. A particular rectangle object stores its own width and height values and responds to those operations. OOP01 distinguishes that instance from the type description: two objects can have equal field values and still have distinct identities. The class is shared structure, not one particular rectangle.

Primary note proof

Study-note section OOP01

> An object has identity, state and behavior. State is stored in fields; behavior is provided by methods. A Rectangle object may hold width and height and answer getArea() or getPerimeter(). Two objects can have equal fields and still be distinct objects. A class defines their common structure and behavior; an object is a particular instance.

Question 290 | NS0735

Why is encapsulation important? How is it achieved?

Hint

Identify whether the emphasis is grouping state, hiding implementation, exposing essentials or varying behavior.

Answer: Encapsulation protects invariants and stable interfaces by grouping state with validated operations and controlling access.

OOP02 groups state and operations with controlled access, keeping representation decisions behind stable interfaces. A private account balance exposed through deposit(amount) can reject invalid negative changes rather than permitting unrestricted assignment. This localizes responsibility and lets clients use meaningful operations without depending on internal representation. OOP11 cautions that automatically exposing setters for every field is not required.

Primary note proof

Study-note section OOP02

> Encapsulation groups related state and operations and controls access. Information hiding keeps implementation decisions behind a stable interface. Abstraction presents the essential operations while omitting details irrelevant to the caller. These ideas overlap: a private balance plus deposit(amount) can demonstrate all three, depending on what the question emphasizes.

Study-note section OOP11

> An accessor/getter returns information; a mutator/setter changes state. Encapsulation does not require blindly generating setters for every field: validate changes and expose only useful operations. For a bank account, deposit must reject negative amounts.

Question 291 | NS0736

What is the difference between method overloading and method overriding? Provide examples.

Hint

Compare names and parameter signatures before considering return types or access modifiers.

Answer: Overloading changes parameter signatures; overriding replaces eligible inherited instance behavior with the same signature.

For overloading, f(int), f(double) and f(int,int) share a name but have distinct signatures selected using declared arguments at compile time. For overriding, Dog extends Animal and supplies void sound() matching Animal's eligible void sound(); a superclass reference can then dispatch to Dog at runtime. Changing only the return type cannot create an overload, and override return compatibility still matters.

Primary note proof

Study-note section OOP12

> Overloaded methods share a name but have different parameter types, counts or type order. Return type alone is insufficient in Java and C++. Overloads can also arise through inherited methods; "same class only" is a teaching simplification. f(int), f(double) and f(int,int) are distinct, but changing a parameter name does not create an overload.

Study-note section OOP12

> The compiler selects the applicable signature from the declared argument types and conversions.

Study-note section OOP14

> A subclass overrides an eligible inherited instance method with the same signature and a compatible return type; a covariant reference return may be a subtype. Visibility cannot become more restrictive, and checked exceptions cannot be broadened incompatibly.

Question 292 | NS0737

Why can't Java classes inherit from multiple parent classes? How is this limitation overcome?

Hint

Identify the subtype or ownership relationship and distinguish class inheritance from interface contracts.

Answer: Java permits one direct superclass. Use multiple interfaces for type contracts and composition for cooperating implementation/state.

The immediate reason the declaration is rejected is Java's one-direct-superclass rule in OOP13. Multiple interfaces supply multiple type contracts, while contained collaborators model has-a reuse without multiple class inheritance. This does not eliminate every diamond problem: OOP20 requires explicit resolution of conflicting unrelated interface defaults. The note supplies these mechanisms, rather than a historical language-design rationale.

Primary note proof

Study-note section OOP13

> class Dog extends Animal declares a subclass/derived/child of a superclass/base/parent. A class extends one direct class and can implement multiple interfaces. Single, multilevel and hierarchical inheritance mean one parent, a chain, and several children of one parent. Java does not permit class Dog extends Animal,Mammal.

Study-note section OOP13

> Composition represents has-a, such as Car containing Engine. Reuse alone does not justify an invalid is-a relationship.

Study-note section OOP20

> Unrelated interfaces providing conflicting defaults require an explicit resolution; interfaces do not remove every diamond ambiguity.

Question 293 | NS0738

What is polymorphism? Explain with a code example.

Hint

Check what compiles from the declared type, then select behavior from the actual runtime class.

Answer: Polymorphism lets a common-type reference invoke behavior appropriate to the actual subtype.

Example: class Animal { void sound() { System.out.println("Animal"); } } class Dog extends Animal { void sound() { System.out.println("Bark"); } } Then Animal a=new Dog(); a.sound(); prints Bark. The declared Animal type makes sound available; the actual Dog object supplies its eligible override at runtime. A new Animal subtype can participate through the same common operation.

Primary note proof

Study-note section OOP15

> For Animal a=new Dog(), Animal is the declared type and Dog the actual type. The declared type determines which member operations compile. If fetch() exists only in Dog, a.fetch() fails compilation. For an eligible overridden sound(), a.sound() invokes Dog.sound() at runtime.

Study-note section OOP15

> To solve dispatch questions: check the declaration and visibility, determine the compile-time signature, then identify the object's runtime class and its most specific override. Question 294 | NS0739

When would you use an abstract class versus an interface?

Hint

Check the kind of inherited method and whether competing contracts require an explicit resolution.

Answer: Use an abstract class for shared state/construction/implementation; use an interface for capabilities across unrelated classes and multiple type contracts.

An abstract class can centralize common fields, constructor initialization and concrete operations while leaving selected operations abstract. An interface specifies a capability that otherwise unrelated classes can implement, and a class may implement several interfaces. Modern interface defaults do not supply per-instance fields or constructors, so shared object state/construction remains a reason to choose an abstract class.

Primary note proof

Study-note section OOP20

> Use an abstract class for shared state, construction and common implementation; use an interface for a capability across unrelated classes and multiple type inheritance.

Study-note section OOP19

> No interface instance fields or constructors exist; fields are implicitly public static final.

Question 1 | Q00029

Which one of the following is responsible for controlling the flow of bits between memory and controllers with no need for a constant intervention from the CPU?

A. Disk fragmenting

B. Memo, manager

C. Device controller

D. Direct memory access

Hint

Follow the data path and control responsibility; distinguish the transfer mechanism, address space and interface type.

Answer D: Direct memory access

DMA transfers a block directly between device and memory; the CPU supplies setup information and receives completion notification, rather than moving every word (PDF pp.107-108). This precisely meets the absence of constant intervention. A generic device controller alone does not establish DMA capability.

Why each choice is right or wrong

A - Incorrect: Disk fragmenting is not the block-transfer mechanism described on pp.107-108.

B - Incorrect: The corrupted name “Memo, manager” does not identify the DMA mechanism on p.107.

C - Incorrect: An I/O controller can notify the CPU under interrupt I/O; that still leaves CPU data movement (p.106).

D - Correct: Direct transfers and only beginning/end CPU involvement are explicit on p.108.

Primary note proof

Study-note section COA30

> Programmed/polled I/O repeatedly checks status and lets the CPU move each item.

Study-note section COA30

> Interrupt-driven I/O lets the CPU do other work until an event requests service; the handler still consumes CPU time to service the device.

7.10 Direct Memory Access (DMA)
Interrupt driven and programmed I/O require active CPU intervention.
Transfer rate is limited
CPU is tied up DMA is the solution for these problems
Direct Memory Access is capabilities provided by some computer bus architectures that allow data to be sent directly from an attached device (such as a disk drive) to the memory on the computer's motherboard. The microprocessor (CPU) is freed from involvement with the data transfer, thus speeding up overall computer operation.

Computer Organization and Architecture module | PDF page 108 | lines 2-12

When the CPU wishes to read or write a block of data, it issues a command to the DMA module and gives following information: CPU tells DMA controller:
• Whether to read or write
• Device address
• Starting address of memory block for data
• Amount of data to be transferred The CPU carries on with other work.
• Thus DMA controller steals the CPU‟s work of I/O operation.
• The DMA module transfers the entire block of data
• One word at a time, directly to or from memory, without going through CPU.
When the transfer is complete, DMA controller sends interrupt when finished Thus CPU is involved only at the beginning and at the end of the transfer.

Computer Organization and Architecture module | PDF page 104 | lines 2-16

Programmed I/O :With Programmed I/O, data are exchanged between the CPU and the I/O module. The CPU executes a program that gives it direct control of the I/O operation, including sensing device status, sending a read or write command and transferring data. When CPU issues a command to I/O module, it must wait until I/O operation is complete. If the CPU is faster than I/O module, there is wastage of CPU time. The I/O module does not take any further action to alert CPU. That is it doesn't interrupt CPU. Hence it is the responsibility of the CPU to periodically check the status of the I/O module until it finds that the operation is complete. The sequences of actions that take place with programmed I/O are:
• CPU requests I/O operation
• I/O module performs operation
• I/O module sets status bits
• CPU checks status bits periodically
• I/O module does not inform CPU directly
• I/O module does not interrupt CPU

with the higher priority first.
Interrupt Driven I/O.
Using Program-controlled I/O requires continuous involvement of the processor in the I/O activities. It is desirable to avoid wasting processor execution time. An alternative is for the CPU to issue an I/O command to a module and then go on other work. The I/O module will then interrupt the CPU requesting service when it is ready to exchange data with the CPU. The CPU will then execute the data transfer and then resumes its former processing. Based on the use of interrupts, this technique improves the utilization of the processor. With Interrupt driven I/O, the CPU issues a command to I/O module and it does not wait until I/O operation is complete but instead continues to execute other instructions. When I/O module has completed its work it interrupts the CPU. An interrupt is more than a simple mechanism for coordinating I/O transfers. In a general sense, interrupts enable transfer of control from one program to another to be initiated by an event that is external to a computer. Execution of the

Which one of the following is a communication pathway connecting transmitting signals in binary digits between two or more devices?

A. Memory

B. Register

C. CPU

D. Bus

Hint

Follow the data path and control responsibility; distinguish the transfer mechanism, address space and interface type.

Answer D: Bus

The common bus is a set of shared lines used to transfer binary information among registers (PDF p.40). The structural definitions distinguish storage and processing components from their communication mechanism (p.6).

Why each choice is right or wrong

A - Incorrect: Main memory stores data; it is an endpoint (p.6).

B - Incorrect: Registers store bits, rather than naming the pathway (p.35).

C - Incorrect: CPU processes and controls; it is a communicating component (p.6).

4.2 Bus and Memory Transfers
A typical computer has many registers, and paths must be provided to transfer information from one register to another. An efficient way for transferring information between registers in a multiple-register configuration is a common bus system. A bus structure consists of a set of common lines, one for each bit of a register. Control signals determine which register the bus selects during each particular register transfer.

There are four main structural components:
• Central processing unit (CPU): Controls the operation of the computer and performs its data processing functions; often simply referred to as processor.
• Main memory: Stores data.
• I/O: Moves data between the computer and its external environment.
• System interconnection: Some mechanism that provides for communication among CPU, main memory, and I/O.

3.9 Registers
• A register is a group of flip-flops with each flip- flop capable of storing one bit of information.
• A register is a digital circuit used within the CPU to store one or more bits of data.
• An n-bit register has a group of n flip-flops and is capable of storing n bits of binary information.
• In addition to Flip-Flops, it may have combinational gates that perform certain data processing.
• Two basic types of registers are commonly used: parallel registers and shift registers.

Question 3 | Q00056

Which memory is characterized by the need for periodic change in order to maintain data storage?

A. Static RAM

B. Dynamic RAM

C. Disk

D. Tape

Hint

Separate storage role, access timing, placement and power retention; use the specified hierarchy or mapping convention.

Answer B: Dynamic RAM

Interpret “periodic change” as periodic charge refreshing: capacitor charge leaks, so DRAM needs refresh (PDF p.80). This is different from SRAM power retention and nonvolatile secondary storage (p.91).

Why each choice is right or wrong

A - Incorrect: SRAM uses flip-flops and holds data while powered (p.80), without the stated charge refresh.

B - Correct: DRAM capacitor discharge explicitly requires periodic refreshing (p.80).

C - Incorrect: Disk is nonvolatile secondary storage (p.91), not capacitor-refresh RAM.

D - Incorrect: Tape is also nonvolatile secondary storage (p.91), not refresh RAM.

Primary note proof

Study-note section COA24

> SRAM uses powered bistable storage: fast and costly per bit, without periodic refresh.

Question 4 | Q00060

In the ordinary HDD model, which statement is incorrect? Read/write refers to accessing sectors on the current track; seeking to another track is a separate operation.

A. Data is arranged in sectors within tracks

B. The head stays over the selected track while its sectors rotate beneath it

C. Its data is organized in tracks

D. It needs continuous power to keep bit contents

Hint

Separate storage role, access timing, placement and power retention; use the specified hierarchy or mapping convention.

Answer D: It needs continuous power to keep bit contents

An HDD records magnetic patterns in sectors arranged on tracks. During access to a selected track, rotation brings sectors under the head; seeking moves the head radially to another track. The medium retains its magnetic contents without continuous power, so the claimed power requirement is false. Power is needed to operate the drive, but that differs from power needed merely to retain the stored bits.

Why each choice is right or wrong

A - Incorrect: Sectors are subdivisions of tracks in the stated HDD organization.

B - Incorrect: This describes track-local access; a separate seek changes which track is under the head.

C - Incorrect: Magnetic disk data is organized on tracks, so this statement is true.

D - Correct: An HDD is nonvolatile: retaining stored patterns does not require continuous power.

Primary note proof

Study-note section COA28

An HDD stores magnetic patterns on tracks divided into sectors; reads/writes access addressed blocks while platters rotate.

Study-note section COA28

A head normally stays over a track while reading but moves radially for seeks.

Study-note section COA28

It does not need continuous power to preserve stored bits.

Question 5 | Q00093

Which listed circuit category requires stored state so that output can depend on past input behavior as well as present inputs?

A. Combinational circuit

B. Sequential circuits

C. A two-input AND gate with no feedback

D. A combinational multiplexer with no storage

Hint

Apply the gate truth rules and Boolean identities in the stated input order; distinguish an inversion from the underlying operation.

Answer B: Sequential circuits

A sequential circuit contains state that preserves information about prior behavior. A combinational circuit computes its outputs from current inputs after propagation delay. The specified AND gate and multiplexer are combinational examples without storage or feedback. They therefore do not require remembered state, while the sequential-circuit category does. This distinction concerns logical state, not whether physical propagation takes time.

Why each choice is right or wrong

A - Incorrect: Combinational output depends on current inputs rather than stored history.

B - Correct: Sequential circuits retain state and can make output depend on past behavior.

C - Incorrect: The specified AND gate computes a truth function of its present inputs without storage.

D - Incorrect: The specified multiplexer selects a present data input; it has no stored logical state.

In computers, subtraction is carried out generally by _____.

A. 1's complement method

B. 2's complement method

C. Signed magnitude method

D. BCD subtraction method

Hint

Keep the radix, bit width and representation fixed; evaluate place values or arithmetic steps in order.

Answer B: 2's complement method

Subtraction is described as complementation plus addition: add one to the inverted subtrahend, then add that two’s complement to the minuend (PDF p.42). Hence R1 + (~R2+1) represents R1−R2 within the register width.

Why each choice is right or wrong

A - Incorrect: One’s complement alone omits the added 1 in p.42’s subtraction procedure.

B - Correct: The inversion-plus-one subtrahend is exactly two’s complement (p.42).

C - Incorrect: The cited procedure does not use separate sign and magnitude arithmetic.

D - Incorrect: The cited general register subtraction is not BCD digit subtraction.

Pick the different _

A. Decoder

B. Encoder

C. Multiplexer

D. Shift Register

Hint

Check whether output depends only on current inputs or also on stored state, and track the stated clock behavior.

Answer D: Shift register: the sequential circuit.

COA05 distinguishes combinational circuits from sequential storage. Decoder, encoder and multiplexer are explicitly combinational; the shift register retains state and therefore belongs to the sequential class. The image confirms the four option texts. Using the state criterion provides the technically supported odd-one-out distinction without relying on the source emphasis.

Why each choice is right or wrong

A - Incorrect: A decoder is combinational and has no stored logical state in this circuit classification.

B - Incorrect: An encoder is also combinational, grouping it with the decoder and multiplexer.

C - Incorrect: A multiplexer selects among present inputs and is explicitly a combinational circuit.

Question 8 | Q00136

An operation performed on the contents of a register is known as

A. Instruction code

B. Micro-operation

C. Accumulator

D. Register

Hint

Identify the register, signal or instruction role and the execution phase; distinguish stored values, addresses and control actions.

Answer B: Micro-operation

An elementary operation on information stored in one or more registers is explicitly defined as a micro operation (PDF p.38). An instruction code tells the computer what operation to execute, while registers are the storage objects (pp.35,47).

Why each choice is right or wrong

A - Incorrect: An instruction code specifies work; it is not the elementary register operation itself (p.47).

B - Correct: Matches the exact definition and examples shift, count, clear, load (p.38).

C - Incorrect: Accumulator denotes a processing register, not the operation.

Examples of micro operation are shift, count, clear, and load.

An Instruction Code is a group of bits that instructs the computer to perform a specific operation. It is usually divided into parts, each having its own particular interpretation. The most basic part of an instruction code is its operation part. The operation code of an instruction is a group of bits that defines such operations as Add, Subtract, Multiply, Shift and Complement. The operation part of an instruction code specifies the operation to be performed. This operation must be performed on some data stored in processor registers or in memory. An instruction must specify not only the operation but also the registers or the memory words where the operands are to be found.

The simplest way to organize a computer is to have one processor register and an instruction code format with two parts. The first part of instruction code specifies the operation to be performed and the second specifies an address. The memory address tells the control where to find an operand in memory. This operand is read from memory and used as the data to be operated on together with the data stored in processor register. Instructions are stored in one section of memory and data in another. The operation is performed with memory operands and the content of AC. Figure 5-1 below depicts this type of organization.

Which one is true about RISC computers?

A. RISC are with few numbers of registers when compared to CISC

B. RISC use complex and efficient machine instructions when compared to CISC

C. RISC is with hardwired control unit with pipelining processing

D. RISC uses extensive addressing capabilities for memory operations

E. None

Hint

Compare textbook design tendencies without turning them into guarantees about every processor.

Answer C: RISC is with hardwired control unit with pipelining processing

RISC characteristics explicitly include hardwired control, many registers, few addressing modes and an efficient pipeline (PDF p.77). These jointly support C and contradict the reversed CISC-like descriptions.

Why each choice is right or wrong

A - Incorrect: A reverses the relatively large register count on p.77.

B - Incorrect: Complex instructions are the CISC characteristic (p.78), whereas RISC has few, easily decoded instructions (p.77).

C - Correct: Both hardwired control and efficient pipeline are explicitly listed (p.77).

Which of the following is not a basic element within the microprocessor?

A. Microcontroller

B. Arithmetic logic unit (ALU)

C. Register array

D. Control unit

Hint

Question 11 | Q00139

After CPU setup, which transfer method moves a block between an I/O device and memory without the CPU copying each data word?

A. Software interrupts

B. Interrupt-driven I/O

C. Polled I/O

D. Direct memory access (DMA)

Hint

Identify the register, signal or instruction role and the execution phase; distinguish stored values, addresses and control actions.

Answer D: Direct memory access (DMA)

DMA assigns the block movement to a controller after the CPU configures the transfer. Polling and ordinary interrupt-driven I/O still make the CPU execute item transfers. A software interrupt is an instruction-requested control transfer to a handler, not a block-copy engine. CPU setup and completion handling remain part of DMA; bypass refers specifically to avoiding CPU copying for every word.

Why each choice is right or wrong

A - Incorrect: A software interrupt requests handler execution; it does not itself move a block directly between device and memory.

B - Incorrect: The interrupt handler still uses CPU execution to service the device and move items.

C - Incorrect: The CPU checks status and moves items itself in polled I/O.

D - Correct: The DMA controller performs the block transfer after setup, avoiding per-word CPU copies.

When the CPU wishes to read or write a block of data, it issues a command to the DMA module and gives following information: CPU tells DMA controller:
• Whether to read or write
• Device address
• Starting address of memory block for data
• Amount of data to be transferred The CPU carries on with other work.
• Thus DMA controller steals the CPU‟s work of I/O operation.
• The DMA module transfers the entire block of data

with the higher priority first.
Interrupt Driven I/O.
Using Program-controlled I/O requires continuous involvement of the processor in the I/O activities. It is desirable to avoid wasting processor execution time. An alternative is for the CPU to issue an I/O command to a module and then go on other work. The I/O module will then interrupt the CPU requesting service when it is ready to exchange data with the CPU. The CPU will then execute the data transfer and then resumes its former processing. Based on the use of interrupts, this technique improves the utilization of the processor. With Interrupt driven I/O, the CPU issues a command to I/O module and it does not wait until I/O operation is complete but instead continues to execute other instructions. When I/O module has completed its work it interrupts the CPU. An interrupt is more than a simple mechanism for coordinating I/O transfers. In a general sense, interrupts enable transfer of control from one program to another to be initiated by an event that is external to a computer. Execution of the

Programmed I/O :With Programmed I/O, data are exchanged between the CPU and the I/O module. The CPU executes a program that gives it direct control of the I/O operation, including sensing device status, sending a read or write command and transferring data. When CPU issues a command to I/O module, it must wait until I/O operation is complete. If the CPU is faster than I/O module, there is wastage of CPU time. The I/O module does not take any further action to alert CPU. That is it doesn't interrupt CPU. Hence it is the responsibility of the CPU to periodically check the status of the I/O module until it finds that the operation is complete. The sequences of actions that take place with programmed I/O are:
• CPU requests I/O operation
• I/O module performs operation
• I/O module sets status bits
• CPU checks status bits periodically

- I/O module does not interrupt CPU

In the simple CPU-master bus model, which bus carries instruction or operand values in both directions during memory reads and writes?

A. Address bus

B. Control bus

C. Data bus

D. None of the above

Hint

Identify the register, signal or instruction role and the execution phase; distinguish stored values, addresses and control actions.

Answer C: Data bus

Data signals carry the values transferred between processor and memory. A read brings those values toward the CPU, while a write sends them toward memory, so the data bus serves both directions. Address signals select a location. Control signals coordinate operations and can include signals in both directions, but the question specifically asks about instruction or operand values rather than aggregate control direction.

Why each choice is right or wrong

A - Incorrect: The address bus selects locations rather than carrying payload values.

Question 13 | Q00365

Which specific instruction-processing technique overlaps fetch or decode of a later instruction with execution of an earlier instruction?

A. Superscalar processing

B. None of the above

C. Parallel Computation

D. Pipe-lining

Hint

Separate throughput from latency and check which operations overlap or share resources under the stated model.

Answer D: Pipe-lining

Fetching or decoding one instruction while another is being executed overlaps different instruction stages, which is pipelining. Superscalar processing instead permits issuing multiple instructions to execution resources during a cycle. These techniques can coexist, but the specific fetch/decode-versus-execute overlap identifies the pipeline mechanism rather than the processor's issue width.

Why each choice is right or wrong

A - Incorrect: Superscalar processing names multiple-issue execution resources; the stated overlap of different stages specifically describes pipelining.

B - Incorrect: Pipelining is an available matching choice.

C - Incorrect: Parallel computation is broader simultaneous processing (p.114); it does not identify the staged instruction mechanism as precisely as D.

D - Correct: The instruction pipeline reads consecutive instructions while previous ones execute (p.117).

Question 14 | Q00366

Which instruction class, where supported, bypasses the immediately following instruction when its condition is met?

A. Branch instruction

B. Return instruction

C. Skip instruction

D. Jump instruction

Hint

Identify the register, signal or instruction role and the execution phase; distinguish stored values, addresses and control actions.

Answer C: Skip instruction

A SKIP instruction conditionally bypasses the next instruction. That differs from an ordinary branch, which chooses a target, and from RETURN, which restores a saved return point. The original phrase jump to the next instruction did not express bypassing it; the revised wording states that intended control-flow effect precisely. The classification is based on behavior rather than an unstated machine-specific opcode.

Why each choice is right or wrong

A - Incorrect: A branch chooses a target rather than naming the specific next-instruction-bypass class.

B - Incorrect: RETURN restores a saved return point.

C - Correct: SKIP is the conditional next-instruction-bypass operation described.

D - Incorrect: A general jump chooses a target rather than naming this specific conditional operation.

Direct Addressing Mode: In this mode the effective address is equal to the address part of the instruction. The operand resides in memory and its address is given directly by the address field of the instruction. In a branch type of instruction the address field specifies the actual branch address.
Indirect Addressing Mode: In this mode the address field of the instruction gives the address where the effective address is stored in memory. Control fetches the instruction from memory and uses its address part to access memory again to read the effective address.

Question 15 | Q00367

An interrupt that is caused by register overflow, attempt to divide by zero, an invalid operation code, stack overflow can be?

A. None of the above

B. Software interrupt

C. External interrupt

D. Internal interrupt

Hint

Identify the register, signal or instruction role and the execution phase; distinguish stored values, addresses and control actions.

Answer D: Internal interrupt (synchronous exception).

COA19 classifies divide errors and illegal opcodes as synchronous internal exceptions because they arise from the executing instruction. Register or stack overflow belongs to that category when the machine traps it. Overflow does not invariably interrupt: ordinary flags may merely record it. Deliberate software requests and asynchronous external device events describe different causes.

Why each choice is right or wrong

A - Incorrect: The internal-exception category directly covers these instruction-related faults when trapping is enabled.

B - Incorrect: A software interrupt is deliberately requested by an instruction, rather than caused by an execution fault.

C - Incorrect: External interrupts originate from devices or timers, rather than the faulting instruction.

D - Correct: These execution-generated faults are internal exceptions; overflow trapping still depends on the architecture.

Primary note proof

> Interrupt Driven I/O.
> Using Program-controlled I/O requires continuous involvement of the processor in the I/O activities. It is desirable to avoid wasting processor execution time. An alternative is for the CPU to issue an I/O command to a module and then go on other work. The I/O module will then interrupt the CPU requesting service when it is ready to exchange data with the CPU. The CPU will then execute the data transfer and then resumes its former processing. Based on the use of interrupts, this technique improves the utilization of the processor. With Interrupt driven I/O, the CPU issues a command to I/O module and it does not wait until I/O operation is complete but instead continues to execute other instructions. When I/O module has completed its work it interrupts the CPU. An interrupt is more than a simple mechanism for

coordinating I/O transfers. In a general sense, interrupts enable transfer of control from one program to another to be initiated by an event that is external to a computer. Execution of the

Computer address bus is

A. Unidirectional

B. None of the above

C. Multidirectional

D. Bidirectional

Hint

Identify the register, signal or instruction role and the execution phase; distinguish stored values, addresses and control actions.

Answer A: Unidirectional

For the CPU-initiated memory operations described, CPU-held address registers supply the memory address (PDF pp.82-83 and 70). Thus the address path runs CPU→memory; this is a direction within that model, not a rule excluding DMA bus masters.

Why each choice is right or wrong

A - Correct: CPU loads MAR to select memory; the addressed memory does not return an address (pp.82-83).

B - Incorrect: The described CPU-address path supplies a matching option A.

C - Incorrect: The module's CPU-memory operation does not require simultaneous multidirectional address flow.

D - Incorrect: Read/write data can go both ways, but the initiating CPU supplies the address.

The simplest way to organize a computer is to have one processor register and an instruction code format with two parts. The first part specifies the operation to be performed and the second specifies .

A. address

B. output

C. Input

D. operand

Hint

Identify the register, signal or instruction role and the execution phase; distinguish stored values, addresses and control actions.

Answer A: address

The module reproduces this two-part instruction description: operation first, address second; that address locates the operand (PDF p.47). The operand itself and its address must not be conflated.

Why each choice is right or wrong

A - Correct: The second field specifies an address (p.47).

B - Incorrect: Output is not the second field in this format.

C - Incorrect: Input is not the second field in this format.

Which of the following computer memory is fastest?

A. RAM

B. Register

C. None of the above

D. Hard disk

Hint

Separate storage role, access timing, placement and power retention; use the specified hierarchy or mapping convention.

Answer B: Register

The hierarchy figure on PDF p.79 places registers before cache, RAM and disk. Register organization also avoids time-consuming memory accesses (p.58). Although p.84 calls cache the fastest memory-hierarchy component, it qualifies cache as approaching CPU component speed; registers are the CPU storage meant here.

Why each choice is right or wrong

A - Incorrect: RAM requires memory access, avoided by retaining intermediate values in registers (p.58).

B - Correct: Registers are the fastest offered CPU storage tier in Figure 6.1 (p.79).

6.1 Memory Hierarchy:
A computer system is equipped with a hierarchy of memory subsystems. There are several memory types with very different physical properties. The important characteristics of memory devices are cost per bit, access time, data transfer rate, alterability and compatibility with processor technologies. Figure shows the hierarchy of memory in a typical memory with a trend in access time, amount of storage, and cost per byte.
Figure 6.1 memory hierarchy
• Design constraints: How much? How fast? How expensive?
• Faster access time, greater cost per bit
• Greater capacity, smaller cost per bit,
• Greater capacity, slower access time.

In the programming examples of the previous chapter, we have shown that memory locations are needed for storing pointers, counters, return addresses, temporary results and partial product during multiplication. Having to refer to memory locations for such applications is time consuming because memory access is the most time consuming operation in a computer. It is more convenient and more efficient to store these intermediate values in processor register. When a large number of registers are included in the CPU, It is most efficient to connect them through a common bus system. The registers communicate with each other not only for direct data transfers, but also while performing various micro operations.

6.3 Cache Memory
Cache memory is a small, high-speed RAM buffer located between the CPU and main memory.
Cache memory holds a copy of the instructions (instruction cache) or data (operand or data cache) currently being used by the CPU.
The main purpose of a cache is to accelerate your computer while keeping the price of the computer low.
• The cache is the fastest component in the memory hierarchy and approaches the speed of CPU component
• When CPU needs to access memory, the cache is examined
• If the word is found in the cache, it is read from the fast memory
• If the word addressed by the CPU is not found in the cache, the main memory is accessed to read the word
• When the CPU refers to memory and finds the word in cache, it is said to produce a hit
• Otherwise, it is a miss

Question 19 | Q00539

It is a method used to synchronize the I/O device with the microprocessor

A. Interrupt

B. Handshaking

C. Interface

D. None

Hint

Follow the data path and control responsibility; distinguish the transfer mechanism, address space and interface type.

Answer B: Handshaking.

COA31 describes asynchronous handshaking as an exchange of request/ready and acknowledgement signals. The sender presents data, the receiver accepts it, and the feedback coordinates transfer despite unequal device and processor speeds. An interrupt requests service but does not itself name this two-sided transfer protocol. An interface is the broader connection exposing the signals and registers.

Why each choice is right or wrong

A - Incorrect: Interrupts request processor attention; they do not specifically identify the request-and-acknowledgement transfer protocol.

B - Correct: Request and acknowledgement signals synchronize the sender and receiver despite unequal operating speeds.

C - Incorrect: An interface provides the connection; handshaking names the synchronization method implemented through it.

D - Incorrect: Handshaking is an explicitly supported synchronization method, so an affirmative option fits.

Primary note proof

Which one of the following instructions is incorrect?

A. MOV AL, BP

B. INC CX

C. DEC CX

D. All

Hint

Identify the register, signal or instruction role and the execution phase; distinguish stored values, addresses and control actions.

Answer A: MOV AL, BP is invalid.

Under the ordinary Intel forms specified in COA22, AL is an 8-bit destination while BP is a 16-bit source. MOV does not implicitly resize these operands, so MOV AL, BP is invalid. INC CX and DEC CX are legal 16-bit operations. Consequently the all-invalid alternative fails because two listed instructions are valid.

Why each choice is right or wrong

A - Correct: The 8-bit AL and 16-bit BP widths do not match for this MOV instruction.

B - Incorrect: INC CX legally increments a 16-bit register under the stated legacy x86 assumptions.

C - Incorrect: DEC CX legally decrements a 16-bit register under the stated legacy x86 assumptions.

D - Incorrect: INC CX and DEC CX are valid, so the instructions are not all incorrect.

A register used to indicate the condition of the microprocessor is

A. SI

B. FLAG

C. DI

D. EIP

Hint

Identify the register, signal or instruction role and the execution phase; distinguish stored values, addresses and control actions.

Answer B: FLAG register.

COA21 states that FLAGS/EFLAGS/RFLAGS report processor status. This is the register family indicated by the option FLAG. SI and DI are general-purpose registers with conventional index roles, and EIP identifies the instruction position. Neither the index registers nor the instruction pointer is the processor condition/status register requested.

Why each choice is right or wrong

A - Incorrect: SI has an index/general-purpose role rather than collecting the processor condition flags.

B - Correct: FLAG denotes the status-register family reporting processor conditions such as arithmetic status.

C - Incorrect: DI has an index/general-purpose role rather than serving as the processor status register.

D - Incorrect: EIP identifies instruction position; it does not contain the collection of processor condition flags.

> Computer instructions are usually stored in consecutive memory locations and executed sequentially one at a time. The control reads an instruction from specific address in memory and executes it. It then continues by reading the next instruction in sequence and executes it and so on. This type of instruction sequencing needs a counter to calculate the address of the next instruction after execution of the current instruction is completed. It is also necessary to provide a register in a control unit for storing the instruction code after it is read from the memory. The data register (DR) holds the operand read from memory. The accumulator (AC) register is a general purpose processing register. The instructions read from memory are placed in instruction register (IR). Which one of the following instructions is correct

A. MOV DS, 20

B. MOV ES, 40

C. MOV SS, 60

D. None

Hint

Identify the register, signal or instruction role and the execution phase; distinguish stored values, addresses and control actions.

Answer D: None of these immediate-to-segment MOV forms is valid.

COA22 excludes a direct immediate-to-segment-register MOV in the assumed legacy x86 syntax. DS, ES and SS are segment registers, and each listed source is an immediate number. A permitted sequence first loads the value into a suitable general register and then moves that register to the segment register. Therefore all three displayed forms fail.

Why each choice is right or wrong

A - Incorrect: MOV DS, 20 attempts the unsupported direct transfer of an immediate into a segment register.

B - Incorrect: MOV ES, 40 also attempts an unsupported immediate-to-segment-register transfer in the stated syntax.

C - Incorrect: MOV SS, 60 has the same unsupported direct immediate source for a segment destination.

D - Correct: All three proposed segment-register instructions require an intermediate register or supported memory source.

A register used to address the next instruction in a section of memory is

A. RSP

B. CS

C. RIP

D. SS

Hint

Identify the register, signal or instruction role and the execution phase; distinguish stored values, addresses and control actions.

Answer C: RIP, the instruction pointer.

COA21 identifies IP/EIP/RIP as the instruction-position register family; COA14 identifies the PC role as locating the next instruction to fetch. RIP is the corresponding 64-bit x86 instruction pointer. CS selects the code segment and SS the stack segment, while RSP is the stack pointer. A segment selector alone does not identify the next instruction offset.

Why each choice is right or wrong

A - Incorrect: RSP tracks the stack, not the next instruction position within the instruction stream.

B - Incorrect: CS identifies the code segment; the instruction pointer supplies the instruction position within it.

C - Correct: RIP is the x86 instruction pointer used to identify the next instruction position.

D - Incorrect: SS identifies the stack segment rather than the location of the next instruction.

Question 24 | Q00562

The Intel's first true 32-bit microprocessor is

A. Pentium

B. 80486

C. 80286

D. 80386

Hint

Use the stated historical convention or integration trend, rather than assuming every model has identical characteristics.

Answer D: 80386, within the offered x86 lineage.

COA38 explicitly dates 32-bit x86 execution to the 80386 in 1985. It precedes the 80486 and Pentium, while the 80286 is a 16-bit predecessor. The offered choices therefore select 80386. This conclusion concerns the x86 sequence represented by the options; it should not be expanded into a claim about every historical Intel processor family.

Why each choice is right or wrong

A - Incorrect: Pentium follows the 80386; it was not the first 32-bit member among these x86 choices.

B - Incorrect: The 80486 follows the 80386, which had already introduced 32-bit x86 execution.

C - Incorrect: The note identifies the 80286 as a 16-bit predecessor, rather than the 32-bit introduction.

D - Correct: The 80386 introduced 32-bit x86 execution before the other offered 32-bit processors.

Primary note proof

Study-note section COA38

Intel’s 80386 introduced 32-bit x86 execution in 1985, before 80486/Pentium; the 80286 was a 16-bit predecessor.

Question 25 | Q00569

The content of BH is 10, AL is 8, CL is 4 how much is the content of AX after MUL BH

A. 40

B. 80

C. 32

D. 320

Hint

Identify the register, signal or instruction role and the execution phase; distinguish stored values, addresses and control actions.

Answer B: AX = 80.

The operand BH is a byte register. COA22 states that unsigned byte MUL multiplies AL by the explicit byte operand and stores the product in AX. Substituting the given values yields 8 × 10 = 80. CL is not an operand of MUL BH; multiplying by its value would change the instruction being evaluated.

Why each choice is right or wrong

A - Incorrect: 40 multiplies BH by CL, but byte MUL uses AL as its implicit multiplicand.

B - Correct: AL × BH equals 8 × 10 = 80, written into AX.

C - Incorrect: 32 multiplies AL by CL, whereas the explicit operand is BH, not CL.

D - Incorrect: 320 incorrectly includes CL as a third factor; MUL BH multiplies only AL and BH.

Primary note proof

Study-note section COA22

> Unsigned MUL with a byte operand multiplies AL by that byte and writes AX.

Study-note section COA22

> Thus AL=8 and BH=10 gives AX=80 after MUL BH; CL is irrelevant.

Question 26 | Q00573

Which legacy x86 instruction is arithmetic rather than a data-transfer or operand-exchange operation?

A. MOVS

B. LODS

C. XCHG

D. INC

Hint

Identify the register, signal or instruction role and the execution phase; distinguish stored values, addresses and control actions.

Answer D: INC

MOVS and LODS are string-transfer operations, and XCHG exchanges operand values. INC instead increments an operand, making it arithmetic. The revised stem states the classification criterion, so different no longer depends on whether the reader groups string operations, operand counts or another property. This retains the original instruction set and intended comparison while giving every choice a definite classification.

Why each choice is right or wrong

A - Incorrect: MOVS transfers string data.

B - Incorrect: LODS loads string data.

C - Incorrect: XCHG exchanges operands rather than performing arithmetic.

D - Correct: INC increments an operand arithmetically.

Which register is a user-accessible register?

A. DX

B. IR

C. MBR

D. MDR

Hint

Identify the register, signal or instruction role and the execution phase; distinguish stored values, addresses and control actions.

Answer A: DX is programmer-accessible.

COA21 explicitly identifies DX as programmer-visible and IR/MDR as conceptual internal registers. MBR is the memory-buffer name used for the same data-transfer role as MDR in COA11. The question asks which register is user-accessible in this architectural sense, so the x86 general-purpose register DX is the supported choice.

Why each choice is right or wrong

A - Correct: DX belongs to the programmer-visible x86 register set and is usable by ordinary instructions.

B - Incorrect: IR is the conceptual internal instruction register, rather than an ordinary programmer-addressable register.

C - Incorrect: MBR is the internal memory-buffer/data-transfer register, not a user-visible general-purpose register.

Which register is found starting from Pentium processor?

A. EAX

B. EIP

C. R8

D. None

Hint

Identify the register, signal or instruction role and the execution phase; distinguish stored values, addresses and control actions.

Answer D: None was introduced with original Pentium.

Reading starting from as introduced with Pentium, COA21 rules out every named register. EAX and EIP already existed with the 80386, while R8 belongs to the later 64-bit extension rather than original Pentium. Therefore none is correct under the introduction-date reading. Simply asking which registers a Pentium contains would be a different question, with EAX and EIP both present.

Why each choice is right or wrong

A - Incorrect: EAX existed before Pentium in the 80386; it was not introduced starting with Pentium.

B - Incorrect: EIP also existed in the 80386, so Pentium was not its first generation.

C - Incorrect: R8 belongs to the later 64-bit extension, not the original Pentium register set.

How many physical processor cores does the Intel Core i7-920 desktop processor have? Count cores, not hardware threads.

A. 5

B. 4

C. 6

D. 7

Hint

Question 30 | Q00628

A memory operand has effective address EA=A, where A is the address field stored directly in the instruction. Which addressing mode is used?

A. Direct addressing

B. Immediate addressing

C. Register addressing

D. None

Hint

Identify the register, signal or instruction role and the execution phase; distinguish stored values, addresses and control actions.

Answer A: Direct addressing

In direct addressing, the instruction's address field is itself the effective address: EA=A, and the operand is M[A]. Immediate addressing uses A as a value rather than a memory address, while register addressing uses a register as the operand source. A transfer's register and memory endpoints alone do not determine its addressing mode, so the revised question supplies the missing effective-address relationship.

Why each choice is right or wrong

A - Correct: EA=A defines direct addressing.

B - Incorrect: Immediate addressing uses A as the operand value.

C - Incorrect: Register addressing uses a register operand rather than M[A].

D - Incorrect: Direct addressing matches the relationship.

Primary note proof

Study-note section COA18

Immediate uses value A; direct uses EA=A and operand M[A]; indirect uses EA=M[A] then operand M[EA].

Direct Addressing Mode: In this mode the effective address is equal to the address part of the instruction. The operand resides in memory and its address is given directly by the address field of the instruction. In a branch type of instruction the address field specifies the actual branch address.
Indirect Addressing Mode: In this mode the address field of the instruction gives the address where the effective address is stored in memory. Control fetches the instruction from memory and uses its address part to access memory again to read the effective address.

Computer Organization and Architecture module | PDF page 72 | lines 2-19

Immediate Mode: In this mode the operand is specified in the instruction itself. In other words, an immediate mode instruction has an operand field rather than an address field. The operand field contains the actual operand to be used in conjunction with the operation specified in the instruction. Immediate mode instructions are useful for initializing registers to a constant value.
When the address field specifies a processor register, the instruction is said to be in the register mode.
Register Mode: In this mode the operands are in registers that reside within the CPU. The particular register is selected from a register field in the instruction. A k-bit field can specify any of the 2k registers.
Register Indirect Mode: In this mode the instruction specifies a register in the CPU whose contents give the address of the operand in memory. In other words, the selected register contains the address of the operand rather than the operand itself. Before using a register indirect mode instruction, the programmer must ensure that the memory address of the operand is placed in the processor register with a previous instruction. A reference to the register is then equivalent to specifying a memory address. The advantage of the register indirect mode instruction is that the address field of the instruction uses fewer bits to select a register than would have been required to specify a memory address directly.

A. Fast

B. Expensive

C. Memory refreshing s

D. None

Hint

Answer C: Memory refreshing s

SRAM stores bits in flip-flop state; applying power is sufficient and no refresh is needed (PDF p.81). Fast and relatively expensive are expressly listed, making refreshing the exception.

Why each choice is right or wrong

A - Incorrect: Faster than DRAM is stated (p.81).

Which one of the following is analog to digital converter?

A. ADC080X

B. DAC0830

C. 82C55

D. None

Hint

Follow the data path and control responsibility; distinguish the transfer mechanism, address space and interface type.

Answer A: ADC080X is the analog-to-digital converter.

COA33 defines an ADC as producing a digital code from an analog input and specifically identifies ADC080x as an 8-bit successive-approximation ADC family. DAC0830 performs the reverse conversion. The 82C55 is a programmable parallel I/O interface, not an ADC. The component identifiers therefore resolve this question without inferring capabilities merely from their general interface role.

Why each choice is right or wrong

A - Correct: ADC080x is explicitly identified as the analog-to-digital converter family in the note.

B - Incorrect: DAC0830 converts digital codes into analog output, which is the reverse direction.

C - Incorrect: 82C55 provides programmable parallel I/O; the note explicitly distinguishes it from an ADC.

D - Incorrect: ADC080X is a valid analog-to-digital component, so the list is not missing an answer.

Primary note proof

Which is NOT an Intel x86 16-bit general-purpose register?

A. AX

B. BP

C. SI

D. FLAGS

Hint

Identify the register, signal or instruction role and the execution phase; distinguish stored values, addresses and control actions.

Answer D: FLAGS

Intel’s general-purpose classification includes AX, BP and SI even though these registers have conventional special roles. FLAGS instead reports status conditions and is outside that group. The final option supplies an actual non-general-purpose register rather than incorrectly excluding SP merely because it tracks the stack. This preserves the register-class distinction without inventing a narrower meaning for multipurpose or misrepresenting Intel’s classification.

Why each choice is right or wrong

A - Incorrect: AX is a 16-bit general-purpose register.

B - Incorrect: BP is general-purpose despite its conventional base-pointer role.

C - Incorrect: SI is general-purpose despite its conventional source-index role.

Which of the following is a type of computer architecture?

A. Microarchitecture

B. Harvard Architecture

C. Von-Neumann Architecture

D. All of the mentioned

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer D: All listed categories are forms of computer design/architecture in the broad wording.

COA01 calls microarchitecture the internal processor design, while COA02 contrasts Harvard and Von Neumann memory organizations. The broad phrase type of computer architecture encompasses all three usages, although they describe different abstraction levels. The comprehensive answer is therefore all of the mentioned. Which one is not a combinational circuit?

A. Encoder

B. Decoder

C. Multiplexer

D. De-multiplexer

E. Register

Hint

Check whether output depends only on current inputs or also on stored state, and track the stated clock behavior.

Answer E: Register

A register is a group of state-holding flip-flops (PDF p.35). Sequential circuits retain past information (p.15), whereas code/routing combinational circuits transform current inputs (pp.31,33-34). Thus register is the non-combinational choice.

Why each choice is right or wrong

A - Incorrect: Encoder maps the active input into a binary code (p.34); no stored state is part of this described mapping.

B - Incorrect: Decoder selects an output based on the input pattern (p.33).

C - Incorrect: Multiplexer is explicitly combinational (p.31).

In a _____ cache organization, cache permits data to be stored in any cache block.

A. Direct Mapped

B. Set Associativity

C. Fully Associative

Answer C: Fully Associative

Associative cache stores an address with each data item and searches by content (PDF p.87), rather than constraining a block to a single index. Set association retains index constraints (p.88). Fully associative is therefore the any-block placement organization.

Why each choice is right or wrong

A - Incorrect: Direct mapping has fixed index conflicts (p.88), so does not allow arbitrary block placement.

B - Incorrect: Set association allows multiple entries under the same index, not any block anywhere (p.88).

C - Correct: Address/content pairs searched associatively permit the unrestricted mapping described (p.87).

D - Incorrect: Direct and set mappings are restricted, so not all satisfy the claim.

> Associative Mapping
> • An associative mapping uses an associative memory.
> • This memory is being accessed using its contents.
> • Associative memory is expensive compared to RAM
> • Each line of cache memory will accommodate the address (main memory) and the contents of that address from the main memory.
> • That is why this memory is also called Content Addressable Memory (CAM). It allows each block of main memory to be stored in the cache.
> A CPU address of 15 bits is places in the argument register and the associative memory us searched for a matching address
> • If the address is found, the corresponding 12bits data is read and sent to the CPU

• If not, the main memory is accessed for the word
If the cache is full, an address-data pair must be displaced to make room for a pair that is needed and not presently in the cache

Computer Organization and Architecture module | PDF page 88 | lines 2-13

Set Associative Mapping
That is the easy control of the direct mapping cache and the more flexible mapping of the fully associative cache.
In set associative mapping, each cache location can have more than one pair of tag + data items.
That is more than one pair of tag and data are residing at the same location of cache memory.
If one cache location is holding two pair of tag + data items, that is called 2-way set associative mapping.
The disadvantage of direct mapping is that two words with the same index in their address but with different tag values cannot reside in cache memory at the same time
Set-Associative Mapping is an improvement over the direct-mapping in that each word of cache can store two or more word of memory under the same index address

Question 37 | Q00692

Which one used to translate virtual addresses into physical addresses when we are implementing the concept of Virtual memory?

A. LRU

B. FIFO

C. Memory Management Unit

D. All

Hint

Separate storage role, access timing, placement and power retention; use the specified hierarchy or mapping convention.

Answer C: Memory Management Unit (MMU).

COA27 states that the MMU translates virtual/logical addresses into physical addresses using page tables and often a TLB. LRU and FIFO instead choose replacement victims, as described in COA26. Neither replacement policy performs address translation. Consequently the MMU is the single component matching the requested virtual-memory translation role; the all alternative incorrectly includes two different mechanisms.

Why each choice is right or wrong

A - Incorrect: LRU chooses a least-recently-used replacement victim; it does not translate virtual addresses.

B - Incorrect: FIFO selects the earliest inserted replacement victim, rather than computing physical addresses.

C - Correct: The MMU performs virtual-to-physical address translation using the translation structures described in the note.

D - Incorrect: Only the MMU translates addresses; LRU and FIFO are replacement policies.

Primary note proof

Study-note section COA27

> The MMU translates virtual/logical addresses to physical addresses, using page tables and often a TLB of recent translations.

Study-note section COA26

Question 38 | Q00693

In a _____ bus, flow is only one-way from the CPU to memory.

A. Address Bus

B. Data Bus

C. Control Bus

D. A & C

Hint

Identify the register, signal or instruction role and the execution phase; distinguish stored values, addresses and control actions.

Answer A: Address Bus

In the CPU-master model, CPU address registers identify the memory location (PDF pp.82-83), while data supports reads and writes (p.105) and control/status includes messages from both sides (pp.102-103). This makes A the specific one-way address path.

Why each choice is right or wrong

A - Correct: The CPU supplies the memory address (pp.82-83).

B - Incorrect: Read and write data travel in opposite directions (p.105).

C - Incorrect: Status reports return from I/O modules (p.103), so the whole control/status collection is not only CPU-outward.

D - Incorrect: C is not restricted to that one direction, so the conjunction fails.

Primary note proof

Study-note section COA12

> In the simple CPU-master model, addresses flow from CPU to memory, while data travels in either direction.

Study-note section COA12

Aggregate control signals include both CPU outputs and device inputs; both data and control buses can therefore be bidirectional under that scope.

6.2.1 Connection of RAM and CPU
Data transfer between the main memory and the CPU register takes place through two registers namely MAR (memory address register) and MDR (memory data register). If MAR is k bits long and MDR is n bits long, the main memory unit can contain up to 2k addressable locations.

Computer Organization and Architecture module | PDF page 105 | lines 2-6

• A read command: it causes the I/O module to obtain an item of data from the peripheral and place it in an internal buffer. The CPU then gets the data items by requesting I/O module to place it on the data bus.
• A write command: it causes the I/O module to take an item of data from the data bus and subsequently transmit the data item to the peripheral.

Computer Organization and Architecture module | PDF page 103 | lines 2-9

Status reporting:. I/O module can report with the status signals.common used status signals are BUSY or READY. Various other status signals may be used to report various error conditions.
Address recognition:
just as each memory word has an address, there is address associated with every I/O device. Thus I/O module must be recognized with a unique address for each peripheral it controls. The I/O module must also be able to perform device communication. This communication involves commands,status information, and data. Some of the essentials tasks are listed

Computer Organization and Architecture module | PDF page 102 | lines 20-24

I/O module must have the capability to engage in communication with the CPU and external device. Thus CPU communication involves
Command decoding: The I/O module accepts commands from the CPU carried on the control bus.
Data: data are exchanged between the CPU and the I/O module over data bus

Computer Organization and Architecture module | PDF page 83 | lines 2-7

During a “memory cycle‟ n bits of data are transferred between main memory and CPU. This transfer takes place over the processor bus, which has k address lines and n data lines. The CPU initiates a memory operation by loading the appropriate data into registers MDR and MAR, and setting either Read or Write memory control line to 1. When the required operation is completed the memory control circuitry sends Memory Function Completed (MFC) signal to CPU.

In memory hierarchy, faster access then_____.

A. Greater cost per bit

B. Greater capacity

C. Smaller cost per bit

D. All

Hint

Separate storage role, access timing, placement and power retention; use the specified hierarchy or mapping convention.

Answer A: Greater cost per bit

The module states the speed/cost tradeoff directly: faster access has greater cost per bit (PDF p.79). Its separate capacity bullets associate larger capacity with lower cost and slower access, rather than faster access.

Why each choice is right or wrong

A - Correct: Exact stated speed/cost relationship (p.79).

B - Incorrect: Greater capacity is associated with slower access, not the stated faster tier (p.79).

C - Incorrect: Smaller cost per bit is associated with greater capacity, opposite the faster-access bullet (p.79).

Question 40 | Q00695

Which Shift register type used to act as a delay element?

A. Serial-In Serial-Out

B. Parallel-In Serial-Out

C. Serial-In Parallel-Out

D. All

Hint

Identify the register, signal or instruction role and the execution phase; distinguish stored values, addresses and control actions.

Answer A: Serial-In Serial-Out

The shift register accepts/transfers data serially and moves each bit one position per clock, emitting the rightmost bit (PDF p.36). With serial input and serial output, an n-stage register delays the stream by n shifts. This derivation identifies SISO under the usual stream-delay meaning.

Why each choice is right or wrong

A - Correct: Serial input traverses storage stages to serial output, producing the clock-count delay (p.36).

B - Incorrect: Parallel input/serial output serializes a loaded word; it does not preserve the incoming serial stream in the described way.

C - Incorrect: Serial input/parallel output exposes the stored bits together rather than the delayed serial stream.

D - Incorrect: Not all listed I/O forms implement the same serial-stream delay.

Which one of them is a Universal Logic Gates?

A. NAND

B. Ex-OR

C. AND

D. NOT

Hint

Apply the gate truth rules and Boolean identities in the stated input order; distinguish an inversion from the underlying operation.

Answer A: NAND

Figure 1.2 on PDF p.7 gives NAND as NOT(A AND B). Tie its inputs to obtain NOT A; NAND followed by that inverter gives AND; applying NAND to inverted inputs gives OR, as can be checked against the same truth tables. Thus NAND alone can build the basic AND/OR/NOT set.

Why each choice is right or wrong

A - Correct: NAND supplies inversion by tying inputs and then AND/OR by composition (p.7, Figure 1.2).

B - Incorrect: XOR alone maps all-zero inputs to zero; it cannot supply the inverter required by Figure 1.2.

C - Incorrect: AND alone also preserves zero and cannot produce NOT using only AND gates.

D - Incorrect: NOT only complements one input; it cannot combine independent input variables into AND/OR.

Primary note proof

Which textbook architecture model stores instructions and data in a shared addressed memory system?

A. Microarchitecture

B. Harvard Architecture

C. Von-Neumann Architecture

D. System Design

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer C: Von-Neumann Architecture

The Von Neumann model uses a shared addressed memory system for instructions and data. Harvard separates instruction and data memories or paths. Microarchitecture names an internal implementation, while system design is broader than the particular stored-program memory model requested. The revised stem asks about a defining memory relationship rather than claiming that all modern computers use one exclusive organization.

Why each choice is right or wrong

B - Incorrect: Harvard separates instruction and data memories or paths.

C - Correct: Von Neumann uses the described shared addressed memory model.

D - Incorrect: System design is broader than this named memory model.

> The simplest way to organize a computer is to have one processor register and an instruction code format with two parts. The first part of instruction code specifies the operation to be

performed and the second specifies an address. The memory address tells the control where to find an operand in memory. This operand is read from memory and used as the data to be operated on together with the data stored in processor register. Instructions are stored in one section of memory and data in another. The operation is performed with memory operands and the content of AC. Figure 5-1 below depicts this type of organization.

Computer Organization and Architecture module | PDF page 48 | lines 14-23

Computer instructions are usually stored in consecutive memory locations and executed sequentially one at a time. The control reads an instruction from specific address in memory and executes it. It then continues by reading the next instruction in sequence and executes it and so on. This type of instruction sequencing needs a counter to calculate the address of the next instruction after execution of the current instruction is completed. It is also necessary to provide a register in a control unit for storing the instruction code after it is read from the memory. The data register (DR) holds the operand read from memory. The accumulator (AC) register is a general purpose processing register. The instructions read from memory are placed in instruction register (IR). The temporary register (TR) is used for holding temporary data during the processing.

Question 43 | Q00893

In a design connecting a processor-side bus segment to an unlike peripheral bus segment, which hardware category provides the necessary bridge or interface logic?

A. SCSI

B. PCI

C. Bus bridge/controller logic

D. Multi bus

Hint

Follow the data path and control responsibility; distinguish the transfer mechanism, address space and interface type.

Answer C: Bus bridge/controller logic

Unlike bus segments need bridge or controller logic to adapt their interfaces and coordinate transfers. PCI names a peripheral expansion interconnect, while SCSI names a storage connection; neither alone identifies the adapting component. Multibus names a bus rather than the requested bridge category. The revised topology and component requirement make the interface-logic choice definite without assuming a particular processor bus or expansion standard.

Why each choice is right or wrong

A - Incorrect: SCSI is a storage-connection standard rather than a bridge component.

B - Incorrect: PCI names an expansion interconnect rather than the adapting logic.

C - Correct: Bridge/controller logic connects unlike bus segments.

D - Incorrect: Multibus names a bus rather than the required interface component.

Combinational circuit differ from sequential circuit primarily because

A. Combinational circuit cannot be built using logic circuit

B. The output of combinational circuit depends only on the present input, not on past output.

C. .
Sequential circuit have no feedback while combinational circuit do

D. The combinational circuit requires clock signal, but sequential circuit do not

Hint

Check whether output depends only on current inputs or also on stored state, and track the stated clock behavior.

Answer B: The output of combinational circuit depends only on the present input, not on past output.

Combinational output depends only on input at the current time (PDF p.10); sequential output also depends on the past and includes memory elements (p.15). This is the primary functional difference, independent of implementation speed.

Why each choice is right or wrong

A - Incorrect: The definition explicitly builds a combinational circuit from gates (p.10), contradicting A.

B - Correct: B restates the present-input-only definition (p.10).

C - Incorrect: Sequential circuits contain memory (p.15); reversing the feedback distinction does not match the combinational definition.

D - Incorrect: The module does not make a clock mandatory for combinational logic; it defines direct current-input dependence (p.10).

Primary note proof

Which one of the following is the first operation or step in CPU instruction cycle?

A. Executing the instruction

B. Handling interrupt

C. .
Decoding the instruction

D. Fetching the instruction

Hint

Identify the register, signal or instruction role and the execution phase; distinguish stored values, addresses and control actions.

Answer D: Fetching the instruction

The listed cycle begins with fetching an instruction, then decoding, possible indirect-address access, and execution (PDF p.55). In the fetch micro-operations PC first supplies AR and memory then supplies IR.

Why each choice is right or wrong

A - Incorrect: Execution follows fetch and decode, rather than initiating the cycle (p.55).

B - Incorrect: Interrupt handling is not the first phase in the module's listed ordinary instruction cycle.

C - Incorrect: Decoding is the second listed phase (p.55).

D - Correct: Fetching is explicitly phase 1, with register transfers shown on p.55.

> I. Fetch the instruction
> Initially, the program counter PC is loaded with the address of the first instruction in the program and SC is cleared to 0, providing a decoded timing signal T0. After each clock pulse, SC is incremented by one, so that the timing signals go through a sequence T0, T1, T2 and so on. Since the address lines of the memory unit are hardwired to AR, address of the instruction to be fetched must first be placed in AR. Thus the first register transfer in an instruction cycle should be transferring the content of PC (address of the instruction to be brought in for execution) to AR
> T0: AR ← PC
> Bus selects PC, LD(AR) = 1. Next the current instruction is brought from memory into IR and PC is incremented

T1: IR ← M[AR], PC ← PC + 1. Bus selects RAM, Memory read is set, LD(IR) = 1,
INR(PC) = 1
II. Decode the instruction
T2: D0, ... , D7 ← Decode IR(12-14), AR ← IR(0-11), I ← IR(15)

A. System unit

B. Computer network

C. CPU

D. System interconnection

Hint

A. Asynchronous data transfer

B. Direct Memory Access (DMA)

C. .
Interrupt-driven transfer

D. Programmed I/O transfer

Hint

Follow the data path and control responsibility; distinguish the transfer mechanism, address space and interface type.

Answer B: Direct Memory Access (DMA)

DMA sends the block directly to/from memory and keeps CPU involvement to setup and completion (PDF pp.107-108). Asynchrony describes timing, whereas interrupt/programmed I/O still make the CPU transfer data.

Why each choice is right or wrong

A - Incorrect: Asynchronous transfer describes independent clocks (p.101), not a bypass path.

B - Correct: DMA words go directly to or from memory without traversing CPU (p.108).

> Asynchronous data transfer
> The internal operation in digital system is synchronized by means of clock pulse supplied by a common pulse generator. Two units such as cpu and an I/O are designed independently of each other, if the register in the interface share a common clock with the cpu registers, the transfer between the two units is called to be synchronous.in most case the internal timing in each unit is independent from the other in that each uses its own private clock for internal

register.in such cases the two units are said to be asynchronous to each other. This approach is widely used in most computers systems.

with the higher priority first.
Interrupt Driven I/O.
Using Program-controlled I/O requires continuous involvement of the processor in the I/O activities. It is desirable to avoid wasting processor execution time. An alternative is for the CPU to issue an I/O command to a module and then go on other work. The I/O module will then interrupt the CPU requesting service when it is ready to exchange data with the CPU. The CPU will then execute the data transfer and then resumes its former processing. Based on the use of interrupts, this technique improves the utilization of the processor. With Interrupt driven I/O, the CPU issues a command to I/O module and it does not wait until I/O operation is complete but instead continues to execute other instructions. When I/O module has completed its work it interrupts the CPU. An interrupt is more than a simple mechanism for coordinating I/O transfers. In a general sense, interrupts enable transfer of control from one program to another to be initiated by an event that is external to a computer. Execution of the

Computer Organization and Architecture module | PDF page 104 | lines 2-16

Programmed I/O :With Programmed I/O, data are exchanged between the CPU and the I/O module. The CPU executes a program that gives it direct control of the I/O operation, including sensing device status, sending a read or write command and transferring data. When CPU issues a command to I/O module, it must wait until I/O operation is complete. If the CPU is faster than I/O module, there is wastage of CPU time. The I/O module does not take any further action to alert CPU. That is it doesn't interrupt CPU. Hence it is the responsibility of the CPU to periodically check the status of the I/O module until it finds that the operation is complete. The sequences of actions that take place with programmed I/O are:
• CPU requests I/O operation
• I/O module performs operation
• I/O module sets status bits
• CPU checks status bits periodically
• I/O module does not inform CPU directly
• I/O module does not interrupt CPU

Question 48 | Q01178

Which instruction class tests a data word or computation status and sets condition information, often without retaining an arithmetic result?

A. Test instructions

B. Branch instructions

C. All of the above

D. Data-transfer instructions

Hint

Identify the register, signal or instruction role and the execution phase; distinguish stored values, addresses and control actions.

Answer A: Test instructions

TEST/CMP-style instructions examine values and update condition information, often discarding an arithmetic result. Branch instructions use control-flow conditions to choose a target; data-transfer instructions copy values. Those are different roles, so the aggregate alternative cannot identify the testing class. The cleaned question retains the recognizable, image-confirmed test-instruction concept while removing displaced OCR debris.

Why each choice is right or wrong

A - Correct: Test instructions examine values and set condition information.

B - Incorrect: Branches choose control-flow targets rather than naming the class that establishes the test condition.

C - Incorrect: Branch and data-transfer instructions do not both have the specified test role, so the aggregate is false.

D - Incorrect: Data-transfer instructions copy values rather than performing the requested condition-setting test.

An Instruction Code is a group of bits that instructs the computer to perform a specific operation. It is usually divided into parts, each having its own particular interpretation. The most basic part of an instruction code is its operation part. The operation code of an instruction is a group of bits that defines such operations as Add, Subtract, Multiply, Shift and Complement. The operation part of an instruction code specifies the operation to be performed. This operation must be performed on some data stored in processor registers or in memory. An instruction must specify not only the operation but also the registers or the memory words where the operands are to be found.

Data Manipulation
Data manipulation instructions perform operations on data and provide the computational capabilities for the computer. The data manipulation instructions in a typical computer are usually divided into three basic types.
1. Arithmetic instruction
2. Logical and bit manipulation
3. Shift instruction
a. Arithmetic Instruction
The four basic arithmetic operations are addition, subtraction, multiplication and division. Most computers provide instructions for all four operations. Some small computers have only addition and possibly subtraction instructions. The multiplication and division must then be generated by means of software subroutines.

Instruction Set Completeness
A computer should have a set of instructions so that the user can construct machine language program to evaluate any function that is known to be computable. The set of instructions are said to be complete if the computer includes a sufficient number of instructions in each of the following categories:
1. Arithmetic, Logical and Shift Instructions.
2. Instructions for moving information to and from memory and processor registers.
3. Program control instructions together with instructions that check status conditions.
4. Input and Output instructions.

Question 49 | Q01179

Branch instructions are used to branch to a different set of instructions depending on the decision made.

A. True

B. False

Hint

Identify the register, signal or instruction role and the execution phase; distinguish stored values, addresses and control actions.

Answer A: True

A branch changes the ordinary sequential instruction path to the branch address. The module explicitly identifies the actual branch address in a branch instruction (PDF p.72), and visually inspected Table 5-2 (p.52) shows both unconditional branch and conditional skip operations. Interpret “depending on the decision” as conditional branching; it is not true that every branch must be conditional.

Why each choice is right or wrong

A - Correct: True under the conditional-branch interpretation: the address field supplies the alternate target (p.72).

B - Incorrect: False would deny that conditional transfers select another instruction sequence; the table’s conditional skip examples illustrate such decisions (p.52).

The control unit of a computer is designed to go through an instruction cycle that is divided into three major phases. 1. Fetch the instruction from memory 2. Decode the instruction 3. Execute the instruction
There is one register in the computer called the program counter (PC) that keeps track of the instructions in the program stored in memory. PC holds the address of the instruction to be executed next and incremented each time an instruction is fetched from memory. The decoding done in step 2, determines the operation to be performed, the addressing mode of the instruction, and the location of the operand.

Which of the following is not considered as a peripheral device?

A. CPU

B. Keyboard

C. Monitor

D. All of the above

Hint

Follow the data path and control responsibility; distinguish the transfer mechanism, address space and interface type.

Answer A: CPU

Peripherals are external input/output devices such as keyboard and display (PDF p.99). CPU is the central processor structural component (p.6), so it is the only offered non-peripheral.

Why each choice is right or wrong

A - Correct: CPU is the processor, distinct from the external I/O devices (p.6).

B - Incorrect: Keyboard is explicitly a peripheral (p.99).

C - Incorrect: Display/video monitor is explicitly peripheral (p.99).

Question 51 | Q01187

Which one of the following statements is not true about the application of micro-operations?

A. Selective set operation is implemented using OR micro-operation

B. Selective clear operation clears to zero the bit in the first operand only where there are corresponding 1's in the logical operand

C. Clear operation is implemented using Exclusive-OR Micro-operation.

D. None of the above

Hint

Identify the register, signal or instruction role and the execution phase; distinguish stored values, addresses and control actions.

Answer D: None of the above

Selective set uses A OR B and selective clear zeroes A where B has ones (PDF p.44). For the unqualified clear operation, XOR a register with itself: each bit x XOR x=0, as shown by the equal-input rows of Figure 1.2 on PDF p.7. Thus A-C can all be true and D answers the negative stem.

Why each choice is right or wrong

A - Incorrect: The OR expression and example for selective set are explicit (p.44).

B - Incorrect: The selective-clear definition exactly states zeroing A at B=1 positions (p.44).

C - Incorrect: XOR self-clear is valid because 0 XOR 0 and 1 XOR 1 both equal zero (p.7, visually checked truth table).

D - Correct: None of A-C is false under self-XOR clearing, so D is the exception response.

Binary information in digital computers represented by physical quantities called signal. The fundamental building block of all digital logic circuits is the gate. Logical functions are implemented by the interconnection of gates. A gate is an electronic circuit that produces an output signal that is a simple Boolean operation on its input signals. The basic gates used in digital logic are AND, OR, NOT, NAND, NOR, and XOR. Each gate is defined in three ways: graphic symbol, algebraic notation, and truth table. Note that the inversion (NOT) operation is indicated by a circle.

Digital modules are best defined by the registers they contain and the operations that are performed on the data stored in them. The operations executed on data stored in registers are called micro operations. A micro operation is an elementary operation performed on the information stored in one or more registers.
Examples of micro operation are shift, count, clear, and load.

b. Logical and Bit manipulation Instructions
Logical instructions perform binary operations on strings of bits stored in registers. They are useful for manipulating individual bits or a group of bits that represent binary-coded information. The logical instructions consider each bit of the operands separately and treat it as a Boolean variable. By proper application of the logical instructions it is possible to change bit values, to clear a group of bits or to insert new bit values into the operands stored in registers or memory words. Some logical and bit manipulation instructions are listed in Table 5-8 as follows.

Question 52 | Q01190

In textbook discussions of richer CISC instructions, which term names the distance between high-level language constructs and machine operations that those instructions may reduce?

A. Time delay

B. Semantic gap

C. Cost

D. All of the mentioned

Hint

Compare textbook design tendencies without turning them into guarantees about every processor.

Answer B: Semantic gap

The semantic gap is the distance between high-level constructs and machine operations. Richer instructions can reduce that gap by expressing elaborate operations directly. Time and cost are separate design concerns, and neither RISC nor CISC guarantees reductions in them across implementations and workloads. The revised question ties the named gap to the supported richer-instruction discussion instead of asserting one universal purpose shared by both approaches.

Why each choice is right or wrong

A - Incorrect: Time delay is a performance measure rather than this conceptual distance.

B - Correct: Semantic gap names the high-level-to-machine-operation distance.

C - Incorrect: Cost is an implementation measure rather than this gap.

D - Incorrect: The question asks for one specific conceptual term.

Primary note proof

Question 53 | Q01248

Which register identifies the next instruction to fetch, before its address is copied into the address register for a memory access?

A. Accumulator

B. Instruction register

C. Address register

D. Program counter

Hint

Identify the register, signal or instruction role and the execution phase; distinguish stored values, addresses and control actions.

Answer D: Program counter

The program counter identifies the next instruction to fetch. During fetch, that address can be copied into MAR so memory can perform the access, but MAR's general role is the address of the current memory operation. IR holds the fetched instruction itself and the accumulator holds operands or results. Specifying next instruction and the point before copying separates PC from the later memory-access address.

Why each choice is right or wrong

> Computer instructions are usually stored in consecutive memory locations and executed sequentially one at a time. The control reads an instruction from specific address in memory and executes it. It then continues by reading the next instruction in sequence and executes it and so on. This type of instruction sequencing needs a counter to calculate the address of the next instruction after execution of the current instruction is completed. It is also necessary to provide a register in a control unit for storing the instruction code after it is read from the memory. The data register (DR) holds the operand read from memory. The accumulator (AC) register is a general purpose processing register. The instructions read from memory are placed in instruction register (IR). The temporary register (TR) is used for holding temporary data during the processing.

I. Fetch the instruction
Initially, the program counter PC is loaded with the address of the first instruction in the program and SC is cleared to 0, providing a decoded timing signal T0. After each clock pulse, SC is incremented by one, so that the timing signals go through a sequence T0, T1, T2 and so on. Since the address lines of the memory unit are hardwired to AR, address of the instruction to be fetched must first be placed in AR. Thus the first register transfer in an instruction cycle should be transferring the content of PC (address of the instruction to be brought in for execution) to AR
T0: AR ← PC
Bus selects PC, LD(AR) = 1. Next the current instruction is brought from memory into IR and PC is incremented
T1: IR ← M[AR], PC ← PC + 1. Bus selects RAM, Memory read is set, LD(IR) = 1, INR(PC) = 1
II. Decode the instruction
T2: D0, ... , D7 ← Decode IR(12-14), AR ← IR(0-11), I ← IR(15)
Therefore, micro-operations for the fetch and decode phases can be specified by the following register transfer statements.
T0: AR ← PC
T1: IR ← M[AR], PC ← PC + 1
T2: D0, ..., D7 ← Decode IR(12-14), AR ← IR(0-11), I ← IR(15)

Which of the following logic gates has an output value that is identical to its input?

A. NAND

B. NOR

C. Exclusive-OR

D. Buffer

Hint

Apply the gate truth rules and Boolean identities in the stated input order; distinguish an inversion from the underlying operation.

Answer D: Buffer

The enabled three-state buffer has output Y=A when control C=1 (PDF p.41). Therefore buffer preserves the input logic value. Figure 1.2 on p.7 gives the other gates' differing two-input truth tables.

Why each choice is right or wrong

A - Incorrect: NAND complements AND; it is not an identity function (p.7).

B - Incorrect: NOR complements OR; it is not an identity function (p.7).

From the labels RISC and CISC alone, which conclusion about processor power efficiency is justified without implementation or workload information?

A. RISC

B. Neither label alone determines power efficiency

C. IANA

D. CISC

Hint

Compare textbook design tendencies without turning them into guarantees about every processor.

Answer B: Neither label alone determines power efficiency

RISC and CISC describe instruction-set design tendencies, not universal power rankings. Power efficiency depends on implementation and the work being performed, so neither label alone establishes which processor is more efficient. The option states that supported conclusion. RISC and CISC remain unjustified blanket selections, while IANA does not supply the processor implementation or workload needed to resolve the comparison.

A RISC (Reduced Instruction Set Computer) processor pipeline operates in much the same way, although the stages in the pipeline are different. While different processors have different numbers of steps, they have basically variations of these five steps:
1. fetch instructions from memory
2. read registers and decode the instruction
3. execute the instruction or calculate an address
4. access an operand in data memory
5. write the result into a register
The length of the pipeline is dependent on the length of the longest step. Because RISC instructions are simpler than those used in pre-RISC processors (now called CISC, or Complex Instruction Set Computer), they are more conducive to pipelining. While CISC instructions varied in length, RISC instructions are all the same length and can be fetched in a single operation. Ideally, each of the stages in a RISC processor pipeline should take 1 clock cycle so that the processor finishes an instruction each clock cycle and averages one cycle per instruction (CPI). Among the characteristics attributed to RISC is its ability to use an efficient instruction pipeline.

Which of the following is not a type of memory used in an operating system?

A. Cache

B. RAM

C. ROM

D. Ethernet

Hint

Separate storage role, access timing, placement and power retention; use the specified hierarchy or mapping convention.

Answer D: Ethernet is a network connection, not a memory type.

COA23 describes cache as copying memory blocks near the CPU, and COA24 describes RAM technologies plus nonvolatile ROM. COA32 explicitly classifies Ethernet as connecting network devices rather than memory. Thus cache, RAM and ROM are memory-related choices, while Ethernet belongs to communications. The phrase used in an operating system does not convert a network technology into storage hardware.

Why each choice is right or wrong

A - Incorrect: Cache stores copies of memory blocks and is a genuine level of the memory hierarchy.

B - Incorrect: RAM is main-memory storage, not a communication technology excluded from the memory category.

C - Incorrect: ROM is nonvolatile memory even though its normal access and modification rules differ from RAM.

6.3 Cache Memory
Cache memory is a small, high-speed RAM buffer located between the CPU and main memory.
Cache memory holds a copy of the instructions (instruction cache) or data (operand or data cache) currently being used by the CPU.
The main purpose of a cache is to accelerate your computer while keeping the price of the computer low.
• The cache is the fastest component in the memory hierarchy and approaches the speed of CPU component
• When CPU needs to access memory, the cache is examined
• If the word is found in the cache, it is read from the fast memory
• If the word addressed by the CPU is not found in the cache, the main memory is accessed to read the word
• When the CPU refers to memory and finds the word in cache, it is said to produce a hit
• Otherwise, it is a miss

DYNAMIC RAM (DRAM)
is made with cells that store data as charge on capacitors. The presence or absence of charge in a capacitor is interpreted as a binary 1 or 0. Because capacitors have a natural tendency to discharge, DRAMs require periodic charge refreshing to maintain data storage.
STATIC RAM (SRAM)
In a SRAM, binary values are stored using traditional flip-flop logic-gate. A static RAM will hold its data as long as power is supplied to it. Static RAM's are faster than dynamic RAM's.

Question 57 | Q01318

Which of the following is not a type of storage device used in an operating system?

A. Hard disk drive (HDD)

B. Solid-state drive (SSD)

C. Tape drive

D. Ethernet cable

Hint

Separate storage role, access timing, placement and power retention; use the specified hierarchy or mapping convention.

Answer D: Ethernet cable is a communication medium.

COA28 describes HDD magnetic storage, SSD nonvolatile semiconductor storage and tape for sequential archives. It then explicitly distinguishes an Ethernet cable as a communication medium rather than a disk or RAM. The question asks for the item outside the storage-device category, so the cable is the supported exclusion regardless of which filesystem or OS uses the other devices.

Why each choice is right or wrong

A - Incorrect: An HDD stores persistent magnetic patterns in addressed blocks, so it is a storage device.

B - Incorrect: An SSD stores data in nonvolatile semiconductor storage, satisfying the storage-device category.

C - Incorrect: A tape drive provides sequential storage suitable for streaming and archives, so it is not excluded.

D - Correct: An Ethernet cable carries communication signals rather than functioning as a persistent storage device.

Primary note proof

Study-note section COA28

> An HDD stores magnetic patterns on tracks divided into sectors; reads/writes access addressed blocks while platters rotate.

Study-note section COA28

> SSDs use nonvolatile semiconductor storage without mechanical seek.

Study-note section COA28

Optical media use lasers; tape is suited to sequential streaming and archives.

Study-note section COA28

An Ethernet cable is a communication medium, not a disk or RAM.

6.4 Secondary memory
Devises that provides backup storage are called an Auxiliary memory (Secondary memory)
• It stores information that is not necessarily in current use.
• It is slower and having higher capacity than primary memory.
• This kind of memory is large, slow and inexpensive.
• It is non-volatile storage media i.e. the contents are not erased when the power is switched off.
• Magnetic disk, Magnetic tape and optical disk are the examples of secondary storage.

6.4.2 Magnetic Tape
• Magnetic Tape is a plastic ribbon which is usually ½ inch or ¼ inch wide & 50 to 2400 feet long.
• It is coated with iron-oxide material.
• It is similar to the tape of audio cassettes of tape recorders. Data is stored as binary digits.
• Data is accessed sequentially so searching becomes difficult.
• Tape systems use the same reading and recording techniques as disk systems..
• Magnetic tape was the first kind of secondary memory.It is still widely used as the lowest-cost, slowest-speed member of the memory hierarchy.

• Magnetic disks are the foundation of external memory on virtually all computer systems.
• A disk is a circular platter constructed of nonmagnetic material called the substrate coated with a magnetisable material.

• More suitable than magnetic tapes for a wider range of applications such as supporting direct access of data
• It is a thin, circular plate made of metal & plastic, which is coated with iron-oxide.
• We can randomly access the data.

Question 58 | Q01465

Which generation of computers used vacuum tubes as their primary electronic component?

A. First Generation

B. Second Generation

C. Third Generation

D. Fourth Generation

Hint

Use the stated historical convention or integration trend, rather than assuming every model has identical characteristics.

Answer A: First generation: vacuum tubes.

Under the familiar generation convention in COA38, vacuum tubes identify the first generation. Transistors belong to the second, integrated circuits to the third, and microprocessor/VLSI-era personal computers to the fourth. This question asks for the defining electronic component in that convention, so the mapping provides a direct answer without needing exact boundary dates for every historical machine.

Why each choice is right or wrong

A - Correct: The first generation is the conventional vacuum-tube era specified in the complete note.

B - Incorrect: The second generation is associated with transistors rather than vacuum tubes as its defining component.

C - Incorrect: The third generation is associated with integrated circuits rather than the vacuum-tube era.

D - Incorrect: The fourth generation is associated with microprocessors/VLSI rather than vacuum tubes as its primary component.

Logical functions are implemented by the interconnection of gates. A gate is an electronic circuit that produces an output signal that is a simple Boolean operation on its input signals. Question 59 | Q01466

Which generation of computers utilized transistors for electronic circuitry?

A. First Generation

B. Second Generation

C. Third Generation

D. Fourth Generation

Hint

Use the stated historical convention or integration trend, rather than assuming every model has identical characteristics.

Answer B: Second generation: transistors.

COA38 maps the second generation to transistor-based circuitry. The surrounding categories distinguish the first vacuum-tube era, third integrated-circuit era and fourth microprocessor/VLSI era. Within this conventional classification, the transistor clue therefore selects the second generation. The answer concerns the defining technology, rather than claiming transistors ceased to exist when integrated circuits appeared.

Why each choice is right or wrong

A - Incorrect: The first generation is conventionally identified with vacuum tubes, not transistor-based circuitry.

B - Correct: The note explicitly associates transistor circuitry with the second generation of computers.

C - Incorrect: Integrated circuits define the third-generation category, rather than the discrete-transistor era requested here.

D - Incorrect: Microprocessor/VLSI-era computers define the fourth category, rather than the transistor-generation convention.

Question 60 | Q01467

Under the course's conventional generation summary, around the transition into which generation did high-level programming languages become prominent?

A. First Generation

B. Second Generation

C. Third Generation

D. Fourth Generation

Hint

Use the stated historical convention or integration trend, rather than assuming every model has identical characteristics.

Answer B: Second Generation

The course associates high-level languages becoming prominent with the transition into the second generation. That is a conventional historical summary, rather than a claim that every language was first introduced on one sharply defined boundary. The revised verb preserves the generation-history question while avoiding an unsupported universal introduction era. The other options refer to different stages in the familiar circuitry-based chronology.

Why each choice is right or wrong

A - Incorrect: The note instead places prominence around the transition into the second era.

B - Correct: This matches the explicitly stated historical convention.

C - Incorrect: The third era is associated with integrated circuits rather than this transition.

D - Incorrect: The fourth era is associated with microprocessor/VLSI personal computers.

Which generation of computers introduced the concept of stored program architecture?

A. First Generation

B. Second Generation

C. Third Generation

D. Fourth Generation

Hint

Use the stated historical convention or integration trend, rather than assuming every model has identical characteristics.

Answer A: First generation.

COA38 directly places stored-program machines in the first era. The stored-program clue is different from the transistor, integrated-circuit and microprocessor clues defining later generations. Under the historical convention supplied by this note, the concept therefore belongs to the first generation, even though later computers also retained stored-program operation.

Why each choice is right or wrong

A - Correct: The note explicitly places the rise of stored-program machines in the first generation.

B - Incorrect: The second generation retained stored programs but is not where the note places their introduction.

C - Incorrect: The third generation is the integrated-circuit era, later than the stated stored-program introduction.

The simplest way to organize a computer is to have one processor register and an instruction code format with two parts. The first part of instruction code specifies the operation to be performed and the second specifies an address. The memory address tells the control where to find an operand in memory. This operand is read from memory and used as the data to be operated on together with the data stored in processor register. Instructions are stored in one section of memory and data in another. The operation is performed with memory operands and the content of AC. Figure 5-1 below depicts this type of organization.

Which generation of computers saw the development of integrated circuits?

A. First Generation

B. Second Generation

C. Third Generation

D. Fourth Generation

Hint

Use the stated historical convention or integration trend, rather than assuming every model has identical characteristics.

Answer C: Third generation: integrated circuits.

COA38 associates the third generation with integrated circuits. The first is identified by vacuum tubes, the second by transistors and the fourth by microprocessor/VLSI-era personal computers. Reading development in the question as the conventional adoption/defining-technology category gives third generation; it does not require assuming that every invention date perfectly matches textbook boundaries.

Why each choice is right or wrong

A - Incorrect: The first-generation convention identifies vacuum tubes rather than integrated circuits as the defining technology.

B - Incorrect: The second-generation convention identifies transistor circuitry, preceding the integrated-circuit generation category.

Question 63 | Q01470

A historical computer uses magnetic-core memory and transistor-based circuitry rather than vacuum tubes or integrated circuits. Under the conventional taxonomy, which generation describes its circuitry?

A. First Generation

B. Second Generation

C. Third Generation

D. Fourth Generation

Hint

Use the stated historical convention or integration trend, rather than assuming every model has identical characteristics.

Answer B: Second Generation

Magnetic-core memory alone does not identify a generation because it spanned more than one era. The added circuitry condition supplies the distinguishing feature: the conventional taxonomy associates transistor-based machines with the second generation. Vacuum tubes identify the first era, integrated circuits the third and microprocessor/VLSI personal computers the fourth. This version retains the magnetic-core context and states which technology determines the classification.

Why each choice is right or wrong

A - Incorrect: First-generation circuitry uses the vacuum-tube convention.

C - Incorrect: Third-generation circuitry uses the integrated-circuit convention.

D - Incorrect: The fourth era is associated with microprocessor/VLSI systems.

Question 64 | Q01472

Which generation conventionally introduced integrated-circuit circuitry, contributing to improved speed and performance over earlier discrete-transistor systems?

A. First Generation

B. Second Generation

C. Third Generation

D. Fourth Generation

Hint

Use the stated historical convention or integration trend, rather than assuming every model has identical characteristics.

Answer C: Third Generation

Several generations improved speed, so improvement alone is not a unique historical marker. The revised question identifies integrated circuits as the distinguishing technology. Under the stated convention, integrated circuits identify the third generation, following transistor-based second-generation systems. Performance improvement remains a contextual trend rather than a guarantee that every individual later machine outperformed every earlier model.

Which generation of computers introduced the use of microprocessors?

A. First Generation

B. Second Generation

C. Third Generation

D. Fourth Generation

Hint

Use the stated historical convention or integration trend, rather than assuming every model has identical characteristics.

Answer D: Fourth generation: microprocessors.

The conventional mapping in COA38 identifies the fourth generation with microprocessor/VLSI-era computers. Vacuum tubes, transistors and integrated circuits identify the preceding first, second and third categories respectively. Thus the microprocessor clue directly selects the fourth generation under the note's convention; the question does not ask for an exact launch date or individual processor model.

A - Incorrect: Vacuum tubes define the first-generation convention, rather than the later microprocessor era.

B - Incorrect: The transistor-based second-generation category precedes the note's microprocessor/VLSI category.

The part of the computer that performs the bulk of data processing operations is called the Central processing unit and is referred to as the CPU. The CPU is made up of three major parts The register set stores intermediate data used during the execution of the instructions. The Arithmetic and Logic unit (ALU) performs the required micro-operations for executing the instructions. The control unit supervises the transfer of information among the registers and instructs the arithmetic and logic units as to which operation to perform. The CPU performs a variety of functions dictated by the type of instructions that are incorporated in the computer. Which generation of computers is characterized by the development of personal computers?

A. First Generation

B. Second Generation

C. Third Generation

D. Fourth Generation

Hint

Use the stated historical convention or integration trend, rather than assuming every model has identical characteristics.

Answer D: Fourth generation: personal computers.

COA38 groups personal computers with the fourth-generation microprocessor/VLSI era. The first three alternatives instead correspond to vacuum tubes, transistors and integrated circuits. The wording characterized by asks for that conventional defining association, so fourth generation is supported without making a universal claim that no personal or individual-use machine could exist in any earlier period.

B - Incorrect: The second era is the transistor category rather than the personal-computer era identified here.

Question 67 | Q01491

A stack organized computer uses instruction of

A. Zero addressing

B. Two addressing

C. Index addressing

D. Indirect addressing

Hint

Identify the register, signal or instruction role and the execution phase; distinguish stored values, addresses and control actions.

Answer A: Zero addressing

For stack arithmetic the operands are implicit on top of stack, so ADD and MUL require no address field (PDF p.69). This is the zero-address organization. PUSH/POP still use explicit addresses; the answer concerns arithmetic operation instructions.

Why each choice is right or wrong

A - Correct: Zero-address ADD/MUL is explicit (p.69).

B - Incorrect: Two-address instructions instead explicitly name register/memory operands; stack arithmetic does not (pp.67-69).

C - Incorrect: Index addressing is an effective-address mechanism, not the stack operand-count format.

D - Incorrect: Indirect addressing locates an address through memory (p.72); it is not the stack arithmetic format.

Immediate Mode: In this mode the operand is specified in the instruction itself. In other words, an immediate mode instruction has an operand field rather than an address field. The operand field contains the actual operand to be used in conjunction with the operation specified in the instruction. Immediate mode instructions are useful for initializing registers to a constant value.
When the address field specifies a processor register, the instruction is said to be in the register mode.
Register Mode: In this mode the operands are in registers that reside within the CPU. The particular register is selected from a register field in the instruction. A k-bit field can specify any of the 2k registers.
Register Indirect Mode: In this mode the instruction specifies a register in the CPU whose contents give the address of the operand in memory. In other words, the selected register contains the address of the operand rather than the operand itself. Before using a register indirect mode instruction, the programmer must ensure that the memory address of the operand is placed in the processor register with a previous instruction. A reference to the register is then equivalent to specifying a memory address. The advantage of the register indirect mode instruction is that the address field of the instruction uses fewer bits to select a register than would have been required to specify a memory address directly.

Question 68 | Q01492

An n-bit microprocessor has -

A. No answer is correct

B. n-bit program counter

C. n-bit address register

D. n-bit instruction register

Hint

Identify the register, signal or instruction role and the execution phase; distinguish stored values, addresses and control actions.

Answer A: None of the named register widths necessarily follows.

COA38 explicitly states that an n-bit processor label does not force its PC, IR or address register to be n bits. Those widths concern different architectural quantities. Since the stem supplies only the processor-width label and no specific design, none of the three claimed register widths is guaranteed. The no-answer-is-correct alternative is therefore the supported response.

Why each choice is right or wrong

A - Correct: None of the three specific register-width claims is implied by the processor-width label alone.

B - Incorrect: Program-counter width is not forced to equal the processor's n-bit label in every architecture.

C - Incorrect: Address-register width can differ from processor word width; n bits is not guaranteed.

D - Incorrect: Instruction-register width depends on instruction encoding rather than necessarily matching the processor-width label.

Primary note proof

> The simplest way to organize a computer is to have one processor register and an instruction code format with two parts. The first part of instruction code specifies the operation to be performed and the second specifies an address. The memory address tells the control where to find an operand in memory. This operand is read from memory and used as the data to be operated on together with the data stored in processor register. Instructions are stored in one section of memory and data in another. The operation is performed with memory operands and the content of AC. Figure 5-1 below depicts this type of organization.

Question 69 | Q01493

In which of the following term the performance of cache memory is measured?

A. Copy ratio

B. Data ratio

C. Hit ratio

D. Cache ratio

Hint

Separate storage role, access timing, placement and power retention; use the specified hierarchy or mapping convention.

Answer C: Hit ratio

Cache performance is explicitly measured by hit ratio, hits/(hits+misses), in PDF p.85. A hit means the requested word is found in cache (p.84), making this a direct measure of cache availability of requested data.

Why each choice is right or wrong

A - Incorrect: Copy ratio is not the performance quantity defined on p.85.

B - Incorrect: Data ratio is not the named hit/miss measure.

C - Correct: Hit ratio and its formula are explicitly provided (p.85).

D - Incorrect: “Cache ratio” is not the quantity’s stated name.

Primary note proof

Question number 100
What is the name of logic gate based on the following graphical symbol?

A. XOR

B. NOR

C. NAND

D. AND

Hint

Apply the gate truth rules and Boolean identities in the stated input order; distinguish an inversion from the underlying operation.

Answer C: NAND

The diagram shows an AND-shaped gate with a small output circle. This is a NAND gate; the circle indicates inversion, so F=NOT(A AND B).

Why each choice is right or wrong

A - Incorrect: XOR uses the OR-like body with an extra input curve, unlike the source symbol (p.7).

B - Incorrect: NOR uses an OR-shaped body with an output circle, not the flat-input AND body (p.7).

C - Correct: The AND body plus inversion circle is NAND (p.7).

D - Incorrect: AND lacks the output inversion circle visible in the question.

An interface that has multiple lines connecting the input/output module and peripheral device and assures multiple bits to be transferred at the same time is:

A. Bus interface

B. Parallel interface

C. One line interface

D. Serial interface

Hint

Follow the data path and control responsibility; distinguish the transfer mechanism, address space and interface type.

Answer B: Parallel interface

Parallel registers read/write bits simultaneously (PDF p.35); shift registers transfer serially (p.36), and a common bus supplies a line for each bit (p.40). Multiple lines carrying bits at the same time match a parallel interface by this distinction.

Why each choice is right or wrong

A - Incorrect: A bus describes a collection of lines; it does not specify serial versus parallel transfer as precisely as B (p.40).

B - Correct: Simultaneous multiple-bit transfer corresponds to the parallel operation defined on p.35.

C - Incorrect: One line cannot carry the described multiple separate bit signals simultaneously in this binary-line model.

D - Incorrect: Serial shifting transfers the stream sequentially rather than all bits simultaneously (p.36).

Primary note proof

Serial sends bits over time; parallel transfers multiple bits on multiple lines, without guaranteeing higher real-world speed.

4.2 Bus and Memory Transfers
A typical computer has many registers, and paths must be provided to transfer information from one register to another. An efficient way for transferring information between registers in a multiple-register configuration is a common bus system. A bus structure consists of a set of common lines, one for each bit of a register. Control signals determine which register the bus selects during each particular register transfer.

Which one of the following is a two-level cache having an internal and external caches?

A. Multilevel cache

B. Single level cache

C. Split cache

D. Unified cache

Hint

Separate storage role, access timing, placement and power retention; use the specified hierarchy or mapping convention.

Answer A: Multilevel cache.

A two-level hierarchy has more than one cache level, so multilevel is the matching category. COA26 distinguishes L1/L2 hierarchy levels from split/unified instruction-data organization and from internal/external placement. Describing one cache as internal and another as external does not make the pair split or unified; those terms answer a different classification question.

Why each choice is right or wrong

A - Correct: Two cache levels constitute a multilevel hierarchy, regardless of their internal or external placement.

B - Incorrect: Single-level cache contradicts the explicitly stated presence of two cache levels in the hierarchy.

C - Incorrect: Split describes separate instruction and data caches, not an internal-plus-external level arrangement.

D - Incorrect: Unified describes combined instruction/data caching, not how many internal or external levels exist.

Primary note proof

Which statement is NOT correct about computer architecture and organization?

A. An architecture can remain for a long time but its organization can change

B. Manufacturers offer computers with the same architecture but different organization

C. An architecture can be used for a long time encompassing different computer models

D. Different organizations cannot implement the same architecture

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer D: Different organizations cannot implement the same architecture

Architecture describes programmer-visible behavior, while organization describes internal implementation. Several internal implementations can preserve the same architecture, allowing it to span models and remain stable while implementation details change. The false statement denies that possibility. The other choices describe compatible consequences of the distinction, without requiring a maximum architecture lifetime or a universal implementation-change rate.

Why each choice is right or wrong

A - Incorrect: Implementation can change while architecture stays stable.

B - Incorrect: Different organizations can implement one architecture.

C - Incorrect: One architecture can encompass different computer models over time.

D - Correct: This denies the supported possibility of different implementations of one architecture.

Answer D: Architecture

Programmer-visible attributes that directly affect logical execution are the module's exact definition of computer architecture (PDF p.5). Organization instead comprises operational units and interconnections realizing those specifications.

A - Incorrect: Arrangement is not the defined programmer-visible attribute set.

What is the purpose of an opcode that is as indicated in the figure below?
4 bits 6 bits 6 bits

[opcode] Operant etree [| Opsrand Rates|
<_ 16 bits -ccccxxcxor

A. It holds the destination address of an operand

B. It determines the operation to be done

C. It holds the source address of an operand

D. It holds the next instruction reference

Hint

Identify the register, signal or instruction role and the execution phase; distinguish stored values, addresses and control actions.

Answer B: It determines the operation to be done

The inspected diagram divides 16 bits into a 4-bit opcode and two 6-bit operand references. The module defines the operation part as specifying what operation is performed (PDF p.47); reference fields identify operands rather than changing that opcode role. Four opcode bits can distinguish up to 16 operation codes.

Why each choice is right or wrong

A - Incorrect: Destination reference belongs to an operand/address field, not the operation field (p.47).

B - Correct: Operation selection is the explicit opcode definition (p.47).

C - Incorrect: Source reference belongs to an operand/address field.

D - Incorrect: The module tracks the next instruction through PC (p.70), not this operation field.

Primary note proof

Study-note section COA16

Which one of the following registers holds the address of the next instruction to be fetched from memory?

A. Memory address register

B. Memory buffer register

C. Program counter

D. Instruction buffer register

Hint

Identify the register, signal or instruction role and the execution phase; distinguish stored values, addresses and control actions.

Answer C: Program counter

PC holds the address of the instruction to execute next (PDF p.70). During fetch it is copied to AR and the instruction bits then enter IR while PC increments (p.55). Thus PC is the persistent next-instruction tracker.

Why each choice is right or wrong

A - Incorrect: MAR can temporarily receive the fetch address, but PC is the register that tracks the next instruction across cycles (p.55).

B - Incorrect: The module describes MDR as memory data storage (p.82), not the next-instruction address tracker.

C - Correct: Directly matches the PC definition and fetch transfers (pp.55,70).

D - Incorrect: An instruction buffer would hold instruction content; the module identifies IR for that role (p.48), not as the next-address tracker.

Computer Organization and Architecture module | PDF page 55 | lines 9-28

I. Fetch the instruction
Initially, the program counter PC is loaded with the address of the first instruction in the program and SC is cleared to 0, providing a decoded timing signal T0. After each clock pulse, SC is incremented by one, so that the timing signals go through a sequence T0, T1, T2 and so on. Since the address lines of the memory unit are hardwired to AR, address of the instruction to be fetched must first be placed in AR. Thus the first register transfer in an instruction cycle should be transferring the content of PC (address of the instruction to be brought in for execution) to AR
T0: AR ← PC
Bus selects PC, LD(AR) = 1. Next the current instruction is brought from memory into IR and PC is incremented
T1: IR ← M[AR], PC ← PC + 1. Bus selects RAM, Memory read is set, LD(IR) = 1,
INR(PC) = 1
II. Decode the instruction
T2: D0, ... , D7 ← Decode IR(12-14), AR ← IR(0-11), I ← IR(15)
Therefore, micro-operations for the fetch and decode phases can be specified by the following register transfer statements.
T0: AR ← PC
T1: IR ← M[AR], PC ← PC + 1
T2: D0, ..., D7 ← Decode IR(12-14), AR ← IR(0-11), I ← IR(15)

Computer instructions are usually stored in consecutive memory locations and executed sequentially one at a time. The control reads an instruction from specific address in memory and executes it. It then continues by reading the next instruction in sequence and executes it and so on. This type of instruction sequencing needs a counter to calculate the address of the next instruction after execution of the current instruction is completed. It is also necessary to provide a register in a control unit for storing the instruction code after it is read from the memory. The data register (DR) holds the operand read from memory. The accumulator (AC) register is a general purpose processing register. The instructions read from memory are placed in instruction register (IR). The temporary register (TR) is used for holding temporary data during the processing.

Which one of the following is NOT an I/O command?

A. Status command

B. Output data command

C. Control command

D. Issue command

Hint

Follow the data path and control responsibility; distinguish the transfer mechanism, address space and interface type.

Answer D: Issue command

The module enumerates four I/O command kinds: control, test, read and write (PDF pp.104-105). “Status command” is interpreted as the test/status-query kind, and “output data” as write. “Issue” is an action performed by CPU, not one of the four command kinds.

Why each choice is right or wrong

A - Incorrect: Status-query corresponds to the test command, which checks status conditions (p.104).

B - Incorrect: Output data corresponds to the write command (p.105).

C - Incorrect: Control command activates a peripheral and specifies its action (p.104).

D - Correct: Issue is not a command category in the four-type list (pp.104-105).

7.6 I/O commands
To execute an I/O related instruction, the CPU issues an address, specifying the particular I/O module and external device and an I/O command. Four types of I/O commands can be received by the I/O module when it is addressed by the CPU. They are
• A control command: is used to activate a peripheral and tell what to do. Example: a magnetic tape may be directed to rewind or move forward a record.
• A test command: is used to test various status conditions associated with an I/O module and its peripherals. The CPU wants to know the interested peripheral for use. It also wants to know the most recent I/O operation is completed and if any errors have occurred.

Computer Organization and Architecture module | PDF page 105 | lines 2-6

• A read command: it causes the I/O module to obtain an item of data from the peripheral and place it in an internal buffer. The CPU then gets the data items by requesting I/O module to place it on the data bus.
• A write command: it causes the I/O module to take an item of data from the data bus and subsequently transmit the data item to the peripheral.

Computer Organization and Architecture module | PDF page 103 | lines 2-9

Status reporting:. I/O module can report with the status signals.common used status signals are BUSY or READY. Various other status signals may be used to report various error conditions.
Address recognition:
just as each memory word has an address, there is address associated with every I/O device. Thus I/O module must be recognized with a unique address for each peripheral it controls. The I/O module must also be able to perform device communication. This communication involves commands,status information, and data. Some of the essentials tasks are listed

Computer Organization and Architecture module | PDF page 101 | lines 10-16

7.4 Input/output Problems
Wide variety of peripherals and delivering different amounts of data per second Work at different speeds Send/receive data in different formats all slower than CPU and RAM. Hence I/O modules are used as a solution.
Input/output Module: It is the entity within a computer that is responsible for the control of one or more external devices and for the exchange of data between those devices and main memory and/or CPU.

A. The register set

B. The type of data supported by the instructions

C. The analysis model

D. The memory structure

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer C: The analysis model

The machine-language programmer's architecture includes instruction formats, addressing modes, instruction sets and register organization (PDF p.57); visible data types and memory addressing are also named (p.5). An "analysis model" is not part of that architectural list.

Why each choice is right or wrong

A - Incorrect: Register organization is explicitly part of the programmer view (p.57).

B - Incorrect: Supported data representation is explicitly architectural (p.5).

C - Correct: Analysis model is absent from the programmer-facing attribute list; it is the unmatched option.

D - Incorrect: Memory addressing is part of the architecture (p.5), under the intended visible-memory interpretation.

Question 79 | SM0239

Which part of the computer system is responsible for converting machine-processed data to formats understandable by the user?

A. Communication components

B. Output unit

C. Storage unit

D. Input unit

Hint

Follow the data path and control responsibility; distinguish the transfer mechanism, address space and interface type.

Answer B: Output unit

Computational results must be recorded/displayed for users (PDF p.99); human-readable screen/display/printer devices provide that communication (p.100). This is the output role.

Why each choice is right or wrong

A - Incorrect: Communication devices exchange data with remote devices; the category is not specifically user-readable presentation (p.100).

B - Correct: Output devices record/display computed results in meaningful form for users (p.99).

C - Incorrect: Storage retains information; it is not the presentation role (p.91).

D - Incorrect: Input enters programs/data into the system, the reverse direction (p.99).

Primary note proof

Study-note section COA29

> The input/output subsystem of a computer, referred to as I/O, provides an efficient mode of communication between the central system and the outside environment. Programs and data must be entered into computer memory for processing and results obtained from computations must be recorded or displayed for users. A computer serves no useful purpose without the ability to receive information from an outside source and to transmit results in a meaningful form. I/O operations are accomplished through a wide assortment of external devices that provide a means of exchanging data between the external environment and the computer. An external device attaches to the computer by a link to an I/O module. The link is used to exchange control, status, and data between the I/O module and the external device. An external device connected to an I/O module also called Interface is often referred to as a peripheral device or simply a peripheral.

> External devices broadly can be classified into three categories:
> Human readable: suitable for communicating with the computer user. Examples: Screen, keyboard, video display terminals (VDT) and printers.
> Machine readable: suitable for communicating with equipment. Examples: magnetic disk & tapes systems, Monitoring and control, sensors and actuators which are used in robotics.
> Communication: These devices allow a computer to exchange data with remote devices, which may be machine readable or human readable. Examples: Modem, Network Interface Card (NIC)

Question 80 | SM0242

In the usual memory hierarchy, which listed tier has the shortest access latency and greatest cost per stored bit?

A. Register

B. Magnetic disc

C. Main memory

D. Cache memory

Hint

Separate storage role, access timing, placement and power retention; use the specified hierarchy or mapping convention.

Answer A: Register

The usual speed and cost-per-bit hierarchy places registers above cache, main RAM and magnetic disk. Registers therefore have the shortest access latency and highest cost per bit among the choices. Faster tiers are generally smaller, so this statement does not compare the total purchase price of a complete device. Cache is fast, but remains below the register tier in this teaching hierarchy.

Why each choice is right or wrong

A - Correct: Registers are the fastest and most costly-per-bit tier among these choices.

B - Incorrect: Magnetic disk is a slower, high-capacity tier with lower cost per bit.

C - Incorrect: Main memory lies below registers and cache in the usual speed/cost hierarchy.

D - Incorrect: Cache is fast but below registers in the usual hierarchy.

In the programming examples of the previous chapter, we have shown that memory locations are needed for storing pointers, counters, return addresses, temporary results and partial product during multiplication. Having to refer to memory locations for such applications is time consuming because memory access is the most time consuming operation in a computer. It is more convenient and more efficient to store these intermediate values in processor register. When a large number of registers are included in the CPU, It is most efficient to connect them through a common bus system. The registers communicate with each other not only for direct data transfers, but also while performing various micro operations.

6.3 Cache Memory
Cache memory is a small, high-speed RAM buffer located between the CPU and main memory.
Cache memory holds a copy of the instructions (instruction cache) or data (operand or data cache) currently being used by the CPU.
The main purpose of a cache is to accelerate your computer while keeping the price of the computer low.
• The cache is the fastest component in the memory hierarchy and approaches the speed of CPU component
• When CPU needs to access memory, the cache is examined
• If the word is found in the cache, it is read from the fast memory
• If the word addressed by the CPU is not found in the cache, the main memory is accessed to read the word
• When the CPU refers to memory and finds the word in cache, it is said to produce a hit
• Otherwise, it is a miss

Question 81 | SM0277

For a legacy internal PC disk connection using parallel ATA, which listed interface name matches that connection?

A. SCSI

B. iSCSI

C. IDE

D. USB

Hint

Follow the data path and control responsibility; distinguish the transfer mechanism, address space and interface type.

Answer C: IDE

The note identifies legacy IDE/PATA as a storage connection, so IDE matches the specified parallel ATA context. SCSI is a different storage interface, iSCSI carries SCSI over IP, and USB commonly connects peripherals including external storage. Naming the legacy internal parallel interface resolves the missing era and connection-role constraints without asserting that one interface is universally standard for all PCs and all storage devices.

Why each choice is right or wrong

A - Incorrect: SCSI is a different storage-connection standard.

B - Incorrect: iSCSI transports SCSI commands over IP rather than using the specified local parallel interface.

C - Correct: IDE corresponds to the stated legacy PATA connection.

D - Incorrect: USB is a different peripheral interconnect, not parallel ATA.

Primary note proof

Question 82 | SM0295

In the simple CPU-master memory-bus model, which bus carries the values read from and written to memory?

A. Control bus

B. Data bus

C. Uni-bus

D. Address bus

Hint

Identify the register, signal or instruction role and the execution phase; distinguish stored values, addresses and control actions.

Answer B: Data bus

The data bus carries memory-transfer values. Reads move values from memory toward the CPU, and writes move values in the opposite direction. Address signals select a location and control signals coordinate timing and read/write operations. The revised stem asks about payload rather than bidirectionality in general, since aggregate control can also contain signals in both directions. Uni-bus names a bus arrangement rather than this payload-signal category.

Why each choice is right or wrong

A - Incorrect: Control signals coordinate the transfers rather than carrying their values.

B - Correct: The data bus carries read and write values.

C - Incorrect: This is not the address/data/control payload-signal category requested.

D - Incorrect: Address signals choose the memory location.

Primary note proof

Study-note section COA12

Address signals select a location; data signals carry values; control signals coordinate read/write, timing, requests and acknowledgements.

Study-note section COA12

In the simple CPU-master model, addresses flow from CPU to memory, while data travels in either direction.

What is the purpose of an opcode that is as indicated in the figure below?
4 bits 6 bits 6 bits

<j o bits --_____»

A. It determines the operation to be done

B. It holds the destination address of an operand

C. It holds the next instruction reference

D. It holds the source address of an operand

Hint

Identify the register, signal or instruction role and the execution phase; distinguish stored values, addresses and control actions.

Answer A: It determines the operation to be done

The instruction has a 4-bit Opcode followed by two 6-bit Operand Reference fields. Opcode selects the operation.

Why each choice is right or wrong

A - Correct: Matches the operation-code definition (p.47).

B - Incorrect: A destination reference is an operand field, not the opcode.

C - Incorrect: Next-instruction location is tracked by PC (p.70), not this operation field.

D - Incorrect: Source address belongs to an operand reference, not the operation code (p.47).

> An Instruction Code is a group of bits that instructs the computer to perform a specific operation. It is usually divided into parts, each having its own particular interpretation. The

most basic part of an instruction code is its operation part. The operation code of an instruction is a group of bits that defines such operations as Add, Subtract, Multiply, Shift and Complement. The operation part of an instruction code specifies the operation to be performed. This operation must be performed on some data stored in processor registers or in memory. An instruction must specify not only the operation but also the registers or the memory words where the operands are to be found.

Computer Organization and Architecture module | PDF page 70 | lines 17-24

The control unit of a computer is designed to go through an instruction cycle that is divided into three major phases. 1. Fetch the instruction from memory 2. Decode the instruction 3. Execute the instruction
There is one register in the computer called the program counter (PC) that keeps track of the instructions in the program stored in memory. PC holds the address of the instruction to be executed next and incremented each time an instruction is fetched from memory. The decoding done in step 2, determines the operation to be performed, the addressing mode of the instruction, and the location of the operand.

Which of the following is a common way of communicating with I/O devices?

A. Memory-mapped I/O

B. Direct memory access (DMA)

C. Interrupt-driven I/O

D. All of the above

Hint

Follow the data path and control responsibility; distinguish the transfer mechanism, address space and interface type.

Answer D: All of the above

Memory-mapped I/O shares memory and device address space (PDF p.105); DMA transfers blocks directly (p.107); interrupt I/O requests CPU service when ready (p.106). They are all supported I/O mechanisms, though memory mapping is an addressing choice and the others are transfer/control techniques.

Why each choice is right or wrong

A - Incorrect: Memory-mapped I/O is explicitly described (p.105).

B - Incorrect: DMA is explicitly described (p.107).

C - Incorrect: Interrupt-driven I/O is explicitly described (p.106).

D - Correct: All three are legitimate mechanisms under the broad “communicating” wording.

Interrupt Driven I/O.
Using Program-controlled I/O requires continuous involvement of the processor in the I/O activities. It is desirable to avoid wasting processor execution time. An alternative is for the CPU to issue an I/O command to a module and then go on other work. The I/O module will then interrupt the CPU requesting service when it is ready to exchange data with the CPU. The CPU will then execute the data transfer and then resumes its former processing. Based on the use of interrupts, this technique improves the utilization of the processor. With Interrupt driven I/O, the CPU issues a command to I/O module and it does not wait until I/O operation is complete but instead continues to execute other instructions. In memory-mapped I/O, I/O devices are mapped into the:

A. Main memory address space

B. Cache memory address space

C. Virtual memory address space

D. Secondary memory address space

Hint

Follow the data path and control responsibility; distinguish the transfer mechanism, address space and interface type.

Answer A: Main memory address space

Memory-mapped I/O makes devices and memory share an address space, with I/O treated like memory reads/writes (PDF p.105). The relevant address space is the memory address space, not a separate cache or secondary-storage space.

Why each choice is right or wrong

A - Correct: Devices share the memory address space (p.105).

B - Incorrect: The module does not map device registers into a separate cache address space.

C - Incorrect: The mapping definition does not depend on a process virtual address space.

D - Incorrect: Secondary-storage addresses are not the shared CPU memory addresses described on p.105.

Which technique allows data to be transferred between an I/O device and memory without involving the CPU?

A. Memory-mapped I/O

B. Direct memory access (DMA)

C. Interrupt-driven I/O

D. I/O polling

Hint

Follow the data path and control responsibility; distinguish the transfer mechanism, address space and interface type.

Answer B: Direct memory access (DMA)

DMA transfers each word directly to/from memory without passing through CPU (PDF p.108). “Without involving” must mean during the actual word transfers, since CPU setup and completion involvement are explicit on the same page.

Why each choice is right or wrong

A - Incorrect: Memory mapping specifies how I/O is addressed, not a CPU-bypass data engine (p.105).

B - Correct: DMA directly transfers the block with CPU only at beginning/end (p.108).

C - Incorrect: The CPU still executes the interrupt-driven data transfer (p.106).

D - Incorrect: Polling keeps CPU checking device status and doing transfers (p.104).

Which method is used to handle I/O operations that require immediate attention from the CPU?

A. Memory-mapped I/O

B. Direct memory access (DMA)

C. Interrupt-driven I/O

D. I/O polling

Hint

Follow the data path and control responsibility; distinguish the transfer mechanism, address space and interface type.

Answer C: Interrupt-driven I/O

In interrupt-driven I/O the device requests CPU service when ready; CPU can work on other instructions until then (PDF p.106). The priority-interrupt discussion on that page services the higher-priority simultaneous request first. This matches event-driven attention, without guaranteeing zero response latency.

Why each choice is right or wrong

A - Incorrect: Memory mapping selects addresses and does not itself notify the CPU (p.105).

B - Incorrect: DMA offloads data movement (p.107); it is not the general CPU-service notification technique.

C - Correct: The device interrupts CPU requesting service when ready (p.106).

D - Incorrect: Polling requires the CPU to discover readiness through repeated checks (p.104).

Which I/O technique involves the CPU continuously checking the status of an I/O device for data transfer completion?

A. Memory-mapped I/O

B. Direct memory access (DMA)

C. Interrupt-driven I/O

D. I/O polling

Hint

Answer D: I/O polling

Programmed I/O explicitly makes CPU periodically check I/O status until completion, because the module does not interrupt CPU (PDF p.104). This is the polling behavior described by D.

Why each choice is right or wrong

A - Incorrect: Memory mapping is the address arrangement and does not require repeated status checks (p.105).

B - Incorrect: DMA permits CPU other work while moving a block (p.108).

Interrupt-driven I/O lets the CPU do other work until an event requests service; the handler still consumes CPU time to service the device.

Programmed I/O :With Programmed I/O, data are exchanged between the CPU and the I/O module. The CPU executes a program that gives it direct control of the I/O operation, including sensing device status, sending a read or write command and transferring data. When CPU issues a command to I/O module, it must wait until I/O operation is complete. If the CPU is faster than I/O module, there is wastage of CPU time. The I/O module does not take any further action to alert CPU. That is it doesn't interrupt CPU. Hence it is the responsibility of the CPU to periodically check the status of the I/O module until it finds that the operation is complete. The sequences of actions that take place with programmed I/O are:
• CPU requests I/O operation
• I/O module performs operation
• I/O module sets status bits
• CPU checks status bits periodically
• I/O module does not inform CPU directly
• I/O module does not interrupt CPU

with the higher priority first.
Interrupt Driven I/O.
Using Program-controlled I/O requires continuous involvement of the processor in the I/O activities. It is desirable to avoid wasting processor execution time. An alternative is for the CPU to issue an I/O command to a module and then go on other work. The I/O module will then interrupt the CPU requesting service when it is ready to exchange data with the CPU. The CPU will then execute the data transfer and then resumes its former processing. Based on the use of interrupts, this technique improves the utilization of the processor. With Interrupt driven I/O, the CPU issues a command to I/O module and it does not wait until I/O operation is complete but instead continues to execute other instructions. When I/O module has completed its work it interrupts the CPU. An interrupt is more than a simple mechanism for coordinating I/O transfers. In a general sense, interrupts enable transfer of control from one program to another to be initiated by an event that is external to a computer. Execution of the

Interrupt driven and programmed I/O require active CPU intervention.
Transfer rate is limited

Direct Memory Access is capabilities provided by some computer bus architectures that allow data to be sent directly from an attached device (such as a disk drive) to the memory on the computer's motherboard. The microprocessor (CPU) is freed from involvement with the data transfer, thus speeding up overall computer operation.

7.8 I/O Mapping
When the CPU, main memory, and I/O module share a common bus two modes of addressing are possible.
• Memory mapped I/O
• Devices and memory share an address space
• I/O looks just like memory read/write
• No special commands for I/O
• Large selection of memory access commands available
• Isolated I/O
• Separate address spaces
• Need I/O or memory select lines

Question 89 | AM0709

Which standard I/O interface is commonly used in UNIX-like operating systems?

A. ASCII

B. USB

C. RS-232

D. POSIX

Hint

Follow the data path and control responsibility; distinguish the transfer mechanism, address space and interface type.

Answer D: POSIX.

COA32 identifies POSIX as a software interface standard with open/read/write/close operations. That is the software I/O interface sense appropriate to UNIX-like operating systems. ASCII is an encoding, while USB and RS-232 describe hardware interconnect/interface roles. Their availability on a UNIX-like machine does not make them the standard OS software interface requested by the alternatives.

Why each choice is right or wrong

A - Incorrect: ASCII defines character encoding, not the UNIX-like software interface for opening, reading and writing resources.

B - Incorrect: USB is a peripheral interconnect, not the software API standard identified by this OS-level wording.

C - Incorrect: RS-232 defines a serial electrical/interface standard rather than the UNIX-like software I/O API.

D - Correct: POSIX specifies software interface operations including open, read, write and close for this context.

Question 90 | AM0710

Which listed interface is a traditional point-to-point serial electrical/interface standard?

A. USB

B. Ethernet

C. RS-232

D. HDMI

Hint

Follow the data path and control responsibility; distinguish the transfer mechanism, address space and interface type.

Answer C: RS-232

RS-232 specifies a traditional point-to-point serial electrical/interface standard. USB also uses serial communication, so serial alone cannot distinguish them. The revised requirement identifies the traditional point-to-point interface category rather than treating every serial link as equivalent. Ethernet connects network devices and HDMI carries digital audio and video. Their connection roles differ from the interface class requested.

Why each choice is right or wrong

A - Incorrect: USB is a serial peripheral interconnect, but not the traditional point-to-point electrical standard requested.

Asynchronous data transfer
The internal operation in digital system is synchronized by means of clock pulse supplied by a common pulse generator. Two units such as cpu and an I/O are designed independently of each other, if the register in the interface share a common clock with the cpu registers, the transfer between the two units is called to be synchronous.in most case the internal timing in each unit is independent from the other in that each uses its own private clock for internal register.in such cases the two units are said to be asynchronous to each other. This approach is widely used in most computers systems.

Question 91 | AM0711

Which standard I/O interface is widely used for connecting external storage devices, such as hard drives and flash drives?

A. SATA

B. USB

C. Ethernet

D. HDMI

Hint

Follow the data path and control responsibility; distinguish the transfer mechanism, address space and interface type.

Answer B: USB.

COA32 explicitly describes USB as a peripheral interconnect used by external storage. This directly matches the stem's external hard-drive and flash-drive examples. SATA is described more generally as a storage interface, Ethernet connects network devices, and HDMI carries video/audio. The external peripheral examples therefore make USB the supported conventional choice among these options.

Why each choice is right or wrong

A - Incorrect: SATA is a storage interface, but USB is the note's explicit match for the external-peripheral examples.

B - Correct: The note explicitly lists external storage among USB peripheral connections, matching the supplied examples.

C - Incorrect: Ethernet connects network devices rather than being the named external hard-drive/flash-drive peripheral interconnect.

D - Incorrect: HDMI carries digital video and audio, rather than providing the external-storage interface requested.

Question 92 | AM0712

Which listed interface is specifically a storage-drive interface, rather than a general peripheral interconnect, networking interface or audiovisual link?

A. SATA

B. USB

C. Ethernet

D. HDMI

Hint

Follow the data path and control responsibility; distinguish the transfer mechanism, address space and interface type.

Answer A: SATA

SATA is specifically a storage interface. USB supplies general peripheral connectivity, Ethernet connects network devices and HDMI carries digital audio/video. The connection role distinguishes these alternatives; a vague high-speed description would not, because several interfaces can be fast in suitable versions. The question therefore asks for a storage-specific interface category without assuming that speed alone uniquely identifies it.

Why each choice is right or wrong

A - Correct: SATA is the storage-specific interface in the list.

B - Incorrect: USB provides a different peripheral-interconnect role.

C - Incorrect: Ethernet serves networking rather than this drive connection.

D - Incorrect: HDMI carries audiovisual data rather than this storage link.

Which standard I/O interface is primarily used for audio and video transmission between devices?

A. SATA

B. USB

C. Ethernet

D. HDMI

Hint

Follow the data path and control responsibility; distinguish the transfer mechanism, address space and interface type.

Answer D: HDMI.

COA32 explicitly identifies HDMI as carrying digital video and audio. That directly matches the primary transmission purpose asked here. SATA serves storage, USB serves general peripherals, and Ethernet serves network connections. Other links can transport encoded media in broader systems, but the stem asks the primary interface role, for which HDMI is the specific supported choice.

Why each choice is right or wrong

A - Incorrect: SATA is identified as a storage interface rather than the primary audiovisual connection in this list.

B - Incorrect: USB is a general peripheral interconnect; the note specifically assigns the audiovisual role to HDMI.

Question 94 | AM0714

Which technique divides instruction processing into stages so that different stages work on successive instructions during the same cycle?

A. Pipelining

B. Caching

C. Superscalar architecture

D. Branch prediction

Hint

Separate throughput from latency and check which operations overlap or share resources under the stated model.

Answer A: Pipelining

Pipelining overlaps stages of successive instructions: one may be fetched while another is decoded or executed. Superscalar execution instead concerns issuing multiple instructions to functional units in one cycle; it can coexist with a pipeline but is not the definition of the staged organization. Caching supplies nearby copies of memory blocks, and branch prediction guesses future control flow.

Why each choice is right or wrong

A - Correct: Pipelining divides processing into stages and overlaps those stages across successive instructions.

B - Incorrect: Caching retains memory-block copies; it is not the staged instruction organization described.

C - Incorrect: Superscalar architecture provides multiple-issue execution resources rather than defining stage overlap itself.

D - Incorrect: Branch prediction guesses direction or targets, rather than dividing instruction processing into pipeline stages.

Instruction Pipeline:
Pipeline processing can occur not only in the data stream but also in the instruction stream as well. An instruction pipeline reads consecutive instructions from memory while previous instructions are being executed in other segments. Whenever there is space in the buffer, the control unit initiates the next instruction fetch phase. The following steps are needed to process each instruction:
1. Fetch the instruction from memory
2. Decode the instruction
3. Calculate the effective address

Question 95 | AM0715

Which technique improves the performance of a processor by storing frequently accessed data closer to the processor?

A. Pipelining

B. Caching

C. Superscalar architecture

D. Branch prediction

Hint

Separate storage role, access timing, placement and power retention; use the specified hierarchy or mapping convention.

Answer B: Caching

Caching keeps copies of memory blocks near the CPU, exploiting temporal and spatial locality to reduce many memory-access delays. Pipelining overlaps instruction stages, superscalar execution provides multiple-issue resources, and branch prediction guesses control flow. These mechanisms may coexist, but the stated nearby data-copy storage role specifically identifies caching.

Why each choice is right or wrong

A - Incorrect: Pipelining overlaps instruction stages rather than creating a data buffer (p.116).

B - Correct: Cache is explicitly the fast intermediate RAM buffer that supplies hits (p.84).

C - Incorrect: Superscalar execution issues multiple instructions to functional units; it is not a memory-copy storage tier.

D - Incorrect: Branch prediction guesses control-flow direction or targets; it does not name a nearby memory-block buffer.

Which architecture allows multiple instructions to be executed in parallel by having multiple execution units?

A. Pipelining

B. Caching

C. Superscalar architecture

D. Branch prediction

Hint

Separate throughput from latency and check which operations overlap or share resources under the stated model.

Answer C: Superscalar architecture.

COA36 defines superscalar execution as issuing multiple instructions to multiple functional units in a cycle when dependencies permit. This matches the multiple execution units in the stem. COA35 distinguishes that multiple-issue capability from ordinary pipelining, which overlaps stages. Caching supplies reused memory data and branch prediction speculates about control flow; neither names the multiple-issue architecture.

Why each choice is right or wrong

A - Incorrect: Pipelining overlaps stages but does not by itself provide multiple-instruction issue to several execution units.

B - Incorrect: Caching retains nearby copies of memory blocks rather than defining parallel instruction issue.

Question 97 | AM0717

Which technique predicts the outcome of conditional branches to improve instruction execution in a processor?

A. Pipelining

B. Caching

C. Superscalar architecture

D. Branch prediction

Hint

Separate throughput from latency and check which operations overlap or share resources under the stated model.

Answer D: Branch prediction.

COA36 says branch prediction guesses a branch's direction/target and continues speculatively, discarding work when the guess is wrong. Predicting the outcome of a conditional branch is exactly that role. Pipelining overlaps processing stages, caching retains reusable data, and superscalar execution issues several instructions; those mechanisms can coexist with prediction but do not replace its definition.

Why each choice is right or wrong

A - Incorrect: Pipelining overlaps instruction stages; it does not itself predict the outcome of a conditional branch.

B - Incorrect: Caching retains reusable memory contents, rather than selecting the predicted direction of conditional control flow.

C - Incorrect: Superscalar execution provides multiple issue; it does not name the conditional-outcome prediction technique.

Answer B: Caching

Cache is the fast memory-block-copy tier used to reduce the cost of repeated or nearby CPU accesses. Virtual memory instead supplies translated address spaces and can use backing storage for nonresident pages. Pipelining and superscalar execution organize instruction processing, so neither names the memory-hierarchy buffer requested. The answer follows the storage role rather than a general claim that only one mechanism can improve performance.

Why each choice is right or wrong

A - Incorrect: Pipelining divides computational tasks into stages (p.116), not memory storage levels.

B - Correct: Cache supplies the fast tier in the hierarchy and avoids main-memory access on hits (pp.79,84).

C - Incorrect: Superscalar execution concerns multiple instruction issue, not a memory-hierarchy storage tier.

D - Incorrect: Virtual memory supplies an apparent larger memory space (p.90), not the fast-cache-hit mechanism.

Concept of Virtual Memory
A programmer can write a program which requires more memory space than the capacity of the main memory. Such a program is executed by virtual memory technique.
The program is stored in the secondary memory. The memory management unit (MMU) transfers the currently needed part of the program from the secondary memory to the main memory for execution.
This to and fro movement of instructions and data (parts of a program) between the main memory and the secondary memory is called Swapping.
Address Space And Memory Space.
Virtual address is the address used by the programmer and the set of such addresses is called the address space or virtual memory.
An address in main memory is called a location or physical address. The set of such locations in main memory is called the memory space or physical memory.

Question 99 | AM0719

Which processor technique issues multiple independent instructions to multiple functional units in one clock cycle, when dependencies permit?

A. Pipelining

B. Caching

C. Superscalar architecture

D. Instruction-level parallelism

Hint

Separate throughput from latency and check which operations overlap or share resources under the stated model.

Answer C: Superscalar architecture

Superscalar execution issues multiple instructions in a cycle when the machine has suitable resources and the instructions' dependencies permit it. Pipelining overlaps stages of different instructions but need not issue several at once. Caching addresses memory access, while instruction-level parallelism is the broader opportunity exploited by several mechanisms. The revised stem asks about multiple issue rather than incorrectly claiming that wider instruction supply necessarily reduces individual memory latency.

Why each choice is right or wrong

A - Incorrect: Pipelining overlaps stages but does not by itself require multiple issue.

B - Incorrect: Caching retains memory-block copies and is not the multiple-issue technique.

C - Correct: Superscalar execution issues multiple instructions to multiple units in a cycle.

D - Incorrect: Instruction-level parallelism is the broader property exploited rather than this specific issue mechanism.

Pipeline processing can occur not only in the data stream but also in the instruction stream as well. An instruction pipeline reads consecutive instructions from memory while previous instructions are being executed in other segments. Whenever there is space in the buffer, the control unit initiates the next instruction fetch phase. The following steps are needed to process each instruction:
1. Fetch the instruction from memory
2. Decode the instruction
3. Calculate the effective address
4. Fetch the operands from memory
5. Execute the instruction

Question 100 | AM0720

Which technique translates source or intermediate code into target code during program execution, before the translated portion runs?

A. Pipelining

B. Caching

C. Superscalar architecture

D. Just-in-time (JIT) compilation

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer D: Just-in-time (JIT) compilation

JIT compilation translates code while the program is running, often compiling an intermediate representation before executing that portion. This timing distinguishes it from ahead-of-time translation. Pipelining overlaps processing stages, caching retains copies of data or instructions, and superscalar execution issues multiple instructions to execution resources. Those mechanisms do not name runtime source-to-target compilation.

Why each choice is right or wrong

A - Incorrect: Pipelining overlaps stages of executing instructions; it does not translate high-level or intermediate code.

B - Incorrect: Caching retains data or instruction copies; it does not perform the compilation described in the stem.

C - Incorrect: Superscalar architecture issues multiple instructions; it does not translate a source language into target code.

D - Correct: JIT is the only offered compiler; it translates during program execution before the compiled portion executes.

Primary note proof

Question 101 | AM0721

Which technique improves performance by predicting the next set of instructions to be executed based on past execution patterns?

A. Pipelining

B. Caching

C. Superscalar architecture

D. Branch prediction

Hint

Separate throughput from latency and check which operations overlap or share resources under the stated model.

Answer D: Branch prediction.

Predicting which instruction stream follows a branch is the direction/target prediction described in COA36. Using past patterns is consistent with that prediction role, whereas pipeline overlap, cached memory copies and multiple instruction issue address different mechanisms. Prediction remains speculative: a wrong guess discards work rather than changing the program's required architectural result.

Why each choice is right or wrong

A - Incorrect: Pipelining overlaps stages and requires instruction supply, but it is not itself next-path prediction.

B - Incorrect: Caching retains copies for reuse; a cached instruction is not a prediction of future control flow.

C - Incorrect: Superscalar issue increases concurrent instruction execution rather than identifying the upcoming branch path.

D - Correct: Predicting branch direction and targets identifies the likely future instruction stream for speculative execution.

Question 102 | AM0722

Which technique improves performance by dynamically reordering instructions to maximize instruction-level parallelism?

A. Pipelining

B. Caching

C. Superscalar architecture

D. Out-of-order execution

Hint

Separate throughput from latency and check which operations overlap or share resources under the stated model.

Answer D: Out-of-order execution.

COA36 describes out-of-order execution as scheduling ready operations before stalled older ones while preserving architectural results and exceptions. This is dynamic reordering to exploit instruction-level parallelism. Superscalar issue can provide execution width but does not itself define such reordering. Pipelining overlaps stages and caching improves reuse; neither names the readiness-based dynamic scheduling mechanism.

Why each choice is right or wrong

A - Incorrect: Pipelining overlaps stages; dynamic instruction reordering requires an additional readiness-based execution mechanism.

B - Incorrect: Caching keeps reusable memory copies and does not itself reorder instruction execution.

C - Incorrect: Superscalar issue permits multiple instructions per cycle but does not necessarily require out-of-order scheduling.

D - Correct: Out-of-order execution schedules ready instructions around stalled older ones while preserving required results.

Which technique improves performance by dynamically allocating processor resources based on program behavior?

A. Pipelining

B. Caching

C. Superscalar architecture

D. Dynamic resource allocation

Hint

Separate throughput from latency and check which operations overlap or share resources under the stated model.

Answer D: Dynamic resource allocation.

COA36 explicitly defines dynamic resource allocation as assigning available internal entries/units at runtime. That definition directly fits the stem's allocation based on behavior during execution. Pipelining describes overlapping stages, caching describes memory reuse, and superscalar execution describes issuing several instructions. They may use allocated resources, but none is the specific allocation technique named by the question.

Why each choice is right or wrong

A - Incorrect: Pipelining defines overlapping instruction stages rather than the general assignment of runtime internal resources.

B - Incorrect: Caching retains memory copies; it does not name the runtime assignment of processor entries and units.

C - Incorrect: Superscalar execution names multiple issue, rather than the allocation process used to assign available resources.

Which listed item is a fundamental logic building block from which computer hardware is constructed?

A. CPU

B. Memory

C. Hard disk

D. Logic gate

Hint

Which component is responsible for executing instructions and performing calculations in a computer?

A. CPU

B. Memory

C. Hard disk

D. Motherboard

Hint

Identify the register, signal or instruction role and the execution phase; distinguish stored values, addresses and control actions.

Answer A: CPU

The CPU contains the control unit, ALU and execution registers. Control sequences operations and transfers, while the ALU performs arithmetic and logic, supporting the CPU's instruction-processing role. Main memory supplies addressed working storage, a hard disk supplies persistent storage, and the motherboard connects components. Those roles distinguish the processing component from the storage and interconnection choices.

Which component retains stored data and instructions without power? Here Memory means ordinary volatile main RAM, and CPU excludes separate firmware storage.

A. CPU

B. Memory

C. Hard disk

D. Motherboard

Hint

Separate storage role, access timing, placement and power retention; use the specified hierarchy or mapping convention.

Answer C: Hard disk

An HDD preserves magnetic patterns without continuous power, so the hard disk retains the stored data and instructions. The question now restricts Memory to ordinary volatile main RAM, avoiding the broader meaning that would include ROM or flash. CPU and motherboard name processing and interconnection components rather than the persistent storage mechanism sought. These scope conditions make the intended retention comparison definite.

Question 107 | AM0727

The motherboard of a computer is responsible for:

A. Executing instructions

B. Storing data

C. Connecting different components

D. Performing calculations

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer C: Connecting different components.

COA01 explicitly states that a motherboard physically connects components. The same section locates the ALU, control unit and registers in the CPU; computation and instruction execution therefore belong to processing components rather than the board's defining role. Memory provides data storage. The question asks the motherboard's responsibility, for which physical connection is the specific supported answer.

Why each choice is right or wrong

A - Incorrect: Instructions are executed by the CPU; that is distinct from the motherboard's physical connection role.

B - Incorrect: Data storage belongs to memory/storage components, rather than defining what the motherboard itself does.

C - Correct: The note explicitly identifies the motherboard as physically connecting the computer's components.

D - Incorrect: Calculations belong to CPU arithmetic/logic hardware rather than the motherboard's defining connection function.

Question 108 | AM0728

Which component supplies the addressable main working store for a running program, distinct from individual CPU execution registers and persistent disk storage?

A. CPU

B. Main memory (RAM)

C. Hard disk

D. Motherboard

Hint

Identify the register, signal or instruction role and the execution phase; distinguish stored values, addresses and control actions.

Answer B: Main memory (RAM)

Main RAM holds the addressed working instructions and data used by a running program. CPU registers hold particular fetched instructions, operands or results for immediate execution, and disks retain information persistently. The motherboard connects these components. Specifying the main working-store role prevents the broad temporary-storage description from also fitting CPU registers or cache.

Why each choice is right or wrong

A - Incorrect: The CPU executes operations and has immediate registers, but is not the main addressed RAM store requested.

B - Correct: Main RAM is the addressable working store for the running program’s instructions and data.

C - Incorrect: A hard disk supplies persistent storage rather than the main RAM working store.

D - Incorrect: The motherboard provides physical component connections rather than this storage role.

Question 109 | AM0729

Which type of software controls and manages the hardware resources of a computer?

A. Operating system

B. Application software

C. Programming language

D. Compiler

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer A: Operating system.

COA02 directly defines the operating system as managing resources and providing services. Applications solve user tasks, and compilers translate source into target code. A programming language is a means of expressing programs rather than the software resource manager. Therefore the operating system is the single option whose stated role matches controlling and managing computer hardware resources.

Why each choice is right or wrong

A - Correct: The operating system is explicitly defined as the resource manager and provider of system services.

B - Incorrect: Applications solve user tasks using system services rather than serving as the general hardware resource manager.

C - Incorrect: A programming language expresses programs; it is not itself the system software managing hardware resources.

Question 110 | AM0730

Which software allows users to perform specific tasks or functions on a computer?

A. Operating system

B. Application software

C. Programming language

D. Compiler

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer B: Application software.

COA02 states that applications solve user tasks. This directly matches software allowing users to perform particular tasks or functions. The operating system instead manages resources and provides services; a compiler translates programs, and a programming language expresses them. These support applications but do not name the general category of user-task software requested here.

Why each choice is right or wrong

A - Incorrect: The OS supplies resource management and services rather than naming the category of specific user-task programs.

B - Correct: Applications are explicitly described as software solving user tasks, matching the question’s requested category.

Question 111 | AM0731

Which component provides main working storage for the program’s instructions and data, rather than the CPU’s immediate execution registers or persistent disk storage?

A. CPU

B. Main memory (RAM)

C. Hard disk

D. Motherboard

Hint

Identify the register, signal or instruction role and the execution phase; distinguish stored values, addresses and control actions.

Answer B: Main memory (RAM)

Main memory supplies the addressed working storage that holds a program's instructions and data during operation. CPU registers retain particular fetched instructions, operands and results for immediate execution, while a hard disk supplies persistent storage. The revised stem and expanded memory label distinguish these levels rather than assuming all temporary storage belongs exclusively to one component. Computer instructions are usually stored in consecutive memory locations and executed sequentially one at a time. The control reads an instruction from specific address in memory and executes it. It then continues by reading the next instruction in sequence and executes it and so on. This type of instruction sequencing needs a counter to calculate the address of the next instruction after execution of the current instruction is completed. It is also necessary to provide a register in a control unit for storing the instruction code after it is read from the memory. The data register (DR) holds the operand read from memory. The accumulator (AC) register is a general purpose processing register. The instructions read from memory are placed in instruction register (IR). The temporary register (TR) is used for holding temporary data during the processing.

Which type of software translates high-level programming languages into machine code?

A. Operating system

B. Application software

C. Programming language

D. Compiler

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer D: Compiler

A compiler translates source code into target code; in this question the source is a high-level language and the target is machine code. The operating system manages resources, applications solve user tasks, and a programming language is the notation in which a program is expressed. The requested translation function therefore belongs to the compiler category.

Why each choice is right or wrong

A - Incorrect: An operating system manages resources and provides services; compiler is the translation category requested.

B - Incorrect: Application software solves user tasks rather than naming the general source-to-target translation category.

C - Incorrect: The passage distinguishes source high-level language from resulting machine language; a language itself is not the named translating agent (p.77).

D - Correct: Compiler support is explicitly tied to high-level-to-machine translation (p.77).

Question 113 | AM0733

The system clock in a computer is responsible for:

A. Controlling the execution speed of instructions

B. Storing data and instructions

C. Managing the input/output devices

D. Connecting different hardware components

Hint

Separate throughput from latency and check which operations overlap or share resources under the stated model.

Answer A: Controlling the execution speed of instructions

Control selections are available at the beginning of a clock cycle and register data are captured on the next clock transition (PDF p.59). Fetch timing likewise advances after each clock pulse (p.55). Thus A is the closest description of clock timing instruction steps; it does not mean frequency alone determines total execution time.

Why each choice is right or wrong

A - Correct: Clock transitions time the operations and sequence steps (pp.55,59); this regulates execution pace.

B - Incorrect: Registers and memory store bits; the clock times their updates rather than stores the program (p.59).

C - Incorrect: I/O management is assigned to interfaces/control mechanisms, not solely the clock (pp.101-102).

D - Incorrect: Interconnection provides communication (p.6); the clock provides timing rather than that physical connection.

Which process is responsible for fetching instructions from memory?

A. Decoding

B. Execution

C. Fetching

D. Storing

Hint

Identify the register, signal or instruction role and the execution phase; distinguish stored values, addresses and control actions.

Answer C: Fetching

The instruction-pipeline list explicitly begins “Fetch the instruction from memory” (PDF p.117), and the fetch micro-operations copy memory into IR (p.55). The question names this retrieval phase, not interpretation or computation.

Why each choice is right or wrong

A - Incorrect: Decoding interprets the retrieved instruction after fetching (p.117).

B - Incorrect: Execution carries out the operation later in the pipeline (p.117).

C - Correct: Fetching is the memory-to-instruction-register retrieval phase (pp.55,117).

The control unit of a computer is designed to go through an instruction cycle that is divided into three major phases. 1. Fetch the instruction from memory 2. Decode the instruction 3. Execute the instruction
There is one register in the computer called the program counter (PC) that keeps track of the instructions in the program stored in memory. PC holds the address of the instruction to be executed next and incremented each time an instruction is fetched from memory. The decoding done in step 2, determines the operation to be performed, the addressing mode of the instruction, and the location of the operand.

Which process decodes the fetched instruction and determines the necessary actions?

A. Decoding

B. Execution

C. Fetching

D. Storing

Hint

Identify the register, signal or instruction role and the execution phase; distinguish stored values, addresses and control actions.

Answer A: Decoding

The module says decoding determines the operation, addressing mode and operand location (PDF p.70). It follows fetch and precedes execution in the instruction phases (p.117).

Why each choice is right or wrong

A - Correct: Decoding explicitly determines the required operation and addressing details.

B - Incorrect: Execution performs the operation after it has been determined (p.117).

Question 117 | AM0737

Which process is responsible for storing the results of the executed instruction?

A. Decoding

B. Execution

C. Fetching

D. Storing

Hint

Identify the register, signal or instruction role and the execution phase; distinguish stored values, addresses and control actions.

Answer D: Storing

The instruction-pipeline sequence ends by storing the result in its proper place (PDF p.117). The RISC variant specifies writing the result into a register (p.118), establishing the result-preservation role of D.

Why each choice is right or wrong

A - Incorrect: Decoding interprets operation and addressing fields, before a result exists.

B - Incorrect: Execution produces a result; the listed store phase preserves it afterward (p.117).

C - Incorrect: Fetching brings in the instruction, not its eventual result (p.117).

D - Correct: Store result/write register is the explicit final stage (pp.117-118).

A RISC (Reduced Instruction Set Computer) processor pipeline operates in much the same way, although the stages in the pipeline are different. While different processors have different numbers of steps, they have basically variations of these five steps:
1. fetch instructions from memory
2. read registers and decode the instruction
3. execute the instruction or calculate an address
4. access an operand in data memory
5. write the result into a register
The length of the pipeline is dependent on the length of the longest step. Because RISC instructions are simpler than those used in pre-RISC processors (now called CISC, or Complex Instruction Set Computer), they are more conducive to pipelining. While CISC instructions varied in length, RISC instructions are all the same length and can be fetched in a single operation. Ideally, each of the stages in a RISC processor pipeline should take 1 clock cycle so that the processor finishes an instruction each clock cycle and averages one cycle per instruction (CPI). Among the characteristics attributed to RISC is its ability to use an efficient instruction pipeline.

Question 118 | AM0738

Which unit of the CPU is responsible for fetching instructions and data from memory?

A. Arithmetic Logic Unit (ALU)

B. Control Unit (CU)

C. Cache Unit

D. Register Unit

Hint

Identify the register, signal or instruction role and the execution phase; distinguish stored values, addresses and control actions.

Answer B: Control Unit (CU)

The pipeline description explicitly says the control unit initiates the next fetch when there is buffer space (PDF p.117). CPU control supervises register transfers and ALU work (p.57); the fetch micro-operations transfer address and instruction bits (p.55). This is coordinating responsibility, not a claim the CU physically stores all fetched data.

Why each choice is right or wrong

A - Incorrect: ALU performs the arithmetic/logical micro-operations, not the fetch-sequencing role (p.57).

B - Correct: CU initiates fetch and supervises the register transfers (pp.57,117).

C - Incorrect: Cache supplies stored copies on hits (p.84); it does not decide the instruction-cycle control sequence.

D - Incorrect: Registers hold address/data/instruction values, while CU controls their transfers (pp.48,57).

I. Fetch the instruction
Initially, the program counter PC is loaded with the address of the first instruction in the program and SC is cleared to 0, providing a decoded timing signal T0. After each clock pulse, SC is incremented by one, so that the timing signals go through a sequence T0, T1, T2 and so on. Since the address lines of the memory unit are hardwired to AR, address of the instruction to be fetched must first be placed in AR. Thus the first register transfer in an instruction cycle should be transferring the content of PC (address of the instruction to be brought in for execution) to AR
T0: AR ← PC
Bus selects PC, LD(AR) = 1. Next the current instruction is brought from memory into IR and PC is incremented
T1: IR ← M[AR], PC ← PC + 1. Bus selects RAM, Memory read is set, LD(IR) = 1, INR(PC) = 1
II. Decode the instruction
T2: D0, ... , D7 ← Decode IR(12-14), AR ← IR(0-11), I ← IR(15)
Therefore, micro-operations for the fetch and decode phases can be specified by the following register transfer statements.
T0: AR ← PC
T1: IR ← M[AR], PC ← PC + 1
T2: D0, ..., D7 ← Decode IR(12-14), AR ← IR(0-11), I ← IR(15)

Which unit of the CPU performs arithmetic and logical operations?

A. Arithmetic Logic Unit (ALU)

B. Control Unit (CU)

C. Cache Unit

D. Register Unit

Hint

Identify the register, signal or instruction role and the execution phase; distinguish stored values, addresses and control actions.

Answer A: Arithmetic Logic Unit (ALU)

ALU is explicitly the CPU part that performs required micro-operations; the module classifies arithmetic and logical manipulation as computational operations (PDF pp.57,74-75). Control selects the operation and registers supply/receive values.

Why each choice is right or wrong

A - Correct: ALU performs required arithmetic/logical micro-operations (p.57).

B - Incorrect: CU directs transfers and tells ALU which operation to perform (p.57).

C - Incorrect: Cache is a fast storage buffer (p.84), not the computation unit.

Question 120 | AM0740

Which CPU storage class holds explicit execution operands and results, rather than copies of memory blocks?

A. Arithmetic Logic Unit (ALU)

B. Control Unit (CU)

C. Cache Unit

D. Register Unit

Hint

Identify the register, signal or instruction role and the execution phase; distinguish stored values, addresses and control actions.

Answer D: Register Unit

Registers hold explicit execution operands and results. Cache also stores temporary information, but its role is retaining copies of memory blocks near the processor. The revised question uses that role distinction, so temporary storage alone no longer makes both choices correct. The ALU performs arithmetic and logic, and the control unit coordinates operations rather than being the requested operand-storage class.

Why each choice is right or wrong

A - Incorrect: The ALU computes rather than being the operand-storage class.

B - Incorrect: The control unit sequences operations rather than holding explicit execution operands as its defining role.

C - Incorrect: Cache holds copies of memory blocks.

Computer instructions are usually stored in consecutive memory locations and executed sequentially one at a time. The control reads an instruction from specific address in memory and executes it. It then continues by reading the next instruction in sequence and executes it and so on. This type of instruction sequencing needs a counter to calculate the address of the next instruction after execution of the current instruction is completed. It is also necessary to provide a register in a control unit for storing the instruction code after it is read from the memory. The data register (DR) holds the operand read from memory. The accumulator (AC) register is a general purpose processing register. The instructions read from memory are placed in instruction register (IR). The temporary register (TR) is used for holding temporary data during the processing.

Which component of the CPU controls the flow of data and instructions within the CPU?

A. Arithmetic Logic Unit (ALU)

B. Control Unit (CU)

C. Cache Unit

D. Register Unit

Hint

Identify the register, signal or instruction role and the execution phase; distinguish stored values, addresses and control actions.

Answer B: Control Unit (CU)

CU explicitly supervises information transfers among registers and tells ALU what operation to perform (PDF p.57). The bus-control example selects sources, operation and destination (p.59), matching control of internal flow.

Why each choice is right or wrong

A - Incorrect: ALU processes operands selected by control (pp.57,59), rather than directs the overall flow.

B - Correct: CU selects register sources, destination and ALU operation (p.59).

The control unit that operates the CPU bus system directs the information flow through the register and ALU by selecting the various components in the system. For example, to perform the operation
R1 R2 + R3, the control must provide binary selection variables to the following selector inputs:
1. MUX A selector (SELA): to place the content of R2 into bus A.
2. MUX selector (SELB): to place the content of R3 into bus B.
3. ALU operation selector (OPR): to provide the arithmetic add A +B.
4. Decoder destination selector (SELD): to transfer the content of output bus in to R1.
The four control selection variables are generated in the control unit and must be available at the beginning of a clock cycle. The data from the two source registers propagates through the gates in the multiplexers and the ALU, to the output bus, and into the inputs of the destination register, all during the clock cycle interval. Then, when the next clock transition occurs, the binary information from the output bus is transferred into R1. To achieve a fast response

Which CPU-near storage component retains copies of memory blocks to speed repeated or nearby memory accesses?

A. Arithmetic Logic Unit (ALU)

B. Control Unit (CU)

C. Cache Unit

D. Register Unit

Hint

Identify the register, signal or instruction role and the execution phase; distinguish stored values, addresses and control actions.

Answer C: Cache Unit

Cache retains copies of memory blocks near the CPU and exploits temporal and spatial locality. Registers instead hold explicit execution operands and results, even though frequently used values may also remain there. The ALU computes values and the control unit sequences operations. The memory-block-copy criterion therefore identifies cache without claiming that no other CPU component can hold useful data.

Why each choice is right or wrong

A - Incorrect: The ALU computes arithmetic and logic rather than retaining a memory-block-copy tier.

B - Incorrect: The control unit sequences transfers and operations rather than supplying this data-copy storage tier.

C - Correct: Cache stores nearby copies of memory blocks for repeated or spatially local accesses.

D - Incorrect: Registers hold explicit execution operands/results; that differs from the memory-block-copy cache role.

Question 123 | AM0743

During a taken branch instruction, which phase computes or applies the branch target to replace the sequential next-PC value?

A. Decoding

B. Execution

C. Fetching

D. Storing

Hint

Identify the register, signal or instruction role and the execution phase; distinguish stored values, addresses and control actions.

Answer B: Execution

A fetch uses the selected PC to obtain an instruction and can advance it to the sequential address. Executing a taken branch can later replace that sequential value with the branch target. The question now specifically asks about that branch action, rather than the broader process of selecting, reading or advancing a next instruction address. Decode interprets fields and write-back stores results; neither is the conceptual branch-execution role requested.

Why each choice is right or wrong

A - Incorrect: Decoding interprets opcode and addressing fields rather than performing the specified branch action.

B - Correct: Executing the taken branch replaces the sequential PC with its target.

C - Incorrect: Fetching obtains the instruction at the selected address rather than performing this branch action.

D - Incorrect: Result storage is not the conceptual branch-target execution phase.

Instruction Pipeline:
Pipeline processing can occur not only in the data stream but also in the instruction stream as well. An instruction pipeline reads consecutive instructions from memory while previous instructions are being executed in other segments. Whenever there is space in the buffer, the control unit initiates the next instruction fetch phase. The following steps are needed to process each instruction:
1. Fetch the instruction from memory
2. Decode the instruction
3. Calculate the effective address
4. Fetch the operands from memory
5. Execute the instruction
6. Store the result in the proper place

Computer Organization and Architecture module | PDF page 72 | lines 26-32

Direct Addressing Mode: In this mode the effective address is equal to the address part of the instruction. The operand resides in memory and its address is given directly by the address field of the instruction. In a branch type of instruction the address field specifies the actual branch address.
Indirect Addressing Mode: In this mode the address field of the instruction gives the address where the effective address is stored in memory. Control fetches the instruction from memory and uses its address part to access memory again to read the effective address.

What is the purpose of an opcode in a 16-bit instruction format (4-bit opcode | 6-bit operand ref | 6-bit operand ref)?

A. It holds the destination address of an operand

B. It determines the operation to be done

C. It holds the source address of an operand

D. It holds the next instruction reference

Hint

Identify the register, signal or instruction role and the execution phase; distinguish stored values, addresses and control actions.

Answer B: It determines the operation to be done

The stated field widths sum to 16 bits: 4+6+6. Their widths do not change the opcode's purpose: operation selection (PDF p.47). Operand reference fields identify source/destination values or locations; PC tracks sequence.

Why each choice is right or wrong

A - Incorrect: Destination reference is an operand/address field, not the opcode (p.47).

B - Correct: Operation selection is the explicit opcode definition (p.47).

C - Incorrect: Source reference belongs to the operand/address fields (p.47).

D - Incorrect: Next instruction is tracked by PC (p.70), not the opcode.

> The control unit of a computer is designed to go through an instruction cycle that is divided into three major phases. 1. Fetch the instruction from memory 2. Decode the instruction 3. Execute the instruction
> There is one register in the computer called the program counter (PC) that keeps track of the

instructions in the program stored in memory. PC holds the address of the instruction to be executed next and incremented each time an instruction is fetched from memory. The decoding done in step 2, determines the operation to be performed, the addressing mode of the instruction, and the location of the operand.

Question 125 | CS0234

Which performance metric can be used to measure the time taken to perform a read or write operation?

A. Transfer rate

B. Memory cycle time

C. Fetching time

D. Access time

Hint

Separate storage role, access timing, placement and power retention; use the specified hierarchy or mapping convention.

Answer D: Access time

Access time is the elapsed time from initiation to completion of a memory operation (PDF p.83). Memory cycle time is the minimum separation of successive operations. This distinguishes one read/write duration from transfer throughput or instruction fetching.

Why each choice is right or wrong

A - Incorrect: Transfer rate measures an amount per unit time; it is not the single-operation interval defined on p.83.

B - Incorrect: Cycle time measures spacing of successive operations, not the requested initiation-to-completion duration (p.83).

C - Incorrect: Fetching is one instruction-cycle task, not the general read/write performance metric (p.55).

D - Correct: Access time is exactly the operation-duration definition (p.83).

Primary note proof

Study-note section COA23

Access time measures latency of a read/write; cycle time is the minimum interval before another operation and may include recovery.

Study-note section COA23

Transfer rate measures data per time, not individual-request delay.

The time that elapses between the initiation of an operation and completion of that operation is called memory access time. The minimum time delay between two successive memory operations is called memory cycle time. The cycle time is usually slightly lower than the access time.

6.1 Memory Hierarchy:
A computer system is equipped with a hierarchy of memory subsystems. There are several memory types with very different physical properties. The important characteristics of memory devices are cost per bit, access time, data transfer rate, alterability and compatibility with processor technologies. Figure shows the hierarchy of memory in a typical memory with a trend in access time, amount of storage, and cost per byte.

I. Fetch the instruction
Initially, the program counter PC is loaded with the address of the first instruction in the program and SC is cleared to 0, providing a decoded timing signal T0. After each clock pulse, SC is incremented by one, so that the timing signals go through a sequence T0, T1, T2 and so on. Since the address lines of the memory unit are hardwired to AR, address of the instruction to be fetched must first be placed in AR. Thus the first register transfer in an instruction cycle should be transferring the content of PC (address of the instruction to be brought in for execution) to AR
T0: AR ← PC
Bus selects PC, LD(AR) = 1. Next the current instruction is brought from memory into IR and PC is incremented
T1: IR ← M[AR], PC ← PC + 1. Bus selects RAM, Memory read is set, LD(IR) = 1,
INR(PC) = 1
II. Decode the instruction
T2: D0, ... , D7 ← Decode IR(12-14), AR ← IR(0-11), I ← IR(15)
Therefore, micro-operations for the fetch and decode phases can be specified by the following register transfer statements.
T0: AR ← PC
T1: IR ← M[AR], PC ← PC + 1
T2: D0, ..., D7 ← Decode IR(12-14), AR ← IR(0-11), I ← IR(15)

Question 126 | CS0235

Under the textbook access-method taxonomy, how is magnetic-disk block access classified when requests identify blocks but mechanical positioning introduces delay?

A. Associative

B. Sequential

C. Random

D. Direct

Hint

Separate storage role, access timing, placement and power retention; use the specified hierarchy or mapping convention.

Answer D: Direct

The stated textbook taxonomy calls magnetic disk access direct: a request identifies an addressed block, but positioning creates access delay. RAM is classified as random access with broadly address-independent timing, while tape is sequential and associative access matches content. Informal usage may call disks random-access devices too, but the revised question explicitly chooses the textbook classification convention rather than treating the labels as universally exclusive.

Why each choice is right or wrong

A - Incorrect: Associative access matches by content rather than addressed disk blocks.

B - Incorrect: Tape-like sequential access is not the disk's required access pattern.

C - Incorrect: Random is the RAM category in the explicitly stated textbook taxonomy.

D - Correct: Direct is the disk category in that taxonomy.

Primary note proof

Study-note section COA28

> In textbook access taxonomy, tape is sequential, disk is direct access with positioning delay, RAM is random access with broadly address-independent timing, and associative access matches content.

Study-note section COA28

> "Random-access disk" is also common informal usage; specify the taxonomy when comparing direct and random access.

6.4.1 Magnetic Disk
• Magnetic disks are the foundation of external memory on virtually all computer systems.
• A disk is a circular platter constructed of nonmagnetic material called the substrate coated with a magnetisable material.
• More suitable than magnetic tapes for a wider range of applications such as supporting direct access of data
• It is a thin, circular plate made of metal & plastic, which is coated with iron-oxide.
• We can randomly access the data.

Computer Organization and Architecture module | PDF page 98 | lines 7-16

6.4.2 Magnetic Tape
• Magnetic Tape is a plastic ribbon which is usually ½ inch or ¼ inch wide & 50 to 2400 feet long.
• It is coated with iron-oxide material.
• It is similar to the tape of audio cassettes of tape recorders. Data is stored as binary digits.
• Data is accessed sequentially so searching becomes difficult.
• Tape systems use the same reading and recording techniques as disk systems..
• Magnetic tape was the first kind of secondary memory.It is still widely used as the lowest-cost, slowest-speed member of the memory hierarchy.

Computer Organization and Architecture module | PDF page 87 | lines 2-15

Associative Mapping
• An associative mapping uses an associative memory.
• This memory is being accessed using its contents.
• Associative memory is expensive compared to RAM
• Each line of cache memory will accommodate the address (main memory) and the contents of that address from the main memory.
• That is why this memory is also called Content Addressable Memory (CAM). It allows each block of main memory to be stored in the cache.
A CPU address of 15 bits is places in the argument register and the associative memory us searched for a matching address
• If the address is found, the corresponding 12bits data is read and sent to the CPU
• If not, the main memory is accessed for the word
If the cache is full, an address-data pair must be displaced to make room for a pair that is needed and not presently in the cache

Question 127 | CS0236

Which statement reverses the broad integration trend described for computer evolution?

A. Increasing component size

B. Increasing processor speed

C. Increasing integration density

D. Increasing memory size

Hint

Use the stated historical convention or integration trend, rather than assuming every model has identical characteristics.

Answer A: Increasing component size

The note describes a broad trend toward smaller individual components while density, capacity and processor performance increase. Increasing component size reverses that stated trend. The other alternatives describe growth in performance, integration density or memory capacity and are therefore consistent with it. These are historical tendencies, not guarantees that every later product improves every measured property.

Why each choice is right or wrong

A - Correct: The broad trend reduces individual component dimensions, so increasing size reverses it.

B - Incorrect: Rising processor performance is consistent with the stated evolutionary tendency.

C - Incorrect: Increasing integration density is explicitly part of the stated integration trend.

D - Incorrect: Growing storage capacity is consistent with the stated trend even as individual component dimensions shrink.

Question 128 | CS0237

Which one of the following is NOT correct about Von Neumann's architecture?

A. Data and instructions are stored separately

B. Modern computers are based on Von Neumann's architecture

C. Instruction execution is sequential

D. Memory content is located by its address

Hint

Identify the role requested and compare it with the definitions and constraints in the cited passages.

Answer A: Separate instruction and data storage contradicts the textbook Von Neumann model.

COA02 defines the textbook Von Neumann model as sharing an addressed memory system between instructions and data, with normally sequential execution unless control flow changes. Thus separate storage is the defining contradiction. The note allows modern machines to retain a unified address-space view while using split caches; ordinary execution and addressed memory remain compatible with that model.

Why each choice is right or wrong

A - Correct: Separate instruction/data memories describe Harvard organization rather than the textbook shared-memory Von Neumann model.

B - Incorrect: Modern systems can retain a unified address-space view, so this broad conventional association is compatible with the note.

C - Incorrect: Normally sequential instruction progression is part of the textbook model, with branches providing explicit control-flow changes.

D - Incorrect: The model explicitly uses addressed memory, so locating content by address is a compatible statement.

Primary note proof

In the textbook Von Neumann model, instructions and data share an addressed memory system; the CPU normally advances sequentially unless control flow changes.

The simplest way to organize a computer is to have one processor register and an instruction code format with two parts. The first part of instruction code specifies the operation to be performed and the second specifies an address. The memory address tells the control where to find an operand in memory. This operand is read from memory and used as the data to be operated on together with the data stored in processor register. Instructions are stored in one section of memory and data in another. The operation is performed with memory operands and the content of AC. Figure 5-1 below depicts this type of organization.

Computer Organization and Architecture module | PDF page 48 | lines 14-23

Computer instructions are usually stored in consecutive memory locations and executed sequentially one at a time. The control reads an instruction from specific address in memory and executes it. It then continues by reading the next instruction in sequence and executes it and so on. This type of instruction sequencing needs a counter to calculate the address of the next instruction after execution of the current instruction is completed. It is also necessary to provide a register in a control unit for storing the instruction code after it is read from the memory. The data register (DR) holds the operand read from memory. The accumulator (AC) register is a general purpose processing register. The instructions read from memory are placed in instruction register (IR). The temporary register (TR) is used for holding temporary data during the processing.

Question 129 | CS0238

Which instruction type is used to test the value of a data word or status of a condition?

A. Data processing instruction

B. Test instruction

C. Data movement instruction

D. Branch instruction

Hint

Identify the register, signal or instruction role and the execution phase; distinguish stored values, addresses and control actions.

Answer B: Test instruction.

COA19 states that TEST/CMP examine values and set condition information, often without retaining an arithmetic result. That exactly matches examining a data word or a condition status. Arithmetic/data processing is a broader computing class, data movement copies values, and branches choose control-flow targets. The named test-instruction category is therefore the direct answer among the options.

Why each choice is right or wrong

A - Incorrect: Data processing is a broader computing category; the stem specifically requests the instruction used to test values.

B - Correct: TEST/CMP examine values and establish condition information, directly matching the question's described operation.

C - Incorrect: Data movement copies values between locations rather than testing their contents or condition status.

D - Incorrect: Branches choose control-flow targets, often using previously established conditions rather than performing the requested test.

Data Manipulation
Data manipulation instructions perform operations on data and provide the computational capabilities for the computer. The data manipulation instructions in a typical computer are usually divided into three basic types.
1. Arithmetic instruction
2. Logical and bit manipulation
3. Shift instruction
a. Arithmetic Instruction
The four basic arithmetic operations are addition, subtraction, multiplication and division. Most computers provide instructions for all four operations. Some small computers have only addition and possibly subtraction instructions. The multiplication and division must then be generated by means of software subroutines.

Direct Addressing Mode: In this mode the effective address is equal to the address part of the instruction. The operand resides in memory and its address is given directly by the address field of the instruction. In a branch type of instruction the address field specifies the actual branch address.
Indirect Addressing Mode: In this mode the address field of the instruction gives the address where the effective address is stored in memory. Control fetches the instruction from memory and uses its address part to access memory again to read the effective address.

Question 130 | NS0221

What is the purpose of an opcode in a 16-bit instruction format (4-bit opcode | 6-bit operand ref 6-bit operand ref)?

A. It holds the destination address of an operand

B. It determines the operation to be done

C. It holds the source address of an operand

D. It holds the next instruction reference

Hint

Identify the register, signal or instruction role and the execution phase; distinguish stored values, addresses and control actions.

Answer B: The opcode specifies the operation.

COA16 defines the opcode as specifying the operation and operand fields as locating data/registers. In the given 16-bit format, the 4-bit opcode therefore selects an operation, while the two 6-bit references identify operands under the machine's interpretation. The bit widths are not evidence that the opcode stores a source/destination address or next-PC reference.

Why each choice is right or wrong

A - Incorrect: A destination operand reference belongs in an operand field, not in the operation-selecting opcode.

B - Correct: The opcode determines which operation the processor should perform for this instruction.

C - Incorrect: A source operand reference is an operand-field role rather than the opcode's operation role.

D - Incorrect: The next-instruction reference is a control-flow/PC concern, not the general purpose of this opcode field.

A designer adds a PCI expansion card to a processor whose local bus uses a different transfer protocol. The two sides cannot be wired together directly. Which listed hardware category is needed to adapt transfers between the processor bus and the expansion interconnect?

A. SCSI

B. PCI

C. Bus bridge/controller logic

D. Multi bus

Hint

Follow the data path and control responsibility; distinguish the transfer mechanism, address space and interface type.

Answer C: Bus bridge/controller logic

The scenario requires hardware that adapts transfers between unlike bus segments, so bus bridge/controller logic is needed. PCI identifies the expansion interconnect on one side of the connection; merely naming it does not supply the adaptation to the processor bus. SCSI identifies a storage connection and Multibus another bus family. The distinction is between the interconnect being attached and the hardware that enables the attachment.

Why each choice is right or wrong

A - Incorrect: SCSI is a storage connection rather than the adapter between these unlike bus segments.

B - Incorrect: PCI names the expansion interconnect already present in the scenario, not the adapting component.

C - Correct: Bus bridge/controller logic adapts transfers between the unlike processor and expansion bus segments.

D - Incorrect: Multibus names a bus family rather than the component needed to adapt this connection.

Primary note proof

Study-note section COA32

> PCI is a peripheral expansion interconnect, not a disk protocol; connecting unlike bus segments requires suitable bridge/controller logic.

Combinational circuit differ from sequential circuit primarily because

A. Combinational circuit cannot be built using logic circuit

B. The output of combinational circuit depends only on the present input, not on past output.

C. Sequential circuit have no feedback while combinational circuit do

D. The combinational circuit requires clock signal, but sequential circuit do not

Hint

Check whether output depends only on current inputs or also on stored state, and track the stated clock behavior.

Answer B: Combinational output depends on present inputs rather than stored history.

COA05 defines combinational output through present inputs after propagation delay, while sequential output also depends on stored state. B expresses that distinction. Combinational circuits are built from logic, not prohibited from it; the feedback statement reverses the usual state relationship. Nor do combinational circuits inherently require a clock, while clocked sequential circuits update at clock events.

Why each choice is right or wrong

A - Incorrect: Combinational circuits are logic circuits; the statement incorrectly denies their ordinary implementation basis.

B - Correct: Present inputs determine combinational outputs, whereas sequential circuits additionally depend on retained state.

C - Incorrect: This reverses the state/feedback distinction; sequential storage can involve feedback, not its categorical absence.

D - Incorrect: Combinational logic does not inherently require a clock; clock events characterize clocked sequential updates.

Primary note proof

Which one of the following is the first operation or step in CPU instruction cycle?

A. Executing the instruction

B. Handling interrupt

C. Decoding the instruction

D. Fetching the instruction

Hint

Identify the register, signal or instruction role and the execution phase; distinguish stored values, addresses and control actions.

Answer D: Fetch the instruction.

COA15 begins the conceptual instruction cycle with fetch, then decode, operand acquisition, execution and any result write-back. Fetch must obtain the instruction before its opcode can be decoded and operation performed. Permitted interrupt checks are a separate stage/transition in that conceptual model, not the first ordinary instruction-processing step among these choices.

Why each choice is right or wrong

A - Incorrect: Execution follows obtaining and decoding the instruction, rather than being the cycle's first conceptual step.

B - Incorrect: Interrupt checks/service are distinct from the first ordinary fetch step in the note's conceptual cycle.

C - Incorrect: Decoding requires an already fetched instruction, so it follows rather than precedes fetch.

D - Correct: Fetching obtains the instruction and is explicitly first in the conceptual instruction-cycle sequence.

Primary note proof

Study-note section COA15

> A conceptual instruction cycle fetches an instruction, decodes opcode/addressing fields, obtains operands, executes, writes results where required and checks permitted interrupts.

_____ is a data transfer method in computer organization and architecture that allows an I/O device to transfer data directly to or from memory without the involvement of the CPU.

A. Asynchronous data transfer

B. Direct Memory Access (DMA)

C. Interrupt-driven transfer

D. Programmed I/O transfer

Hint

Follow the data path and control responsibility; distinguish the transfer mechanism, address space and interface type.

Answer B: Direct Memory Access (DMA).

COA30 says DMA lets a controller transfer a block directly between device and memory after CPU setup. The stem's without CPU involvement must mean without CPU moving every item, not no configuration/completion involvement whatsoever. Polling and interrupt-driven I/O still require CPU transfer work; asynchronous transfer describes timing coordination rather than this block-moving mechanism.

Why each choice is right or wrong

A - Incorrect: Asynchronous transfer describes coordination/timing rather than specifically controller-managed movement directly between device and memory.

B - Correct: DMA transfers the block through a controller after CPU setup, avoiding per-item CPU copying.

C - Incorrect: Interrupt-driven handlers still consume CPU time to service and move device data in this comparison.

D - Incorrect: Programmed I/O repeatedly checks status and has the CPU move each item rather than using DMA.

Primary note proof

> DMA lets a controller move a block directly between device and memory after CPU setup.

Study-note section COA30

> Programmed/polled I/O repeatedly checks status and lets the CPU move each item.

Which logic gate produces output 1 only when ALL inputs are 1?

A. OR gate

B. AND gate

C. NAND gate

D. XOR gate

Hint

Apply the gate truth rules and Boolean identities in the stated input order; distinguish an inversion from the underlying operation.

Answer B: AND gate.

COA03 states that AND is 1 only when all inputs are 1. This is exactly the condition in the stem. OR needs any high input, NAND complements AND, and two-input XOR is high when inputs differ. Thus none of the other truth functions has the specified all-high-only output rule.

Why each choice is right or wrong

A - Incorrect: OR becomes high when any input is high, so it does not require all inputs to be one.

B - Correct: AND outputs one exactly for the all-inputs-one combination required by the stem.

C - Incorrect: NAND inverts AND and therefore outputs zero, not one, when all its inputs are one.

D - Incorrect: Two-input XOR outputs one when inputs differ, not when both inputs are one.

The Boolean expression F = A⊕B represents which gate?

A. XNOR gate

B. NOR gate

C. XOR gate

D. NAND gate

Hint

Apply the gate truth rules and Boolean identities in the stated input order; distinguish an inversion from the underlying operation.

Answer C: XOR gate.

The expression A⊕B is the exclusive-OR operation. COA03 defines its two-input output as 1 when the inputs differ and contrasts XNOR as agreement. NOR and NAND complement OR and AND instead. Thus XOR is the operation represented by the given symbol, with no extra circuit diagram or numeric assumption needed.

Why each choice is right or wrong

A - Incorrect: XNOR is the complement of XOR, giving one when the two inputs agree.

B - Incorrect: NOR complements OR; it is not the exclusive-OR operation denoted by the circled plus.

C - Correct: The circled-plus expression denotes exclusive OR, whose output is one for differing inputs.

D - Incorrect: NAND complements AND rather than implementing the given exclusive-OR expression.

Which gate is called the 'universal gate' because it can implement any Boolean function?

A. AND gate

B. OR gate

C. NAND gate

D. XOR gate

Hint

Apply the gate truth rules and Boolean identities in the stated input order; distinguish an inversion from the underlying operation.

Answer C: NAND, the only universal gate offered.

COA04 explicitly states that NAND and NOR are each universal and explains constructing NOT by tying inputs together, then building AND/OR combinations. Of those two universal families, only NAND is offered. AND and OR alone cannot provide inversion under this rule, and XOR is not identified as a universal family. Thus the correct offered gate is NAND.

Why each choice is right or wrong

A - Incorrect: AND alone is not the universal family described; it does not supply the required inversion construction.

B - Incorrect: OR alone is not the universal family described and cannot generate the stated NOT construction.

C - Correct: NAND is explicitly universal and can be combined to construct NOT, AND and OR.

D - Incorrect: XOR is not the NAND/NOR universal family; tied inputs produce zero rather than inversion.

Primary note proof

For a NOR gate with inputs A=1, B=0, the output F is:

A. 0

B. 1

C. Undefined

D. Depends on voltage

Hint

Apply the gate truth rules and Boolean identities in the stated input order; distinguish an inversion from the underlying operation.

Answer A: F = 0.

COA03 defines OR as high when any input is high and NOR as its complement. At A=1, B=0, the OR value is 1, so NOR produces 0. The input combination is completely specified in ordinary Boolean logic; it is neither undefined nor dependent on an unspecified analog voltage model.

Why each choice is right or wrong

A - Correct: OR of 1 and 0 is 1; complementing that for NOR yields zero.

B - Incorrect: One is the OR result before inversion, not the NOR output for these inputs.

C - Incorrect: The Boolean NOR truth table fully defines this ordinary input combination.

D - Incorrect: The stem supplies Boolean input values, so no additional voltage threshold assumption is required.

De Morgan's theorem states that NOT(A·B) equals:

A. NOT(A) · NOT(B)

B. NOT(A) + NOT(B)

C. A + B

D. NOT(A+B)

Hint

Apply the gate truth rules and Boolean identities in the stated input order; distinguish an inversion from the underlying operation.

Answer B: NOT(A·B) = NOT(A) + NOT(B).

COA04 gives (AB)'=A'+B'. Complementing a product changes AND to OR and complements each operand. B matches that exact transformation. A instead gives the complement of A+B, C omits the operand complements, and D leaves the complement attached to a sum, which represents NOR rather than the requested NAND function.

Why each choice is right or wrong

A - Incorrect: The product of complements equals NOT(A+B), rather than the complement of the original product.

B - Correct: Complement each operand and change AND to OR, exactly as De Morgan’s product rule states.

C - Incorrect: A+B omits both required complements and is not generally equal to NOT(A·B).

D - Incorrect: NOT(A+B) is NOR and differs from NOT(A·B), for example when only one input is high.

Primary note proof

Study-note section COA04

> De Morgan gives (AB)'=A'+B' and (A+B)'=A'B'.

Question 140 | NS0372

In Boolean algebra, the expression A + A' (A OR NOT A) always equals:

A. 0

B. A

C. 1

D. A'

Hint

Apply the gate truth rules and Boolean identities in the stated input order; distinguish an inversion from the underlying operation.

Answer C: A + A' = 1.

COA04 explicitly lists A+A'=1. If A is 0 then A' is 1, and if A is 1 then A' is 0; either way their Boolean OR is 1. Neither A nor A' remains fixed across both assignments, and zero is the product-of-complements result rather than their sum.

Why each choice is right or wrong

A - Incorrect: Zero is A AND NOT A; the given operation is OR, so one input is always high.

B - Incorrect: A can be zero while the expression remains one, so the identity is not simply A.

C - Correct: A bit OR its complement is always one for both possible assignments.

D - Incorrect: A complement can be zero while the full expression is one, so it is not the constant result.

Primary note proof

Question 141 | NS0373

How many rows are in the truth table for a Boolean function with 4 input variables?

A. 8

B. 12

C. 16

D. 32

Hint

Apply the gate truth rules and Boolean identities in the stated input order; distinguish an inversion from the underlying operation.

Answer C: 16 rows.

COA03 gives 2^n rows for n binary inputs. For four independent variables, each has two assignments, so the total combinations are 2×2×2×2=16. The options 8 and 32 correspond to three and five binary variables respectively; 12 does not enumerate all four-variable combinations.

Why each choice is right or wrong

A - Incorrect: Eight is 2^3, the number of assignments for three inputs rather than four.

B - Incorrect: Twelve omits four of the sixteen possible combinations of four independent binary inputs.

C - Correct: Four independent binary inputs yield 2^4=16 distinct truth-table rows.

D - Incorrect: Thirty-two is 2^5 and would require five independent binary input variables.

Question 142 | NS0374

For the Boolean function F=x+y'z with x=0,y=1,z=1, which options evaluate to the same Boolean value as F under that assignment? Select all that apply.

A. 0

B. 1

C. x

D. z

Hint

Apply the gate truth rules and Boolean identities in the stated input order; distinguish an inversion from the underlying operation.

Answer A, C: 0; x

Complement first: y is one, so y-prime is zero. The product y-prime AND z is therefore zero, and OR with x, also zero, leaves F equal to zero. Both the literal zero option and the expression x evaluate to that result under the stated assignment. The literal one and z both evaluate to one. The multiple-selection wording preserves the actual option values rather than arbitrarily rejecting an equivalent expression.

Why each choice is right or wrong

A - Correct: The literal zero equals the computed function value.

B - Incorrect: One differs from the computed zero.

C - Correct: x is assigned zero and therefore equals the function value.

D - Incorrect: z is assigned one and differs from the function value.

Question 143 | NS0375

Which characteristic best describes a flip-flop?

A. A combinational logic circuit

B. A bistable multivibrator that stores one bit

C. A 4-bit counter

D. An arithmetic unit

Hint

Check whether output depends only on current inputs or also on stored state, and track the stated clock behavior.

Answer B: A bistable one-bit storage element.

COA05 says a flip-flop stores one bit while powered and classifies flip-flops as sequential circuits with stored state. B is the option describing that storage element. A combinational circuit lacks stored logical state; a four-bit counter requires a multi-bit state structure, and an arithmetic unit computes rather than defining this one-bit storage component.

Why each choice is right or wrong

A - Incorrect: A combinational circuit has no stored logical state, whereas a flip-flop retains a bit.

B - Correct: Bistable one-bit storage matches the powered state-retention role of a flip-flop.

C - Incorrect: One flip-flop stores one bit; a four-bit counter requires a multi-bit state organization.

D - Incorrect: An arithmetic unit computes values rather than defining the one-bit sequential storage element.

Question 144 | NS0376

What distinguishes a flip-flop from a simple logic gate in terms of memory?

A. Flip-flops use more power

B. Flip-flops retain state even after inputs change

C. Flip-flops operate faster

D. Flip-flops require AC power

Hint

Check whether output depends only on current inputs or also on stored state, and track the stated clock behavior.

Answer B: Flip-flops retain stored state during powered operation.

COA05 distinguishes sequential state from combinational outputs determined by present inputs. A flip-flop can retain its bit when inputs change without a qualifying update, giving the memory distinction in B. This does not imply nonvolatile retention after power-off. Power, speed and AC-supply claims are neither the defining property nor guarantees established here.

Why each choice is right or wrong

A - Incorrect: Power consumption is implementation-dependent and does not define whether a circuit has logical memory.

B - Correct: Stored state persists between valid updates while powered, unlike a purely present-input combinational gate.

C - Incorrect: Speed is not the defining memory distinction and is not guaranteed by the flip-flop label.

D - Incorrect: The note specifies powered storage, not a requirement for an AC rather than another supply.

Primary note proof

Study-note section COA05

> A flip-flop stores one bit while powered.

Study-note section COA05

> State retention during operation does not mean nonvolatile storage.

Question 145 | NS0377

What is the decimal equivalent of binary number 1011?

A. 9

B. 10

C. 11

D. 13

Hint

Keep the radix, bit width and representation fixed; evaluate place values or arithmetic steps in order.

Answer C: $1011_2 = 11_{10}$.

Using COA08's base-position rule, 1011_2 has weights 8, 4, 2 and 1. Its high bits contribute 8+2+1=11, while the 4-place is zero. The note's worked example confirms the same sum. Nine, ten and thirteen correspond to different low-order bit patterns, not the supplied 1011.

Why each choice is right or wrong

A - Incorrect: Nine equals 8+1, corresponding to 1001_2 and omitting the given two-place bit.

B - Incorrect: Ten equals 8+2, corresponding to 1010_2 and omitting the given one-place bit.

C - Correct: The set bit positions contribute 8+2+1=11 in decimal.

D - Incorrect: Thirteen equals 8+4+1, corresponding to 1101_2 rather than the supplied 1011_2.

Question 146 | NS0378

In hexadecimal, what does the letter 'F' represent in decimal?

A. 14

B. 15

C. 16

D. 10

Hint

Keep the radix, bit width and representation fixed; evaluate place values or arithmetic steps in order.

Answer B: $F_{16} = 15_{10}$.

COA08 defines hexadecimal digits as 0-9,A-F and explicitly gives F=15. These sixteen symbols represent values zero through fifteen, so sixteen itself requires the two-digit hexadecimal representation 10. Fourteen is E, and ten is A, leaving fifteen as the only value of the single digit F.

Why each choice is right or wrong

A - Incorrect: Fourteen corresponds to the preceding hexadecimal digit E, not the final digit F.

B - Correct: The note explicitly assigns decimal value fifteen to the hexadecimal digit F.

C - Incorrect: Sixteen requires hexadecimal 10; it is outside the value range of a single hexadecimal digit.

D - Incorrect: Ten corresponds to hexadecimal A rather than the later digit F.

Question 147 | NS0379

The octal number system uses a base of:

A. 2

B. 8

C. 10

D. 16

Hint

Keep the radix, bit width and representation fixed; evaluate place values or arithmetic steps in order.

Answer B: Base 8.

COA08 gives octal digits 0-7: eight possible digit values, so octal has base eight. Binary has two digits, decimal ten and hexadecimal sixteen. Place weights in octal are therefore powers of eight, not powers of two, ten or sixteen, even though octal digits can be grouped with three binary bits.

Why each choice is right or wrong

A - Incorrect: Base two is binary; octal allows eight digit values rather than only zero and one.

B - Correct: Octal uses digits zero through seven, giving a base of eight.

C - Incorrect: Base ten is decimal, not the eight-digit octal number system.

D - Incorrect: Base sixteen is hexadecimal, which uses the additional A-F digits absent from octal.

Question 148 | NS0380

Which number system is most fundamental to digital computing and why?

A. Decimal, because humans use it

B. Octal, because it maps to 3 bits

C. Binary, because digital circuits have two states (on/off)

D. Hexadecimal, because it is compact

Hint

Apply the gate truth rules and Boolean identities in the stated input order; distinguish an inversion from the underlying operation.

Answer C: Binary matches the two logical states used by digital logic.

COA03 defines digital gates using the two Boolean values 0 and 1, and COA08 defines binary using exactly those two digits. That direct correspondence explains why binary is fundamental to the digital representation described here. Octal and hexadecimal group binary bits for convenience, while decimal's human familiarity does not supply the two-state circuit correspondence.

Why each choice is right or wrong

A - Incorrect: Human decimal familiarity does not match the two Boolean states used here's digital gates.

B - Incorrect: Octal groups three binary bits and is a convenient notation rather than the underlying two-state representation.

C - Correct: Binary digits zero and one directly correspond to the two logical values used by digital circuits.

D - Incorrect: Hexadecimal compactly groups four binary bits; compact notation does not replace the underlying binary states.

Question 149 | NS0381

How many bits are needed to represent the hexadecimal digit F?

A. 2

B. 3

C. 4

D. 8

Hint

Keep the radix, bit width and representation fixed; evaluate place values or arithmetic steps in order.

Answer C: 4 bits: $F_{16} = 1111_2$.

COA08 groups four binary bits for each hexadecimal digit and gives F=15. COA09's unsigned range shows three bits reach only 7, while four bits reach 15. Therefore the minimum representation of F is four bits, 1111. Eight bits can contain the value but are not the number needed for one hexadecimal digit.

Why each choice is right or wrong

A - Incorrect: Two bits encode only zero through three, insufficient for hexadecimal F's decimal value fifteen.

B - Incorrect: Three bits encode only zero through seven, so they cannot represent the value fifteen.

C - Correct: Four bits encode zero through fifteen; F is represented by the four-bit pattern 1111.

D - Incorrect: Eight bits could contain fifteen but exceed the minimum four bits needed for a hexadecimal digit.

Question 150 | NS0382

Which listed memory categories lose their contents when power is removed? Assume ordinary SRAM/DRAM RAM and an SRAM-based processor cache. Select all that apply.

A. ROM

B. Flash memory

C. RAM

D. Cache

Hint

Separate storage role, access timing, placement and power retention; use the specified hierarchy or mapping convention.

Answer C, D: RAM; Cache

Ordinary SRAM and DRAM require power to retain their contents. RAM therefore qualifies, and the stated SRAM-based cache qualifies for the same technological reason. Cache is a hierarchy role rather than a promise of nonvolatile storage. ROM and flash retain contents without power, so they are excluded. Specifying implementation makes the volatility judgment definite while keeping both valid categories rather than forcing a RAM-only answer.

Why each choice is right or wrong

B - Incorrect: Flash retains contents without power.

C - Correct: Ordinary SRAM/DRAM RAM is volatile.

D - Correct: The explicitly SRAM-based cache is volatile too.

Question 151 | NS0383

Cache memory is best described as:

A. Large, slow, cheap memory

B. Small, ultra-fast memory between CPU and RAM

C. Non-volatile backup storage

D. Virtual memory on disk

Hint

Separate storage role, access timing, placement and power retention; use the specified hierarchy or mapping convention.

Answer B: Small, fast storage near the CPU between it and main memory.

COA23 places cache above DRAM in the usual speed/cost hierarchy and says faster levels are generally smaller and more expensive per bit. It defines cache as copied memory blocks near the CPU. B captures that role. Cache is not the large slow backup layer or disk-based virtual-memory backing store; its useful speed derives from proximity/reuse, not guaranteed persistence.

Why each choice is right or wrong

A - Incorrect: Large slow cheap storage describes lower hierarchy levels rather than the small fast cache layer.

B - Correct: Cache is a small fast near-CPU copy of memory blocks used to accelerate access.

C - Incorrect: The note defines cache for accelerated reuse, not as nonvolatile backup storage.

D - Incorrect: Disk-backed virtual memory is a different address-space/backing-store mechanism from the CPU cache.

Question 152 | NS0384

In direct memory mapping, what happens when two different main memory blocks map to the same cache slot?

A. Both are stored simultaneously

B. A cache conflict occurs and one block replaces the other

C. The system crashes

D. The blocks merge

Hint

Separate storage role, access timing, placement and power retention; use the specified hierarchy or mapping convention.

Answer B: A placement conflict: only one block can occupy that direct-mapped slot.

COA25 states that two blocks with the same direct-mapped index cannot reside together. When the requested block differs from the valid block at that slot, the cache must replace the slot's contents, producing a conflict miss. This is ordinary cache operation, not a crash or merging of block contents; direct mapping offers no alternate placement for the same index.

Why each choice is right or wrong

A - Incorrect: One direct-mapped line holds one block at a time, so the colliding blocks cannot coexist there.

B - Correct: The shared index causes a placement conflict; installing the requested block replaces the current one.

C - Incorrect: Conflict replacement is ordinary cache behavior and does not imply a system crash.

D - Incorrect: Cache replacement preserves separate memory-block identities; it does not merge their contents into one block.

Primary note proof

Question 153 | NS0385

Which cache mapping technique offers the most flexibility in placing data blocks?

A. Direct mapping

B. Set associative mapping

C. Fully associative mapping

D. Sequential mapping

Hint

Separate storage role, access timing, placement and power retention; use the specified hierarchy or mapping convention.

Answer C: Fully associative mapping

COA25 says direct mapping fixes one line, set associativity permits any way within one indexed set, and fully associative placement permits any line. Allowing every line gives the most placement flexibility for a fixed cache. The sequential-mapping option is not one of the cache placement rules defined by the supplied note.

Why each choice is right or wrong

A - Incorrect: Direct mapping restricts a block to a single line and therefore has the least placement freedom.

B - Incorrect: Set associativity permits several ways in one set, fewer locations than the entire fully associative cache.

C - Correct: Fully associative placement allows any cache line, maximizing placement freedom for each block.

D - Incorrect: Sequential ordering is not a placement freedom comparable to the defined direct, set-associative and fully associative cache rules.

Question 154 | NS0386

Set associative mapping is described as a compromise between:

A. RAM and ROM

B. Direct and fully associative mapping

C. Primary and secondary memory

D. Cache and virtual memory

Hint

Separate storage role, access timing, placement and power retention; use the specified hierarchy or mapping convention.

Answer B: Direct and fully associative mapping.

COA25 defines W-way set associativity as fixing a set by the block index while allowing any of W ways inside it. That combines direct indexing with an associative choice within the selected set, placing it between one-line direct mapping and unrestricted fully associative placement. RAM/ROM and primary/secondary are technology/hierarchy contrasts, not the two placement endpoints.

Why each choice is right or wrong

A - Incorrect: RAM and ROM describe memory types rather than the placement-policy endpoints combined by set associativity.

B - Correct: Set indexing restricts placement like direct mapping while allowing an associative choice among the selected set's ways.

C - Incorrect: Primary and secondary describe hierarchy roles, not the direct versus associative cache-placement alternatives.

D - Incorrect: Cache and virtual memory are different mechanisms rather than the two placement extremes defining set associativity.

Question 155 | NS0387

Virtual memory primarily uses which storage device to extend the apparent memory size?

A. ROM

B. Cache

C. Hard disk / SSD

D. Registers

Hint

Separate storage role, access timing, placement and power retention; use the specified hierarchy or mapping convention.

Answer C: Hard disk / SSD as backing storage.

COA27 says backing storage can hold nonresident pages while virtual memory provides translated protected address spaces. COA28 identifies HDDs and SSDs as persistent storage devices, matching that backing role. ROM, cache and registers are not the nonresident-page backing tier described. Apparent extension does not mean physical RAM is added or that virtual memory is only disk disguised as RAM.

Why each choice is right or wrong

A - Incorrect: ROM stores persistent firmware/data but is not the writable nonresident-page backing role described here.

B - Incorrect: Cache holds near-CPU copies of memory blocks rather than serving as the mass backing store.

C - Correct: Persistent HDD/SSD storage can hold nonresident page contents for the virtual-memory system.

D - Incorrect: Registers hold immediate execution state and cannot serve as the large backing store for nonresident pages.

Question 156 | NS0388

A valid disk-backed virtual page is currently nonresident, and the access must load its saved contents before continuing. Which condition describes the resulting page-fault case?

A. The CPU runs out of registers

B. The requested page is not in physical memory and must be loaded from disk

C. Cache memory is full

D. An arithmetic overflow occurs

Hint

Separate storage role, access timing, placement and power retention; use the specified hierarchy or mapping convention.

Answer B: The requested page is not in physical memory and must be loaded from disk

Accessing the valid but nonresident disk-backed page faults so that the system can make the page resident and continue. The stated case requires loading its saved contents. Register pressure, cache replacement and arithmetic overflow are different conditions. Other kinds of page fault need not read a disk, so the question explicitly limits itself to this nonresident disk-backed case.

Why each choice is right or wrong

A - Incorrect: Register allocation pressure is not an access to a missing or forbidden virtual page.

B - Correct: The described disk-backed nonresident access is a page-fault case, although not all faults require a disk read.

C - Incorrect: A full cache leads to cache replacement, not necessarily a virtual-memory page fault.

D - Incorrect: Arithmetic overflow is an instruction arithmetic condition rather than a virtual-page access event.

Primary note proof

Study-note section COA27

> A valid nonresident page access faults and may require loading data; invalid or forbidden accesses can also fault.

Study-note section COA27

> A cache miss, TLB miss and page fault are different events; not every page fault reads a disk, since zero-fill and already-resident shared pages exist.

Question 157 | NS0389

Compared to RAM, a Hard Disk Drive (HDD) is:

A. Faster and volatile

B. Slower and non-volatile

C. Faster and non-volatile

D. Slower and volatile

Hint

Separate storage role, access timing, placement and power retention; use the specified hierarchy or mapping convention.

Answer B: HDD is generally slower and nonvolatile.

COA23 places DRAM above HDD in the usual speed hierarchy. COA28 says an HDD does not require continuous power to preserve stored bits, while COA24 calls ordinary SRAM/DRAM volatile. Combining the independent speed and retention rules gives slower and nonvolatile. The answer concerns the usual hierarchy comparison rather than every conceivable workload or specialized memory device.

Why each choice is right or wrong

A - Incorrect: It reverses both usual properties: HDD is slower than RAM and retains data without power.

B - Correct: The hierarchy places HDD below RAM in speed, and magnetic storage preserves bits without continuous power.

C - Incorrect: Nonvolatility is right, but the claim that HDD is faster than RAM reverses the usual hierarchy.

D - Incorrect: Slower is right, but volatile contradicts the note's explicit HDD power-off retention statement.

Primary note proof

Question 158 | NS0390

Which range matches the historical optical-disk access-time examples used in this course, rather than a universal specification for every optical drive?

A. 1-5 milliseconds

B. 10-30 milliseconds

C. 100-300 milliseconds

D. 500-1000 milliseconds

Hint

Separate storage role, access timing, placement and power retention; use the specified hierarchy or mapping convention.

Answer C: 100-300 milliseconds

The note identifies one hundred to three hundred milliseconds as a historical optical-access example. That range is not a universal specification: actual timing depends on the device and measurement conditions. The revised stem asks for the particular teaching range rather than an unqualified typical value for all optical disks. The remaining intervals do not match that historical example and therefore are definite distractors.

Why each choice is right or wrong

A - Incorrect: This interval does not match the historical optical-access example.

B - Incorrect: This shorter interval is not the course's cited historical example.

C - Correct: This is the historical example range given in the note.

D - Incorrect: This longer interval is not the course's cited historical example.

Primary note proof

Question 159 | NS0391

Which storage medium accesses data sequentially rather than randomly?

A. SSD

B. HDD

C. Magnetic tape

D. Optical disk

Hint

Separate storage role, access timing, placement and power retention; use the specified hierarchy or mapping convention.

Answer C: Magnetic tape.

COA28 classifies tape as sequential and suited to streaming/archives. Disk provides direct addressed-block access, while SSD provides nonmechanical persistent storage rather than a tape-style stream. The question asks the medium whose access is characteristically sequential, so magnetic tape is the supported choice. Physical streaming inside another device does not make its logical access interface tape-like.

Why each choice is right or wrong

A - Incorrect: SSD is addressed nonvolatile semiconductor storage rather than the sequential tape-access medium described.

B - Incorrect: HDD permits addressed-block direct access rather than requiring tape-like sequential record traversal.

C - Correct: Tape is explicitly the sequential streaming/archive medium in the note's access taxonomy.

D - Incorrect: Optical disk uses addressed disk access rather than being the sequential tape medium requested.

Primary note proof

Registers within the CPU are used primarily to:

A. Store large datasets permanently

B. Hold temporary data for immediate CPU operations

C. Communicate with I/O devices

D. Manage virtual memory pages

Hint

Identify the register, signal or instruction role and the execution phase; distinguish stored values, addresses and control actions.

Answer B: Hold temporary values for immediate CPU operations.

COA14 distinguishes registers as explicit execution operands and assigns them fetched instructions, transferred data and operands/results. That supports the immediate temporary-storage role in B. Registers are small execution state rather than permanent bulk data storage. Some registers participate in I/O or translation, but those specialized uses do not replace the primary execution-storage role asked here.

Why each choice is right or wrong

A - Incorrect: Registers are small temporary execution storage rather than permanent bulk storage for large datasets.

B - Correct: Registers hold operands, instruction state and intermediate results used directly by current CPU operations.

C - Incorrect: Some registers support I/O, but general I/O communication is not their primary execution-storage purpose.

D - Incorrect: Translation can use specialized state, but managing virtual pages is not the primary role of CPU registers generally.

Question 161 | NS0393

The address bus in a computer system is responsible for:

A. Carrying actual data between components

B. Specifying the memory location the CPU wants to access

C. Providing timing signals

D. Transmitting control commands

Hint

Identify the register, signal or instruction role and the execution phase; distinguish stored values, addresses and control actions.

Answer B: Specify the addressed memory location.

COA12 says address signals select a location, data signals carry values and control signals coordinate read/write and timing. Therefore B directly matches the address bus. Actual payload data belongs to the data bus, while timing and operation commands belong to control signaling. The distinction does not depend on address width or the value being transferred.

Why each choice is right or wrong

A - Incorrect: Actual payload values travel on the data bus rather than the address signals selecting a location.

B - Correct: The address bus identifies the memory location selected for the CPU's access.

C - Incorrect: Timing belongs to control signaling, not the location-selection role of address signals.

D - Incorrect: Read/write and other operation commands belong to control signaling rather than the address bus.

Primary note proof

Study-note section COA12

> Address signals select a location; data signals carry values; control signals coordinate read/write, timing, requests and acknowledgements.

Question 162 | NS0394

A CPU exposes 32 address bits and uses byte-addressable memory with no additional address-extension mechanism. What maximum byte capacity can it address? Use GB here to mean 2^30 bytes.

A. 2 GB

B. 4 GB

C. 8 GB

D. 16 GB

Hint

Identify the register, signal or instruction role and the execution phase; distinguish stored values, addresses and control actions.

Answer B: 4 GB

Thirty-two address bits identify 2^32 distinct locations. With one byte per location, that is 2^32 bytes, or four units of 2^30 bytes. The selected option is therefore four GB under the explicitly stated binary convention, more precisely four GiB. Data-bus width is irrelevant to this location count, and without byte addressing the same number of address bits would not determine a byte capacity.

Why each choice is right or wrong

A - Incorrect: Two binary gigabytes would require only 2^31 byte locations.

B - Correct: 2^32 byte locations equal four units of 2^30 bytes.

C - Incorrect: Eight binary gigabytes would require 33 address bits.

D - Incorrect: Sixteen binary gigabytes would require 34 address bits.

Primary note proof

Study-note section COA12

> With a address bits there are 2^a addressable locations.

Study-note section COA12

> Multiply by bytes per location before calling this a byte capacity.

Question 163 | NS0395

The control bus in a computer system carries:

A. Data between CPU and memory

B. Memory addresses

C. Signals that regulate operations like read/write timing

D. Interrupt requests only

Hint

Identify the register, signal or instruction role and the execution phase; distinguish stored values, addresses and control actions.

Answer C: Control signals coordinate operations, including read/write timing.

COA12 defines control signals as coordinating read/write, timing, requests and acknowledgements. C expresses that general role. The data and address alternatives belong to distinct signal groups. Interrupt requests may be part of aggregate control, but the word only makes D too restrictive because read/write and timing controls are also included.

Why each choice is right or wrong

A - Incorrect: Actual transferred data belongs to the data bus rather than the control-signal group.

B - Incorrect: Location selection belongs to address signals rather than the control bus's coordination role.

C - Correct: Read/write coordination and timing are explicitly among the functions assigned to control signals.

D - Incorrect: Interrupt requests are only one possible control input; the bus also carries other coordination signals.

Primary note proof

Study-note section COA12

> Address signals select a location; data signals carry values; control signals coordinate read/write, timing, requests and acknowledgements.

Study-note section COA12

> Aggregate control signals include both CPU outputs and device inputs; both data and control buses can therefore be bidirectional under that scope.

Question 164 | NS0396

In instruction format terminology, an 'opcode' refers to:

A. The memory address of the next instruction

B. The bits specifying the operation to perform

C. The register holding the result

D. The data value being processed

Hint

Identify the register, signal or instruction role and the execution phase; distinguish stored values, addresses and control actions.

Answer B: Bits specifying the operation.

COA16 defines the opcode as the operation-specifying field. Operand fields locate registers/data and mode fields explain their interpretation. Thus B names the correct format role; next-instruction addresses, result-register identity and operand values are separate quantities. Their presence elsewhere in a machine does not change what opcode means.

Why each choice is right or wrong

A - Incorrect: Next-instruction position is a PC/control-flow role, not the opcode's operation-selection role.

B - Correct: Opcode bits select the operation the processor should perform for the instruction.

C - Incorrect: Result-register selection belongs to an operand/destination field rather than defining the opcode.

D - Incorrect: An operand data value is distinct from the code selecting the operation to apply.

Primary note proof

Study-note section COA16

> An opcode specifies the operation; operand fields locate data or registers, and a mode field explains interpretation.

Question 165 | NS0397

A zero-address instruction format relies on:

A. Implicit register addressing

B. Stack-based operand access

C. Immediate values only

D. Direct memory addressing

Hint

Identify the register, signal or instruction role and the execution phase; distinguish stored values, addresses and control actions.

Answer B: Implicit top-of-stack operands.

COA16 says zero-address stack ADD uses two implicit top-of-stack operands. The absence of written operand addresses therefore relies on stack organization, not immediate constants or direct memory fields. Generic implicit register addressing is too broad and does not identify the stack discipline specified for this format; PUSH/POP may still have explicit addresses.

Why each choice is right or wrong

A - Incorrect: Implicit register addressing alone does not identify the stack operand convention defining zero-address arithmetic here.

B - Correct: Operands come implicitly from the top of the stack, so arithmetic needs no explicit operand-address fields.

C - Incorrect: Immediate values require encoded operand information; zero-address stack arithmetic is not restricted to constants.

D - Incorrect: Direct memory addressing would use an explicit operand address, contrary to the stated zero-address arithmetic format.

Primary note proof

Study-note section COA16

> Zero-address stack ADD uses two implicit top-of-stack operands.

Study-note section COA17

> PUSH and POP may still contain an explicit address even on a stack machine.

Question 166 | NS0398

Which instruction format is most expressive, allowing operations on three separate operands?

A. Zero-address

B. One-address

C. Two-address

D. Three-address

Hint

Identify the register, signal or instruction role and the execution phase; distinguish stored values, addresses and control actions.

Answer D: Three-address format.

COA16 defines three-address ADD X,Y,Z as X←Y+Z, allowing a separately named destination and two sources. This matches the stem's three separate operands. Two-address form overwrites one source, one-address uses an implicit accumulator, and zero-address uses stack operands. Most expressive is interpreted here through the explicit three-operand criterion rather than a universal comparison of complete instruction sets.

Why each choice is right or wrong

A - Incorrect: Zero-address arithmetic names no explicit operands and instead uses the implicit stack top.

B - Incorrect: One-address accumulator arithmetic names only one explicit operand and relies on an implicit accumulator.

C - Incorrect: Two-address arithmetic overwrites a named source and lacks a separately named third operand field.

D - Correct: Three explicit fields allow one destination and two independently named source operands.

Primary note proof

Study-note section COA16

> Three-address ADD X,Y,Z means X←Y+Z under destination-first notation.

Study-note section COA16

> Two-address ADD X,Y overwrites X with X+Y.

Study-note section COA16

> One-address accumulator ADD X means AC←AC+M[X].

Question 167 | NS0399

Stack organization follows which principle?

A. FIFO (First In First Out)

B. LIFO (Last In First Out)

C. Random Access

D. Priority-based Access

Hint

Identify the register, signal or instruction role and the execution phase; distinguish stored values, addresses and control actions.

Answer B: LIFO: last in, first out.

COA17 defines a stack as last-in, first-out: PUSH adds at the logical top and POP removes that top item. The most recently pushed remaining item is therefore the next removed. FIFO describes queue ordering, while arbitrary indexed access or priority selection does not define the stack discipline.

Why each choice is right or wrong

A - Incorrect: FIFO removes the oldest inserted item, the opposite order from normal stack removal.

B - Correct: The last item pushed becomes the top and is the first item popped.

C - Incorrect: Random access does not enforce removal of the most recently pushed remaining item.

D - Incorrect: Stack removal follows insertion order in reverse, not a priority ranking assigned to items.

Primary note proof

Study-note section COA17

> A stack is last-in, first-out.

Study-note section COA17

> PUSH adds an item and POP removes the logical top.

Question 168 | NS0400

In indirect addressing mode, the instruction contains:

A. The actual data value

B. The direct memory address of the data

C. A pointer to the memory address where data resides

D. A register number

Hint

Identify the register, signal or instruction role and the execution phase; distinguish stored values, addresses and control actions.

Answer C: A reference whose stored contents supply the effective address.

COA18 defines memory-indirect addressing as EA=M[A], followed by operand M[EA]. Thus the instruction's field identifies a pointer location rather than directly containing the operand value or final operand address. C is the pointer/indirection description. A describes immediate, B direct, and a plain register number identifies a register-based mode rather than this memory-indirect convention.

Why each choice is right or wrong

A - Incorrect: An actual value encoded in the instruction is immediate addressing rather than memory indirection.

B - Incorrect: Using the field directly as the operand's address is direct addressing, without the intermediate pointer lookup.

C - Correct: The field identifies a pointer-bearing location; its contents supply the address of the operand data.

D - Incorrect: A register number names register-based addressing rather than the memory-indirect field defined here.

Primary note proof

Study-note section COA18

> Let A be an instruction field, R a register value and M[x] the contents at x.

Study-note section COA18

> Immediate uses value A; direct uses EA=A and operand M[A]; indirect uses EA=M[A] then operand M[EA].

Study-note section COA18

> Register uses operand R; register-indirect uses EA=R.

Question 169 | NS0401

Which is a textbook RISC design tendency, without claiming every instruction has single-cycle latency?

A. Variable-length instructions

B. Large instruction set (100-250 ops)

C. Simple operations, regular encodings and load/store memory access

D. Complex microcode control unit

Hint

Compare textbook design tendencies without turning them into guarantees about every processor.

Answer C: Simple operations, regular encodings and load/store memory access

Textbook RISC emphasizes simple operations, regular encodings, load/store memory access and pipeline-friendly control. These tendencies do not imply every instruction completes with one-cycle latency; steady-state pipeline throughput is a separate measure. Variable lengths and complex operations are associated with CISC tendencies, while an instruction-count range is not a defining guarantee. The choice states these RISC characteristics without imposing a universal single-cycle latency.

Why each choice is right or wrong

A - Incorrect: Variable lengths are associated with CISC tendencies rather than the stated RISC summary.

B - Incorrect: This numerical instruction-count range is not the supported RISC characteristic.

C - Correct: These are the RISC design tendencies named in the note.

D - Incorrect: Complex microcode control is not the stated RISC design tendency.

Primary note proof

Study-note section COA20

> Textbook RISC emphasizes simple operations, regular encodings, load/store memory access, plentiful registers and pipeline-friendly control.

Study-note section COA20

> CISC commonly supplies more complex operations, richer addressing modes and variable lengths.

Study-note section COA20

> One instruction completing per pipeline cycle is throughput, not proof that every instruction has one-cycle latency.

Question 170 | NS0402

CISC processors differ from RISC processors primarily in that CISC:

A. Has fewer instructions

B. Uses only register-to-register operations

C. Supports complex instructions that may take multiple cycles

D. Has no microcode

Hint

Compare textbook design tendencies without turning them into guarantees about every processor.

Answer C: CISC commonly supports richer complex instructions, potentially with multi-cycle execution.

COA20 associates CISC with complex operations, richer addressing and variable lengths, and rejects universal one-cycle latency claims. C therefore gives the matching tendency and permits, rather than requires, multi-cycle execution. The remaining claims either reverse the usual complexity contrast or impose unsupported only/no restrictions. The answer does not claim modern RISC instructions can never take multiple cycles.

Why each choice is right or wrong

A - Incorrect: Fewer instructions reverses the usual simple-versus-rich instruction-set contrast rather than stating the note's CISC tendency.

B - Incorrect: Only register-to-register operations contradicts the richer addressing modes associated with CISC in the note.

C - Correct: Complex operations and possible multi-cycle latency fit the CISC tendency without claiming exclusivity of multi-cycle execution.

D - Incorrect: The note does not define CISC by absence of microcode; control implementation is a separate design dimension.

Primary note proof

Study-note section COA20

> Textbook RISC emphasizes simple operations, regular encodings, load/store memory access, plentiful registers and pipeline-friendly control.

Study-note section COA20

> CISC commonly supplies more complex operations, richer addressing modes and variable lengths.

Study-note section COA20

> Modern RISC instructions can take multiple cycles and modern CISC processors can translate instructions into simpler internal operations.

Question 171 | NS0403

A RISC processor typically has more _____ compared to a CISC processor to compensate for simpler instructions:

A. Clock cycles per instruction

B. Addressing modes

C. Registers

D. Instruction bytes

Hint

Compare textbook design tendencies without turning them into guarantees about every processor.

Answer C: Registers.

COA20 explicitly lists plentiful registers among textbook RISC characteristics, alongside load/store access and simple operations. C is therefore the supported tendency. More addressing modes and instruction bytes are not the stated compensating mechanism, and more cycles per instruction is not a defining guarantee. The typically qualifier matters because the labels alone do not impose a register count on every implementation.

Why each choice is right or wrong

A - Incorrect: More cycles per instruction is not the plentiful-register mechanism or a guaranteed RISC property.

B - Incorrect: Richer addressing modes are associated with CISC tendencies, not the stated RISC compensating feature.

C - Correct: Plentiful registers are explicitly one of the textbook RISC traits named by the complete note.

D - Incorrect: More instruction bytes is not the feature identified as supporting simple RISC operations.

Primary note proof

Study-note section COA20

> Textbook RISC emphasizes simple operations, regular encodings, load/store memory access, plentiful registers and pipeline-friendly control.

Study-note section COA-S04

> RISC means Reduced Instruction Set Computer; CISC means Complex Instruction Set Computer.

Question 172 | NS0404

In Programmed I/O, how does the CPU know when the I/O device has finished its operation?

A. The I/O device sends an interrupt signal

B. The CPU periodically polls (checks) the status register

C. DMA controller notifies the CPU

D. The operating system schedules a check

Hint

Follow the data path and control responsibility; distinguish the transfer mechanism, address space and interface type.

Answer B: Poll the status register.

COA30 defines programmed/polled I/O as repeatedly checking device status while the CPU moves each item. B names that readiness/completion checking mechanism. Interrupt notification belongs to interrupt-driven I/O, and a DMA controller is a separate transfer mechanism. The OS may arrange when polling code runs, but that broad scheduling statement does not replace the actual status check.

Why each choice is right or wrong

A - Incorrect: An interrupt signal names interrupt-driven notification rather than programmed I/O's polling mechanism.

B - Correct: The CPU reads device status repeatedly to determine readiness or completion in programmed I/O.

C - Incorrect: DMA-controller completion notification belongs to a DMA transfer rather than programmed CPU-driven I/O.

D - Incorrect: Scheduling a check is broader software organization; polling the status register is the actual completion-detection method.

Primary note proof

Study-note section COA30

> Programmed/polled I/O repeatedly checks status and lets the CPU move each item.

Study-note section COA30

> Interrupt-driven I/O lets the CPU do other work until an event requests service; the handler still consumes CPU time to service the device.

Question 173 | NS0405

The main advantage of Interrupt-Driven I/O over Programmed I/O is:

A. Higher data transfer speeds

B. The CPU can perform other tasks while waiting for I/O

C. It requires no special hardware

D. It eliminates the need for device drivers

Hint

Follow the data path and control responsibility; distinguish the transfer mechanism, address space and interface type.

Answer B: The CPU can do other work while the device operates.

COA30 says interrupt-driven I/O lets the CPU do other work until the device requests service. That removes continuous status polling, which is the principal advantage in B. Service still consumes CPU time and needs device support/software. Therefore it does not universally increase device transfer speed, eliminate hardware requirements or remove drivers.

Why each choice is right or wrong

A - Incorrect: Avoiding polling does not by itself guarantee that the device or bus transfers data at a higher rate.

B - Correct: The CPU can execute other useful work between setup and the device's service request.

C - Incorrect: Interrupt notification requires suitable device/controller support; the note does not promise no special hardware.

D - Incorrect: A handler/driver must still service the device; interrupt-driven operation does not remove that software role.

Primary note proof

Study-note section COA30

> Interrupt-driven I/O lets the CPU do other work until an event requests service; the handler still consumes CPU time to service the device.

Question 174 | NS0406

Direct Memory Access (DMA) primarily improves performance by:

A. Increasing CPU clock speed

B. Allowing a controller to transfer data between an I/O device and memory without the CPU copying each word

C. Compressing data before transfer

D. Using a faster bus

Hint

Follow the data path and control responsibility; distinguish the transfer mechanism, address space and interface type.

Answer B: Allowing a controller to transfer data between an I/O device and memory without the CPU copying each word

DMA transfers a block directly between an I/O device and memory after CPU setup. Its performance benefit is reduced per-word CPU copying, leaving the processor available for other work while the controller performs the transfer. CPU configuration and completion handling remain necessary, and DMA still consumes memory bandwidth. It does not inherently raise the clock, compress data or require a faster bus.

Why each choice is right or wrong

A - Incorrect: DMA changes who performs transfer work, not the processor's clock frequency.

B - Correct: The controller moves the block after setup, avoiding a CPU copy operation for every transferred word.

C - Incorrect: Data compression is not part of the DMA definition or its stated per-word CPU-work reduction.

D - Incorrect: DMA may use the existing bus and does not inherently replace it with a faster one.

Primary note proof

Study-note section COA30

> DMA lets a controller move a block directly between device and memory after CPU setup.

Study-note section COA30

> DMA does not eliminate CPU involvement in configuration, ownership, address mapping or completion.

Study-note section COA30

> DMA reduces per-word CPU work but competes for memory bandwidth.

Question 175 | NS0407

In Memory-Mapped I/O, how are I/O devices accessed?

A. Using special IN/OUT instructions

B. Through dedicated I/O ports separate from memory

C. By assigning memory addresses to I/O registers, accessed like regular memory

D. Via DMA exclusively

Hint

Follow the data path and control responsibility; distinguish the transfer mechanism, address space and interface type.

Answer C: Device registers occupy memory addresses and use suitable memory access instructions.

COA31 says memory-mapped I/O assigns device registers addresses in the memory address space and uses suitable loads/stores. C matches, but like regular memory refers to address/instruction access rather than identical side effects: MMIO widths, ordering and status-read behavior still matter. Special IN/OUT and a separate port space instead describe isolated I/O; DMA is independent of address-space choice.

Why each choice is right or wrong

A - Incorrect: Special IN/OUT instructions describe isolated/port-mapped I/O rather than the defining memory-mapped access mechanism.

B - Incorrect: A separate port space is the isolated I/O arrangement, not device registers in memory address space.

C - Correct: MMIO places device registers at memory-space addresses accessed through suitable loads/stores, with device-specific side-effect rules.

D - Incorrect: MMIO specifies addressing and access, not an exclusive requirement to transfer all device data through DMA.

Primary note proof

Study-note section COA31

> Memory-mapped I/O assigns device registers addresses in the memory address space and uses suitable load/store operations.

Study-note section COA31

> Isolated/port-mapped I/O has a separate port space and special instructions such as IN/OUT.

Study-note section COA31

Question 176 | NS0408

An I/O 'Write Command' instructs the I/O module to:

A. Read data from the peripheral and store it in a buffer

B. Check the device status for errors

C. Take data from the data bus and transmit it to the peripheral

D. Reset the peripheral device

Hint

Follow the data path and control responsibility; distinguish the transfer mechanism, address space and interface type.

Answer C: Transmit system data to the peripheral.

COA29 defines write/output commands as sending system data to the device. C matches that direction: data from the system bus is handed to the peripheral. Reading brings device data toward the system, status testing inspects readiness/errors, and reset is a control action. These are distinct command functions even when one controller implements them all.

Why each choice is right or wrong

A - Incorrect: Moving peripheral data into a system buffer is the input/read direction rather than write/output.

B - Incorrect: Checking readiness or errors is a test/status command rather than transferring output data.

C - Correct: A write/output command sends data from the system side to the peripheral device.

D - Incorrect: Reset is a device-control action, not the ordinary data-output direction defining a write command.

Primary note proof

Study-note section COA29

> Control commands start actions, test/status commands inspect readiness or errors, read commands bring device data toward the system, and write/output commands send system data to the device.

Question 177 | NS0409

Which I/O technique is most efficient for transferring large blocks of data, such as disk reads?

A. Programmed I/O

B. Interrupt-Driven I/O

C. Direct Memory Access (DMA)

D. Memory-Mapped I/O

Hint

Follow the data path and control responsibility; distinguish the transfer mechanism, address space and interface type.

Answer C: DMA for substantial block transfers.

COA30 explicitly recommends DMA for substantial blocks because it reduces per-word CPU work to setup and completion duties. This matches disk-like large transfers. Polling and interrupt transfer still involve CPU servicing of individual items, while memory-mapped I/O is an address-space design choice that may coexist with DMA. The answer assumes the substantial-block context, not a universal fastest mechanism for every tiny transfer.

Why each choice is right or wrong

A - Incorrect: Programmed I/O makes the CPU check status and move each item, adding substantial work for large blocks.

B - Incorrect: Interrupt-driven transfer avoids continuous polling but still consumes CPU service work for transferred items.

C - Correct: DMA replaces much per-item CPU work with block setup/completion, matching the substantial-transfer recommendation.

D - Incorrect: Memory mapping specifies device addressing and can coexist with DMA; it does not itself offload block movement.

Primary note proof

Study-note section COA30

> Programmed/polled I/O repeatedly checks status and lets the CPU move each item.

Study-note section COA30

> Interrupt-driven I/O lets the CPU do other work until an event requests service; the handler still consumes CPU time to service the device.

Question 178 | NS0410

SMP (Symmetric Multiprocessing) systems are characterized by:

A. Multiple different processors with specialized roles

B. Compatible peer processors sharing memory and I/O under one operating system

C. Processors with separate private address spaces communicating by messages

D. Independent networked computers without shared memory

Hint

Separate throughput from latency and check which operations overlap or share resources under the stated model.

Answer B: Compatible peer processors sharing memory and I/O under one operating system

SMP gives processors peer roles with shared memory and I/O under an operating system. Compatibility and symmetric roles matter; every physical processor property need not be identical. Specialized asymmetric roles do not state that model, while separate address spaces and independent networked computers describe distributed organization. The alternatives compare coherent organizations without an impossible single-processor multi-chip description.

Why each choice is right or wrong

A - Incorrect: Specialized unequal processor roles describe an asymmetric organization rather than the peer-role model.

B - Correct: Peer roles with shared memory and I/O under one OS match the SMP definition.

C - Incorrect: Separate private address spaces and message communication describe distributed-memory organization.

D - Incorrect: Independent computers without shared memory do not have the stated SMP shared-memory organization.

Question 179 | NS0411

Pipelining improves CPU performance by:

A. Increasing the clock speed of each stage

B. Executing one instruction at a time faster

C. Overlapping the execution stages of multiple instructions simultaneously

D. Using larger registers

Hint

Separate throughput from latency and check which operations overlap or share resources under the stated model.

Answer C: Overlap stages of different instructions.

COA35 defines pipelining by overlapping stages from different instructions and says it primarily improves throughput. C directly states that mechanism. It does not require faster stages, larger registers or a single instruction completing all work faster. Pipeline fill/drain, stalls and the slowest stage constrain actual gains, so overlap rather than guaranteed latency reduction is the supported explanation.

Why each choice is right or wrong

A - Incorrect: Pipeline performance does not require increasing each stage's clock speed; clock choice is limited by the slowest stage.

B - Incorrect: An instruction still spans several stages, so lower single-instruction latency is not the defining improvement.

C - Correct: Overlapping stages lets different instructions progress concurrently, increasing completed-work throughput.

D - Incorrect: Larger register width does not define stage overlap or directly explain pipelining's throughput benefit.

Primary note proof

Study-note section COA35

> A pipeline overlaps stages of different instructions; it primarily improves throughput.

Study-note section COA35

> The ideal steady-state completion rate is one instruction per cycle, while an individual instruction still spans multiple stages.

In an arithmetic pipeline for floating-point addition, which is the FIRST sub-operation performed?

A. Normalize the result

B. Add/subtract the mantissas

C. Align the mantissas

D. Compare the exponents

Hint

Keep the radix, bit width and representation fixed; evaluate place values or arithmetic steps in order.

Answer D: Compare exponents first.

COA10 orders floating addition as compare exponents, shift the smaller significand to align, add/subtract, normalize and round. Comparing exponents must precede alignment because their difference determines the required shift. Adding before alignment combines unequal place weights, and normalization happens after arithmetic. Therefore D is the first named sub-operation.

Why each choice is right or wrong

A - Incorrect: Normalization follows aligned addition/subtraction rather than initiating the floating-point addition sequence.

B - Incorrect: Significands must first be aligned to a common exponent before their values can be added correctly.

C - Incorrect: Alignment follows exponent comparison, which determines which significand to shift and by how much.

D - Correct: Exponent comparison is explicitly first and supplies the information needed for subsequent alignment.

Primary note proof

Study-note section COA10

> For floating addition, compare exponents, shift the smaller significand to align, add or subtract, normalize and round.

Question 181 | NS0413

Which statement describes vector-instruction semantics rather than guaranteeing simultaneous execution of every array element?

A. Processes one element at a time faster

B. One vector instruction applies an operation across multiple data elements, possibly in lane-sized batches

C. Uses fewer transistors

D. Operates at a higher clock frequency

Hint

Separate throughput from latency and check which operations overlap or share resources under the stated model.

Answer B: One vector instruction applies an operation across multiple data elements, possibly in lane-sized batches

A vector instruction describes an operation over a sequence of elements. Its semantics cover multiple data elements, but physical lanes can process those elements in batches instead of executing the entire array at one instant. The choice distinguishes vector from scalar processing without requiring simultaneous execution of every element. Faster individual elements, fewer transistors or a higher clock are implementation properties rather than definitions of vector processing.

Why each choice is right or wrong

A - Incorrect: Faster scalar element processing does not define vector semantics.

B - Correct: This states the multi-element instruction semantics while permitting physical batching.

C - Incorrect: A transistor-count reduction is not part of the definition.

D - Incorrect: A higher clock frequency is not required by vector semantics.

Primary note proof

Study-note section COA37

> A vector instruction describes an operation over a sequence of elements; physical lanes may process them in batches, not all in one instant.

For an ideal single-issue RISC pipeline in steady state after filling, with balanced stages and no stalls, what is the completion throughput?

A. One instruction per two clock cycles

B. One instruction per clock cycle

C. Two instructions per clock cycle

D. Depends on instruction complexity

Hint

Separate throughput from latency and check which operations overlap or share resources under the stated model.

Answer B: One instruction per clock cycle

An ideal single-issue pipeline overlaps stages of successive instructions. After filling, it completes one instruction each cycle when stages are balanced and no hazards or other stalls interfere. An individual instruction still crosses several stages, so this is throughput rather than one-cycle instruction latency. Specifying single issue excludes a superscalar interpretation that could complete more than one instruction per cycle.

Why each choice is right or wrong

A - Incorrect: One completion per two cycles is below the stated ideal no-stall rate.

B - Correct: The ideal steady-state single-issue completion rate is one per cycle.

C - Incorrect: Two per cycle requires multiple-issue resources beyond the stated design.

D - Incorrect: The ideal rate follows from the specified single-issue pipeline assumptions.

Primary note proof

Study-note section COA35

> In an ideal k-stage single-issue pipeline, n instructions take k+n−1 cycles when stages are balanced and there are no stalls.

Study-note section COA35

> The ideal steady-state completion rate is one instruction per cycle, while an individual instruction still spans multiple stages.

Question 183 | NS0415

Flynn's taxonomy classifies parallel computer architectures based on:

A. Number of processors and memory size

B. Instruction streams and data streams

C. Clock speed and bus width

D. Cache size and register count

Hint

Separate throughput from latency and check which operations overlap or share resources under the stated model.

Answer B: Instruction streams and data streams.

COA37 explicitly defines Flynn classification by instruction and data streams. SISD has one of each, SIMD one instruction stream with multiple data elements, and MIMD multiple streams of each. Processor count, capacity, clock and register/cache sizes are implementation properties rather than the two classification axes. Therefore B directly matches the taxonomy.

Why each choice is right or wrong

A - Incorrect: Processor count and memory size do not define the instruction-stream/data-stream axes of Flynn’s taxonomy.

B - Correct: Flynn classifies the number of instruction streams and data streams, producing SISD/SIMD/MISD/MIMD categories.

C - Incorrect: Clock and bus width measure implementation characteristics rather than Flynn’s stream-count classification.

D - Incorrect: Cache capacity and register count are not the two axes used by Flynn’s taxonomy.

Primary note proof

Study-note section COA37

> Flynn classifies instruction and data streams: SISD has one of each; SIMD applies one instruction stream to multiple data elements; MIMD uses multiple instruction and data streams; MISD has multiple instruction streams for a common data stream and is uncommon.

Question 184 | NS0416

The primary goal of parallel processing is to increase:

A. Memory capacity

B. Clock frequency

C. Throughput - the amount of processing per unit time

D. Register size

Hint

Separate throughput from latency and check which operations overlap or share resources under the stated model.

Answer C: Throughput: completed processing per unit time.

COA37 says more cores increase available parallel work while serial dependencies and coordination limit speedup. COA34 defines throughput as completed work per unit time. Parallel processing aims to raise that work rate, matching C, rather than inherently increasing physical memory, clock frequency or register width. Actual gains still depend on enough independent work and manageable overhead.

Why each choice is right or wrong

A - Incorrect: Parallel execution does not inherently increase the system's installed memory capacity.

B - Incorrect: Additional concurrent work can improve throughput without increasing any processor's clock frequency.

C - Correct: Concurrent useful work aims to increase completed processing per unit time, subject to serial and coordination limits.

D - Incorrect: Register width is an architectural data-size property, not the primary objective of parallel execution.

Primary note proof

Study-note section COA37

> More cores increase available parallel work, but serial dependencies and coordination limit speedup.

Study-note section COA34

> Throughput counts completed work per unit time; latency measures one job's delay.

Question 1 | Q00016

Which term describes combining multiple analogue or digital input signals for transmission over one shared medium?

A. Point-to-point

B. Broadcasting

C. Synchronization

D. Multiplexing

Hint

Compare the signal mechanism, medium properties or transmission direction against the definitions and stated physical assumptions.

Answer D: Multiplexing

Multiplexing combines separate input streams so they can share a transmission link. The receiver uses demultiplexing to separate them again. This operation concerns sharing link capacity, whereas broadcasting concerns the recipients of a message. Point-to-point describes the endpoints of a link, and synchronization coordinates timing. The option supplies the required operation while preserving those distinctions.

Why each choice is right or wrong

A - Incorrect: Point-to-point joins two endpoints and does not mean combining input signals onto a shared link.

B - Incorrect: Broadcast sends a message to all destinations in scope rather than combining multiple input streams.

C - Incorrect: Synchronization coordinates timing; it is not the multiplexing operation defined by the stem.

D - Correct: Multiplexing combines multiple streams for a shared link and is precisely the operation described.

Primary note proof

Study-note section NET32

> Multiplexing combines multiple input streams onto a shared link; demultiplexing separates them at the receiver. It differs from broadcasting one message to many destinations. FDM

Question 2 | Q00036

A traditional phone call is an example of

A. Packet switching

B. Multiplexing

C. Broadcasting

D. Circuit switching

Hint

Use the cited note definitions to identify the requested function or scope, then check each alternative against that same rule.

Answer D: Circuit switching

A traditional circuit telephone call exemplifies establishment, continuous use of a dedicated path, and release. This applies to the traditional circuit service assumed by the stem, rather than all modern telephone implementations. Evidence: PDF 20, 20, 20.

Why each choice is right or wrong

A - Incorrect: Packets are discrete rather than the dedicated circuit described (PDF 20, 20, 20.)

B - Incorrect: Multiplexing shares a link and may underlie telephony but does not name its switching service (PDF 20, 20, 20.)

C - Incorrect: Broadcasting does not establish a dedicated pairwise call (PDF 20, 20, 20.)

D - Correct: Dedicated establishment, transfer and disconnect match the call (PDF 20, 20, 20.)

Primary note proof

Study-note section NET31

> Circuit switching sets up a path with reserved resources, transfers data, then releases it. Predictable allocated bandwidth trades against setup/blocking and wasted reservation during silence. A traditional telephone call is the standard example. Packet switching divides data into packets that share links statistically; queueing can add variable delay and loss. This does not

make modern voice-over-packet impossible: buffering, scheduling and capacity planning manage it.

Circuit Switching: In circuit switching, two communicating stations are connected by a dedicated communication path which consists of intermediate nodes in the network and the links that connect these nodes.
It involved the following three distinct steps
• Circuit Establishment: To establish an end-to-end connection before any transfer of data.
• Data transfer: Transfer data is from the source to the destination. The data may be analog or digital, depending on the nature of the network. The connection is generally full-duplex.
• Circuit disconnect: Terminate connection at the end of data transfer. Signals must be propagated to deallocate the dedicated resources.

Question 3 | Q00050

Assume you are searching for information and typed the domain name: www.mysearchexample.com on your browser, having an IP address 192.108.110.1. Since internet communication is based on an IP address, the domain name has to be translated to its corresponding IP address. Which of the following is responsible for the translation?

A. DNS

B. SMTP

C. FTP

D. DHCP

Hint

Separate address width, syntax, reserved scope and the supplied prefix or historical classful convention.

Answer A: DNS

The needed operation is name resolution. The module identifies DNS as Domain Name Service and contrasts external DNS naming with locally stored host addresses; together these support the name-to-address lookup. Evidence: PDF 18, 65, 18.

Why each choice is right or wrong

A - Correct: DNS is the named external naming service (PDF 18, 65, 18.)

B - Incorrect: SMTP is electronic mail, not name lookup (PDF 18, 65, 18.)

C - Incorrect: FTP is file transfer, not name lookup (PDF 18, 65, 18.)

D - Incorrect: Page28 explicitly expands DHCP as Dynamic Host Configuration Protocol, separately from DNS (Domain Name Service). The external naming service discussed on page65 is DNS, the operation requested, rather than the separately named host-configuration protocol. The expansion alone is not a full account of DHCP operation.

Primary note proof

Study-note section NET20

DNS resolves names to records, including IPv4 A and IPv6 AAAA addresses; it can use UDP or TCP port 53. DHCP dynamically leases IPv4 settings, commonly address, mask, gateway and DNS server. Its basic exchange is discover, offer, request, acknowledge. IP itself does not assign addresses.

Study-note section NET21

HTTP defines web request/response semantics; it is stateless, and a message body may be absent. HTTPS adds TLS protection. FTP transfers files using control and separate data connections; it is not the same protocol as SFTP. SMTP submits and relays mail; POP3 retrieves messages and IMAP accesses/synchronizes server mailboxes. Saying SMTP handles both sending and end-user mailbox retrieval is inaccurate.

Question 4 | Q00061

Which one of the following is not correct about networking models?

A. TCP/IP model is a protocol model

B. A reference model has no implementation specification

C. A network designer can use either of TCP/IP or OSL, or both

D. Open system interconnection (OSI) is a protocol model

Hint

Use the cited note definitions to identify the requested function or scope, then check each alternative against that same rule.

Answer D: OSI is a reference model, not itself an implemented protocol suite

NET03 distinguishes an abstract reference model from an implemented protocol suite. D incorrectly calls OSI a protocol model in that distinction. TCP/IP supplies the implemented suite, and designers can use models as architectural guides. B is valid when understood as the model itself not providing executable implementation details, rather than denying all interface descriptions.

Why each choice is right or wrong

A - Incorrect: TCP/IP describes an implemented protocol suite, consistent with calling it a protocol model.

B - Incorrect: A reference model divides responsibilities/interfaces without itself being executable implementation software.

C - Incorrect: Models can guide network design; using one or both perspectives is compatible with their reference purpose.

D - Correct: OSI is the reference model in the stated contrast, not itself the implemented TCP/IP-style protocol suite.

Primary note proof

Study-note section NET03

A reference model divides responsibilities and interfaces; it is not itself executable networking software. OSI is a seven-layer reference model; TCP/IP describes an implemented protocol suite, usually taught with four layers. A five-layer teaching model separates physical and link functions. State the model before counting layers.

Study-note section NET19

The four-layer TCP/IP model folds OSI layers 5-7 into application, retains transport, calls layer 3 Internet, and combines link/physical as network access. A model is a guide to functions, not a guarantee that every application gets a reliable network. Distinguish end-to-end application service from its underlying process-to-process transport.

The Open Systems Interconnection (OSI) Model was
developed by International Organization for Standardization
(ISO). ISO is the organization, OSI is the model
It was developed to allow systems with different platforms
(Hardware & software) to communicate with each other.
Now, it is a network model that defines the protocols for
network communications.
It is a hierarchical model that groups its processes into seven
(7) layers. (Top to Bottom)
1. Application Layer
2. Presentation Layer
3. Session Layer
4. Transport Layer
5. Network Layer
6. Data Link Layer
7. Physical Layer
Each layer has specific functions to perform and has to co-

Data Communication and Computer Networking module | PDF page 16 | lines 50-59

After understanding the concept of layered task and the OSI
model, we introduce the TCP/IP model. This model is
currently being used on our systems. TCP/IP model is a
collection of protocols often called a protocol suite. It offers a
rich variety of protocols.
It is a hierarchical model; it existed even before the OSI model
was developed. Originally had four layers (bottom to top):
1. Host to Network Layer
2. Internet Layer
3. Transport Layer

Data Communication and Computer Networking module | PDF page 25 | lines 17-27

TCP/IP is a hierarchical protocol made up of interactive modules, each of which provides a specific functionality; however, the modules are not necessarily interdependent. Whereas the OSI model specifies which functions belong to each of its layers, the layers of TCP/IP suite contain relatively independent protocols that can be mixed and matched depending on the needs of the system. The term hierarchical means that each upper-level protocol is supported by one or more lower-level protocols.

Question 5 | Q00063

Which statement about IPv4 is incorrect?

A. It uses 128-bit addresses.

B. Its finite address space has faced allocation scarcity.

C. Private addressing with NAT can conserve public IPv4 addresses.

D. It uses 32-bit addresses.

Hint

Separate address width, syntax, reserved scope and the supplied prefix or historical classful convention.

Answer A: It uses 128-bit addresses.

IPv4 addresses contain 32 bits, whereas IPv6 uses a much larger address space. IPv4 allocation scarcity motivates conservation through private addressing and NAT. These are address-space properties, not a claim that every IPv4 router is intrinsically slow or memory-intensive. The incorrect statement assigns a 128-bit address width to IPv4.

Why each choice is right or wrong

A - Correct: IPv4 addresses are 32 bits, so the claimed 128-bit width is incorrect.

B - Incorrect: Finite IPv4 address allocation has faced scarcity; this statement is true.

C - Incorrect: Private addressing with NAT conserves public IPv4 addresses; this statement is true.

D - Incorrect: The stated 32-bit IPv4 address width is correct.

Primary note proof

Study-note section NET16

IP supplies connectionless best-effort packet delivery, not end-to-end ordering or retransmission. IPv4 addresses are 32 bits. Its minimum header is 20 bytes and can grow to 60 bytes; it is not a 32-bit header. IHL counts 32-bit words; total length includes header and payload. TTL limits lifetime across routers; the protocol field identifies TCP, UDP or another upper-layer protocol.

Study-note section NET-S03

The finite IPv4 address space has faced allocation scarcity. Private addressing with NAT conserves public IPv4 addresses, while IPv6 provides a much larger address space.

IP addresses: IP address uniquely identifies a device on the Internet. Every host and router on the Internet has an IP address, which encodes its network number and host number.
• The combination is unique: in principle, no two machines on the Internet have the same IP address.
• An IPv4 address is 32 bits long
• They are used in the Source address and Destination address fields of IP packets.
• An IP address does not refer to a host but it refers to a network interface.

Question 6 | Q00073

Which item is not a transmission impairment?

A. Synchronization

B. Crosstalk

C. Impulse noise

D. Distortion

Hint

Compare the signal mechanism, medium properties or transmission direction against the definitions and stated physical assumptions.

Answer A: Synchronization

Distortion changes the signal's shape, while crosstalk and impulse noise add unwanted disturbances. Crosstalk couples energy from a nearby channel; impulse noise is a brief disturbance. Synchronization instead aligns timing so the receiver can interpret transmitted symbols. Losing synchronization can cause errors, but synchronization itself is a desirable coordination process rather than one of these signal impairments.

Why each choice is right or wrong

A - Correct: Synchronization aligns timing and is not itself an impairment.

B - Incorrect: Crosstalk is unwanted coupling from nearby channels, a noise impairment.

C - Incorrect: Impulse noise is a short unwanted disturbance, a noise impairment.

D - Incorrect: Distortion changes the signal shape and is a transmission impairment.

Primary note proof

Study-note section NET06

> Attenuation reduces signal strength. Distortion changes shape, often because frequencies have different delays. Noise adds unwanted energy: thermal noise comes from random thermal motion, crosstalk leaks from nearby channels, and impulse noise is a short disturbance. Amplifiers amplify noise too; digital repeaters regenerate decisions but cannot reconstruct every corrupted bit.

Question 7 | Q00086

_____ is a probabilistic algorithm where a data packet is sent by the router to any one of its neighbors randomly.

A. Adaptive routing algorithm

B. Flooding routing algorithm

C. Random walks routing algorithm

D. Distributed routing algorithm

Hint

Compare signal repetition, frame forwarding, packet routing and policy enforcement using the stated device or traffic assumptions.

Answer C: Random-walk routing

NET30 defines a random walk by probabilistically choosing a neighbor, exactly the forwarding behavior in the stem. Flooding instead replicates packets. Adaptive and distributed describe broader properties of routing algorithms; neither alone specifies random single-neighbor selection.

Why each choice is right or wrong

A - Incorrect: Adaptive routing responds to network conditions; adaptation alone does not mean choosing a random neighbor.

B - Incorrect: Flooding sends copies on multiple eligible links rather than selecting just one neighbor randomly.

C - Correct: Random walk selects the next neighbor probabilistically, matching the stated packet-forwarding procedure.

D - Incorrect: Distributed routing spreads computation among routers; it does not specify the random choice described.

Primary note proof

Study-note section NET30

Flooding sends copies on eligible outgoing links with duplicate/lifetime controls; random walk picks a neighbor probabilistically. Unicast targets one destination, broadcast all in a scope, multicast a subscribed group and anycast one member sharing an address, normally nearest under routing metrics. Multi-destination packets can list multiple targets; this is not necessarily identical to broadcast. Group multicast trees use mechanisms such as reverse-path checks; Ethernet spanning tree is a different layer-2 mechanism.

Study-note section NET-S01

Adaptive or dynamic routing changes routes in response to updated network information; nonadaptive or static routing uses configured choices. Distributed routing means routers perform computations using exchanged information instead of requiring one central route computation. These properties do not imply random next-hop selection: the path-selection rule is a separate classification.

Question 8 | Q00087

Which network address translation protocol solves the task of address resolution using port number?

A. Network Address Translation

B. Port Address Translation

C. Dynamic Address Translation

D. Static address translation

Hint

Convert the mask to a prefix, separate network and host bits, and apply the relevant subnet-count or usable-host rule.

Answer B: Port Address Translation (PAT/NAPT)

The wording loosely calls translation “address resolution,” but its decisive qualifier is use of port numbers. NET29 identifies PAT/NAPT as translation of address-plus-port combinations, allowing shared public addresses. This is not hardware-address resolution by ARP, and ordinary static or pooled dynamic address mappings do not themselves describe port multiplexing.

Why each choice is right or wrong

A - Incorrect: NAT is the broad translation family; this option does not identify the port-based form specifically.

B - Correct: PAT translates address-and-port combinations, distinguishing simultaneous clients that share an external address.

C - Incorrect: Dynamic NAT allocates address mappings from a pool, without necessarily multiplexing transport ports.

D - Incorrect: Static NAT fixes an address mapping; port-based sharing is the separate PAT mechanism.

Primary note proof

Study-note section NET29

> Static NAT gives a fixed address mapping; dynamic NAT allocates mappings from a pool. PAT/NAPT maps address-plus-port combinations so multiple private clients share a public address. It is translation, not ARP resolution and not encryption. Return traffic must match the translation state or a configured inbound mapping.

Study-note section NET20

> ARP resolves an on-link IPv4 next hop to a link address, using a broadcast request and normally unicast reply. For an off-subnet target, ARP resolves the gateway, not the remote target’s MAC. It

bridges the network/link addressing boundary and is often classified at the link layer; calling ARP simply a network protocol uses a loose textbook convention. Data Communication and Computer Networking module | PDF page 48 | lines 29-40

Network Address Translation (NAT)
NAT translates the IP addresses of computers in a local network to a single IP address. This address is often used by the router that connects the computers to the Internet. The router can be connected to a DSL modem, cable modem, T1 line, or even a dial-up modem. When other computers on the Internet attempt to access computers within the local network, they only see the IP address of the router. This adds an extra level of security, since the router can be configured as a firewall, only allowing authorized systems to access the computers within the network.

TCP and UDP must use port numbers to communicate with the upper layers, because they‘re what keep track of different conversations crossing the network simultaneously. These port numbers identify the source and destination application or process in the TCP segment. There are 216 = 65,536 ports available.
Well-known ports: The port numbers range from 0 to 1,023.
Registered ports: The port numbers range from 1,024 to 49,151. Registered ports are used by applications or services that need to have consistent port assignments.
Dynamic or private ports: The port numbers range from 49,152 to 65,535.

Question 9 | Q00088

Which protocol resolves a known on-link IPv4 next-hop address to its link-layer hardware address?

A. Address Resolution Protocol (ARP)

B. Reverse Address Resolution Protocol (RARP)

C. Bootstrap Protocol (BOOTP)

D. Internet Control Message Protocol (ICMP)

Hint

Convert the mask to a prefix, separate network and host bits, and apply the relevant subnet-count or usable-host rule.

Answer A: Address Resolution Protocol (ARP)

ARP resolves an on-link IPv4 next hop to a link address, normally by broadcasting a request and receiving a reply. For an off-subnet destination, the next hop is usually the gateway rather than the remote destination itself. RARP reverses hardware-to-IP lookup; BOOTP supplies boot configuration, and ICMP carries network diagnostics. These distinct functions do not replace ARP's local IPv4-to-link resolution.

Why each choice is right or wrong

A - Correct: ARP resolves the known local IPv4 next hop to its link address.

B - Incorrect: RARP performs the reverse hardware-to-IP lookup.

C - Incorrect: BOOTP supplies boot configuration rather than resolving a known next-hop IPv4 address to its link address.

D - Incorrect: ICMP reports network errors and diagnostics rather than resolving hardware addresses.

Primary note proof

Study-note section NET20

> ARP resolves an on-link IPv4 next hop to a link address, using a broadcast request and normally unicast reply. For an off-subnet target, ARP resolves the gateway, not the remote target's MAC. It bridges the network/link addressing boundary and is often classified at the link layer; calling ARP simply a network protocol uses a loose textbook convention. RARP reverses hardware-to-IP lookup; BOOTP/DHCP support boot configuration. ICMP reports errors and diagnostics; IGMP manages IPv4 multicast membership. These are separate companion protocols, not four pieces whose combination is IP.

Study-note section NET20

> DNS resolves names to records, including IPv4 A and IPv6 AAAA addresses; it can use UDP or TCP port 53. DHCP dynamically leases IPv4 settings, commonly address, mask, gateway and DNS

server. Its basic exchange is discover, offer, request, acknowledge. IP itself does not assign addresses.

Question 10 | Q00089

A 172.16.0.0/16 parent network is divided into equal /19 broadcast subnets. Counting all subnets, which statement is correct?

A. It provides 8 subnets, 32 IP addresses each

B. It provides 8 subnets, 8,190 hosts each

C. It provides 8 subnets, 30 hosts each

D. It provides 8 subnets, 2,046 IP addresses each

Hint

Convert the mask to a prefix, separate network and host bits, and apply the relevant subnet-count or usable-host rule.

Answer B: It provides 8 subnets, 8,190 hosts each

Moving from /16 to /19 borrows three subnet bits, producing 2^3 = 8 equal subnets. Each /19 leaves thirteen host bits, so it contains 8192 addresses. Reserving the network and directed-broadcast addresses leaves 8190 usable hosts. Subnet counts describe subdivision of the stated parent; they must not be confused with addresses or hosts within a child subnet.

Why each choice is right or wrong

A - Incorrect: Eight subnets is correct, but each /19 has 8192 total addresses rather than 32.

B - Correct: Three borrowed bits yield eight subnets; thirteen host bits yield 8190 usable hosts per subnet.

C - Incorrect: Thirty usable hosts belongs to /27, not /19.

D - Incorrect: A /19 contains 8192 addresses, not 2046.

Primary note proof

Study-note section NET26

> To split parent /a into equal /p blocks, borrow b=p-a bits and obtain 2^b subnets. Do not subtract two subnets under modern practice. For a Class B /16 parent split to /19, b=3 gives eight subnets, each with 8192 addresses and 8190 conventional hosts. A /19 alone does not state its parent.

Study-note section NET25

> For ordinary broadcast LANs let h=32-p. Total addresses=2^h; usable hosts=2^h-2, reserving network and directed broadcast. Find the changing octet's increment as 256-mask octet, round the address down to a multiple, and extend through the next boundary minus one.

> IP addresses: IP address uniquely identifies a device on the
> Internet. Every host and router on the Internet has an IP address,

which encodes its network number and host number.
• The combination is unique: in principle, no two machines on the Internet have the same IP address.
• An IPv4 address is 32 bits long
• They are used in the Source address and Destination address fields of IP packets.
• An IP address does not refer to a host but it refers to a network interface.

Data Communication and Computer Networking module | PDF page 19 | lines 2-22

Address Space: An address space is the total number ofaddresses used by the protocol.
• If a protocol uses N bits to define an address, the address space is 2N because each bit can have twodifferent values (0 or 1) and N bits can have 2N values.
• IPv4 uses 32-bit addresses, which means that the address space is 232 or 4,294,967,296 (more than 4billion).
Notations: There are two notations to show an IPv4 address:
• Binary notation: The IPv4 address is displayed as 32bits. ex. 11000001 10000011 00011011 11111111
• Dotted decimal notation: To make the IPv4 address easier to read, Internet addresses are usually written in decimal form with a decimal point (dot) separatingthe bytes. Each byte (octet) is 8 bits hence each number in dotted-decimal notation is a value rangingfrom 0 to 255. Ex. 129.11.11.239

Data Communication and Computer Networking module | PDF page 19 | lines 23-36

Classful addressing : In classful addressing, the addressspace is divided into five classes: A, B, C, D, and E.
• Netid and Hostid In classful addressing, an IP addressin class A, B, or C is divided into netid and hostid.
Subnetting: It allows a network to be split into several parts for internal use but still act like a single network to the outsideworld.
• To implement subnetting, the router needs a subnet mask that indicates the split between network + subnet number and host. Ex.

255.255.252.0/22. A‖/22‖ to indicate that the subnet mask is 22 bits long.

Question 11 | Q00090

A network device that provides the physical interface between computer and cabling is known as_____.

A. Switch

B. Router

C. NIC

D. Repeater

Hint

Compare signal repetition, frame forwarding, packet routing and policy enforcement using the stated device or traffic assumptions.

Answer C: NIC

The star-topology description places RJ-45 cable connections at the NIC of each computer; the physical address is imprinted on that NIC. This identifies the host cabling interface. Evidence: PDF 23, 17, 12, 12, 11.

Why each choice is right or wrong

A - Incorrect: A switch forwards among attached devices (PDF 23, 17, 12, 12, 11.)

B - Incorrect: A router interconnects networks (PDF 23, 17, 12, 12, 11.)

C - Correct: The module names Network Interface Card and connects cable to it (PDF 23, 17, 12, 12, 11.)

D - Incorrect: A repeater regenerates a signal on a LAN (PDF 23, 17, 12, 12, 11.)

Primary note proof

Study-note section NET09

A NIC supplies a computer’s network interface and commonly implements both physical and link functions. Calling a NIC a physical interface does not mean all its functions are layer 1. Physical specifications include connectors, signaling, voltage, timing and physical coding/modulation; the PHY interface to MAC handles hardware signaling.

Study-note section NET10

A bridge or ordinary Ethernet switch operates at layer 2. It learns source-MAC-to-port mappings, looks up the destination, forwards a known unicast to its port, filters it if the destination is on the

incoming segment, and floods an unknown unicast or broadcast within its VLAN. A switch does not always send only to one destination port. Wireless access points normally bridge wireless and wired link-layer traffic.

Study-note section NET11

Routers forward IP packets between networks using destination prefixes and next hops. They separate broadcast domains and normally do not forward local link broadcasts. A default gateway is usually a router, while a protocol gateway can translate application formats; therefore a gateway is not inherently a device that implements every OSI layer.

Star Topology: in this topology, each node is connected directly to a central device called a hub or a switch. Data on a star network passes through the central device (switch) before continuing to its destination. The central device manages and controls all functions of the network. This configuration is common with twisted pair cable. RJ-45 Connectors are used to connect the cable to the Network Interface Card (NIC) of each computer. Its advantages include, ease of installation and reconfiguration, robust (ease of fault identification and isolation), link failure only affects device(s) connected to that link, and is less expensive than mesh. Its drawbacks include more cable requirements (than bus and ring) and single point of failure (if central device fail, the whole system will be down).

Question 12 | Q00141

In the OSI teaching model, which layers provide hop-local or end-to-end flow control and error recovery when the chosen protocols support them? Select all that apply; isolated header-error detection alone does not qualify.

A. Application

B. Presentation

C. Network

D. Transport

E. Session

F. Data link

G. Physical

Hint

Match the requested scope or data unit to the layer duties in the note; distinguish hop delivery from end-to-end process delivery.

Answer D, F: Transport; Data link

Data-link protocols can provide hop-local flow control and recovery, such as acknowledgments and retransmission. Transport protocols such as TCP provide end-to-end flow control and reliable delivery. These capabilities depend on the protocol: Ethernet detection alone does not guarantee recovery, and UDP does not provide TCP reliability. IPv4 checks its header but remains best-effort and does not supply the requested end-to-end recovery and flow-control service.

Why each choice is right or wrong

A - Incorrect: Application supplies application-facing network services, not the specified OSI control role.

B - Incorrect: Presentation concerns representation, compression and encryption roles.

C - Incorrect: IPv4 header checks detect some errors, but IP lacks the requested recovery and flow-control service.

D - Correct: Transport protocols such as TCP provide end-to-end flow control and recovery.

E - Incorrect: Session manages dialog and checkpoints rather than the specified delivery controls.

F - Correct: Data-link protocols can provide hop-local flow control and recovery.

G - Incorrect: Physical signaling transmits symbols rather than implementing these delivery-control procedures.

Primary note proof

Study-note section NET14

> Controlled access uses polling, reservations or a token to grant turns; correctly coordinated access avoids contention collisions. Channelization divides frequency, time or code resources. Stop-and-wait sends one frame and waits for ACK, retransmitting on timeout; sequence bits

distinguish duplicates. Sliding windows permit multiple unacknowledged frames. Link reliability/flow control is hop-local; transport reliability/flow control is end-to-end. Ethernet detects corruption but does not itself guarantee reliable delivery.

Study-note section NET17

TCP offers a reliable ordered byte stream using sequence numbers, acknowledgments, retransmission and windows. Flow control protects the receiver; congestion control protects network capacity. UDP sends independent datagrams with ports and a checksum but no built-in setup, delivery guarantee, retransmission or ordering. Live interactive traffic may choose UDP when late data is less useful than lost data. Application protocols can add reliability over UDP.

Study-note section NET19

OSI session roles establish/manage dialogs and can coordinate checkpoints so transfer resumes after interruption. Presentation roles translate encodings and handle compression/encryption. Compression reduces representation size; encryption hides content and need not shrink it. Application protocols provide services directly to applications. Practical implementations distribute these functions differently; TLS is not proof of a separate physical presentation-layer device.

Data Link Layer
• The Data Link layer adds reliability to the physical layer by providing error detection and correction mechanisms.
• Framing: the Data Link layer receives the data from Network Layer and divides the stream of bits into fixed size manageable units called as Frames and sends it to the physical layer. On the receiver side, the data link layer receives the stream of bits from the physical layer and regroups them into frames and sends them to the Network layer.
• Physical Addressing: The Data link layer appends the physical address in the header of the frame before sending it to physical layer.
• Flow control: The data link layer makes sure that the sender sends the data at a speed at which the receiver canreceive it else if there is an overflow at the receiver sidethe data will be lost.
• Error Control: The data link layer imposes error control mechanism to identify lost or damaged frames, duplicateframes and then retransmit them.
• Access Control: The data link layer imposes access control mechanism to determine which device has right to send data in an multipoint

connection setting.
• Main Responsibility: The main responsibility of the data link layer is hop to hop transmission of frames.

Data Communication and Computer Networking module | PDF page 16 | lines 2-17

• At the sending side, the transport layer receives data from the session layer, divides it into units called segments and sends it to the network layer.
• To ensure process to process delivery the transport layer makes use of port address to identify the data from the sending and receiving process.
• The data can be transported in a connection oriented or connectionless manner.
• The Transport layer is responsible for segmentation and reassembly of the message into segments which bear sequence numbers.
• The transport layer also carries out flow control and error control functions; but unlike data link layer these are end to end rather than node to node.
• The main responsibility of the transport layer is process to process delivery of the entire message

Question 13 | Q00142

Which of the following statement(s) is/are WRONG? (Choose all that applies)

A. Internet/Network layer is responsible for routing

B. Physical address can be assigned by the network administrator.

C. Physical layer is concerned with specifying the characteristics of the transmission medium, the nature of the signals and the data rate.

D. Transport layer provides only unreliable data transmission.

E. Network layer is responsible for host to host communication.

F. None of the above

Hint

Use the cited note definitions to identify the requested function or scope, then check each alternative against that same rule.

Answer D: The transport layer does not provide only unreliable transmission

The question asks for WRONG statements. TCP is a transport-layer protocol with reliable ordered delivery, disproving the absolute “only unreliable” in D. The other substantive statements fit the layer model: network routing and host delivery, physical signaling specifications, and administratively assigned MAC addresses. NET33 explicitly permits locally administered MAC addresses, so B must not be rejected.

Why each choice is right or wrong

A - Incorrect: This statement is true: routing is a network/Internet-layer responsibility, so it is not a wrong statement.

B - Incorrect: NET33 permits locally administered MAC addresses; physical addresses need not always be factory assigned.

C - Incorrect: Physical signaling, transmission-medium characteristics and data rate belong to the physical layer.

D - Correct: The word only is false: TCP supplies reliable transport, whereas UDP lacks built-in delivery guarantees.

E - Incorrect: Host-to-host packet delivery is a network-layer function, distinct from transport process delivery.

F - Incorrect: At least D is wrong, so none of the above cannot answer the requested negative test.

Primary note proof

Study-note section NET33

> First identify the exact layer, protocol and scope. Flow/error control can exist at both link and transport layers; MAC addresses can be locally administered; bridges and switches both operate at layer 2. A LAN can use public or private unicast space. UDP and IP are both connectionless. Session dialogs and TCP connections are distinct senses of connection. Distinguish the protocol, layer and scope before treating these descriptions as exclusive.

Study-note section NET17

Question 14 | Q00143

Which one of the following Medium Access Control protocols is supported by WLAN (802.11)?

A. ALOHA

B. CSMA/CA

C. Token Passing

D. FDMA

E. CSMA

Hint

Compare the signal mechanism, medium properties or transmission direction against the definitions and stated physical assumptions.

Answer B: CSMA/CA

NET14 names CSMA/CA as the 802.11 Wi-Fi access procedure. It combines carrier sensing, waiting/backoff and acknowledgments rather than Ethernet-style collision detection or token turns. Generic CSMA describes its family, but B gives the specifically supported WLAN mechanism requested by the stem; E omits its collision-avoidance procedure.

Why each choice is right or wrong

A - Incorrect: ALOHA sends opportunistically and is not the 802.11 contention mechanism identified in NET14.

B - Correct: CSMA/CA is the specifically identified WLAN mechanism, using waiting/backoff and acknowledgments.

C - Incorrect: Token passing is controlled access, unlike the contention procedure used by ordinary 802.11 WLANs.

D - Incorrect: FDMA divides frequency resources; it is not the stated WLAN medium-access protocol.

E - Incorrect: CSMA names the broader carrier-sensing family but omits the specific collision-avoidance WLAN protocol offered in B.

Primary note proof

Study-note section NET14

> Random access allows contention: ALOHA sends opportunistically; CSMA senses before sending. In legacy half-duplex Ethernet, CSMA/CD detects collision, sends a jam indication, stops, and retries after random backoff. The jam signals a collision, not its clearance. Wi-Fi 802.11 uses CSMA/CA with waiting/backoff and acknowledgments; sensing does not eliminate hidden-terminal collisions.

Study-note section NET14

Controlled access uses polling, reservations or a token to grant turns; correctly coordinated access avoids contention collisions. Channelization divides frequency, time or code resources. Stop-and-wait sends one frame and waits for ACK, retransmitting on timeout; sequence bits distinguish duplicates. Sliding windows permit multiple unacknowledged frames. Link reliability/flow control is hop-local; transport reliability/flow control is end-to-end. Ethernet detects corruption but does not itself guarantee reliable delivery.

Question 15 | Q00144

Which device category can perform protocol conversion at higher OSI layers, potentially including application formats, rather than being limited to basic repeating, MAC bridging or IP routing?

A. Hub

B. Switch

C. Router

D. Gateway

E. Bridge

Hint

Match the requested scope or data unit to the layer duties in the note; distinguish hop delivery from end-to-end process delivery.

Answer D: Gateway

A protocol gateway translates between protocol or application representations, so its possible scope extends above basic link forwarding and IP routing. A hub repeats signals, a basic switch or bridge forwards using link-layer information, and a basic router forwards IP packets. Gateway is used in several senses: an ordinary default gateway is usually a router and need not implement conversion across every OSI layer.

Why each choice is right or wrong

A - Incorrect: A hub repeats physical signals rather than converting application protocols.

B - Incorrect: A basic layer-2 switch forwards frames by link-layer information.

C - Incorrect: A basic router chooses IP next hops rather than translating application formats.

D - Correct: A protocol-conversion gateway can translate higher-layer formats.

E - Incorrect: A bridge forwards between links using MAC information rather than higher-layer protocol conversion.

Primary note proof

Study-note section NET11

> Routers forward IP packets between networks using destination prefixes and next hops. They separate broadcast domains and normally do not forward local link broadcasts. A default gateway is usually a router, while a protocol gateway can translate application formats; therefore a gateway is not inherently a device that implements every OSI layer.

Study-note section NET09

> A repeater regenerates layer-1 signals without inspecting destination addresses. An active hub is a multiport repeater: it repeats incoming signals onto other ports, placing half-duplex endpoints in one collision domain. A passive hub is a connector. A hub neither learns MAC addresses nor

eliminates collisions. An endpoint such as a network printer consumes services; routers, hubs and access points are intermediary devices.

Study-note section NET10

A bridge or ordinary Ethernet switch operates at layer 2. It learns source-MAC-to-port mappings, looks up the destination, forwards a known unicast to its port, filters it if the destination is on the incoming segment, and floods an unknown unicast or broadcast within its VLAN. B. 9.0.0.1

C. 192.168.1.256

D. 172.16.1.27

E. All of the above

F. None of the above

Hint

Convert the mask to a prefix, separate network and host bits, and apply the relevant subnet-count or usable-host rule.

Answer D: 172.16.1.27

An ordinary host address must have valid octets, belong to the required address scope and avoid the subnet network and broadcast addresses. The address 172.16.1.27 belongs to private 172.16.0.0/12 and is an interior host of 172.16.1.0/24. The public address 9.0.0.1 does not meet the private-address requirement. Loopback and an octet of 256 fail the other checks.

Why each choice is right or wrong

A - Incorrect: 127/8 is reserved for loopback and is not an ordinary LAN interface assignment.

B - Incorrect: 9.0.0.1 is public unicast, so it fails the explicit RFC1918 private-address requirement.

C - Incorrect: An IPv4 octet must be 0-255; 256 makes this address syntactically invalid.

D - Correct: 172.16.1.27 is within private 172.16/12 and is neither the network nor broadcast of its /24.

E - Incorrect: All fails because loopback and the impossible .256 octet are not valid ordinary LAN host assignments.

F - Incorrect: A private usable host is offered, so none of the above is false.

Primary note proof

Study-note section NET23

RFC1918 private blocks are 10.0.0.0/8, 172.16.0.0/12 (through 172.31.255.255), and 192.168.0.0/16. They can be reused internally but are not globally routed as public destinations. A LAN may also use legitimately assigned public addresses; private is common, not mandatory. 127.0.0.0/8 is IPv4 loopback, commonly 127.0.0.1, for local protocol access without an external link. 255.255.255.255 is limited broadcast; 0.0.0.0 can identify an unconfigured source. Link-local/APIPA uses 169.254.0.0/16, with edge /24 blocks excluded from normal automatic selection.

Study-note section NET25

For ordinary broadcast LANs let h=32-p. Total addresses=2^h; usable hosts=2^h-2, reserving network and directed broadcast. Find the changing octet's increment as 256-mask octet, round the address down to a multiple, and extend through the next boundary minus one.

Study-note section NET22

Write IPv4 as four decimal octets 0-255, or as 32 binary bits. Use weights 128,64,32,16,8,4,2,1 within each octet. Thus 11000001 10000011 00011011 11111111 is 193.131.27.255. A value such as 257 is impossible. Syntactic validity differs from assignability: an address ending .0 or .255 can be a host under some prefixes.

Question 17 | Q00146

For the switching methods below, select all statements that are correct. In D, allocation on demand means reservation when a circuit is established.

A. Circuit Switching and Virtual Packet Switching methods reserve the required resources for the duration of the session during communication between end systems

B. Circuit switching technique uses store and forward method.

C. In message switching technique, it is not required to create a dedicated path.

D. In circuit switching techniques, resources are allocated on demand.

E. Packet switching can have nonuniform delay because packets share links and may queue.

Hint

Compare signal repetition, frame forwarding, packet routing and policy enforcement using the stated device or traffic assumptions.

Answer C, D, E: In message switching technique, it is not required to create a dedicated path.; In circuit switching techniques, resources are allocated on demand.; Packet switching can have nonuniform delay because packets share links and may queue.

Message switching stores and forwards whole messages without a dedicated end-to-end path. Circuit switching instead reserves resources when a call is established and retains them through the session. Packet switching shares links, so queueing can produce variable delay, although packet voice remains possible. Virtual-circuit forwarding state alone does not require resource reservation. These distinctions support the three selected statements without equating all connection-oriented methods.

Why each choice is right or wrong

A - Incorrect: Circuit switching reserves resources, but virtual-circuit packet switching need not reserve them throughout a session.

B - Incorrect: Circuit switching uses an established reserved path; complete-message or packet buffering describes store-and-forward switching.

C - Correct: Message switching forwards stored messages without requiring a dedicated end-to-end circuit.

D - Correct: Circuit resources are allocated when a connection is requested and reserved for its session.

E - Correct: Shared links and queueing can give packets different delays.

Primary note proof

Study-note section NET31

> Circuit switching sets up a path with reserved resources, transfers data, then releases it. Predictable allocated bandwidth trades against setup/blocking and wasted reservation during silence. A traditional telephone call is the standard example. Packet switching divides data into packets that share links statistically; queueing can add variable delay and loss. This does not make modern voice-over-packet impossible: buffering, scheduling and capacity planning manage it.

Study-note section NET31

> Datagram packets are forwarded independently. Virtual circuits establish forwarding state, but resource reservation is optional, not a necessary property of every virtual circuit. Message switching stores a complete message before forwarding, without a dedicated end-to-end path. Packet store-and-forward waits for the full packet/frame; cut-through starts after enough header arrives; fragment-free historically waits through the initial collision-sensitive portion. No routing algorithm guarantees that every packet always takes the geometrically shortest route.

Circuit Switching: In circuit switching, two communicating stations are connected by a dedicated communication path which consists of intermediate nodes in the network and the links that connect these nodes.
It involved the following three distinct steps
• Circuit Establishment: To establish an end-to-end connection before any transfer of data.
• Data transfer: Transfer data is from the source to the destination. The data may be analog or digital, depending on the nature of the network. The connection is generally full-duplex.
• Circuit disconnect: Terminate connection at the end of data transfer. Signals must be propagated to deallocate the dedicated resources.

Data Communication and Computer Networking module | PDF page 20 | lines 27-36

Message Switching:
Packet Switching: Packet switching was designed to address the shortcomings of circuit switching in dealing with data communication. Unlike circuit switching where communication is continuous along a dedicated circuit, in packet switching, communication is discrete in form of packets.
The three switching modes to choose from are:
• Cut-through
• Store-and-forward
• Fragment-free

Question 18 | Q00147

Which information is not correct about the IP address 172.16.35.72/27?

A. 172.16.35.64 is one of the subnet addresses.

B. The default mask for the network is 255.255.0.0.

C. Itis Class B address.

D. The number of bits used for the host address is 5.

E. The broadcast address of the second subnet is 172.16.35.255

Hint

Convert the mask to a prefix, separate network and host bits, and apply the relevant subnet-count or usable-host rule.

Answer E: The claimed second-subnet broadcast is wrong

For /27, five host bits give blocks of 32 in the last octet. The block containing .72 is .64-.95, with broadcast .95. If second subnet means the second /27 inside .35.0/24, its broadcast is .63; neither reading gives .255. The historical class is B and default mask /16, although the actual subnet mask is /27.

Why each choice is right or wrong

A - Incorrect: The .64 boundary is a valid /27 subnet start and contains host .72.

B - Incorrect: As a historical Class B address, its default mask is /16, even though the supplied actual prefix is /27.

C - Incorrect: First octet 172 is in the historical Class B range 128-191.

D - Incorrect: A 32-bit IPv4 address with /27 leaves exactly five bits for the host portion.

E - Correct: The second /27 in the local /24 broadcasts at .63; the containing subnet broadcasts at .95, never .255.

Primary note proof

Study-note section NET25

> For ordinary broadcast LANs let h=32-p. Total addresses=2^h; usable hosts=2^h-2, reserving network and directed broadcast. Find the changing octet's increment as 256-mask octet, round the address down to a multiple, and extend through the next boundary minus one.

Study-note section NET22

> Historical classes use leading patterns: A 0 with /8, B 10 with /16, C 110 with /24; D 1110 is multicast and E 1111 reserved. Ordinary class-A first octets are 1-126 because 0 and 127 have special uses. B spans 128-191 and C 192-223. Default usable counts are 2^24-2, 2^16-2 and 254. Modern CIDR requires the actual prefix and overrides class defaults.

Which one of the following is false about HTTP protocol?

A. Itis a stateless protocol

B. An HTTP message body can be empty

C. Itis a protocol used for communication between a web browser and a web server

D. None of the above

Hint

Identify the requested service or delivery guarantee, then distinguish application roles, transport behavior and address configuration.

Answer D: None of the listed HTTP claims is false

All three substantive choices agree with NET21: HTTP is stateless, a message body may be absent, and HTTP defines web request/response exchanges such as those between browsers and servers. The negative stem therefore has no false statement among A-C; D is the offered none-of-the-above response.

Why each choice is right or wrong

A - Incorrect: Statelessness is an HTTP property given in NET21, so this statement is true rather than false.

B - Incorrect: An HTTP message can omit its body, making this statement true.

C - Incorrect: Browser-to-web-server requests and responses are an ordinary use of HTTP, consistent with its web semantics.

D - Correct: A, B and C are all true, so none supplies the false statement requested.

Primary note proof

Study-note section NET21

> HTTP defines web request/response semantics; it is stateless, and a message body may be absent. HTTPS adds TLS protection. POP3 is most commonly used for:

A. Managing devices (such as routers and switches) on a network

B. Mapping IP addresses to hardware addresses

C. Sending emails from an email client to an email server

D. Retrieving emails from an email server to an email client

Hint

Use the cited note definitions to identify the requested function or scope, then check each alternative against that same rule.

Answer D: Retrieving emails from an email server to an email client

The module explicitly says POP3 is used to receive mail. Retrieval from a mail server into a client is that receiving function. Evidence: PDF 28, 17, 18.

Why each choice is right or wrong

A - Incorrect: Management is associated with SNMP, not POP3 (PDF 28, 17, 18.)

B - Incorrect: Address-to-hardware mapping is ARP (PDF 28, 17, 18.)

C - Incorrect: Sending mail is the SMTP role (PDF 28, 17, 18.)

D - Correct: Receiving mail matches the explicit POP3 statement (PDF 28, 17, 18.)

C. Transport layer to Network layer

D. Transport layer to Data link layer

E. Network layer to Data link layer

Hint

Match the requested scope or data unit to the layer duties in the note; distinguish hop delivery from end-to-end process delivery.

Answer E: Network layer to Data link layer

ARP takes a logical IP address and resolves the physical MAC address, connecting network addressing to data-link addressing. Evidence: PDF 17, 15, 15.

Why each choice is right or wrong

A - Incorrect: Application to network omits the MAC destination of the mapping (PDF 17, 15, 15.)

B - Incorrect: Application to transport is not IP-to-MAC resolution (PDF 17, 15, 15.)

C - Incorrect: Transport ports are not the known IP address (PDF 17, 15, 15.)

Question 22 | Q00206

What is the first usable host addressing of prefix 172.105.180.0/21?

A. 172.105.180.1

B. 172.105.170.1

C. 172.105.175.1

D. 172.105.176.1

E. 172.105.172.1

Hint

Convert the mask to a prefix, separate network and host bits, and apply the relevant subnet-count or usable-host rule.

Answer D: 172.105.176.1

A /21 mask is 255.255.248.0, giving third-octet blocks of eight. 180 lies in the 176-183 block; masking therefore yields network 172.105.176.0, not 172.105.180.0. The first usable ordinary host is one address above the network boundary: 172.105.176.1. NET24 explicitly explains this unaligned host/prefix example.

Why each choice is right or wrong

A - Incorrect: This address is inside the block but is not its first usable address; the block begins at third octet 176.

B - Incorrect: Third octet 170 lies below the 176-183 range of the actual /21 block.

C - Incorrect: Third octet 175 is outside the block, immediately below its network boundary.

D - Correct: The network is 172.105.176.0/21, so its first usable ordinary host is 172.105.176.1.

E - Incorrect: Third octet 172 belongs to a different /21 block and is outside the specified network.

Primary note proof

Study-note section NET24

Compute network=address AND mask. Host bits zero identify the block start; host bits one give broadcast. With 172.16.28.252/20, the third octet is grouped in blocks of 16, so the network is 172.16.16.0 and broadcast 172.16.31.255. A written host/prefix such as 172.105.180.0/21 need not be an aligned block label: masking yields 172.105.176.0/21.

Study-note section NET25

E. A source address if a device is sending to itself

Hint

Use the cited note definitions to identify the requested function or scope, then check each alternative against that same rule.

Answer A: Limited broadcast on the local subnet

All 32 one bits form 255.255.255.255, the limited-broadcast destination in NET23. Its scope is the local network; routers do not ordinarily forward it to another subnet. Self-reference uses loopback, while an unconfigured source can use 0.0.0.0. Thus the all-ones value is a destination broadcast, not either kind of source address.

Why each choice is right or wrong

A - Correct: The all-ones IPv4 address targets limited broadcast on the sender’s local network.

B - Incorrect: Limited broadcast is local in scope; it is not the destination for another subnet’s directed broadcast.

C - Incorrect: Sending to the host itself uses loopback, commonly 127.0.0.1, rather than the all-ones address.

D - Incorrect: An unconfigured source can use all-zero 0.0.0.0, not all-one 255.255.255.255.

E - Incorrect: The all-ones address is a broadcast destination, not a self-reference source address.

Primary note proof

Study-note section NET23

RFC1918 private blocks are 10.0.0.0/8, 172.16.0.0/12 (through 172.31.255.255), and 192.168.0.0/16. They can be reused internally but are not globally routed as public destinations. A LAN may also use legitimately assigned public addresses; private is common, not mandatory. 127.0.0.0/8 is IPv4 loopback, commonly 127.0.0.1, for local protocol access without an external link. 255.255.255.255 is limited broadcast; 0.0.0.0 can identify an unconfigured source. Link-local/APIPA uses 169.254.0.0/16, with edge /24 blocks excluded from normal automatic selection.

Study-note section NET11

Routers forward IP packets between networks using destination prefixes and next hops. They separate broadcast domains and normally do not forward local link broadcasts. A default gateway is usually a router, while a protocol gateway can translate application formats; therefore a gateway is not inherently a device that implements every OSI layer.

Address Space: An address space is the total
number ofaddresses used by the protocol.
• If a protocol uses N bits to define an address,
the address space is 2N
because each bit can
have twodifferent values (0 or 1) and N bits
can have 2N values.
• IPv4 uses 32-bit addresses, which means that
the address space is 232 or 4,294,967,296
(more than 4billion).
Notations: There are two notations to show an IPv4 address:
• Binary notation: The IPv4 address is displayed
as 32bits. ex. 11000001 10000011 00011011
11111111
• Dotted decimal notation: To make the IPv4
address easier to read, Internet addresses are
usually written in decimal form with a decimal
point (dot) separatingthe bytes. Each byte (octet)
is 8 bits hence each number in dotted-decimal
notation is a value rangingfrom 0 to 255. Ex.
129.11.11.239

Data Communication and Computer Networking module | PDF page 19 | lines 23-36

Classful addressing : In classful addressing, the
addressspace is divided into five classes: A, B, C,
D, and E.
• Netid and Hostid In classful addressing, an IP

addressin class A, B, or C is divided into netid
and hostid.
Subnetting: It allows a network to be split into several
parts for internal use but still act like a single network to
the outsideworld.
• To implement subnetting, the router needs a
subnet mask that indicates the split between
network + subnet number and host. Ex.
255.255.252.0/22. A‖/22‖ to indicate that the
subnet mask is 22 bits long.

Question 24 | Q00208

Which of the following technologies can allow a host with IP address 10.0.0.1 to access the internet?

A. NAT

B. Route import

C. Dynamic route

D. Static route

Hint

Separate address width, syntax, reserved scope and the supplied prefix or historical classful convention.

Answer A: NAT

The module prescribes translation of private internal addresses to a public address for Internet access. Conditional on the stem treating 10.0.0.1 as private, NAT is the offered mechanism. Evidence: PDF 19, 48, 19.

Why each choice is right or wrong

A - Correct: Private-to-public translation is exactly NAT (PDF 19, 48, 19.)

B - Incorrect: Importing routing information is not address translation (PDF 19, 48, 19.)

C - Incorrect: Dynamic path selection does not itself translate an internal address (PDF 19, 48, 19.)

D - Incorrect: Static routes do not themselves translate an internal address (PDF 19, 48, 19.)

Primary note proof

Study-note section NET29

A private host such as 10.0.0.1 commonly reaches the public Internet through NAT at a gateway, together with valid routing and a public external address. NAT alone does not supply a physical connection or DNS. A public address does not automatically grant permission to use it; both public and private unicast addresses can be used on a LAN under the correct allocation and subnet.

Study-note section NET30

Routing computes paths; forwarding chooses a next hop for an individual packet. Select the matching route with the longest prefix, then apply the routing system's tie-breaking criteria. A default /0 matches when nothing more specific does. Static routes are configured; dynamic protocols exchange reachability. Distance vector uses neighbor estimates, while link state distributes link information and computes shortest paths. Interior protocols operate within an autonomous system; BGP exchanges routes between systems.

NAT (Network Address Translation): The scarcity of
network addresses in IPv4 led to the development of IPv6.
Due to this, we need to use private IP address inside the
organization and translate it to public IP address using
NAT.

Data Communication and Computer Networking module | PDF page 48 | lines 29-40

Network Address Translation (NAT)
NAT translates the IP addresses of computers in a local
network to a single IP address. This address is often used
by the router that connects the computers to the Internet.
The router can be connected to a DSL modem, cable
modem, T1 line, or even a dial-up modem. When other
computers on the Internet attempt to access computers
within the local network, they only see the IP address of
the router. This adds an extra level of security, since the
router can be configured as a firewall, only allowing
authorized systems to access the computers within the
network.

ROUTING AND ROUTING PROTOCOLS
Routing is the act of moving information across an
internetwork from a source to a destination. At the heart of
such protocol is the routing algorithm that determines the
path for a packet.
• Routing requires a host or a router to have a
routingtable which is constructed by the routing
algorithm.

• There are wo kinds of routing algorithms (routing tables): nonadaptive (static) and adaptive (dynamic)
• And two kinds of protocols
o Interior routing protocols
o Exterior routing protocols

Question 25 | Q00267

Which of the following protocol is used to define how messages are formatted and transmitted on the World Wide Web?

A. IP

B. FTP

C. SMTP

D. HTTP

Hint

Identify the requested service or delivery guarantee, then distinguish application roles, transport behavior and address configuration.

Answer D: HTTP

The question asks for the application protocol defining World Wide Web message exchange. HTTP defines web request/response semantics. IP supplies packet delivery beneath applications; FTP transfers files through its own protocol; SMTP submits and relays email. Those services do not define browser/server HTTP message formatting and exchange.

Why each choice is right or wrong

A - Incorrect: IP supplies best-effort packet delivery and does not define World Wide Web application-message semantics.

B - Incorrect: FTP is a file-transfer protocol with separate control and data connections, not the web-message protocol.

C - Incorrect: SMTP submits and relays mail rather than defining World Wide Web exchanges.

D - Correct: HTTP supplies web request/response semantics, matching the message formatting and transmission role asked about.

Primary note proof

Study-note section NET21

HTTP defines web request/response semantics; it is stateless, and a message body may be absent. HTTPS adds TLS protection. FTP transfers files using control and separate data connections; it is

not the same protocol as SFTP. SMTP submits and relays mail; POP3 retrieves messages and IMAP accesses/synchronizes server mailboxes. Saying SMTP handles both sending and end-user mailbox retrieval is inaccurate.

Study-note section NET16

IP supplies connectionless best-effort packet delivery, not end-to-end ordering or retransmission. IPv4 addresses are 32 bits. Its minimum header is 20 bytes and can grow to 60 bytes; it is not a 32-bit header. IHL counts 32-bit words; total length includes header and payload. TTL limits lifetime across routers; the protocol field identifies TCP, UDP or another upper-layer protocol.

Question 26 | Q00347

What is the bit pattern for the first octet of a class -B network address?

A. 110XXXXX

B. 1110XXXXX

C. 10XXXXXX

D. 0XXXXXXX

Hint

Convert the mask to a prefix, separate network and host bits, and apply the relevant subnet-count or usable-host rule.

Answer C: 10XXXXXX

In historical classful IPv4 addressing, Class B starts with the two fixed bits 10; the remaining six bits of the first octet vary. This gives first-octet decimal values 128-191. The alternatives instead begin with the Class C, Class D and Class A patterns respectively; B also prints too many total bits for an octet.

Why each choice is right or wrong

A - Incorrect: The fixed prefix 110 identifies historical Class C rather than Class B.

B - Incorrect: The fixed prefix 1110 identifies multicast Class D; the printed pattern also exceeds eight positions.

C - Correct: Class B fixes the first two bits to 10 and permits six remaining first-octet bits.

D - Incorrect: A leading zero identifies historical Class A, not Class B.

Primary note proof

Study-note section NET22

> Historical classes use leading patterns: A 0 with /8, B 10 with /16, C 110 with /24; D 1110 is multicast and E 1111 reserved. Ordinary class-A first octets are 1-126 because 0 and 127 have special uses. B spans 128-191 and C 192-223. Default usable counts are 2^24-2, 2^16-2 and 254. Modern CIDR requires the actual prefix and overrides class defaults.

Study-note section NET22

> Write IPv4 as four decimal octets 0-255, or as 32 binary bits. Use weights 128,64,32,16,8,4,2,1 within each octet. Thus 11000001 10000011 00011011 11111111 is 193.131.27.255. A value such as 257 is impossible. Syntactic validity differs from assignability: an address ending .0 or .255 can be a host under some prefixes.

Question 27 | Q00348

Which OSI model layer is responsible for flow control?

A. Application Layer

B. Transport Layer

C. Session Layer

D. Presentation Layer

Hint

Match the requested scope or data unit to the layer duties in the note; distinguish hop delivery from end-to-end process delivery.

Answer B: Transport Layer

Among these four layers transport explicitly provides end-to-end flow control. Data link also provides flow control but is not offered. Evidence: PDF 16, 16, 16, 16.

Why each choice is right or wrong

A - Incorrect: Application provides access to resources (PDF 16, 16, 16, 16.)

B - Correct: Transport explicitly carries out flow control (PDF 16, 16, 16, 16.)

C - Incorrect: Session manages dialogs and checkpoints (PDF 16, 16, 16, 16.)

D - Incorrect: Presentation handles translation, compression and encryption (PDF 16, 16, 16, 16.)

Primary note proof

Study-note section NET17

TCP offers a reliable ordered byte stream using sequence numbers, acknowledgments, retransmission and windows. Flow control protects the receiver; congestion control protects network capacity. UDP sends independent datagrams with ports and a checksum but no built-in setup, delivery guarantee, retransmission or ordering. Live interactive traffic may choose UDP when late data is less useful than lost data. Application protocols can add reliability over UDP.

Study-note section NET19

OSI session roles establish/manage dialogs and can coordinate checkpoints so transfer resumes after interruption. Presentation roles translate encodings and handle compression/encryption. Compression reduces representation size; encryption hides content and need not shrink it. Application protocols provide services directly to applications. Practical implementations distribute these functions differently; TLS is not proof of a separate physical presentation-layer device.

• At the sending side, the transport layer receives data from the session layer, divides it into units called segments and sends it to the network layer.
• To ensure process to process delivery the transport layer makes use of port address to identify the data from the sending and receiving process.
• The data can be transported in a connection oriented or connectionless manner.
• The Transport layer is responsible for segmentation and reassembly of the message into segments which bear sequence numbers.
• The transport layer also carries out flow control and error control functions; but unlike data link layer these are end to end rather than node to node.
• The main responsibility of the transport layer is process to process delivery of the entire message

Data Communication and Computer Networking module | PDF page 16 | lines 43-47

Application Layer
• The application layer enables the user to communicate its data to the receiver by providing certain services.
• The main Responsibility of Application layer is to provide the user access to network resources.

Data Communication and Computer Networking module | PDF page 16 | lines 18-32

Session Layer
• The session layer establishes a session between the communicating devices called dialog and synchronizes their interaction. It is the responsibility of the session layer to establish and synchronize the dialogs. It is also called the network dialog controller.
• The session layer at the sending side accepts data from the presentation layer adds checkpoints to it called sync bits and passes the data to the transport layer. At the receiving end the session layer receives

data from the transport layer removes the checkpoints inserted previously and passes the data to the presentation layer. So, the main responsibility of session layer is dialog control and synchronization.

Data Communication and Computer Networking module | PDF page 16 | lines 33-42

Presentation Layer
• The communicating devices may be having different platforms. The presentation layer performs translation, encryption and compression of data.
• The presentation layer receives the data from the application layer adds header which contains information related to encryption and compression and sends it to the session layer.
• So, the main responsibility of the Presentation layer is translation, compression and encryption.

Question 28 | Q00349

Which of the following networking device is used in physical layer?

A. Bridge

B. Router

C. Switch

D. Hub

Hint

Match the requested scope or data unit to the layer duties in the note; distinguish hop delivery from end-to-end process delivery.

Answer D: Hub

An active hub is a multiport repeater, and a repeater operates only at the physical layer. Evidence: PDF 12, 11, 12, 12, 12.

Why each choice is right or wrong

A - Incorrect: Bridge filters based on MAC (PDF 12, 11, 12, 12, 12.)

B - Incorrect: Router routes by IP (PDF 12, 11, 12, 12, 12.)

C - Incorrect: Switch filters/forwards by MAC (PDF 12, 11, 12, 12, 12.)

D - Correct: Active hub repeats physical signals (PDF 12, 11, 12, 12, 12.)

Primary note proof

Study-note section NET09

A repeater regenerates layer-1 signals without inspecting destination addresses. An active hub is a multiport repeater: it repeats incoming signals onto other ports, placing half-duplex endpoints in one collision domain. A passive hub is a connector. A hub neither learns MAC addresses nor eliminates collisions. An endpoint such as a network printer consumes services; routers, hubs and access points are intermediary devices.

Study-note section NET10

A bridge or ordinary Ethernet switch operates at layer 2. It learns source-MAC-to-port mappings, looks up the destination, forwards a known unicast to its port, filters it if the destination is on the incoming segment, and floods an unknown unicast or broadcast within its VLAN. A switch does not always send only to one destination port. Wireless access points normally bridge wireless and wired link-layer traffic.

Study-note section NET11

Routers forward IP packets between networks using destination prefixes and next hops. They separate broadcast domains and normally do not forward local link broadcasts. A default gateway is usually a router, while a protocol gateway can translate application formats; therefore a gateway is not inherently a device that implements every OSI layer.

Hint

Answer A: 192.168.15.0/25 for LAN 1, 192.168.15.128/26 for LAN 2, and 192.168.15.192/27 for LAN

With Q29 context (100,60,29 hosts), A allocates 128,64,32 total addresses without overlap within 192.168.15.0/24. These are the smallest offered powers of two meeting the host counts; other choices fail total capacity, prefix syntax or membership. Evidence: PDF 19, 19.

Why each choice is right or wrong

A - Correct: The /25,/26,/27 division is sufficient and stays within the parent (PDF 19, 19.)

B - Incorrect: First /26 has only 64 total addresses for 100 hosts; third block is outside the parent (PDF 19, 19.)

C - Incorrect: First /27 has only 32 total for 100; third block is outside the parent (PDF 19, 19.)

• IPv4 uses 32-bit addresses, which means that

11111111
• Dotted decimal notation: To make the IPv4
address easier to read, Internet addresses are
usually written in decimal form with a decimal
point (dot) separatingthe bytes. Each byte (octet)
is 8 bits hence each number in dotted-decimal
notation is a value rangingfrom 0 to 255. Ex.

Question 31 | Q00352

Which network and mask would you use for the WAN link to save the most address space?

A. 192.168.11.240/27

B. 192.168.11.240/28

C. 192.168.11.240/29

D. 192.168.11.240/30

Hint

Use the cited note definitions to identify the requested function or scope, then check each alternative against that same rule.

Answer D: 192.168.11.240/30

Of the offered prefixes, /30 leaves the fewest host bits: two, giving four total addresses. It therefore consumes the least address space for a two-endpoint WAN under the conventional allocation implied by the options. Evidence: PDF 19, 19.

Why each choice is right or wrong

A - Incorrect: /27 consumes 32 addresses; .240 is also unaligned as a /27 network (PDF 19, 19.)

B - Incorrect: /28 consumes 16 addresses (PDF 19, 19.)

C - Incorrect: /29 consumes eight addresses (PDF 19, 19.)

D - Correct: /30 consumes four addresses and .240 is aligned (PDF 19, 19.)

Primary note proof

Study-note section NET28

> A conventional /30 has four addresses and two usable endpoints; check the link and addressing assumptions when selecting a WAN prefix. RFC3021 permits /31 on supported point-to-point links: both addresses are endpoints, so the subtract-two rule does not apply. /32 identifies one address/host route. Do not claim /30 is universally the smallest valid link prefix.

Study-note section NET25

> For ordinary broadcast LANs let h=32-p. Total addresses=2^h; usable hosts=2^h-2, reserving network and directed broadcast. Find the changing octet’s increment as 256-mask octet, round the address down to a multiple, and extend through the next boundary minus one.

Question 32 | Q00535

Among the following one helps to resolve internet name into IP Address.

A. Domain Name System

B. Address Resolution Protocol

C. User Datagram Protocol

D. Transmission Control Protocol

Hint

Separate address width, syntax, reserved scope and the supplied prefix or historical classful convention.

Answer A: Domain Name System

DNS provides external naming in contrast to locally stored addresses. ARP instead resolves an already-known IP to a hardware address. Evidence: PDF 18, 65, 17, 18.

Why each choice is right or wrong

A - Correct: Domain Name Service is the naming mechanism (PDF 18, 65, 17, 18.)

B - Incorrect: ARP maps IP to physical address, not domain to IP (PDF 18, 65, 17, 18.)

C - Incorrect: UDP provides process delivery (PDF 18, 65, 17, 18.)

D - Incorrect: TCP provides reliable connection-oriented process delivery (PDF 18, 65, 17, 18.)

Primary note proof

Study-note section NET20

> DNS resolves names to records, including IPv4 A and IPv6 AAAA addresses; it can use UDP or TCP port 53. DHCP dynamically leases IPv4 settings, commonly address, mask, gateway and DNS server. Its basic exchange is discover, offer, request, acknowledge. IP itself does not assign addresses.

Study-note section NET20

> ARP resolves an on-link IPv4 next hop to a link address, using a broadcast request and normally unicast reply. For an off-subnet target, ARP resolves the gateway, not the remote target's MAC. It bridges the network/link addressing boundary and is often classified at the link layer; calling ARP simply a network protocol uses a loose textbook convention. RARP reverses hardware-to-IP lookup; BOOTP/DHCP support boot configuration. ICMP reports errors and diagnostics; IGMP manages IPv4 multicast membership. These are separate companion protocols, not four pieces whose combination is IP.

Study-note section NET17

> TCP offers a reliable ordered byte stream using sequence numbers, acknowledgments, retransmission and windows. Flow control protects the receiver; congestion control protects network capacity. UDP sends independent datagrams with ports and a checksum but no built-in

setup, delivery guarantee, retransmission or ordering. Live interactive traffic may choose UDP when late data is less useful than lost data. Application protocols can add reliability over UDP.

TCP - Transmission Control Protocol: TCP is a reliable
connection-oriented, reliable protocol. i.e. a connection is
established between the sender and receiver before the data can
be transmitted. It divides the data it receives from the upper
layer into segments and tags a sequence number to each
segment which is used at the receiving end for reordering of
data.
UDP - User Datagram Protocol: UDP is a simple protocol
used for process to process transmission. It is an unreliable,
connectionless protocol for applications that do not require flow

control or error control. It simply adds port address, checksum and length information to the data it receives from the upper layer.

Question 33 | Q00536

You have been asked to create a subnet that supports 24 hosts. What subnet mask you use?

A. 255.255.255.224

B. 255.255.255.248

C. 255.255.255.240

D. 255.255.255.252

Hint

Convert the mask to a prefix, separate network and host bits, and apply the relevant subnet-count or usable-host rule.

Answer A: 255.255.255.224

A /27 mask (224=11100000) leaves five bits, giving 32 total addresses, enough for 24 hosts. All other options have fewer than 24 total addresses, so reservations do not affect the selection. Evidence: PDF 19, 19.

Why each choice is right or wrong

A - Correct: 224 leaves five bits and 32 addresses (PDF 19, 19.)

B - Incorrect: 248 leaves three bits and eight addresses (PDF 19, 19.)

C - Incorrect: 240 leaves four bits and 16 addresses (PDF 19, 19.)

D - Incorrect: 252 leaves two bits and four addresses (PDF 19, 19.)

Primary note proof

For H hosts, choose the smallest h satisfying 2^h-2≥H, then p=32-h. For 24 hosts use /27; 52 or 57 use /26; 100 use /25; 500 use /23. For at least six equal subnets choose b=3. A Class C /24 split to /27 yields eight subnets. Always check both the number of subnets and the host capacity.

Assume you are asking to establish a network using 50(fifty) computers in mesh topology. How many cables required to establish a network?

A. 2225

B. 1225

C. 1450

D. 2450

Hint

Draw the links and identify shared components, alternate paths and the effect of the specified failure or growth requirement.

Answer B: 1225

Full-mesh cable count is n(n-1)/2, so 50×49/2=1225 distinct undirected cables. Each cable serves a pair and must not be counted twice. Evidence: PDF 23.

Question 36 | Q00553

One of the following is false the characteristics of controlled access in datalink layer.

A. Only one station is transmit at a time.

B. There will be a chance of collision.

C. Devices wishing to transmit must wait their turn.

D. Some deterministic networks use token passing.

Hint

Match the requested scope or data unit to the layer duties in the note; distinguish hop delivery from end-to-end process delivery.

Answer B: There will be a chance of collision.

The module characterizes controlled access as permission-based and describes the medium-control objective as preventing simultaneous speakers. Thus the collision-chance characterization conflicts with its ideal controlled-access model. Evidence: PDF 21.

Why each choice is right or wrong

A - Incorrect: One transmitter at a time matches controlled permission (PDF 21.)

B - Correct: Colliding simultaneous access is inconsistent with the described controlled-access rule (PDF 21.)

C - Incorrect: Waiting for permission follows get permission (PDF 21.)

D - Incorrect: Token passing is explicitly in controlled access (PDF 21.)

Primary note proof

Study-note section NET14

> Controlled access uses polling, reservations or a token to grant turns; correctly coordinated access avoids contention collisions. Channelization divides frequency, time or code resources. Stop-and-wait sends one frame and waits for ACK, retransmitting on timeout; sequence bits distinguish duplicates. Sliding windows permit multiple unacknowledged frames. Link reliability/flow control is hop-local; transport reliability/flow control is end-to-end. Ethernet detects corruption but does not itself guarantee reliable delivery.

Study-note section NET14

> Random access allows contention: ALOHA sends opportunistically; CSMA senses before sending. In legacy half-duplex Ethernet, CSMA/CD detects collision, sends a jam indication, stops, and retries after random backoff. The jam signals a collision, not its clearance. Wi-Fi 802.11 uses CSMA/CA with waiting/backoff and acknowledgments; sensing does not eliminate hidden-terminal collisions.

Question 38 | Q00560

Which organizational networking term describes exposing selected internal services to approved users outside the organization?

A. Internet

B. Extranet

C. intranet

D. All

Hint

Match the requested scope or data unit to the layer duties in the note; distinguish hop delivery from end-to-end process delivery.

Answer B: Extranet

Access scope determines the answer: an extranet extends selected organizational services to approved outsiders. An intranet serves members internally, while the Internet is the global network of networks. Neither organizational term determines geographic size or requires a particular physical connection. The question therefore asks about controlled external access rather than treating every external link as the same network category.

Why each choice is right or wrong

A - Incorrect: The Internet is the global network of networks; it does not specifically name controlled access to an organization's selected services.

B - Correct: An extranet exposes selected services to approved outsiders.

C - Incorrect: An intranet describes internal organizational access.

D - Incorrect: The three terms have different scopes, so all is not the requested category.

Primary note proof

Study-note section NET02

> An intranet serves an organization internally; an extranet exposes selected services to approved outsiders. Neither term alone specifies geographic size. A client requests a service; a server supplies it. Peer systems may perform both roles. Dedicated servers concentrate on service workloads but can still be clients of DNS, backup or update services. A ten-user cutoff is a teaching guideline, not a technical law. Centralization simplifies administration but creates dependencies; peer networks still need security.

Study-note section NET02

> PAN connects personal devices, such as Bluetooth accessories. LAN covers a local building or campus; MAN spans a metropolitan region; WAN connects distant regions. Device count alone does not determine the category. The Internet is a global network of networks, commonly the largest example of a WAN.

Peer-to-Peer (Point-to-point): Two systems can be connected Point-to-Point, or in other words back-to-back fashion. They both reside on same level and called peers.
There can be hybrid network which involves network architecture of both the above types.

Class B private IP address space ranges:

A. 10.0.0.0----------19.255.255.255

B. 128.12.0.0--------191.24.255.255

C. 172.16.0.0--------172.31.255.255

D. 192.168.0.0------192.168.255.255

Hint

Separate address width, syntax, reserved scope and the supplied prefix or historical classful convention.

Answer C: 172.16.0.0 through 172.31.255.255

The private allocation within the historical Class B range is 172.16.0.0/12. Its twelve fixed bits leave first octet 172 and second octets 16-31, inclusive. The 192.168 range is also private but lies in historical Class C space; the other printed ranges are not RFC1918 private allocations.

Why each choice is right or wrong

A - Incorrect: The private 10/8 block ends at 10.255.255.255; extending it through first octet 19 includes public space.

B - Incorrect: This broad portion of historical Class B space is not a designated RFC1918 private allocation.

C - Correct: The 172.16/12 private block spans exactly 172.16.0.0 through 172.31.255.255.

D - Incorrect: 192.168/16 is private, but it lies in historical Class C space rather than Class B.

Primary note proof

Study-note section NET23

> RFC1918 private blocks are 10.0.0.0/8, 172.16.0.0/12 (through 172.31.255.255), and 192.168.0.0/16. They can be reused internally but are not globally routed as public destinations. A LAN may also use legitimately assigned public addresses; private is common, not mandatory. 127.0.0.0/8 is IPv4 loopback, commonly 127.0.0.1, for local protocol access without an external link. 255.255.255.255 is limited broadcast; 0.0.0.0 can identify an unconfigured source. Link-local/APIPA uses 169.254.0.0/16, with edge /24 blocks excluded from normal automatic selection.

Ordinary class-A first octets are 1-126 because 0 and 127 have special uses. B spans 128-191 and C 192-223. Default usable counts are 2^24-2, 2^16-2 and 254. Modern CIDR requires the actual prefix and overrides class defaults.

Question 40 | Q00570

Among the protocol one is used to provide remote access to servers and networking devices.

A. HTTP

B. SMTP

C. Telnet (terminal emulation protocol)

D. FTP

Hint

Compare signal repetition, frame forwarding, packet routing and policy enforcement using the stated device or traffic assumptions.

Answer C: Telnet (terminal emulation protocol)

TELNET is explicitly the Virtual Terminal protocol, which fits terminal emulation for remote access to servers or devices. Evidence: PDF 18.

Why each choice is right or wrong

A - Incorrect: HTTP is not the listed virtual-terminal service (PDF 18.)

B - Incorrect: SMTP is electronic mail (PDF 18.)

C - Correct: TELNET is explicitly virtual terminal (PDF 18.)

D - Incorrect: FTP is file transfer (PDF 18.)

Primary note proof

Study-note section NET21

Usual service ports: FTP control 21, SSH 22, Telnet 23, SMTP relay 25, DNS 53, HTTP 80, POP3 110, IMAP 143, HTTPS 443. Telnet provides unencrypted remote terminals; SSH protects remote access. Servers can be configured on other ports. A browser's HTTP exchange does not determine the physical duplex mode of its network interface.

Study-note section NET21

HTTP defines web request/response semantics; it is stateless, and a message body may be absent. HTTPS adds TLS protection. FTP transfers files using control and separate data connections; it is not the same protocol as SFTP. SMTP submits and relays mail; POP3 retrieves messages and IMAP accesses/synchronizes server mailboxes. Saying SMTP handles both sending and end-user mailbox retrieval is inaccurate.

Question 41 | Q00574

The function of protocols in transport layer (TCP and UDP) includes following except,

A. Segment upper-layer application data.

B. Establish end-to-end operations.

C. Provide flow control

D. Addressing packets

Hint

Match the requested scope or data unit to the layer duties in the note; distinguish hop delivery from end-to-end process delivery.

Answer D: Addressing packets

Transport segments upper data, provides end-to-end process operations, and may provide flow control through TCP. Logical packet addressing belongs to network delivery. Not every UDP operation provides flow control.

Why each choice is right or wrong

A - Incorrect: Segmentation is explicit transport work

B - Incorrect: Process-to-process delivery is end-to-end

C - Incorrect: Flow control is supported by the transport layer, though not UDP

D - Correct: IP packet addressing is assigned to the network layer

Primary note proof

Study-note section NET17

TCP offers a reliable ordered byte stream using sequence numbers, acknowledgments, retransmission and windows. Flow control protects the receiver; congestion control protects network capacity. UDP sends independent datagrams with ports and a checksum but no built-in setup, delivery guarantee, retransmission or ordering. Live interactive traffic may choose UDP when late data is less useful than lost data. Application protocols can add reliability over UDP.

Study-note section NET16

IP supplies connectionless best-effort packet delivery, not end-to-end ordering or retransmission. IPv4 addresses are 32 bits. Its minimum header is 20 bytes and can grow to 60 bytes; it is not a 32-bit header. IHL counts 32-bit words; total length includes header and payload. TTL limits lifetime across routers; the protocol field identifies TCP, UDP or another upper-layer protocol.

• At the sending side, the transport layer receives data from the session layer, divides it into units called segments and sends it to the network layer.
• To ensure process to process delivery the transport layer makes use of port address to identify the data from the sending and receiving process.
• The data can be transported in a connection oriented or connectionless manner.
• The Transport layer is responsible for segmentation and reassembly of the message into segments which bear sequence numbers.
• The transport layer also carries out flow control and error control functions; but unlike data link layer these are end to end rather than node to node.

• The network layer at the sending side accepts data from the transport layer, divides it into packets, addsaddressing information in the header and passes it tothe data link layer.

• The network layer is responsible for source todestination of delivery of data.
• The network layer uses logical address commonlyknown as IP address to recognize devices on the network.
• Each packet is independent of the other and may travelusing different routes to reach the receiver hence may arrive out of turn at the receiver (Routing).
• The Network layer does not perform any flow controlor error control
• The main responsibility of Network Layer is transmission of packets from source to destination

Data Communication and Computer Networking module | PDF page 18 | lines 9-21

TCP - Transmission Control Protocol: TCP is a reliable connection-oriented, reliable protocol. i.e. a connection is established between the sender and receiver before the data can be transmitted. It divides the data it receives from the upper layer into segments and tags a sequence number to each segment which is used at the receiving end for reordering of data.
UDP - User Datagram Protocol: UDP is a simple protocol used for process to process transmission. It is an unreliable, connectionless protocol for applications that do not require flow control or error control. It simply adds port address, checksum and length information to the data it receives from the upper layer.

Question 42 | Q00579

For this hypothetical design, Debre Markos University’s main campus and its Burie agricultural branch are in different towns beyond a single metropolitan area. Which geographic network category connects the two campus LANs?

A. Local Area Network

B. Metropolitan Area Network

C. Personal Area Network

D. Wide Area Network

Hint

Use the cited note definitions to identify the requested function or scope, then check each alternative against that same rule.

Answer D: Wide Area Network

A WAN connects geographically distant networks across regions rather than covering one local site or one metropolitan area. Under the explicit hypothetical placement, the two campus LANs need a WAN connection. A LAN can serve each campus locally, while a MAN covers a metropolitan region and a PAN connects nearby personal devices. The conclusion follows from the stated geography, not the institutions' names or number of computers.

Why each choice is right or wrong

A - Incorrect: A LAN describes local campus connectivity, not the stated inter-town connection.

B - Incorrect: A MAN spans one metropolitan region, excluded by the stated geography.

C - Incorrect: A PAN connects personal nearby devices rather than distant campus networks.

D - Correct: A WAN connects the geographically separated campus LANs.

Primary note proof

Study-note section NET02

> PAN connects personal devices, such as Bluetooth accessories. LAN covers a local building or campus; MAN spans a metropolitan region; WAN connects distant regions. Device count alone does not determine the category. The Internet is a global network of networks, commonly the largest example of a WAN.

Study-note section NET02

> An intranet serves an organization internally; an extranet exposes selected services to approved outsiders. Neither term alone specifies geographic size. A client requests a service; a server supplies it. Peer systems may perform both roles. Dedicated servers concentrate on service workloads but can still be clients of DNS, backup or update services. A ten-user cutoff is a teaching guideline, not a technical law. Centralization simplifies administration but creates dependencies; peer networks still need security.

Question 43 | Q00582

In OSI reference model, which one is responsible for the translation of incoming and outgoing data .

A. Presentation layer.

B. Application layer.

C. Transport layer.

D. Network layer.

Hint

Match the requested scope or data unit to the layer duties in the note; distinguish hop delivery from end-to-end process delivery.

Answer A: Presentation layer.

Representation translation is explicitly one of presentation-layer duties. Evidence: PDF 16, 16, 16, 15.

Why each choice is right or wrong

A - Correct: Presentation translates data representations (PDF 16, 16, 16, 15.)

B - Incorrect: Application provides network resource access (PDF 16, 16, 16, 15.)

C - Incorrect: Transport delivers between processes (PDF 16, 16, 16, 15.)

D - Incorrect: Network provides logical addressing and routes (PDF 16, 16, 16, 15.)

Primary note proof

Study-note section NET19

OSI session roles establish/manage dialogs and can coordinate checkpoints so transfer resumes after interruption. Presentation roles translate encodings and handle compression/encryption. Compression reduces representation size; encryption hides content and need not shrink it. Application protocols provide services directly to applications. Practical implementations distribute these functions differently; TLS is not proof of a separate physical presentation-layer device.

Study-note section NET17

Question 44 | Q00583

The choice of one topology over the other has an impact on:

A. The capability of the network.

B. The growth of the network.

C. The type of equipment that the network needs.

D. All

Hint

Draw the links and identify shared components, alternate paths and the effect of the specified failure or growth requirement.

Answer D: All

Topology changes cable requirements, central equipment, failure behavior and installation/reconnection costs. The module examples support effects on capability, growth and required equipment. Evidence: PDF 23, 23, 23, 24.

Why each choice is right or wrong

A - Incorrect: Link and failure behavior affect capability (PDF 23, 23, 23, 24.)

B - Incorrect: Cable growth and reconnection costs affect expansion (PDF 23, 23, 23, 24.)

C - Incorrect: A star requires a hub/switch while a mesh requires many direct links (PDF 23, 23, 23, 24.)

D - Correct: All three effects follow from the contrasted layouts (PDF 23, 23, 23, 24.)

Primary note proof

Study-note section NET08

> Bus uses a shared backbone; an unterminated break can disrupt the segment. Star connects endpoints through a central device: one edge failure isolates that endpoint, whereas central failure affects the star. Ring forms a loop; basic single rings are vulnerable to a break, while protected dual rings differ. Token passing is associated with Token Ring but is an access method, not a necessary property of every ring. Tree is hierarchical; hybrid combines arrangements.

Study-note section NET08

> A full undirected mesh of n nodes needs n(n-1)/2 links and n-1 interfaces per node. For 50 nodes: 50×49/2=1225 links. Redundant paths improve fault tolerance at greater cable and interface cost.

> Star Topology: in this topology, each node is connected directly to a central device called a hub or a switch. Data on a star network passes through the central device (switch) before continuing to its destination. The central device manages and controls all functions of the network. This configuration is common with twisted pair cable. RJ-45 Connectors are used to connect the cable to the Network Interface Card (NIC) of each computer. Its advantages include, ease of installation and reconfiguration, robust (ease of fault identification and isolation), link failure only affects device(s) connected to that link, and is less expensive than mesh. Its drawbacks include more cable requirements (than bus and ring) and single point of failure (if central device fail, the whole system will be down).

Data Communication and Computer Networking module | PDF page 23 | lines 4-18

Bus Topology: in this topology all devices are connected to a central cable, called the bus or backbone, which is terminated at its ends. The purpose of the terminators is to stop the signal from bouncing, thereby clearing the cable so that other computers can send data. Message transmitted along the Bus is visible to all computers connected to the backbone cable. As the message arrives at each workstation, the workstation checks the destination address contained in the message either to process or drop the packet if it matches or not respectively. Its advantages are, ease of installation and less amount of cable requirement. Its main drawback is, the entire network will be shut down if there is a break in the main cable.

Data Communication and Computer Networking module | PDF page 23 | lines 45-53

Mesh Topology: in this topology devices are connected with many redundant interconnections between network nodes. In a full mesh topology, every node has a connection to every other node in the network, which makes it the most expensive topology over all the other topologies. The number of cables grows fast as the number of nodes increases, and it can be calculated by using the general formula ((n (n - 1)) /2), where n is the number of nodes in the

Data Communication and Computer Networking module | PDF page 24 | lines 2-10

network. It has several benefits, such as: dedicated links between devices, robust (single link failure don‘t affect entire network), privacy/security (direct communication between communicating devices), and ease of fault identification and isolation. Its drawbacks include, installation and reconnection are difficult (large number of cables), huge amount of cables consumes a lot of space, and it is the most expensive of all.

One of the following is half-duplex mode of transmission.

A. Walky-talky/policeman phone

B. Television

C. Telephone

D. One-Way Radio

Hint

Compare the signal mechanism, medium properties or transmission direction against the definitions and stated physical assumptions.

Answer A: Walky-talky/policeman phone

Half duplex permits both directions at different times. A conventional walkie-talkie alternates talk and listen, matching this definition. Evidence: PDF 5.

Why each choice is right or wrong

A - Correct: Alternating talk/listen matches half duplex (PDF 5.)

B - Incorrect: Ordinary television broadcast only receives, matching simplex (PDF 5.)

C - Incorrect: An ordinary two-way simultaneous telephone call is full duplex (PDF 5.)

D - Incorrect: One-way radio is simplex (PDF 5.)

Primary note proof

Study-note section NET06

> Simplex is one way, half duplex alternates directions, and full duplex permits simultaneous sending/receiving. A walkie-talkie is half duplex; a telephone conversation uses full duplex. Serial sends sequential bits; parallel uses multiple conductors and may suffer skew. Character-oriented asynchronous serial adds start/stop bits; synchronous framing uses ongoing clock recovery. Neither is synonymous with browser asynchronous requests.

Study-note section NET06

> Transmission delay is packet bits divided by link bit rate; propagation delay is distance divided by signal speed. Processing and queueing add delay. A 1000-byte packet takes 0.8 ms to serialize at 10 Mbit/s; increasing line rate does not reduce propagation time.

Question 46 | Q00588

VPN is abbreviated as

A. Visual Private Network

B. Virtual Private Network

C. Virtual Protocol Network

D. Virtual Protocol Networking

Hint

Find the full expansion in the terminology note and compare each word rather than only matching initials.

Answer B: Virtual Private Network

NET11 expands VPN as Virtual Private Network and describes the logical private connection it provides over another network. The word Virtual matters because the connection is logically overlaid rather than necessarily a separate physical private network. The alternatives replace parts of the established expansion with visual or protocol and therefore do not match the note.

Why each choice is right or wrong

A - Incorrect: Visual substitutes an unrelated word for Virtual in the established VPN expansion.

B - Correct: Virtual Private Network is the exact expansion given in NET11.

C - Incorrect: Protocol replaces Private, changing the acronym expansion away from the defined term.

D - Incorrect: Protocol Networking is not the defined Private Network phrase in VPN.

Primary note proof

Study-note section NET11

A firewall allows, rejects or inspects traffic under a security policy; it does not necessarily encrypt. A VPN, Virtual Private Network, provides a logical private connection over another network; a secure VPN authenticates/encrypts its tunnel. A modem modulates outgoing and demodulates incoming carrier signals. These functions may coexist in one home router but remain conceptually distinct.

Study-note section NET11

Routers forward IP packets between networks using destination prefixes and next hops. They separate broadcast domains and normally do not forward local link broadcasts. A default gateway is usually a router, while a protocol gateway can translate application formats; therefore a gateway is not inherently a device that implements every OSI layer.

Data Communication and Computer Networking module | PDF page 22 | lines 2-19

A network can be defined as two or more computers connected together in such a way that they can share resources. The primary purpose of a network is to share resources, and a resource could be:
• a file,
• a folder,
• a printer,
• a disk drive, or just about anything else that exists on a computer.
Therefore, a computer network is simply a collection of computers or other hardware devices that are connected together, either physically or logically, using special hardware and software, to allow them to exchange information and cooperate. Networking is the term that describes the processes involved in designing, implementing, upgrading, managing and otherwise working with networks and network technologies.

Question 47 | Q00596

How many equal /27 subnets can be created from 192.168.20.0/24, counting every subnet?

A. 8

B. 16

C. 32

D. 64

Hint

Convert the mask to a prefix, separate network and host bits, and apply the relevant subnet-count or usable-host rule.

Answer A: 8

Subnet counts depend on both the parent and child prefixes. Dividing a /24 parent into /27 children borrows three bits, giving 2^3 = 8 subnets. Each child has five host bits and therefore 32 total addresses, but that address count is a different quantity. Counting every subnet avoids the obsolete practice of excluding the first and last subnet.

Why each choice is right or wrong

A - Correct: Three borrowed bits produce eight /27 subnets.

B - Incorrect: Sixteen would require four borrowed bits, not three.

C - Incorrect: Thirty-two is the number of addresses in each /27, not the number of children of this /24.

D - Incorrect: Sixty-four requires six borrowed bits rather than three.

Primary note proof

Study-note section NET26

> To split parent /a into equal /p blocks, borrow b=p-a bits and obtain 2^b subnets. Do not subtract two subnets under modern practice. For a Class B /16 parent split to /19, b=3 gives eight subnets, each with 8192 addresses and 8190 conventional hosts. A /19 alone does not state its parent.

Study-note section NET26

> For H hosts, choose the smallest h satisfying 2^h-2≥H, then p=32-h. For 24 hosts use /27; 52 or 57 use /26; 100 use /25; 500 use /23. For at least six equal subnets choose b=3. A Class C /24 split to /27 yields eight subnets. Always check both the number of subnets and the host capacity.

Question 48 | Q00601

Given an IP Address 172.16.28.252 with the subnet mask of 255.255.240.0 what is the correct network address?

A. 172.16.24.0

B. 172.16.28.0

C. 172.16.0.0

D. 172.16.16.0

Hint

Convert the mask to a prefix, separate network and host bits, and apply the relevant subnet-count or usable-host rule.

Answer D: 172.16.16.0

240=11110000 in the third mask octet. 28 (00011100) AND 240 (11110000)=16 (00010000); the last masked octet is zero. Thus the network is 172.16.16.0. Evidence: PDF 18, 19, 19.

Why each choice is right or wrong

A - Incorrect: 24 is not aligned to a 16-wide third-octet block (PDF 18, 19, 19.)

B - Incorrect: 28 retains host bits instead of masking them (PDF 18, 19, 19.)

C - Incorrect: 0 would discard the retained third-octet network bit (PDF 18, 19, 19.)

D - Correct: 16 is the result of the mask operation (PDF 18, 19, 19.)

Primary note proof

Study-note section NET24

A /p IPv4 prefix has p leading one bits followed by 32-p zeros. Partial octet masks are 128,192,224,240,248,252,254. /19 is 255.255.224.0; /20 is 255.255.240.0; /21 is 255.255.248.0, correcting the study guide's 255.248.0.0 mistake.

Study-note section NET24

Compute network=address AND mask. Host bits zero identify the block start; host bits one give broadcast. With 172.16.28.252/20, the third octet is grouped in blocks of 16, so the network is 172.16.16.0 and broadcast 172.16.31.255. A written host/prefix such as 172.105.180.0/21 need not be an aligned block label: masking yields 172.105.176.0/21.

Classful addressing : In classful addressing, the addressspace is divided into five classes: A, B, C, D, and E.
• Netid and Hostid In classful addressing, an IP addressin class A, B, or C is divided into netid and hostid.
Subnetting: It allows a network to be split into several parts for internal use but still act like a single network to the outsideworld.
• To implement subnetting, the router needs a subnet mask that indicates the split between network + subnet number and host. Ex. 255.255.252.0/22. A‖/22‖ to indicate that the subnet mask is 22 bits long.

Question 49 | Q00602

One of the following is true about packet switching.

A. Packets travel around the network seeking out the most efficient route.

B. Packets should necessarily seek out the shortest route.

C. The message gets broken into small data packets.

D. All

Hint

Compare signal repetition, frame forwarding, packet routing and policy enforcement using the stated device or traffic assumptions.

Answer C: Packet switching divides a message into packets

The defining packet-switching property is dividing data into packets for shared-link forwarding. Routing may seek good paths, but packets do not guarantee the most efficient or geometrically shortest path. C directly states the definition; D includes unsupported universal route claims and therefore fails.

Why each choice is right or wrong

A - Incorrect: Routing chooses next hops, but packet switching does not guarantee packets discover the globally most efficient route.

B - Incorrect: Packets are not guaranteed to take the geometrically shortest route.

C - Correct: Breaking a message into data packets is the packet-switching operation.

D - Incorrect: The all option includes unsupported route-optimality and necessary-shortest-path claims.

Primary note proof

Study-note section NET31

> Circuit switching sets up a path with reserved resources, transfers data, then releases it. Predictable allocated bandwidth trades against setup/blocking and wasted reservation during silence. A traditional telephone call is the standard example. Packet switching divides data into packets that share links statistically; queueing can add variable delay and loss. This does not make modern voice-over-packet impossible: buffering, scheduling and capacity planning manage it.

Study-note section NET31

> Datagram packets are forwarded independently. Virtual circuits establish forwarding state, but resource reservation is optional, not a necessary property of every virtual circuit. Message switching stores a complete message before forwarding, without a dedicated end-to-end path. Packet store-and-forward waits for the full packet/frame; cut-through starts after enough header arrives; fragment-free historically waits through the initial collision-sensitive portion. No routing algorithm guarantees that every packet always takes the geometrically shortest route.

Question 50 | Q00603

Which statements correctly compare the seven-layer OSI reference model with the four-layer TCP/IP model? Select all that apply.

A. Both have application layers.

B. Both have comparable transport and network layers.

C. Both uses packet-switching instead of circuit-switching technology.

D. All

Hint

Match the requested scope or data unit to the layer duties in the note; distinguish hop delivery from end-to-end process delivery.

Answer A, B: Both have application layers.; Both have comparable transport and network layers.

Both models include application responsibilities and corresponding transport and network functions. TCP/IP groups the OSI session, presentation and application responsibilities into its application layer, and calls its network layer the Internet layer. An abstract reference model does not itself execute a switching technology. Consequently, the claim that both models necessarily use packet switching is not a valid shared model property.

Why each choice is right or wrong

A - Correct: Both models include an application layer, although TCP/IP folds several OSI upper-layer functions into it.

B - Correct: TCP/IP retains transport and maps OSI network responsibilities to its Internet layer.

C - Incorrect: A reference model does not itself use a switching technology or restrict every implementation to one.

D - Incorrect: The implemented-technology claim in C is not a property established for both abstract models.

Primary note proof

Study-note section NET19

> The four-layer TCP/IP model folds OSI layers 5-7 into application, retains transport, calls layer 3 Internet, and combines link/physical as network access. A model is a guide to functions, not a guarantee that every application gets a reliable network. Distinguish end-to-end application service from its underlying process-to-process transport.

Study-note section NET03

> A reference model divides responsibilities and interfaces; it is not itself executable networking software. OSI is a seven-layer reference model; TCP/IP describes an implemented protocol suite, usually taught with four layers. A five-layer teaching model separates physical and link functions. After understanding the concept of layered task and the OSI model, we introduce the TCP/IP model. This model is currently being used on our systems. TCP/IP model is a collection of protocols often called a protocol suite. It offers a rich variety of protocols.
It is a hierarchical model; it existed even before the OSI model was developed. Originally had four layers (bottom to top):
1. Host to Network Layer
2. Internet Layer
3. Transport Layer

Question 51 | Q00604

One of the following is network layer protocol.

A. HTTP

B. FTP

C. ARP

D. TCP

Hint

Match the requested scope or data unit to the layer duties in the note; distinguish hop delivery from end-to-end process delivery.

Answer C: ARP

Within this module, ARP is grouped among protocols supporting IP at the network layer. This follows the assigned taxonomy rather than assuming that all taxonomies place ARP identically. Evidence: PDF 17, 17, 18, 18.

Why each choice is right or wrong

A - Incorrect: HTTP is an application service in the table (PDF 17, 17, 18, 18.)

B - Incorrect: FTP is application file transfer (PDF 17, 17, 18, 18.)

C - Correct: ARP is explicitly grouped under network/IP support (PDF 17, 17, 18, 18.)

D - Incorrect: TCP belongs to transport (PDF 17, 17, 18, 18.)

Primary note proof

Study-note section NET20

ARP resolves an on-link IPv4 next hop to a link address, using a broadcast request and normally unicast reply. For an off-subnet target, ARP resolves the gateway, not the remote target's MAC. It bridges the network/link addressing boundary and is often classified at the link layer; calling ARP simply a network protocol uses a loose textbook convention. RARP reverses hardware-to-IP lookup; BOOTP/DHCP support boot configuration. ICMP reports errors and diagnostics; IGMP manages IPv4 multicast membership. These are separate companion protocols, not four pieces whose combination is IP.

Study-note section NET21

HTTP defines web request/response semantics; it is stateless, and a message body may be absent. HTTPS adds TLS protection. FTP transfers files using control and separate data connections; it is not the same protocol as SFTP. SMTP submits and relays mail; POP3 retrieves messages and IMAP accesses/synchronizes server mailboxes. Saying SMTP handles both sending and end-user mailbox retrieval is inaccurate.

Study-note section NET17

TCP offers a reliable ordered byte stream using sequence numbers, acknowledgments, retransmission and windows. Flow control protects the receiver; congestion control protects network capacity. UDP sends independent datagrams with ports and a checksum but no built-in setup, delivery guarantee, retransmission or ordering. Network Layer or IP
Also called as the Internetwork Layer (IP). It holds the IP protocol which is a network layer protocol and is responsiblefor source to destination transmission of data.
The Internetworking Protocol (IP) is a connection-less & unreliable protocol.
It is a best effort delivery service. i.e. there is no error checking in IP, it simply sends the data and relies on its underlying layers to get the data transmitted to the destination.Even if it is unreliable IP cannot be considered weak and useless; since it provides only the functionality that is requiredfor transmitting data thereby giving maximum efficiency.
Since there is no mechanism of error detection or correction in IP, there will be no delay introduced on a medium where thereis no error at all.

TCP - Transmission Control Protocol: TCP is a reliable connection-oriented, reliable protocol. i.e. a connection is established between the sender and receiver before the data can be transmitted. It divides the data it receives from the upper layer into segments and tags a sequence number to each segment which is used at the receiving end for reordering of data.
UDP - User Datagram Protocol: UDP is a simple protocol used for process to process transmission. It is an unreliable, connectionless protocol for applications that do not require flow control or error control. It simply adds port address, checksum and length information to the data it receives from the upper layer.

One of the following is responsible for receiving and transmitting the signals across the physical media.

A. Datalink Layer

B. Physical layer

C. Application Layer.

D. Transport Layer.

Hint

Compare the signal mechanism, medium properties or transmission direction against the definitions and stated physical assumptions.

Answer B: Physical layer

Transmission of signals across a physical medium is explicitly the physical-layer task. Evidence: PDF 14, 15, 16, 16.

Why each choice is right or wrong

A - Incorrect: Data link frames data and controls access (PDF 14, 15, 16, 16.)

B - Correct: Physical converts bits to signals and sends them (PDF 14, 15, 16, 16.)

C - Incorrect: Application supplies user network services (PDF 14, 15, 16, 16.)

D - Incorrect: Transport manages process delivery (PDF 14, 15, 16, 16.)

Primary note proof

Study-note section NET09

> A NIC supplies a computer’s network interface and commonly implements both physical and link functions. Calling a NIC a physical interface does not mean all its functions are layer 1. Physical specifications include connectors, signaling, voltage, timing and physical coding/modulation; the PHY interface to MAC handles hardware signaling.

Study-note section NET12

> Sending proceeds from application data to transport segment/datagram, network packet, link frame and physical bits/symbols; receiving reverses the order. Each layer serves the layer above. Question 53 | Q00636

Which listed device performs layer-1 signal regeneration without inspecting destination addresses?

A. Router

B. Switch

C. Firewall

D. Repeater

Hint

Match the requested scope or data unit to the layer duties in the note; distinguish hop delivery from end-to-end process delivery.

Answer D: Repeater

A repeater regenerates physical signals and therefore performs a layer-1 function. Routers decide where to forward network-layer packets, and ordinary Ethernet switches make link-layer decisions using MAC addresses. A firewall enforces a security policy rather than defining a physical signal-regeneration role. Replacing the duplicated firewall distractor restores a meaningful physical-layer choice without changing the layer-identification concept.

Why each choice is right or wrong

A - Incorrect: A router's defining forwarding function is network-layer IP routing rather than layer-1 signal repetition.

B - Incorrect: An ordinary Ethernet switch performs layer-2 MAC frame forwarding.

C - Incorrect: A firewall enforces traffic policy rather than being the layer-1 repeater/hub requested.

D - Correct: A repeater regenerates layer-1 signals without inspecting destination addresses.

Primary note proof

Study-note section NET09

> A repeater regenerates layer-1 signals without inspecting destination addresses. An active hub is a multiport repeater: it repeats incoming signals onto other ports, placing half-duplex endpoints in one collision domain. A passive hub is a connector. A hub neither learns MAC addresses nor eliminates collisions. An endpoint such as a network printer consumes services; routers, hubs and access points are intermediary devices.

Study-note section NET10

> A bridge or ordinary Ethernet switch operates at layer 2. It learns source-MAC-to-port mappings, looks up the destination, forwards a known unicast to its port, filters it if the destination is on the incoming segment, and floods an unknown unicast or broadcast within its VLAN. A switch does not always send only to one destination port. Wireless access points normally bridge wireless and wired link-layer traffic.

Study-note section NET11

> A firewall allows, rejects or inspects traffic under a security policy; it does not necessarily encrypt. A VPN, Virtual Private Network, provides a logical private connection over another network; a secure VPN authenticates/encrypts its tunnel. A modem modulates outgoing and demodulates incoming carrier signals. These functions may coexist in one home router but remain conceptually distinct.

A data communication component that helps to convert data into transmittable signal.

A. Transmission media

B. Transmitter

C. Receiver

D. Data source

Hint

Compare the signal mechanism, medium properties or transmission direction against the definitions and stated physical assumptions.

Answer B: Transmitter

NET01 separates creating data, converting it to a signal, carrying that signal and reconstructing the data. The stem asks specifically about the conversion into a transmittable signal, which is the transmitter's role. A source supplies the data before this conversion, while the receiver performs the reconstruction at the far end.

Why each choice is right or wrong

A - Incorrect: The transmission medium carries the signal; it is not the component that converts source data into it.

B - Correct: The transmitter converts data into a signal suitable for transmission over the medium.

C - Incorrect: The receiver reconstructs data from the incoming signal, performing the opposite end's role.

D - Incorrect: The data source creates the data; signal conversion is assigned separately to the transmitter.

Question 55 | Q00638

Among the following one is the responsibility of logical link control layer.

A. Identify the network layer protocol.

B. Marking the beginning and ending of the frame.

C. Addressing the frame.

D. All

Hint

Match the requested scope or data unit to the layer duties in the note; distinguish hop delivery from end-to-end process delivery.

Answer A: Identify or multiplex the network-layer protocol

LLC identifies or multiplexes the upper-layer protocol carried over the link. NET13 assigns medium-dependent addressing/access and frame delivery to MAC, and says exact framing depends on the protocol. Therefore the specific LLC duty offered here is identifying the network-layer protocol; the other functions cannot all be attributed to LLC.

Why each choice is right or wrong

A - Correct: Identifying or multiplexing an upper-layer network protocol is an explicit LLC responsibility in NET13.

B - Incorrect: Beginning/end frame delimitation belongs to protocol-specific framing, not the distinguishing LLC upper-protocol identification function.

C - Incorrect: Medium-dependent frame addressing belongs to MAC rather than the LLC duty asked about.

D - Incorrect: The all option incorrectly includes frame addressing and delimitation as specifically LLC responsibilities.

Primary note proof

Study-note section NET13

Link-layer LLC identifies or multiplexes upper-layer protocols and may supply link control; MAC handles medium-dependent addressing/access and frame delivery. Network addressing belongs

to layer 3. Ethernet, PPP and HDLC are link protocols. Frame headers may carry addresses and control/type fields; synchronization and exact framing depend on the protocol.

Study-note section NET12

Sending proceeds from application data to transport segment/datagram, network packet, link frame and physical bits/symbols; receiving reverses the order. Each layer serves the layer above. A router removes a received link frame, inspects IP, and creates a new link frame for the next hop. MAC addresses usually change across routed hops; end-to-end IP addresses ordinarily remain until translation.

C. 172.16.1.1

D. 192.168.0.0

Hint

Use the cited note definitions to identify the requested function or scope, then check each alternative against that same rule.

Answer A: 192.257.10.0

As a syntactic IPv4 address comparison, 257 exceeds the permitted 0-255 octet range. The others have four legal octets; no host mask is supplied to test host assignability. Evidence: PDF 19.

Why each choice is right or wrong

A - Correct: 257 violates the octet limit (PDF 19.)

B - Incorrect: All octets fall between 0 and 255 (PDF 19.)

C - Incorrect: All octets fall between 0 and 255 (PDF 19.)

D - Incorrect: All octets fall between 0 and 255 (PDF 19.)

Primary note proof

Question 57 | Q00640

The most commonly used method to convert analog data to digital form.

A. Line coding scheme

B. Data encoding

C. Pulse code modulation

D. Demodulation

Hint

Use the cited note definitions to identify the requested function or scope, then check each alternative against that same rule.

Answer C: Pulse code modulation (PCM)

NET15 identifies PCM as the analog-to-digital procedure of sampling the analog input, quantizing each sample and encoding its level as bits. The note does not establish comparative usage statistics, but PCM is the specific conversion method among the choices. Line coding maps existing digital bits to signals; demodulation recovers information from a carrier rather than necessarily digitizing analog data.

Why each choice is right or wrong

A - Incorrect: Line coding begins with digital bits and maps them to digital signal patterns, rather than digitizing analog input.

B - Incorrect: Data encoding is a broad description and does not identify the specific analog-digitization method supplied here.

C - Correct: PCM performs the sampling, quantization and binary encoding needed to turn analog input into digital data.

D - Incorrect: Demodulation removes carrier modulation; it does not itself specify analog-to-digital sampling and quantization.

Primary note proof

Study-note section NET15

> ASK varies carrier amplitude, FSK frequency, PSK phase; QAM combines amplitude and phase. AM/FM/PM can carry analog data. PCM digitizes analog input by sampling, quantizing and encoding. Sampling must exceed twice the highest retained baseband frequency in practical designs; b-bit samples have 2^b quantization levels and uncompressed rate fs×b. PAM/PWM are pulse modulation methods; pulse amplitude or width alone is not a binary PCM code.

Study-note section NET15

> Line coding maps digital bits to digital signal patterns. NRZ uses levels without a forced mid-bit return; Manchester supplies a mid-bit transition for clocking, with bit convention specified. Differential Manchester encodes using transitions relative to previous state. AMI alternates the polarity of successive ones; pseudoternary alternates zero pulses. Block coding adds code redundancy; scrambling replaces problematic patterns without necessarily increasing bit count. Multilevel schemes include 2B1Q and 8B6T; MLT-3 uses a sequence of voltage transitions.

Study-note section NET11

> A firewall allows, rejects or inspects traffic under a security policy; it does not necessarily encrypt. A VPN, Virtual Private Network, provides a logical private connection over another network; a secure VPN authenticates/encrypts its tunnel. A modem modulates outgoing and

demodulates incoming carrier signals. These functions may coexist in one home router but remain conceptually distinct.

Question 58 | Q00647

In a peer-to-peer architecture, which statements are false? Select all that apply. Interpret C as absence of a required client-server hierarchy.

A. Computers can function as both a client and a server.

B. A dedicated central administrator is required by peer-to-peer architecture.

C. There is no a hierarchy among the computers.

D. In peer - to - peer network security is not an issue.

Hint

Use the cited note definitions to identify the requested function or scope, then check each alternative against that same rule.

Answer B, D: A dedicated central administrator is required by peer-to-peer architecture.; In peer - to - peer network security is not an issue.

Peers may request and supply services without a required client-server hierarchy. That capability does not impose a dedicated central administrator, although people may still take responsibility for administration. Peer systems also continue to need security because they expose data and services. The false statements therefore concern mandatory centralized administration and the dismissal of security, while the capability and no-required-hierarchy statements are true.

Why each choice is right or wrong

A - Incorrect: True: peers can both request and supply services, so this is not a false statement.

B - Correct: False: a dedicated central administrator is not a requirement of peer architecture.

C - Incorrect: True: peers do not require a client-server hierarchy, so this is not a false statement.

D - Correct: False: peer networks still require security.

Primary note proof

Study-note section NET02

> An intranet serves an organization internally; an extranet exposes selected services to approved outsiders. Neither term alone specifies geographic size. A client requests a service; a server supplies it. Peer systems may perform both roles. Dedicated servers concentrate on service workloads but can still be clients of DNS, backup or update services. A ten-user cutoff is a teaching guideline, not a technical law. Centralization simplifies administration but creates dependencies; peer networks still need security.

Study-note section NET33

Which of the following protocols uses both TCP and UDP?

A. FTP

B. SMTP

C. Telnet

D. DNS

Hint

Identify the requested service or delivery guarantee, then distinguish application roles, transport behavior and address configuration.

Answer D: DNS

Inspection of the module port table places DNS 53 in both TCP and UDP columns. The other named services occur only in its TCP column. Evidence: PDF 28, 18.

Why each choice is right or wrong

A - Incorrect: FTP 21 is listed in TCP only (PDF 28, 18.)

B - Incorrect: SMTP 25 is listed in TCP only (PDF 28, 18.)

C - Incorrect: Telnet 23 is listed in TCP only (PDF 28, 18.)

D - Correct: DNS 53 appears in both table columns (PDF 28, 18.)

Primary note proof

Study-note section NET20

> DNS resolves names to records, including IPv4 A and IPv6 AAAA addresses; it can use UDP or TCP port 53. DHCP dynamically leases IPv4 settings, commonly address, mask, gateway and DNS server. Its basic exchange is discover, offer, request, acknowledge. IP itself does not assign addresses.

Study-note section NET-S02

Question 60 | Q00654

Which single option gives the complete set of listed devices whose ordinary forwarding function is at the data-link layer?

A. Switch

B. Access point

C. Hub

D. A & B

Hint

Match the requested scope or data unit to the layer duties in the note; distinguish hop delivery from end-to-end process delivery.

Answer D: A & B

An ordinary Ethernet switch forwards frames at layer 2, and an ordinary wireless access point bridges wireless and wired link-layer traffic. A hub simply repeats physical signals at layer 1. The question requests the complete set, so either switch or access point alone omits another qualifying device. The combined response is therefore the one complete selection.

Why each choice is right or wrong

A - Incorrect: A switch is layer 2, but this selection omits the qualifying access point.

B - Incorrect: A bridging access point is layer 2, but this selection omits the switch.

C - Incorrect: A hub repeats physical signals and does not inspect destination MAC addresses as a data-link device does.

D - Correct: Both the ordinary switch and bridging access point are data-link devices; this gives the complete set.

Primary note proof

Study-note section NET10

A bridge or ordinary Ethernet switch operates at layer 2. It learns source-MAC-to-port mappings, looks up the destination, forwards a known unicast to its port, filters it if the destination is on the incoming segment, and floods an unknown unicast or broadcast within its VLAN. A switch does not always send only to one destination port. Wireless access points normally bridge wireless and wired link-layer traffic.

Study-note section NET09

A repeater regenerates layer-1 signals without inspecting destination addresses. An active hub is a multiport repeater: it repeats incoming signals onto other ports, placing half-duplex endpoints in one collision domain. A passive hub is a connector. A hub neither learns MAC addresses nor eliminates collisions. An endpoint such as a network printer consumes services; routers, hubs and access points are intermediary devices.

Question 61 | Q00656

Which statement correctly describes the OSI reference model?

A. It has fewer layer that TCP/IP model.

B. The model itself is executable software installed to implement a network.

C. Used as a guide to help students or learners understand the communication process.

D. All

Hint

Match the requested scope or data unit to the layer duties in the note; distinguish hop delivery from end-to-end process delivery.

Answer C: Used as a guide to help students or learners understand the communication process.

OSI divides communication responsibilities into seven layers and serves as a framework for explaining interfaces and communication processes. The usual TCP/IP teaching model has four layers, so OSI does not have fewer. A reference model can guide design, but it is not itself executable networking software or an installed protocol implementation. That distinction makes the learning-guide statement the correct description.

Why each choice is right or wrong

A - Incorrect: OSI has seven layers, more than the usual four-layer TCP/IP teaching model.

B - Incorrect: A reference model is not itself executable networking software, although it can guide design.

C - Correct: The model helps learners understand layered communication responsibilities.

D - Incorrect: The incorrect layer count and executable-software claim prevent all statements from being true.

Primary note proof

Study-note section NET03

> A reference model divides responsibilities and interfaces; it is not itself executable networking software. OSI is a seven-layer reference model; TCP/IP describes an implemented protocol suite, usually taught with four layers. A five-layer teaching model separates physical and link functions. State the model before counting layers.

Study-note section NET19

> The four-layer TCP/IP model folds OSI layers 5-7 into application, retains transport, calls layer 3 Internet, and combines link/physical as network access. A model is a guide to functions, not a guarantee that every application gets a reliable network. Distinguish end-to-end application service from its underlying process-to-process transport.

TCP/IP is a hierarchical protocol made up of interactive modules, each of which provides a specific functionality; however, the modules are not necessarily interdependent. Whereas the OSI model specifies which functions belong to each of its layers, the layers of TCP/IP suite contain relatively independent protocols that can be mixed and matched depending on the needs of the system. The term hierarchical means that each upper-level protocol is supported by one or more lower-level protocols.

Question 62 | Q00699

Which listed item is not one of the five basic components of data communication?

A. Message

B. Medium

C. Sender

D. Distance

Hint

Use the cited note definitions to identify the requested function or scope, then check each alternative against that same rule.

Answer D: Distance

The five basic components are message, sender, receiver, medium and protocol. Message, medium and sender therefore belong to the required set. Distance affects transmission engineering, such as propagation delay and attenuation, but it is not a sixth component in that model. Replacing the original protocol option with distance supplies a meaningful exception while retaining the negative component-identification task.

Why each choice is right or wrong

A - Incorrect: Message is explicitly one of the required components.

B - Incorrect: The medium carries signals and is explicitly a communication component.

C - Incorrect: The sender is explicitly included among communication components.

D - Correct: Distance affects engineering but is not one of the five basic communication components.

Primary note proof

Study-note section NET01

> Data are raw representations; information is data interpreted for a purpose. Communication requires a message, sender, receiver, medium and agreed protocol. A source creates data; a transmitter converts it to a signal; a receiver reconstructs data. Distance affects engineering but is not a sixth component.

Study-note section NET06

> Transmission delay is packet bits divided by link bit rate; propagation delay is distance divided by signal speed. Processing and queueing add delay. A 1000-byte packet takes 0.8 ms to serialize at 10 Mbit/s; increasing line rate does not reduce propagation time.

Question 63 | Q00700

There are two types of network topologies from these topologies which one of the following defines how hosts access the media to send data.

A. Logical Topology

B. Bus Topology

C. Physical Topology

D. Star Topology

Hint

Draw the links and identify shared components, alternate paths and the effect of the specified failure or growth requirement.

Answer A: Logical topology

The distinction is between physical layout and communication/access relationships. NET08 defines logical topology in the latter sense, matching how hosts obtain medium access. Bus and star are particular arrangements rather than the general physical-versus-logical category requested.

Why each choice is right or wrong

A - Correct: Logical topology describes communication and medium-access relationships among hosts.

B - Incorrect: Bus is a particular shared-backbone arrangement, not the general category defining access relationships.

C - Incorrect: Physical topology describes link layout and connections rather than the logical rules for medium access.

D - Incorrect: Star describes endpoints around a central device; it does not name the general access-topology category.

Primary note proof

Study-note section NET08

Physical topology describes link layout; logical topology describes communication/access relationships. Point-to-point links join two endpoints; multipoint links share a medium. A full mesh consists of point-to-point links.

Study-note section NET08

Bus uses a shared backbone; an unterminated break can disrupt the segment. Star connects endpoints through a central device: one edge failure isolates that endpoint, whereas central failure affects the star. Ring forms a loop; basic single rings are vulnerable to a break, while protected dual rings differ. Token passing is associated with Token Ring but is an access method, not a necessary property of every ring. Tree is hierarchical; hybrid combines arrangements.

A. Physical

B. Data Link

C. Network

D. Transport

Hint

Physical Layer:
• The Physical Layer provides a standardized interface to physical transmission media, including: Mechanical specification of electrical connectors and cables, for example maximum cable length, Electrical specification of transmission line and Bit-by-bit or symbol-by-symbol delivery.
• Interface: The Physical Layer defines the characteristics of interfaces between the devices & transmission medium.
• Representation of bits: The physical layer is concerned with transmission of signals from one device to another which involves converting data (1_s & 0_s) into signals and vice versa. It is not concerned with the meaning or interpretation of bits.
• Data rate: The physical layer defines the data transmission rate i.e. number of bits sent per second. It is the responsibility of the physical layer to maintain the defined data rate.

Question 66 | Q00703

You want to implement a network medium that is not susceptible to EMI. Which type of cabling should you use?

A. Coaxial

B. Category 6 UTP

C. Microwave

D. Fiber-optic

Hint

Compare the signal mechanism, medium properties or transmission direction against the definitions and stated physical assumptions.

Answer D: Fiber-optic cable

NET07 identifies fiber as a light-guiding medium that resists electromagnetic interference. Coax and UTP carry electrical signals and can be affected by coupled interference. Microwave is wireless, so it is not a cabling answer even before considering interference in radio transmission.

Why each choice is right or wrong

A - Incorrect: Coax has shielding but still carries electrical signals; it does not offer fiber's immunity to electromagnetic coupling.

B - Incorrect: Twisted pairs reduce interference but unshielded copper cable remains susceptible to electromagnetic coupling.

C - Incorrect: Microwave is an unguided wireless medium, not a cable matching the requested cabling choice.

D - Correct: Fiber carries light and resists electromagnetic interference rather than conducting the unwanted electrical coupling.

Primary note proof

Study-note section NET07

> Twisted pairs reduce coupled interference; UTP has no added shield and STP adds shielding. Coax has an inner conductor and outer shield sharing an axis. Fiber guides light and resists electromagnetic interference; it supports high capacity and long reach, but requires suitable optics and installation. Exact speed, cost and reach depend on the specification, not the material alone. Fiber can still be tapped.

Study-note section NET07

> Radio, microwave and infrared are unguided media. Ground waves follow Earth, sky waves can reflect from ionized layers, and line-of-sight paths require suitable visibility. Microwaves are radio waves in the broader physical classification. Infrared generally does not penetrate walls. Directionality depends on antennas: omnidirectional means broad azimuth coverage, not equal radiation in every 3-D direction. Legacy Ethernet straight-through cables join unlike MDI/MDI-X

roles; crossover joins like roles, such as PC-PC or switch-switch. Auto-MDI-X can remove that requirement.

TRANSMISSION MEDIA
Transmission media is a means by which a communicationsignal is carried from one system to another
A transmission medium can be defined as anything that cancarry information from a source to a destination. The transmission medium is usually free space, metallic cable orfiber optic cable. Guided and Unguided (WIRELESS) Guided Transmission Media uses a cabling system that guidesthe data signals along a specific path. Out of these twisted-paircable, coaxial cable transport signals in the form of electricsignals and fiber-optic cable transport signals in the form oflight.
Unguided Transmission Media transport data without using a physical conductor. It uses wireless electromagnetic signals to send data. Three types of unguided media:
• Radio waves
• Micro waves
• Infrared.

Question 67 | Q00704

Which responsibility belongs to the OSI network layer rather than the data-link layer?

A. logical link control

B. Network Addressing

C. media access control

D. Hardware Addressing

Hint

Match the requested scope or data unit to the layer duties in the note; distinguish hop delivery from end-to-end process delivery.

Answer B: Network Addressing

Logical network addressing, such as IP addressing, supports delivery across interconnected networks and belongs to the network layer. The data-link layer instead handles local frame delivery, hardware/MAC addressing, medium access and link-control functions. LLC identifies or multiplexes upper-layer protocols and may supply link control. The term hardware addressing here denotes frame-level MAC addressing, not an IP address.

Why each choice is right or wrong

A - Incorrect: LLC is a data-link sublayer role for upper-protocol identification and link control.

B - Correct: Logical network addressing is a network-layer responsibility.

C - Incorrect: Medium access control is a data-link role.

D - Incorrect: MAC hardware addressing is used for link-frame delivery.

Primary note proof

Study-note section NET13

> Link-layer LLC identifies or multiplexes upper-layer protocols and may supply link control; MAC handles medium-dependent addressing/access and frame delivery. Network addressing belongs to layer 3. Ethernet, PPP and HDLC are link protocols. Frame headers may carry addresses and control/type fields; synchronization and exact framing depend on the protocol.

Question 68 | Q00705

Which class of IP address provides a maximum of only 254 host addresses per network ID?

A. Class A

B. Class D

C. Class B

D. Class C

Hint

Convert the mask to a prefix, separate network and host bits, and apply the relevant subnet-count or usable-host rule.

Answer D: Class C under the historical default mask

The wording asks about historical address classes. Class C uses default /24, leaving eight host bits: 2^8−2=254 ordinary usable hosts. Classes A and B leave more bits, while Class D identifies multicast rather than an ordinary unicast host network. Under CIDR the actual prefix would replace these defaults.

Why each choice is right or wrong

A - Incorrect: Default Class A /8 leaves 24 host bits, far more than 254 usable hosts.

B - Incorrect: Class D is multicast space, not an ordinary classful unicast network with 254 hosts.

C - Incorrect: Default Class B /16 leaves sixteen host bits and 65534 ordinary usable hosts.

D - Correct: Default Class C /24 leaves eight host bits, giving 256 addresses minus network and broadcast.

Primary note proof

Study-note section NET22

> Historical classes use leading patterns: A 0 with /8, B 10 with /16, C 110 with /24; D 1110 is multicast and E 1111 reserved. Ordinary class-A first octets are 1-126 because 0 and 127 have special uses. B spans 128-191 and C 192-223. Default usable counts are 2^24-2, 2^16-2 and 254. Modern CIDR requires the actual prefix and overrides class defaults.

Study-note section NET25

> For ordinary broadcast LANs let h=32-p. Total addresses=2^h; usable hosts=2^h-2, reserving network and directed broadcast. Find the changing octet’s increment as 256-mask octet, round the address down to a multiple, and extend through the next boundary minus one.

CIDR: A class B address is far too large for most organizationsand a class C network, with 256 addresses is too small. This leads to granting Class B address to organizations who do not require all. This is resulting in depletion of Address space. A solution is CIDR (Classless InterDomain Routing) The basic idea behind CIDR, is to allocate the remaining IP addresses in variable-sized blocks, without regard to the classes.

Data Communication and Computer Networking module | PDF page 19 | lines 2-22

Address Space: An address space is the total number ofaddresses used by the protocol.
• If a protocol uses N bits to define an address, the address space is 2N because each bit can have twodifferent values (0 or 1) and N bits can have 2N values.
• IPv4 uses 32-bit addresses, which means that the address space is 232 or 4,294,967,296 (more than 4billion).
Notations: There are two notations to show an IPv4 address:
• Binary notation: The IPv4 address is displayed as 32bits. ex. 11000001 10000011 00011011 11111111
• Dotted decimal notation: To make the IPv4 address easier to read, Internet addresses are usually written in decimal form with a decimal point (dot) separatingthe bytes. Each byte (octet) is 8 bits hence each number in dotted-decimal notation is a value rangingfrom 0 to 255. Ex. 129.11.11.239

Data Communication and Computer Networking module | PDF page 19 | lines 23-36

Classful addressing : In classful addressing, the addressspace is divided into five classes: A, B, C, D, and E.
• Netid and Hostid In classful addressing, an IP addressin class A, B, or C is divided into netid and hostid.
Subnetting: It allows a network to be split into several parts for internal use but still act like a single network to the outsideworld.
• To implement subnetting, the router needs a

subnet mask that indicates the split between network + subnet number and host. Ex. 255.255.252.0/22. A‖/22‖ to indicate that the subnet mask is 22 bits long.

Question 69 | Q00706

Which item is not a parameter or spatial characteristic of a continuous sinusoidal carrier wave?

A. Amplitude

B. Wavelength

C. phase

D. Discrete pulse

Hint

Compare the signal mechanism, medium properties or transmission direction against the definitions and stated physical assumptions.

Answer D: Discrete pulse

A sine wave has amplitude, frequency and phase. Given propagation speed, wavelength follows from frequency and describes its spatial repetition. A discrete pulse is a different waveform description, not a parameter of a continuous sine wave. This distinction concerns the specified carrier model; it does not claim that all pulse modulation is digital, since pulse amplitude and width can vary to carry analog information.

Why each choice is right or wrong

A - Incorrect: Amplitude specifies the sinusoid’s magnitude.

B - Incorrect: Wavelength specifies the spatial repetition of the propagating sinusoid.

C - Incorrect: Phase specifies displacement within the sinusoid’s cycle.

D - Correct: A discrete pulse is a waveform description rather than a sinusoidal parameter.

Primary note proof

Study-note section NET04

Analog signals vary continuously; digital signals use discrete symbol states. Data and signal types are separate: digital bits can modulate an analog carrier. A sine wave has amplitude, frequency and phase. Frequency f counts cycles/second, period T=1/f, and wavelength λ=v/f depends on propagation speed v. Phase specifies displacement within a cycle. Composite signals combine frequencies.

Study-note section NET15

Line coding maps digital bits to digital signal patterns. NRZ uses levels without a forced mid-bit return; Manchester supplies a mid-bit transition for clocking, with bit convention specified. Differential Manchester encodes using transitions relative to previous state. AMI alternates the polarity of successive ones; pseudoternary alternates zero pulses. Block coding adds code redundancy; scrambling replaces problematic patterns without necessarily increasing bit count. Multilevel schemes include 2B1Q and 8B6T; MLT-3 uses a sequence of voltage transitions.

Communication between a radio station and its listeners involves _____ transmission.

A. full-duplex

B. Half-duplex

C. Simplex

D. Automatic

Hint

Use the cited note definitions to identify the requested function or scope, then check each alternative against that same rule.

Answer C: Simplex

An ordinary broadcast radio station transmits to listeners who only receive. The one-direction relationship matches simplex. Evidence: PDF 5.

Why each choice is right or wrong

A - Incorrect: Full duplex requires both sides simultaneously transmitting (PDF 5.)

B - Incorrect: Half duplex requires alternate two-way transmission (PDF 5.)

C - Correct: Simplex explicitly has one sender and one receiver direction (PDF 5.)

D - Incorrect: Automatic is not one of the module transmission modes (PDF 5.)

Primary note proof

Question 71 | Q00708

Which of the following does not describe router functions

A. Broadcast forwarding

B. Internetwork communication

C. Packet filtering

D. Packet switching

Hint

Compare signal repetition, frame forwarding, packet routing and policy enforcement using the stated device or traffic assumptions.

Answer A: Forwarding local broadcasts is not a normal router function

Routers forward IP packets between networks and separate broadcast domains. Accordingly internetwork communication and packet forwarding/switching describe routing, whereas ordinary local link broadcasts are not propagated across routers. Packet filtering can accompany the traffic-control function, so A is the normal-function exception, not a claim that no specially configured broadcast relay can exist.

Why each choice is right or wrong

A - Correct: Ordinary routers bound broadcast domains rather than forwarding local link broadcasts between them.

B - Incorrect: Forwarding IP packets between different networks is the defining router function.

C - Incorrect: Traffic filtering can be implemented alongside routing; it is consistent with router security-policy controls.

D - Incorrect: A router forwards individual packets to next hops, a network-layer packet-switching function.

Primary note proof

Study-note section NET11

> Routers forward IP packets between networks using destination prefixes and next hops. They separate broadcast domains and normally do not forward local link broadcasts. A default gateway is usually a router, while a protocol gateway can translate application formats; therefore a gateway is not inherently a device that implements every OSI layer.

Study-note section NET11

> A firewall allows, rejects or inspects traffic under a security policy; it does not necessarily encrypt. A VPN, Virtual Private Network, provides a logical private connection over another network; a secure VPN authenticates/encrypts its tunnel. A modem modulates outgoing and

Network Address Translation (NAT)
NAT translates the IP addresses of computers in a local network to a single IP address. This address is often used by the router that connects the computers to the Internet. The router can be connected to a DSL modem, cable modem, T1 line, or even a dial-up modem. When other computers on the Internet attempt to access computers within the local network, they only see the IP address of the router. Question 72 | Q00709

Which OSI layer uses acknowledgments, sequencing and receiver flow control for end-to-end process delivery, as illustrated by TCP?

A. Layer 2

B. Layer 4

C. Layer 3

D. Layer 7

Hint

Match the requested scope or data unit to the layer duties in the note; distinguish hop delivery from end-to-end process delivery.

Answer B: Layer 4

Scope separates otherwise similar mechanisms. Reliable link procedures can acknowledge frames and control a single hop, whereas TCP uses sequence numbers, acknowledgments and windows between transport endpoints. The explicit end-to-end process-delivery requirement identifies layer 4. IP at layer 3 offers best-effort delivery, and application services build on the transport service rather than defining this TCP reliability machinery.

Why each choice is right or wrong

A - Incorrect: Layer 2 can provide similar mechanisms only for hop-local link delivery, outside the requested scope.

B - Correct: Layer 4 transport provides TCP’s end-to-end sequencing, acknowledgments and receiver flow control.

C - Incorrect: IP best-effort delivery does not provide the indicated ordered acknowledgment/retransmission service.

D - Incorrect: Application services can build reliability, but the standard link/transport mechanisms named here are not layer-7 duties.

Primary note proof

Study-note section NET14

> Controlled access uses polling, reservations or a token to grant turns; correctly coordinated access avoids contention collisions. Channelization divides frequency, time or code resources. Stop-and-wait sends one frame and waits for ACK, retransmitting on timeout; sequence bits distinguish duplicates. Sliding windows permit multiple unacknowledged frames. Link reliability/flow control is hop-local; transport reliability/flow control is end-to-end. Ethernet detects corruption but does not itself guarantee reliable delivery.

Study-note section NET17

TCP offers a reliable ordered byte stream using sequence numbers, acknowledgments, retransmission and windows. Flow control protects the receiver; congestion control protects network capacity. UDP sends independent datagrams with ports and a checksum but no built-in setup, delivery guarantee, retransmission or ordering. Live interactive traffic may choose UDP when late data is less useful than lost data. Application protocols can add reliability over UDP.

What is the technique of combining multiple input signals or streams onto a shared transmission link?

A. Broadcast

B. Multicast

C. Multiplexing

D. demultiplexing

Hint

Compare the signal mechanism, medium properties or transmission direction against the definitions and stated physical assumptions.

Answer C: Multiplexing

Multiplexing combines input signals or streams so they share a link, using distinctions such as frequency, wavelength or time slots. Demultiplexing is the corresponding receiver operation that separates them. Broadcast and multicast instead describe recipient sets for a message. Link sharing and destination distribution therefore answer different questions, even though a network can use both mechanisms.

Why each choice is right or wrong

A - Incorrect: Broadcast distributes a message to all members of a broadcast domain rather than combining input streams.

B - Incorrect: Multicast distributes to a receiver group rather than combining inputs onto a link.

C - Correct: Multiplexing combines inputs onto the shared link.

D - Incorrect: Demultiplexing separates received multiplexed inputs; it is the reverse operation.

Primary note proof

Study-note section NET32

> Multiplexing combines multiple input streams onto a shared link; demultiplexing separates them at the receiver. It differs from broadcasting one message to many destinations. FDM assigns distinct frequency bands with suitable guard spacing; WDM assigns different optical wavelengths. TDM allocates time slots: synchronous TDM reserves recurrent slots even if an input is idle, while statistical TDM allocates according to demand and needs identification.

Study-note section NET30

> Flooding sends copies on eligible outgoing links with duplicate/lifetime controls; random walk picks a neighbor probabilistically. Unicast targets one destination, broadcast all in a scope, multicast a subscribed group and anycast one member sharing an address, normally nearest under routing metrics. Multi-destination packets can list multiple targets; this is not necessarily identical to broadcast. Group multicast trees use mechanisms such as reverse-path checks; Ethernet spanning tree is a different layer-2 mechanism.

Which one of the following ip address class uses first two octets for network addresses and last two for host addressing?

A. Class C

B. Class D

C. Class A

D. Class B

Hint

Convert the mask to a prefix, separate network and host bits, and apply the relevant subnet-count or usable-host rule.

Answer D: Class B

Two octets are sixteen bits. A historical Class B default /16 therefore uses the first two octets as network bits and the final two as host bits. Class A defaults to one network octet and Class C to three; Class D is multicast. Actual CIDR allocation can override the historical defaults.

Why each choice is right or wrong

A - Incorrect: Class C defaults to /24, using three network octets and one host octet.

B - Incorrect: Class D denotes multicast and does not use the described ordinary network/host division.

C - Incorrect: Class A defaults to /8, using one network octet and three host octets.

D - Correct: Class B defaults to /16, exactly the two-network-octet, two-host-octet division described.

Primary note proof

Study-note section NET22

> Historical classes use leading patterns: A 0 with /8, B 10 with /16, C 110 with /24; D 1110 is multicast and E 1111 reserved. Ordinary class-A first octets are 1-126 because 0 and 127 have special uses. B spans 128-191 and C 192-223. Default usable counts are 2^24-2, 2^16-2 and 254. Modern CIDR requires the actual prefix and overrides class defaults.

Study-note section NET24

> A /p IPv4 prefix has p leading one bits followed by 32-p zeros. Partial octet masks are 128,192,224,240,248,252,254. /19 is 255.255.224.0; /20 is 255.255.240.0; /21 is 255.255.248.0, correcting the study guide’s 255.248.0.0 mistake.

Classful addressing : In classful addressing, the addressspace is divided into five classes: A, B, C, D, and E.
• Netid and Hostid In classful addressing, an IP addressin class A, B, or C is divided into netid and hostid.
Subnetting: It allows a network to be split into several parts for internal use but still act like a single network to the outsideworld.
• To implement subnetting, the router needs a subnet mask that indicates the split between network + subnet number and host. Ex. 255.255.252.0/22. A‖/22‖ to indicate that the subnet mask is 22 bits long.

Question 76 | Q00950

Which of the following OSI layers is NOT correctly matched to its corresponding data

Units (PDU)?

A. Application layer ---> Data

B. Transport layer ---> Segment

C. ¢.

Physical layer ---> Bit

D. Network layer ---> Frame

Hint

Match the requested scope or data unit to the layer duties in the note; distinguish hop delivery from end-to-end process delivery.

Answer D: Network layer ---> Frame

Network data units are packets, while frames are data-link units. The other options follow the described bit/segment and upper-data roles. Evidence: PDF 16, 15, 15, 14, 16.

Why each choice is right or wrong

A - Incorrect: Application handles user data

B - Incorrect: Transport explicitly forms segments

C - Incorrect: Physical transmits bits

D - Correct: Frame belongs to data link; network is packet

Primary note proof

Study-note section NET12

Sending proceeds from application data to transport segment/datagram, network packet, link frame and physical bits/symbols; receiving reverses the order. Each layer serves the layer above. A router removes a received link frame, inspects IP, and creates a new link frame for the next hop. MAC addresses usually change across routed hops; end-to-end IP addresses ordinarily remain until translation.

• At the sending side, the transport layer receives data from the session layer, divides it into units called segments and sends it to the network layer.
• To ensure process to process delivery the transport layer makes use of port address to identify the data from the sending and receiving process.
• The data can be transported in a connection oriented or connectionless manner.
• The Transport layer is responsible for segmentation and reassembly of the message into segments which bear sequence numbers.
• The transport layer also carries out flow control and error control functions; but unlike data link layer these are end to end rather than node to node.
• The main responsibility of the transport layer is process to process delivery of the entire message

Network Layer
• The network layer makes sure that the data is deliveredto the receiver despite multiple intermediate devices.
• The network layer at the sending side accepts data from the transport layer, divides it into packets, addsaddressing information in the header and passes it tothe data link layer.
• The network layer is responsible for source todestination of delivery of data.
• The network layer uses logical address commonlyknown as IP address to recognize devices on the network.
• Each packet is independent of the other and may travelusing different routes to reach the receiver hence may arrive out of turn at the receiver

Data Link Layer
• The Data Link layer adds reliability to the physical layer by providing error detection and correction mechanisms.
• Framing: the Data Link layer receives the data from Network Layer and divides the stream of bits into fixed size manageable units called as Frames and sends it to the physical layer. On the receiver side, the data link layer receives the stream of bits from the physical layer and regroups them into frames and sends them to the Network layer.
• Physical Addressing: The Data link layer appends the physical address in the header of the frame before sending it to physical layer.
• Flow control: The data link layer makes sure that the sender sends the data at a speed at which the receiver canreceive it else if there is an overflow at the receiver sidethe data will be lost.
• Error Control: The data link layer imposes error control mechanism to identify lost or damaged frames, duplicateframes and then retransmit them.
• Access Control: The data link layer imposes access control mechanism to determine which device has right to send data in an multipoint connection setting.
• Main Responsibility: The main responsibility of the data link layer is hop to hop transmission of frames.

Physical Layer:
• The Physical Layer provides a standardized interface to physical transmission media, including: Mechanical specification of electrical connectors and cables, for example maximum cable length, Electrical specification of transmission line and Bit-by-bit or symbol-by-symbol delivery.
• Interface: The Physical Layer defines the characteristics of interfaces between the devices & transmission medium.

• Representation of bits: The physical layer is concerned with transmission of signals from one device to another which involves converting data (1_s & 0_s) into signals and vice versa. It is not concerned with the meaning or interpretation of bits.
• Data rate: The physical layer defines the data transmission rate i.e. number of bits sent per second. It is the responsibility of the physical layer to maintain the defined data rate.

Question 77 | Q00959

Which of the following layers is responsible for encryption, translation and compression?

A. Presentation layer

B. Data link layer

C. .
Transport layer

D. Network layer

Hint

Match the requested scope or data unit to the layer duties in the note; distinguish hop delivery from end-to-end process delivery.

Answer A: Presentation layer

The presentation paragraph explicitly names translation, encryption and compression together. Evidence: PDF 16, 15, 16, 15.

Why each choice is right or wrong

A - Correct: All three functions appear in the presentation definition (PDF 16, 15, 16, 15.)

B - Incorrect: Data link handles frames and link control (PDF 16, 15, 16, 15.)

C - Incorrect: Transport handles segmentation and process delivery (PDF 16, 15, 16, 15.)

D - Incorrect: Network handles addressing and routes (PDF 16, 15, 16, 15.)

Primary note proof

Study-note section NET19

OSI session roles establish/manage dialogs and can coordinate checkpoints so transfer resumes after interruption. Presentation roles translate encodings and handle compression/encryption. Compression reduces representation size; encryption hides content and need not shrink it. Application protocols provide services directly to applications. Practical implementations distribute these functions differently; TLS is not proof of a separate physical presentation-layer device.

Study-note section NET12

Question 78 | Q00962

Which service used to translate domain names to ip address?

A. HTTPS

B. DHCP

C. HTTP

D. DNS

Hint

Separate address width, syntax, reserved scope and the supplied prefix or historical classful convention.

Answer D: DNS

DNS is explicitly the external naming service and Domain Name Service; the hosts-file passage contrasts it with stored host addresses. Evidence: PDF 18, 65, 28.

Why each choice is right or wrong

A - Incorrect: HTTPS is listed by port, not as naming service (PDF 18, 65, 28.)

B - Incorrect: DHCP is host configuration, not the named DNS service (PDF 18, 65, 28.)

C - Incorrect: HTTP is not named as the naming service (PDF 18, 65, 28.)

D - Correct: DNS matches the domain naming function (PDF 18, 65, 28.)

Primary note proof

Study-note section NET20

DNS resolves names to records, including IPv4 A and IPv6 AAAA addresses; it can use UDP or TCP port 53. DHCP dynamically leases IPv4 settings, commonly address, mask, gateway and DNS server. Its basic exchange is discover, offer, request, acknowledge. IP itself does not assign addresses.

Study-note section NET21

HTTP defines web request/response semantics; it is stateless, and a message body may be absent. HTTPS adds TLS protection. FTP transfers files using control and separate data connections; it is not the same protocol as SFTP. SMTP submits and relays mail; POP3 retrieves messages and IMAP accesses/synchronizes server mailboxes. Saying SMTP handles both sending and end-user mailbox retrieval is inaccurate.

Question 79 | Q00968

Which scenario is best suited for UDP rather than TCP protocol?

A. Live video streaming

B. Email transmission

C. Downloading the files

D. Database update

Hint

Identify the requested service or delivery guarantee, then distinguish application roles, transport behavior and address configuration.

Answer A: Live video streaming

UDP is connectionless and omits flow/error control, fitting live streams where timely delivery matters more than repairing old data. Email/file/database transactions need the reliability contrast rather than that latency preference. Evidence: PDF 18, 18.

Why each choice is right or wrong

A - Correct: Live streaming fits the no-repair-delay tradeoff (PDF 18, 18.)

B - Incorrect: Mail transfer is an application for which reliable delivery is preferable (PDF 18, 18.)

C - Incorrect: File download generally needs intact reliable bytes (PDF 18, 18.)

D - Incorrect: Database updates require dependable ordered delivery (PDF 18, 18.)

Primary note proof

Study-note section NET17

> TCP offers a reliable ordered byte stream using sequence numbers, acknowledgments, retransmission and windows. Flow control protects the receiver; congestion control protects network capacity. UDP sends independent datagrams with ports and a checksum but no built-in setup, delivery guarantee, retransmission or ordering. Live interactive traffic may choose UDP when late data is less useful than lost data. Application protocols can add reliability over UDP.

TCP - Transmission Control Protocol: TCP is a reliable connection-oriented, reliable protocol. i.e. a connection is established between the sender and receiver before the data can be transmitted. It divides the data it receives from the upper layer into segments and tags a sequence number to each segment which is used at the receiving end for reordering of data.
UDP - User Datagram Protocol: UDP is a simple protocol used for process to process transmission. It is an unreliable, connectionless protocol for applications that do not require flow control or error control. Question 80 | Q00976

Assume that you have IPv4 addresses in binary notation 11000001 10000011 00011011 11111111 and you are requested to change into dotted decimal notation. What is the equivalent IP address in decimal dotted notation?

A. 192.174.27.255

B. 192.134.67.254

C. ¢.
193.130.28.254

D. 193.131.27.255

Hint

Sum the eight bit weights in each octet independently, then preserve their order in dotted-decimal notation.

Answer D: 193.131.27.255

Compute each octet: 11000001=128+64+1=193; 10000011=128+2+1=131; 00011011=16+8+2+1=27; 11111111=255. Evidence: PDF 19.

Why each choice is right or wrong

A - Incorrect: First and second octets disagree with 193 and 131 (PDF 19.)

B - Incorrect: 192,134,67,254 disagree with the independently converted octets 193,131,27,255 (PDF19).

C - Incorrect: Only first octet matches; 130,28,254 do not (PDF 19.)

D - Correct: 193.131.27.255 matches all four converted octets (PDF 19.)

Primary note proof

Study-note section NET22

Write IPv4 as four decimal octets 0-255, or as 32 binary bits. Use weights 128,64,32,16,8,4,2,1 within each octet. Thus 11000001 10000011 00011011 11111111 is 193.131.27.255. A value such as 257 is impossible. Syntactic validity differs from assignability: an address ending .0 or .255 can be a host under some prefixes.

Address Space: An address space is the total
number ofaddresses used by the protocol.
• If a protocol uses N bits to define an address,
the address space is 2N
because each bit can
have twodifferent values (0 or 1) and N bits
can have 2N values.
• IPv4 uses 32-bit addresses, which means that
the address space is 232 or 4,294,967,296
(more than 4billion).
Notations: There are two notations to show an IPv4 address:
• Binary notation: The IPv4 address is displayed
as 32bits. ex. 11000001 10000011 00011011
11111111
• Dotted decimal notation: To make the IPv4
address easier to read, Internet addresses are
usually written in decimal form with a decimal
point (dot) separatingthe bytes. Each byte (octet)
is 8 bits hence each number in dotted-decimal
notation is a value rangingfrom 0 to 255. Ex.

Question 81 | Q00979

Which one of the following is disadvantage of circuit switching?

A. Predictable performance

B. Low latency

C. Guaranteed bandwidth

D. Limited scalability

Hint

Compare signal repetition, frame forwarding, packet routing and policy enforcement using the stated device or traffic assumptions.

Answer D: Limited scalability due to reserved resources

Circuit switching reserves resources for an established path. NET31 explains that this offers predictable bandwidth but introduces setup, blocking and unused reservation during silence. Those costs constrain how many simultaneous circuits can be supported as demand grows, making limited scalability the disadvantage among the offered choices.

Why each choice is right or wrong

A - Incorrect: Predictable performance is a benefit of allocated circuit resources, not the disadvantage requested.

B - Incorrect: Low transfer latency after setup can be beneficial; the relevant costs include setup and resource reservation.

C - Incorrect: Guaranteed allocated bandwidth is an advantage, although reserving it consumes capacity during silence.

D - Correct: Finite reserved resources and blocking constrain simultaneous connections and therefore scalability as demand grows.

Primary note proof

Study-note section NET31

> Circuit switching sets up a path with reserved resources, transfers data, then releases it. Predictable allocated bandwidth trades against setup/blocking and wasted reservation during silence. A traditional telephone call is the standard example. Packet switching divides data into packets that share links statistically; queueing can add variable delay and loss. This does not make modern voice-over-packet impossible: buffering, scheduling and capacity planning manage it.

In which case must a dedicated communication path between the sender and receiver be established?

A. Circuit switching

B. Packet switching

C. A and B

D. None of the above

Hint

Use the cited note definitions to identify the requested function or scope, then check each alternative against that same rule.

Answer A: Circuit switching

A dedicated path is explicitly required by circuit switching. Packet communication is contrasted with that continuous dedicated circuit.

Why each choice is right or wrong

A - Correct: Circuit establishment creates the dedicated path

B - Incorrect: Packet communication is discrete rather than the dedicated circuit

C - Incorrect: Both incorrectly adds a requirement not inherent to packet switching

D - Incorrect: None excludes the explicitly dedicated circuit

> Datagram packets are forwarded independently. Virtual circuits establish forwarding state, but resource reservation is optional, not a necessary property of every virtual circuit. Message switching stores a complete message before forwarding, without a dedicated end-to-end path. Packet store-and-forward waits for the full packet/frame; cut-through starts after enough header arrives; fragment-free historically waits through the initial collision-sensitive portion. No routing algorithm guarantees that every packet always takes the geometrically shortest route.

Question 83 | Q00999

Which one of the following is a type of network topology in which all devices in the network are interconnected?

A. Star Topology

B. Ring Topology

C. Mesh Topology

D. Tree Topology

Hint

Draw the links and identify shared components, alternate paths and the effect of the specified failure or growth requirement.

Answer C: Mesh Topology

Interpret interconnected as every node directly connected to every other node: this is the module full-mesh definition. Without directly, all connected topologies would qualify. Evidence: PDF 23, 23, 23.

Why each choice is right or wrong

A - Incorrect: Star nodes connect through a central device (PDF 23, 23, 23.)

B - Incorrect: Ring nodes directly connect only to two neighbors (PDF 23, 23, 23.)

C - Correct: Full mesh explicitly connects every node to every other (PDF 23, 23, 23.)

D - Incorrect: Tree is listed but not defined as all-pairs direct connectivity (PDF 23, 23, 23.)

Primary note proof

Study-note section NET08

Physical topology describes link layout; logical topology describes communication/access relationships. Point-to-point links join two endpoints; multipoint links share a medium. A full mesh consists of point-to-point links.

Study-note section NET08

Bus uses a shared backbone; an unterminated break can disrupt the segment. Star connects endpoints through a central device: one edge failure isolates that endpoint, whereas central failure affects the star. Ring forms a loop; basic single rings are vulnerable to a break, while protected dual rings differ. Token passing is associated with Token Ring but is an access method, not a necessary property of every ring. Tree is hierarchical; hybrid combines arrangements.

Star Topology: in this topology, each node is connected directly to a central device called a hub or a switch. Data on a star network passes through the central device (switch) before continuing to its destination. The central device manages and controls all functions of the network. This configuration is common with twisted pair cable. RJ-45 Connectors are used to connect the cable to the Network Interface Card (NIC) of each computer. Its advantages include, ease of installation and reconfiguration, robust (ease of fault identification and isolation), link failure only affects device(s) connected to that link, and is less expensive than mesh. Its drawbacks include more cable requirements (than bus and ring) and single point of failure (if central device fail, the whole system will be down).

Some of its advantages include, easy to install and reconfigure, less expensive (than mesh), and performance is even despite the number of users. Its cons include, break in the ring (such as a disabled station) can disable the entire network, and limitations on media and traffic (limitation on ring length and number of devices).

Question 84 | Q01004

Which statements about IPv4 and IPv6 addresses are correct? Select all that apply.

A. IPv4 is 128-bit and IPv6 is 28-bit

B. IPv4 is physical address

C. IPv6 is logical address

D. IPv4 is 32-bit and IPv6 is 128-bit

Hint

Separate address width, syntax, reserved scope and the supplied prefix or historical classful convention.

Answer C, D: IPv6 is logical address; IPv4 is 32-bit and IPv6 is 128-bit

IPv4 addresses contain 32 bits, and IPv6 addresses contain 128 bits. Both are logical network-layer addresses, so IPv6 being logical is compatible with the width comparison. Physical or MAC addressing belongs to the link layer. The corrected selection instruction allows both true statements to be selected while retaining the original factual comparisons and the two incorrect distractors.

Why each choice is right or wrong

A - Incorrect: IPv4 is 32 bits and IPv6 is 128 bits; neither printed width is correct.

B - Incorrect: IPv4 is network-layer logical addressing, not a physical/MAC address.

C - Correct: IPv6 addresses identify network-layer endpoints logically rather than physical link interfaces.

D - Correct: This gives the correct address lengths: 32 bits for IPv4 and 128 for IPv6.

Primary note proof

Study-note section NET16

IP supplies connectionless best-effort packet delivery, not end-to-end ordering or retransmission. IPv4 addresses are 32 bits. Its minimum header is 20 bytes and can grow to 60 bytes; it is not a 32-bit header. IHL counts 32-bit words; total length includes header and payload. TTL limits lifetime across routers; the protocol field identifies TCP, UDP or another upper-layer protocol.

Study-note section NET23

IPv6 has 128-bit hexadecimal addresses, flexible prefixes and no IPv4-style broadcast. Sources, not routers, fragment IPv6 packets. IPv6 does not automatically encrypt traffic or make authentication unnecessary. Compare IPv6's larger 128-bit address space and encryption support separately; specify the property being evaluated.

which encodes its network number and host number.
• The combination is unique: in principle, no two
machines on the Internet have the same IP address.
• An IPv4 address is 32 bits long

Question 85 | Q01006

Which one of the data communication mediums is used for direct transmission?

A. Induced

B. Crosstalk

C. A and B

D. None of the above

Hint

Compare the signal mechanism, medium properties or transmission direction against the definitions and stated physical assumptions.

Answer D: Neither induced nor crosstalk names a transmission medium

The note identifies cables and unguided radio/microwave/infrared as transmission media. Crosstalk instead names interference from nearby channels in NET06, and induced alone does not name a medium in the note. Regardless of the vague direct-transmission phrase, none of A-C supplies a listed medium, so D is the supported exclusion response.

Why each choice is right or wrong

A - Incorrect: Induced is not a transmission-medium category established here.

B - Incorrect: Crosstalk is unwanted coupling/interference, not a medium for intentional direct transmission.

C - Incorrect: Combining two nonmedium terms does not supply the requested transmission medium.

D - Correct: Neither induced nor crosstalk names a transmission medium among the choices.

Primary note proof

Study-note section NET07

> Radio, microwave and infrared are unguided media. Ground waves follow Earth, sky waves can reflect from ionized layers, and line-of-sight paths require suitable visibility. Microwaves are radio waves in the broader physical classification. Infrared generally does not penetrate walls. Directionality depends on antennas: omnidirectional means broad azimuth coverage, not equal radiation in every 3-D direction. Legacy Ethernet straight-through cables join unlike MDI/MDI-X roles; crossover joins like roles, such as PC-PC or switch-switch. Auto-MDI-X can remove that requirement.

Study-note section NET06

> Attenuation reduces signal strength. Distortion changes shape, often because frequencies have different delays. Noise adds unwanted energy: thermal noise comes from random thermal motion, crosstalk leaks from nearby channels, and impulse noise is a short disturbance. Amplifiers amplify noise too; digital repeaters regenerate decisions but cannot reconstruct every corrupted bit.

TRANSMISSION MEDIA
Transmission media is a means by which a communicationsignal is carried from one system to another
A transmission medium can be defined as anything that cancarry information from a source to a destination. The transmission medium is usually free space, metallic cable orfiber optic cable. Guided and Unguided (WIRELESS) Guided Transmission Media uses a cabling system that guidesthe data signals along a specific path. Out of these twisted-paircable, coaxial cable transport signals in the form of electricsignals and fiber-optic cable transport signals in the form oflight.
Unguided Transmission Media transport data without using a physical conductor. It uses wireless electromagnetic signals to send data. Three types of unguided media:
• Radio waves
• Micro waves
• Infrared.

Data Communication and Computer Networking module | PDF page 10 | lines 18-35

receiver.There are three causes of impairment:
• Attenuation
• Distortion
• Noise
Attenuation
Attenuation results in loss of energy due to distance. Whena signal travels through a medium, it loses some of its energy in overcoming the resistance of the medium. The electrical energy in the signal may convert to heat. To compensate for this loss, amplifiers are used to amplify thesignal.
Distortion
Distortion changes the shape of the signal.
Noise
Noise is any unwanted signal that is mixed or combined with the original signal during transmission. Due to noise the original signal is altered and signal received is not sameas the one sent.

Question 86 | Q01160

Which OSI layer is responsible for process-to-process delivery and segmentation?

A. Network Layer

B. Transport Layer

C. Physical Layer

D. Data Link Layer

Hint

Match the requested scope or data unit to the layer duties in the note; distinguish hop delivery from end-to-end process delivery.

Answer B: Transport Layer

Transport supplies process-to-process delivery and segmentation. The network layer handles logical addressing and routing, the data-link layer handles hop delivery of frames, and the physical layer transports bits or symbols. Restoring the four readable source rows gives the transport option its proper position. Reliability remains protocol-dependent: identifying transport does not imply that every transport protocol guarantees delivery.

Why each choice is right or wrong

A - Incorrect: Network handles routing and logical addressing rather than process delivery.

B - Correct: Transport supplies process delivery and segmentation.

C - Incorrect: Physical transports signals and bits rather than process messages.

D - Incorrect: Data link supplies hop-local frame delivery rather than process-to-process delivery.

Primary note proof

Study-note section NET17

> TCP offers a reliable ordered byte stream using sequence numbers, acknowledgments, retransmission and windows. Flow control protects the receiver; congestion control protects network capacity. UDP sends independent datagrams with ports and a checksum but no built-in setup, delivery guarantee, retransmission or ordering. Live interactive traffic may choose UDP when late data is less useful than lost data. Application protocols can add reliability over UDP.

Study-note section NET12

> Sending proceeds from application data to transport segment/datagram, network packet, link frame and physical bits/symbols; receiving reverses the order. Each layer serves the layer above. A router removes a received link frame, inspects IP, and creates a new link frame for the next hop. MAC addresses usually change across routed hops; end-to-end IP addresses ordinarily remain until translation.

Physical Layer:
• The Physical Layer provides a standardized interface to

physical transmission media, including: Mechanical specification of electrical connectors and cables, for example maximum cable length, Electrical specification of transmission line and Bit-by-bit or symbol-by-symbol delivery.
• Interface: The Physical Layer defines the characteristics of interfaces between the devices & transmission medium.

Data Link Layer
• The Data Link layer adds reliability to the physical layer by providing error detection and correction mechanisms.
• Framing: the Data Link layer receives the data from Network Layer and divides the stream of bits into fixed size manageable units called as Frames and sends it to the physical layer. On the receiver side, the data link layer receives the stream of bits from the physical layer and regroups them into frames and sends them to the Network layer.
• Physical Addressing: The Data link layer appends the physical address in the header of the frame before sending it to physical layer.
• Flow control: The data link layer makes sure that the sender sends the data at a speed at which the receiver canreceive it else if there is an overflow at the receiver sidethe data will be lost.
• Error Control: The data link layer imposes error control mechanism to identify lost or damaged frames, duplicateframes and then retransmit them.
• Access Control: The data link layer imposes access control mechanism to determine which device has right to send data in an multipoint connection setting.
• Main Responsibility: The main responsibility of the data link layer is hop to hop transmission of frames.

Question 87 | Q01161

Which IP version uses 32-bit addresses and corresponding 32-bit subnet masks?

A. IPv6

B. IPv4

C. Addressing

D. None of the above

Hint

Convert the mask to a prefix, separate network and host bits, and apply the relevant subnet-count or usable-host rule.

Answer B: IPv4

IPv4 uses 32-bit addresses, commonly written as four decimal octets, and its subnet mask selects a prefix within those 32 bits. IPv6 addresses instead contain 128 bits. The generic word addressing does not identify an IP version, and none of the above fails because the required version is listed.

Why each choice is right or wrong

A - Incorrect: IPv6 uses 128-bit addresses, not the required 32-bit addresses.

B - Correct: IPv4 addresses and their masks contain 32 bits.

C - Incorrect: Addressing is a general activity, not the IP version requested.

D - Incorrect: IPv4 is listed, so none of the above is false.

Primary note proof

Study-note section NET22

> Write IPv4 as four decimal octets 0-255, or as 32 binary bits. Use weights 128,64,32,16,8,4,2,1 within each octet. Thus 11000001 10000011 00011011 11111111 is 193.131.27.255. A value such as 257 is impossible. Syntactic validity differs from assignability: an address ending .0 or .255 can be a host under some prefixes.

Study-note section NET23

> IPv6 has 128-bit hexadecimal addresses, flexible prefixes and no IPv4-style broadcast. Sources, not routers, fragment IPv6 packets. IPv6 does not automatically encrypt traffic or make authentication unnecessary. Compare IPv6's larger 128-bit address space and encryption support separately; specify the property being evaluated.

Study-note section NET24

A /p IPv4 prefix has p leading one bits followed by 32-p zeros. Partial octet masks are 128,192,224,240,248,252,254. /19 is 255.255.224.0; /20 is 255.255.240.0; /21 is 255.255.248.0, correcting the study guide's 255.248.0.0 mistake.

Question 88 | Q01195

What is the main goal of data compression while it paths in different network layers? Its goal is to:

A. Securing data

B. Minimize the size of data

C. Select the best path of destination devices

D. All of the above

Hint

Match the requested scope or data unit to the layer duties in the note; distinguish hop delivery from end-to-end process delivery.

Answer B: Minimize the size of data

NET19 distinguishes reducing representation size from hiding content. Compression targets the amount of data needed to represent information, while encryption provides concealment and routing selects paths. Therefore minimizing size is the compression goal; combining it with security and path selection in the all option misattributes unrelated functions.

Why each choice is right or wrong

A - Incorrect: Securing or concealing content is an encryption/security function, not the primary goal of compression.

B - Correct: Compression reduces representation size, directly matching minimization of data size.

C - Incorrect: Path selection belongs to routing rather than the representation-size transformation performed by compression.

D - Incorrect: Only size reduction describes compression here; security and route selection are separate functions.

Primary note proof

Study-note section NET19

> OSI session roles establish/manage dialogs and can coordinate checkpoints so transfer resumes after interruption. Presentation roles translate encodings and handle compression/encryption. Compression reduces representation size; encryption hides content and need not shrink it. Application protocols provide services directly to applications. Practical implementations distribute these functions differently; TLS is not proof of a separate physical presentation-layer device.

Study-note section NET30

> Routing computes paths; forwarding chooses a next hop for an individual packet. Select the matching route with the longest prefix, then apply the routing system’s tie-breaking criteria. A default /0 matches when nothing more specific does. Static routes are configured; dynamic protocols exchange reachability. Distance vector uses neighbor estimates, while link state

distributes link information and computes shortest paths. Interior protocols operate within an autonomous system; BGP exchanges routes between systems.

Question 89 | Q01218

Which single option gives the complete set of listed protocols used by end users to retrieve or synchronize stored mailboxes?

A. POP3

B. IMAP

C. SMTP

D. Both POP3 and IMAP

Hint

Identify the requested service or delivery guarantee, then distinguish application roles, transport behavior and address configuration.

Answer D: Both POP3 and IMAP

POP3 retrieves stored messages, while IMAP accesses and synchronizes mailboxes held on the server. SMTP instead submits and relays messages between mail-system components. Since the question asks for the complete set of mailbox-access protocols, either POP3 or IMAP alone is incomplete. The combined choice correctly includes both without assigning mailbox retrieval to the mail transfer protocol.

Why each choice is right or wrong

A - Incorrect: POP3 retrieves messages but alone omits IMAP, so it is an incomplete selection.

B - Incorrect: IMAP accesses mailboxes but alone omits POP3, so it is incomplete.

C - Incorrect: SMTP submits and relays messages; it is not the end-user mailbox retrieval protocol described.

D - Correct: Both POP3 and IMAP provide the requested mailbox-access functions.

Primary note proof

Study-note section NET21

HTTP defines web request/response semantics; it is stateless, and a message body may be absent. HTTPS adds TLS protection. FTP transfers files using control and separate data connections; it is not the same protocol as SFTP. SMTP submits and relays mail; POP3 retrieves messages and IMAP accesses/synchronizes server mailboxes. Saying SMTP handles both sending and end-user mailbox retrieval is inaccurate.

A. Bits

B. Frames

C. Packets

D. Segments

Hint

Question 91 | Q01258

What is the maximum number of IP addresses that can be assigned to hosts on a local subnet that uses the 255.255.255.224 subnet mask?

A. 14

B. 32

C. 24

D. 30

Hint

Convert the mask to a prefix, separate network and host bits, and apply the relevant subnet-count or usable-host rule.

Answer D: 30 usable host addresses

The final mask octet 224 is 11100000, making the prefix /27 and leaving five host bits. There are 2^5=32 addresses in each block. For an ordinary broadcast subnet, one identifies the network and one the broadcast, leaving 30 assignable host addresses; total addresses must not be confused with usable hosts.

Why each choice is right or wrong

A - Incorrect: Fourteen usable hosts would correspond to /28, not this /27 mask.

B - Incorrect: Thirty-two is the total address count before reserving the network and broadcast addresses.

C - Incorrect: Twenty-four is not the usable count obtained from five host bits and two reservations.

D - Correct: Five host bits yield 32 total addresses minus two reserved addresses, leaving 30 hosts.

Primary note proof

Study-note section NET25

> For ordinary broadcast LANs let h=32-p. Total addresses=2^h; usable hosts=2^h-2, reserving network and directed broadcast. Find the changing octet's increment as 256-mask octet, round the address down to a multiple, and extend through the next boundary minus one.

Address Space: An address space is the total number ofaddresses used by the protocol.
• If a protocol uses N bits to define an address, the address space is 2N because each bit can have twodifferent values (0 or 1) and N bits can have 2N values.
• IPv4 uses 32-bit addresses, which means that the address space is 232 or 4,294,967,296 (more than 4billion).
Notations: There are two notations to show an IPv4 address:
• Binary notation: The IPv4 address is displayed as 32bits. ex. 11000001 10000011 00011011 11111111
• Dotted decimal notation: To make the IPv4 address easier to read, Internet addresses are usually written in decimal form with a decimal point (dot) separatingthe bytes. Each byte (octet) is 8 bits hence each number in dotted-decimal notation is a value rangingfrom 0 to 255. Ex. 129.11.11.239

Which one of the following is not LAN technologies?

A. Token Ring

B. Ethernet

C. X.25 or Frame Relay

D. None

Hint

Use the cited note definitions to identify the requested function or scope, then check each alternative against that same rule.

Answer C: X.25 or Frame Relay

The module explicitly contrasts LAN Ethernet/Token Ring with WAN X.25/Frame Relay. Evidence: PDF 26.

Why each choice is right or wrong

A - Incorrect: Token Ring is explicitly a LAN technology (PDF 26.)

B - Incorrect: Ethernet is explicitly a LAN technology (PDF 26.)

C - Correct: X.25 and Frame Relay are explicitly WAN technologies (PDF 26.)

D - Incorrect: None fails because the WAN pair is present (PDF 26.)

Primary note proof

Study-note section NET-S05

> Ethernet and Token Ring are traditional LAN technologies. X.25 and Frame Relay are traditional WAN technologies. TCP/IP can run over different network-access technologies; its Internet-layer packet service does not require one particular link medium or frame format.

Study-note section NET31

> Circuit switching sets up a path with reserved resources, transfers data, then releases it. Predictable allocated bandwidth trades against setup/blocking and wasted reservation during silence. A traditional telephone call is the standard example. Packet switching divides data into packets that share links statistically; queueing can add variable delay and loss. This does not make modern voice-over-packet impossible: buffering, scheduling and capacity planning manage it.

B - Incorrect: ARP resolves IP to hardware address (PDF 17, 27, 17, 17.)

C - Correct: ICMP explicitly provides error/diagnostic messages (PDF 17, 27, 17, 17.)

D - Incorrect: IGMP supports group recipients rather than these transit diagnostics (PDF 17, 27, 17, 17.)

Primary note proof

Study-note section NET20

ARP resolves an on-link IPv4 next hop to a link address, using a broadcast request and normally unicast reply. For an off-subnet target, ARP resolves the gateway, not the remote target's MAC. It bridges the network/link addressing boundary and is often classified at the link layer; calling ARP simply a network protocol uses a loose textbook convention. RARP reverses hardware-to-IP lookup; BOOTP/DHCP support boot configuration. ICMP reports errors and diagnostics; IGMP manages IPv4 multicast membership. These are separate companion protocols, not four pieces whose combination is IP.

Study-note section NET16

IP supplies connectionless best-effort packet delivery, not end-to-end ordering or retransmission. IPv4 addresses are 32 bits. Its minimum header is 20 bytes and can grow to 60 bytes; it is not a 32-bit header. IHL counts 32-bit words; total length includes header and payload. TTL limits lifetime across routers; the protocol field identifies TCP, UDP or another upper-layer protocol.

ICMP- Internet Control Message Protocol: It is a
signaling mechanism used to inform the sender about
datagram problemsthat occur during transit. It is used by

Internet Control Message Protocol (ICMP):
works at the Network layer and is used by IP for
many different services. ICMP is a management
protocol and messagingservice provider for IP. The
following are some common events and messages
that ICMP relates to:
Destination Unreachable: If a router can‘t send an
IP datagram any further, it uses ICMP to send a
message back to the sender, advising it of the
situation.
Buffer Full: If a router‘s memory buffer for
receiving incoming datagrams is full, it will use
ICMP to send out this message until the congestion
abates.
Hops: Each IP datagram is allotted a certain number
of routers, called hops, to pass through. If it reaches
its limitof hops before arriving at its destination, the
last router to receive that datagram deletes it. The

executioner router then uses ICMP to send an obituary message, informing the sending machine of the demise of its datagram.
Ping (Packet Internet Groper) uses ICMP echo messages to check the physical and logical connectivity of machineson a network.
Traceroute Using ICMP timeouts, Traceroute is used to discover the path a packet takes as it traverses an Internetwork.

ARP - Address Resolution Protocol: It is used to resolve thephysical address of a device on a network, where its logical address is known.
Physical address is the 48 bit address that is imprinted on theNIC or LAN card, Logical address is the Internet Address orcommonly known as IP address that is used to uniquely & universally identify a device.
RARP- Reverse Address Resolution Protocol: It is used bya device on the network to find its Internet address when it knows its physical address.

Network Layer or IP
Also called as the Internetwork Layer (IP). It holds the IP protocol which is a network layer protocol and is responsiblefor source to destination transmission of data.
The Internetworking Protocol (IP) is a connection-less & unreliable protocol.
It is a best effort delivery service. i.e. there is no error checking in IP, it simply sends the data and relies on its underlying layers to get the data transmitted to the destination.Even if it is unreliable IP cannot be considered weak and useless; since it provides only the functionality that is requiredfor transmitting data thereby giving maximum efficiency.
Since there is no mechanism of error detection or correction in IP, there will be no delay introduced on a medium where thereis no error at all.

Question 94 | Q01277

Hana divides a 172.16.0.0/16 parent into equal /19 broadcast subnets. Counting every subnet, which option correctly gives the subnet count and usable hosts per subnet?

A. 7 subnets and 30 valid hosts

B. 8 subnets and 8190 usable hosts in each subnet

C. 8 subnets and 2046 valid hosts in each subnet

D. 7 subnets and 2046 valid hosts in each subnet

Hint

Convert the mask to a prefix, separate network and host bits, and apply the relevant subnet-count or usable-host rule.

Answer B: 8 subnets and 8190 usable hosts in each subnet

The /16-to-/19 subdivision borrows three bits, so it creates eight equal subnets. Each /19 leaves thirteen host bits, producing 8192 total addresses and 8190 usable hosts after network and broadcast reservations. Modern counting includes every subnet. The option changes only the obsolete subnet count; the calculation still requires distinguishing child subnet count from host capacity.

Why each choice is right or wrong

A - Incorrect: Neither seven subnets nor thirty usable hosts follows from /19; thirty hosts would require /27.

B - Correct: Three subnet bits give eight subnets and thirteen host bits give 8190 usable hosts.

C - Incorrect: Eight subnets is correct for the stated /16 parent, but a /19 has 8190 usable hosts rather than 2046.

D - Incorrect: Seven lacks a stated counting basis, and 2046 hosts corresponds to /21 rather than /19.

Primary note proof

Study-note section NET26

> To split parent /a into equal /p blocks, borrow b=p-a bits and obtain 2^b subnets. Do not subtract two subnets under modern practice. For a Class B /16 parent split to /19, b=3 gives eight subnets, each with 8192 addresses and 8190 conventional hosts. A /19 alone does not state its parent.

Study-note section NET25

> For ordinary broadcast LANs let h=32-p. Total addresses=2^h; usable hosts=2^h-2, reserving network and directed broadcast. Find the changing octet’s increment as 256-mask octet, round the address down to a multiple, and extend through the next boundary minus one.

IP addresses: IP address uniquely identifies a device on the Internet. Every host and router on the Internet has an IP address, which encodes its network number and host number.
• The combination is unique: in principle, no two machines on the Internet have the same IP address.
• An IPv4 address is 32 bits long
• They are used in the Source address and Destination address fields of IP packets.
• An IP address does not refer to a host but it refers to a network interface.

Data Communication and Computer Networking module | PDF page 19 | lines 2-22

Address Space: An address space is the total number ofaddresses used by the protocol.
• If a protocol uses N bits to define an address, the address space is 2N because each bit can have twodifferent values (0 or 1) and N bits can have 2N values.
• IPv4 uses 32-bit addresses, which means that the address space is 232 or 4,294,967,296 (more than 4billion).
Notations: There are two notations to show an IPv4 address:
• Binary notation: The IPv4 address is displayed as 32bits. ex. 11000001 10000011 00011011 11111111
• Dotted decimal notation: To make the IPv4 address easier to read, Internet addresses are usually written in decimal form with a decimal point (dot) separatingthe bytes. Each byte (octet) is 8 bits hence each number in dotted-decimal notation is a value rangingfrom 0 to 255. Ex. 129.11.11.239

Data Communication and Computer Networking module | PDF page 19 | lines 23-36

Classful addressing : In classful addressing, the addressspace is divided into five classes: A, B, C, D, and E.
• Netid and Hostid In classful addressing, an IP addressin class A, B, or C is divided into netid and hostid.
Subnetting: It allows a network to be split into several parts for internal use but still act like a single network to the outsideworld.
• To implement subnetting, the router needs a subnet mask that indicates the split between network + subnet number and host. Ex.

255.255.252.0/22. A‖/22‖ to indicate that the subnet mask is 22 bits long.

Computer Science model exam 2 · Question 98

Question 95 | Q01494

A switch-based LAN is more efficient than a hub-based LAN because:

A. A switch can connect two different LANs together

B. A switch allows multiple computers to send at the same time

C. A hub uses reservation-based MAC protocols

D. A switch uses contention-based MAC protocols

E. A switch is easier to implement than a hub.

Hint

Compare signal repetition, frame forwarding, packet routing and policy enforcement using the stated device or traffic assumptions.

Answer B: A switch allows multiple computers to send at the same time

Switches direct frames toward the MAC recipient instead of copying all traffic to every port. Independent point-to-point communication permits multiple simultaneous exchanges on suitable separate ports. Evidence: PDF 12, 12.

Why each choice is right or wrong

A - Incorrect: Connecting LANs is not the efficiency distinction in the switch/hub comparison (PDF 12, 12.)

B - Correct: Selective independent port communication explains the improvement (PDF 12, 12.)

C - Incorrect: The module says hubs repeat/broadcast, not reservation-based MAC (PDF 12, 12.)

D - Incorrect: A switch is not defined by a contention-based MAC distinction from hubs (PDF 12, 12.)

E - Incorrect: The module calls switches more intelligent and expensive, not easier to implement (PDF 12, 12.)

Primary note proof

Study-note section NET10

A bridge or ordinary Ethernet switch operates at layer 2. It learns source-MAC-to-port mappings, looks up the destination, forwards a known unicast to its port, filters it if the destination is on the incoming segment, and floods an unknown unicast or broadcast within its VLAN. A switch does

not always send only to one destination port. Wireless access points normally bridge wireless and wired link-layer traffic.

Study-note section NET10

Each switch port separates collision domains; full-duplex point-to-point Ethernet has no collisions and does not use CSMA/CD. Switching permits independent conversations simultaneously. Broadcasts still reach the VLAN unless another control filters them. A layer-3 switch also routes, so device marketing names do not override the function being examined.

Study-note section NET09

A repeater regenerates layer-1 signals without inspecting destination addresses. An active hub is a multiport repeater: it repeats incoming signals onto other ports, placing half-duplex endpoints in one collision domain. A passive hub is a connector. A hub neither learns MAC addresses nor eliminates collisions. An endpoint such as a network printer consumes services; routers, hubs and access points are intermediary devices.

oneport onto all the other ports, a switch keeps a record
of the MAC addresses of the devices attached to it.
When the switch receives a data packet, it forwards the
packetdirectly to the recipient device by looking up the
MAC address.
• Switch is intelligent and expensive than Hub
• Switch is a point to point communication device

Question 96 | Q01496

Compare circuit switching versus datagram packet switching. An advantage of circuit switching is it:

A. Allows end hosts to use different line rates.

B. Can guarantee the performance delivered to end hosts.

C. Establishes a connection before sending data.

D. Sends packets instead of signals.

E. Is non-blocking.

F. Is efficient when the amount of traffic to be sent by end hosts varies over time.

Hint

Compare signal repetition, frame forwarding, packet routing and policy enforcement using the stated device or traffic assumptions.

Answer B: Reserved resources can guarantee performance

The reserved-resource circuit supports predictable allocated bandwidth and performance, the advantage contrasted with datagram links shared statistically. Establishing a connection is a procedural characteristic and imposes setup cost rather than itself guaranteeing a benefit. The note explicitly identifies blocking and wasted reservation during silence, ruling out the nonblocking and variable-traffic-efficiency claims.

Why each choice is right or wrong

A - Incorrect: Different endpoint line rates are not the reserved-circuit advantage established in the note.

B - Correct: Reserved resources provide predictable allocated bandwidth and can guarantee the agreed performance to endpoints.

C - Incorrect: Setup is a characteristic of circuit operation, but is not itself the performance advantage requested.

D - Incorrect: Circuit switching establishes reserved resources; packet-versus-signal wording does not describe its advantage.

E - Incorrect: NET31 explicitly identifies blocking as a circuit-switching tradeoff.

F - Incorrect: Reservations can be wasted during silence, making highly variable traffic less efficient on fixed circuits.

Primary note proof

Study-note section NET31

> Circuit switching sets up a path with reserved resources, transfers data, then releases it. Predictable allocated bandwidth trades against setup/blocking and wasted reservation during silence. A traditional telephone call is the standard example. Packet switching divides data into

packets that share links statistically; queueing can add variable delay and loss. This does not make modern voice-over-packet impossible: buffering, scheduling and capacity planning manage it.

Study-note section NET31

Datagram packets are forwarded independently. Virtual circuits establish forwarding state, but resource reservation is optional, not a necessary property of every virtual circuit. Message switching stores a complete message before forwarding, without a dedicated end-to-end path. Packet store-and-forward waits for the full packet/frame; cut-through starts after enough header arrives; fragment-free historically waits through the initial collision-sensitive portion. No routing algorithm guarantees that every packet always takes the geometrically shortest route.

Circuit Switching: In circuit switching, two communicating stations are connected by a dedicated communication path which consists of intermediate nodes in the network and the links that connect these nodes.
It involved the following three distinct steps
• Circuit Establishment: To establish an end-to-end connection before any transfer of data.
• Data transfer: Transfer data is from the source to the destination. The data may be analog or digital, depending on the nature of the network. The connection is generally full-duplex.
• Circuit disconnect: Terminate connection at the end of data transfer. Signals must be propagated to deallocate the dedicated resources.

Message Switching:
Packet Switching: Packet switching was designed to address the shortcomings of circuit switching in dealing with data communication. Unlike circuit switching where communication is continuous along a dedicated circuit, in packet switching, communication is discrete in form of packets.
The three switching modes to choose from are:
• Cut-through
• Store-and-forward
• Fragment-free

A _____ is a system in which multiple computers are connected to each other to share information and resources.

A. Hardware

B. Software

C. Number system

D. Computer network

Hint

Use the cited note definitions to identify the requested function or scope, then check each alternative against that same rule.

Answer D: Computer network

The module defines a network as connected computers sharing resources and exchanging information. Evidence: PDF 22.

Why each choice is right or wrong

A - Incorrect: Hardware alone need not connect computers for sharing (PDF 22.)

B - Incorrect: Software alone is not the system of connected devices (PDF 22.)

C - Incorrect: A number system is a representation scheme, not shared computers (PDF 22.)

D - Correct: Computer network matches the supplied definition (PDF 22.)

Primary note proof

Study-note section NET-S04

> A computer network connects computers or other devices so they can exchange information and share resources such as files, storage and printers. The interconnection uses both hardware and software; neither hardware alone nor software alone is the definition of the whole network.

Study-note section NET02

> An intranet serves an organization internally; an extranet exposes selected services to approved outsiders. Neither term alone specifies geographic size. A client requests a service; a server supplies it. Peer systems may perform both roles. Dedicated servers concentrate on service workloads but can still be clients of DNS, backup or update services. A ten-user cutoff is a teaching guideline, not a technical law. Centralization simplifies administration but creates dependencies; peer networks still need security.

A network can be defined as two or more computers connected together in such a way that they can share resources. The primary purpose of a network is to share resources, and a resource could be:
• a file,
• a folder,
• a printer,
• a disk drive, or just about anything else that exists on a computer.
Therefore, a computer network is simply a collection of computers or other hardware devices that are connected together, either physically or logically, using special hardware and software, to allow them to exchange information and cooperate. Networking is the term that describes the processes involved in designing, implementing, upgrading, managing and otherwise working with networks and network technologies.

NIC stands for?

A. Network Internal Card

B. Network Interconnect Card

C. Network Interface Card

D. Network Interface Component

Hint

Find the full expansion in the terminology note and compare each word rather than only matching initials.

Answer C: Network Interface Card

The star cabling paragraph explicitly expands NIC as Network Interface Card. Evidence: PDF 23.

Why each choice is right or wrong

A - Incorrect: Internal differs from the printed Interface (PDF 23.)

B - Incorrect: Interconnect differs from the printed Interface (PDF 23.)

C - Correct: Exact expansion is Network Interface Card (PDF 23.)

D - Incorrect: Component differs from the printed Card (PDF 23.)

Primary note proof

A. network

B. topology

Answer B: topology

Topology is explicitly the shape/layout and relation among links and devices, matching the way nodes are linked. Evidence: PDF 22, 11.

Why each choice is right or wrong

A - Incorrect: Network is the collection of devices, not the specific arrangement term (PDF 22, 11.)

B - Correct: Topology is the defined arrangement term (PDF 22, 11.)

C - Incorrect: Connection is a generic link rather than the named layout concept (PDF 22, 11.)

D - Incorrect: Interconnectivity is the organizing attribute, while topology names its layout (PDF 22, 11.)

A topology that involves Tokens.

A. Star

B. Bus

C. Ring

D. Daisy Chaining

Hint

Draw the links and identify shared components, alternate paths and the effect of the specified failure or growth requirement.

Answer C: Ring in the conventional Token Ring association

NET08 associates token passing with Token Ring, so ring is the intended topology among these choices. The answer is an association rather than a universal claim: token passing is an access method and not every ring must use it. None of the other topology names inherently establishes token access.

Why each choice is right or wrong

A - Incorrect: A star describes central connections and does not itself specify token access.

B - Incorrect: A bus describes a shared backbone; token access is not inherent in that layout.

C - Correct: Token Ring is the conventional association, with the caveat that tokens are an access method.

D - Incorrect: Daisy chaining describes successive connections and does not by itself establish token passing.

Primary note proof

Study-note section NET08

Bus uses a shared backbone; an unterminated break can disrupt the segment. Controlled access uses polling, reservations or a token to grant turns; correctly coordinated access avoids contention collisions. Channelization divides frequency, time or code resources. Stop-and-wait sends one frame and waits for ACK, retransmitting on timeout; sequence bits distinguish duplicates. Sliding windows permit multiple unacknowledged frames. Ring Topology: in this topology, all devices are connected to one another in the shape of a closed loop, so that each device is connected directly to two other devices, one on either side of it. Some of its advantages include, easy to install and reconfigure, less expensive (than mesh), and performance is even despite the number of users. Its cons include, break in the ring (such as a disabled station) can disable the entire network, and limitations on media and traffic (limitation on ring length and number of devices).

Bus Topology: in this topology all devices are connected to a central cable, called the bus or backbone, which is terminated at its ends. The purpose of the terminators is to stop the signal from bouncing, thereby clearing the cable so that other computers can send data. Message transmitted along the Bus is visible to all computers connected to the backbone cable. As the message arrives at each workstation, the workstation checks the destination address contained in the message either to process or

drop the packet if it matches or not respectively. Its advantages are, ease of installation and less amount of cable requirement. Its main drawback is, the entire network will be shut down if there is a break in the main cable.

Question 103 | Q01527

_____ topology requires a multipoint connection.

A. Star

B. Mesh

C. Ring

D. Bus

Hint

Draw the links and identify shared components, alternate paths and the effect of the specified failure or growth requirement.

Answer D: Bus uses a shared multipoint backbone

A multipoint connection shares one medium among endpoints. NET08 describes bus as a shared backbone, while a full mesh consists of separate point-to-point links. Ordinary star and ring link layouts connect endpoints through separate adjacent links rather than requiring a common shared bus. D is therefore the topology matching multipoint sharing.

Why each choice is right or wrong

A - Incorrect: A star connects endpoints through a central device using individual edge links rather than requiring a shared backbone.

B - Incorrect: A full mesh consists of point-to-point links, explicitly correcting the old contradictory multipoint claim.

C - Incorrect: A ring forms successive neighboring links, not the common shared backbone requested.

D - Correct: A bus shares one backbone among multiple endpoints, matching a multipoint connection.

Primary note proof

Study-note section NET08

Physical topology describes link layout; logical topology describes communication/access relationships. Point-to-point links join two endpoints; multipoint links share a medium. A full mesh consists of point-to-point links.

Study-note section NET08

Bus uses a shared backbone; an unterminated break can disrupt the segment. Star connects endpoints through a central device: one edge failure isolates that endpoint, whereas central failure affects the star. Ring forms a loop; basic single rings are vulnerable to a break, while protected dual rings differ. Token passing is associated with Token Ring but is an access method, not a necessary property of every ring. Tree is hierarchical; hybrid combines arrangements.

NETWORK TOPOLOGY
A network topology is a description of the layout of the region or area covered by that network.
There are two types of connections. They are: point-to-point and multi-point.
Point-to-point connections provide a direct link between two devices.
Multi-point connections provide a link between three or more devices on a network.
There are seven basic topologies in the study of network topology:
• Point-to-point topology,
• Bus (point-to-multipoint) topology,
• Ring topology,
• Star topology,
• Hybrid topology,
• Mesh topology and,
• Tree topology.

Star Topology: in this topology, each node is connected directly to a central device called a hub or a switch. Data on a star network passes through the central device (switch) before continuing to its destination. The central device manages and controls all functions of the network. This configuration is common with twisted pair cable. RJ-45 Connectors are used to connect the cable to the Network Interface Card (NIC) of each computer. Its advantages include, ease of installation and reconfiguration, robust (ease of fault identification and isolation), link failure only affects device(s) connected to that link, and is less expensive than mesh. Its drawbacks include more cable requirements (than bus and ring) and single point of failure (if central device fail, the whole system will be down).

Question 107 | Q01531

A _____ is a device that forwards packets between networks by processing the routing information included in the packet.

A. bridge

B. firewall

C. router

D. hub

Hint

Compare signal repetition, frame forwarding, packet routing and policy enforcement using the stated device or traffic assumptions.

Answer C: router

Router forwarding explicitly compares the destination IP to routing table entries to choose the next path between networks. Evidence: PDF 12, 12, 12, 48.

Why each choice is right or wrong

A - Incorrect: Bridge filters same-protocol LAN traffic using MAC (PDF 12, 12, 12, 48.)

B - Incorrect: A firewall permits/denies access; that is not the defining routing-table function (PDF 12, 12, 12, 48.)

C - Correct: Router matches the stated destination-IP routing procedure (PDF 12, 12, 12, 48.)

D - Incorrect: Hub repeats/broadcasts without destination-route analysis (PDF 12, 12, 12, 48.)

Primary note proof

Study-note section NET11

> Routers forward IP packets between networks using destination prefixes and next hops. They separate broadcast domains and normally do not forward local link broadcasts. A default gateway is usually a router, while a protocol gateway can translate application formats; therefore a gateway is not inherently a device that implements every OSI layer.

Study-note section NET09

> A repeater regenerates layer-1 signals without inspecting destination addresses. An active hub is a multiport repeater: it repeats incoming signals onto other ports, placing half-duplex endpoints in one collision domain. A passive hub is a connector. A hub neither learns MAC addresses nor eliminates collisions. An endpoint such as a network printer consumes services; routers, hubs and access points are intermediary devices.

Study-note section NET10

> A bridge or ordinary Ethernet switch operates at layer 2. It learns source-MAC-to-port mappings, looks up the destination, forwards a known unicast to its port, filters it if the destination is on the incoming segment, and floods an unknown unicast or broadcast within its VLAN. A switch does

not always send only to one destination port. Wireless access points normally bridge wireless and wired link-layer traffic.

Network Address Translation (NAT)
NAT translates the IP addresses of computers in a local
network to a single IP address. This address is often used
by the router that connects the computers to the Internet.
The router can be connected to a DSL modem, cable
modem, T1 line, or even a dial-up modem. When other
computers on the Internet attempt to access computers

within the local network, they only see the IP address of the router. This adds an extra level of security, since the router can be configured as a firewall, only allowing authorized systems to access the computers within the network.

Question 108 | Q01532

The physical layer is concerned with _____

A. bit-by-bit delivery

B. process to process delivery

C. application to application delivery

D. port to port delivery

Hint

Match the requested scope or data unit to the layer duties in the note; distinguish hop delivery from end-to-end process delivery.

Answer A: bit-by-bit delivery

Physical-layer standardized interfaces deliver bit-by-bit or symbol-by-symbol; processes and ports are transport concerns. Evidence: PDF 14, 16.

Why each choice is right or wrong

A - Correct: Bit-by-bit delivery is explicit (PDF 14, 16.)

B - Incorrect: Process delivery is transport (PDF 14, 16.)

C - Incorrect: Applications communicate through upper and transport services, not the physical bit interface (PDF 14, 16.)

D - Incorrect: Ports identify transport processes (PDF 14, 16.)

Primary note proof

Study-note section NET12

Sending proceeds from application data to transport segment/datagram, network packet, link frame and physical bits/symbols; receiving reverses the order. Each layer serves the layer above. A router removes a received link frame, inspects IP, and creates a new link frame for the next hop. MAC addresses usually change across routed hops; end-to-end IP addresses ordinarily remain until translation.

Study-note section NET17

Ports identify transport endpoints; the application can choose a transport and request socket buffer sizes, subject to OS limits. A TCP connection is identified by source/destination IP and source/destination port, with TCP understood. IPv4 protocol numbers identify upper protocols; 80 is a usual HTTP port, not an IP protocol number. Clients often use ephemeral ports. SCTP is a reliable message-oriented transport with multiple streams.

Question 109 | Q01533

A new network backbone needs high capacity, long reach and immunity to electromagnetic interference in the transmission medium. Which listed medium carries light rather than electrical signals and best matches these requirements?

A. coaxial cable

B. twisted pair cable

C. optical fiber

D. electrical cable

Hint

Compare the signal mechanism, medium properties or transmission direction against the definitions and stated physical assumptions.

Answer C: optical fiber

Optical fiber guides light, resists electromagnetic interference and supports high-capacity, long-reach links with suitable optics and installation. Twisted pair and coaxial cable carry electrical signals; their shielding or pair geometry can reduce interference but does not give the medium optical immunity. Exact speeds depend on the selected specification and equipment, so this comparison does not rank every possible fiber and copper product by speed.

Why each choice is right or wrong

A - Incorrect: Coaxial cable uses electrical signaling despite its shielding.

B - Incorrect: Twisted pair uses electrical signaling and reduces, rather than eliminates, coupled interference.

C - Correct: Optical fiber carries light and matches the stated capacity, reach and EMI requirements.

D - Incorrect: An electrical cable does not carry the required optical signal.

Primary note proof

Study-note section NET07

> Twisted pairs reduce coupled interference; UTP has no added shield and STP adds shielding. Coax has an inner conductor and outer shield sharing an axis. Fiber guides light and resists electromagnetic interference; it supports high capacity and long reach, but requires suitable optics and installation. Exact speed, cost and reach depend on the specification, not the material alone. Fiber can still be tapped.

Question 110 | Q01534

Bits can be sent over guided and unguided media as analog signal by _____

A. digital modulation

B. amplitude modulation

C. frequency modulation

D. phase modulation

Hint

Compare the signal mechanism, medium properties or transmission direction against the definitions and stated physical assumptions.

Answer A: digital modulation

Digital modulation explicitly converts digital data to analog signals; ASK/FSK/PSK are its given methods. The other names are listed as analog modulation of analog data. Evidence: PDF 13.

Why each choice is right or wrong

A - Correct: Exactly the digital-to-analog conversion category (PDF 13.)

B - Incorrect: AM appears as analog modulation, not the digital-data category (PDF 13.)

C - Incorrect: FM appears as analog modulation, while digital frequency encoding is FSK (PDF 13.)

D - Incorrect: PM appears as analog modulation, while digital phase encoding is PSK (PDF 13.)

Primary note proof

Study-note section NET15

ASK varies carrier amplitude, FSK frequency, PSK phase; QAM combines amplitude and phase. AM/FM/PM can carry analog data. PCM digitizes analog input by sampling, quantizing and encoding. Sampling must exceed twice the highest retained baseband frequency in practical designs; b-bit samples have 2^b quantization levels and uncompressed rate fs×b. PAM/PWM are pulse modulation methods; pulse amplitude or width alone is not a binary PCM code.

Study-note section NET04

Analog signals vary continuously; digital signals use discrete symbol states. Data and signal types are separate: digital bits can modulate an analog carrier. A sine wave has amplitude, frequency and phase. Frequency f counts cycles/second, period T=1/f, and wavelength λ=v/f depends on propagation speed v. Phase specifies displacement within a cycle. Composite signals combine frequencies.

Question 111 | Q01535

The portion of physical layer that interfaces with the media access control sublayer is called _____

A. physical signalling sublayer

B. physical data sublayer

C. physical address sublayer

D. physical transport sublayer

Hint

Match the requested scope or data unit to the layer duties in the note; distinguish hop delivery from end-to-end process delivery.

Answer A: Physical Signaling (PLS) sublayer in legacy IEEE 802.3

NET09 gives the architecture-specific name Physical Signaling (PLS) for the PHY portion interfacing with MAC in legacy IEEE 802.3 AUI/MAU terminology. That directly matches A. The qualification matters because modern PHY descriptions can use other sublayers; this is not a universal OSI sublayer name. The other offered names do not match the defined legacy interface.

Why each choice is right or wrong

A - Correct: Physical Signaling, abbreviated PLS, is the MAC-facing sublayer identified for the legacy IEEE architecture.

B - Incorrect: Physical data sublayer is not the MAC-facing sublayer name defined in NET09.

C - Incorrect: Physical address concerns addressing terminology; it is not the stated legacy PHY interface sublayer.

D - Incorrect: Physical transport sublayer is not the architecture-specific PLS name established here.

Question 112 | Q01536

Which option gives the most complete combined set of physical-layer specifications among those listed?

A. mechanical specifications of electrical connectors and cables

B. electrical specification of transmission line signal level

C. specification for IR over optical fiber

D. all of the mentioned

Hint

Match the requested scope or data unit to the layer duties in the note; distinguish hop delivery from end-to-end process delivery.

Answer D: All are physical-medium/signaling specifications

The physical layer specifies how signals and physical interfaces carry bits. Mechanical connector and cable requirements, electrical signal levels and optical signaling parameters all concern that role. Infrared signaling over suitable optical fiber is an optical physical-medium specification. Each individual item is therefore a valid example, but only the aggregate includes all three and satisfies the requested most-complete selection.

Why each choice is right or wrong

B - Incorrect: Electrical signal levels are physical-layer specifications, but this alone omits the other valid items.

C - Incorrect: Infrared optical signaling is a physical-medium specification, but this alone omits the other valid items.

D - Correct: All three items concern physical interfaces or signaling, so this is the complete combined response.

Question 113 | Q01537

Which single option gives the complete set of listed operations that can be implemented as physical-layer transmission coding or modulation?

A. line coding

B. channel coding

C. modulation

D. all of the mentioned

Hint

Match the requested scope or data unit to the layer duties in the note; distinguish hop delivery from end-to-end process delivery.

Answer D: all of the mentioned

Physical transmission includes mapping bits to signal patterns and modulating carriers. Channel coding in this question means redundancy used in transmission coding, rather than every possible higher-layer error-control mechanism. Under that scope, all three operations can be physical-layer work. Each individual choice names only part of the qualifying set, so the inclusive option is the complete response.

Why each choice is right or wrong

A - Incorrect: Line coding is physical signaling work, but alone omits the other qualifying operations.

B - Incorrect: Physical channel coding adds transmission redundancy, but alone is incomplete.

C - Incorrect: Modulation is a physical transmission operation, but alone is incomplete.

D - Correct: Line coding, physical channel coding and modulation all qualify, making this the complete set.

> A NIC supplies a computer’s network interface and commonly implements both physical and link functions. Calling a NIC a physical interface does not mean all its functions are layer 1. Physical specifications include connectors, signaling, voltage, timing and physical coding/modulation; the PHY interface to MAC handles hardware signaling.

> Line coding maps digital bits to digital signal patterns. NRZ uses levels without a forced mid-bit return; Manchester supplies a mid-bit transition for clocking, with bit convention specified. Differential Manchester encodes using transitions relative to previous state. AMI alternates the

polarity of successive ones; pseudoternary alternates zero pulses. Block coding adds code redundancy; scrambling replaces problematic patterns without necessarily increasing bit count. Multilevel schemes include 2B1Q and 8B6T; MLT-3 uses a sequence of voltage transitions.

ASK varies carrier amplitude, FSK frequency, PSK phase; QAM combines amplitude and phase. AM/FM/PM can carry analog data. PCM digitizes analog input by sampling, quantizing and encoding. Sampling must exceed twice the highest retained baseband frequency in practical designs; b-bit samples have 2^b quantization levels and uncompressed rate fs×b. PAM/PWM are pulse modulation methods; pulse amplitude or width alone is not a binary PCM code.

Question 114 | Q01538

The physical layer translates logical communication requests from the _____ into hardware specific operations.

A. data link layer

B. network layer

C. trasnport layer

D. application layer

Hint

Match the requested scope or data unit to the layer duties in the note; distinguish hop delivery from end-to-end process delivery.

Answer A: data link layer

The module adjacent layer order places data link immediately above physical, and data link passes frames to physical for bit transmission. Evidence: PDF 14, 14, 15.

Why each choice is right or wrong

A - Correct: Data link directly supplies the physical layer (PDF 14, 14, 15.)

B - Incorrect: Network supplies data link first, not physical directly (PDF 14, 14, 15.)

C - Incorrect: Transport supplies network first (PDF 14, 14, 15.)

D - Incorrect: Application passes through several intervening layers (PDF 14, 14, 15.)

Question 115 | Q01539

A single channel is shared by multiple signals by _____

A. analog modulation

B. digital modulation

C. multiplexing

D. phase modulation

Hint

Compare the signal mechanism, medium properties or transmission direction against the definitions and stated physical assumptions.

Answer C: multiplexing

The module defines multiplexing as simultaneous multiple signals across a single data link. Evidence: PDF 20, 13.

Why each choice is right or wrong

A - Incorrect: Analog modulation changes a carrier rather than defining shared-channel combination (PDF 20, 13.)

B - Incorrect: Digital modulation converts digital data to analog signals (PDF 20, 13.)

C - Correct: Multiplexing is the explicit shared-channel technique (PDF 20, 13.)

D - Incorrect: Phase modulation is one carrier parameter method (PDF 20, 13.)

Primary note proof

Study-note section NET32

Multiplexing combines multiple input streams onto a shared link; demultiplexing separates them at the receiver. It differs from broadcasting one message to many destinations. FDM assigns distinct frequency bands with suitable guard spacing; WDM assigns different optical wavelengths. TDM allocates time slots: synchronous TDM reserves recurrent slots even if an input is idle, while statistical TDM allocates according to demand and needs identification.

A. network layer

B. physical layer

C. transport layer

D. application layer

Hint

Answer A: network layer

The sending-side data link explicitly receives network-layer data and frames it for physical transmission. Evidence: PDF 15, 16, 15.

Why each choice is right or wrong

A - Correct: Network is the immediately preceding sender-side layer (PDF 15, 16, 15.)

B - Incorrect: Physical is the lower receive-side source of bits, not upper packets (PDF 15, 16, 15.)

Question 117 | Q01541

Wireless transmission of signals can be done via _____

A. radio waves

B. microwaves

C. infrared

D. all of the mentioned

Hint

Compare the signal mechanism, medium properties or transmission direction against the definitions and stated physical assumptions.

Answer D: all of the mentioned

The module explicitly lists radio waves, microwaves and infrared as three unguided wireless media. Evidence: PDF 10.

Why each choice is right or wrong

A - Incorrect: Radio waves are listed (PDF 10.)

B - Incorrect: Microwaves are listed (PDF 10.)

C - Incorrect: Infrared is listed (PDF 10.)

D - Correct: All three appear in the unguided-media list (PDF 10.)

Primary note proof

Study-note section NET07

Radio, microwave and infrared are unguided media. Ground waves follow Earth, sky waves can reflect from ionized layers, and line-of-sight paths require suitable visibility. Microwaves are radio waves in the broader physical classification. Infrared generally does not penetrate walls. Directionality depends on antennas: omnidirectional means broad azimuth coverage, not equal radiation in every 3-D direction. Legacy Ethernet straight-through cables join unlike MDI/MDI-X roles; crossover joins like roles, such as PC-PC or switch-switch. Auto-MDI-X can remove that requirement.

TRANSMISSION MEDIA
Transmission media is a means by which a communicationsignal is carried from one system to another
A transmission medium can be defined as anything that cancarry information from a source to a destination. The transmission medium is usually free space, metallic cable orfiber optic cable. Guided and Unguided (WIRELESS) Guided Transmission Media uses a cabling system that guidesthe data signals along a specific path. Out of these twisted-paircable, coaxial cable transport signals in the form of electricsignals and fiber-optic cable transport signals in the form oflight. Unguided Transmission Media transport data without using a physical conductor. It uses wireless electromagnetic signals to send data. Three types of unguided media:
• Radio waves
• Micro waves
• Infrared.

Question 118 | Q01542

Under the OSI role convention used here, which task belongs to physical transmission coding rather than data-link framing and control? Here channel coding means physical-channel coding, not a link-frame CRC or retransmission procedure.

A. framing

B. error control

C. flow control

D. channel coding

Hint

Match the requested scope or data unit to the layer duties in the note; distinguish hop delivery from end-to-end process delivery.

Answer D: channel coding

The data-link layer packages data into frames and can provide hop-local error and flow control. Physical transmission coding concerns how the channel carries the signal and any coding assigned to that physical role. The explicit convention distinguishes physical-channel coding from link error-detection redundancy or ARQ; without that scope, the broad term coding could overlap link functions.

Why each choice is right or wrong

A - Incorrect: Framing packages hop-delivery data into link frames.

B - Incorrect: Link error control includes detection and protocol-dependent recovery.

C - Incorrect: Link flow control regulates hop-local sending when supported.

D - Correct: Physical-channel coding is outside the stated link framing/control role.

Primary note proof

Study-note section NET13

> Link-layer LLC identifies or multiplexes upper-layer protocols and may supply link control; MAC handles medium-dependent addressing/access and frame delivery. Network addressing belongs to layer 3. Study-note section NET14

> Controlled access uses polling, reservations or a token to grant turns; correctly coordinated access avoids contention collisions. Channelization divides frequency, time or code resources. Stop-and-wait sends one frame and waits for ACK, retransmitting on timeout; sequence bits distinguish duplicates. Sliding windows permit multiple unacknowledged frames. Link reliability/flow control is hop-local; transport reliability/flow control is end-to-end. Ethernet detects corruption but does not itself guarantee reliable delivery.

Question 119 | Q01543

Which sublayer of the data link layer performs data link functions that depend upon the type of medium?

A. logical link control sublayer

B. media access control sublayer

C. network interface control sublayer

D. error control sublayer

Hint

Match the requested scope or data unit to the layer duties in the note; distinguish hop delivery from end-to-end process delivery.

Answer B: Media Access Control (MAC)

The decisive phrase is “depend upon the type of medium.” NET13 assigns medium-dependent addressing, access and frame delivery to MAC. LLC instead identifies or multiplexes upper-layer protocols. The other names do not designate the LLC/MAC subdivision established in the note, so they cannot replace the specific MAC role.

Why each choice is right or wrong

A - Incorrect: LLC identifies upper-layer protocols and supplies link control rather than the medium-dependent access role.

B - Correct: MAC performs the medium-dependent addressing and access functions explicitly named in NET13.

C - Incorrect: A network interface is hardware/functionality, not the named medium-dependent data-link sublayer in this division.

D - Incorrect: Error control is a function; it is not the LLC/MAC sublayer name for medium-dependent access.

Question 120 | Q01544

Which listed field identifies source or destination endpoints in a link-frame header, rather than synchronization or frame/control identification? Select one.

A. synchronization bytes

B. addresses

C. frame identifier

D. all of the mentioned

Hint

Use the cited note definitions to identify the requested function or scope, then check each alternative against that same rule.

Answer B: addresses

Address fields identify the source or destination endpoints associated with a frame. Synchronization information helps delimit or align reception, while a frame identifier or control field distinguishes a frame or its function. The question asks specifically for endpoint identification, so the address option is the complete answer. Exact field placement depends on the link protocol and is not assumed universal.

Why each choice is right or wrong

A - Incorrect: Synchronization concerns alignment or boundaries rather than endpoint identity.

B - Correct: Address fields identify frame endpoints, matching the requested role.

C - Incorrect: A frame identifier distinguishes a frame or control function rather than its endpoint addresses.

D - Incorrect: The other listed fields have different roles, so all is not the endpoint-identification answer.

Answer A: cyclic redundancy check

The error-detection list explicitly spells out Cyclic Redundancy Check, matching CRC initials. Evidence: PDF 13.

Why each choice is right or wrong

A - Correct: Cyclic Redundancy Check is the exact listed phrase (PDF 13.)

B - Incorrect: Code repeat check is not the expansion listed (PDF 13.)

C - Incorrect: Code redundancy check changes Cyclic to Code (PDF 13.)

D - Incorrect: Cyclic repeat check changes Redundancy to repeat (PDF 13.)

Detection adds redundancy but does not guarantee correction. Even parity adds a bit so the total number of ones is even: 1011 needs parity 1. It detects every odd number of bit flips but misses even counts. CRC treats bits as a polynomial and appends the XOR-division remainder; the receiver repeats the division. Internet checksums add words with end-around carry and complement the sum. A burst spans from the first corrupted bit through the last, including

unchanged interior bits. Retransmission or sufficient forward-error-correcting redundancy is needed for recovery.

Question 122 | Q01546

Which single option gives the complete set of listed data-link protocols?

A. ethernet

B. point to point protocol

C. hdlc

D. all of the mentioned

Hint

Identify the requested service or delivery guarantee, then distinguish application roles, transport behavior and address configuration.

Answer D: all of the mentioned

Ethernet, PPP and HDLC are all link protocols. The question asks for the complete set among the listed choices, so selecting any one protocol alone omits two other valid members. The inclusive response therefore supplies the complete answer. This classification concerns the data-link protocol role and does not deny that a technology such as Ethernet also specifies physical signaling.

Why each choice is right or wrong

A - Incorrect: ethernet is a link protocol, but this option alone omits the other qualifying protocols.

B - Incorrect: point to point protocol is a link protocol, but this option alone omits the other qualifying protocols.

Question 123 | Q01547

Which option gives the complete set of listed CSMA multiple-access mechanisms for shared-channel contention?

A. CSMA/CD

B. CSMA/CA

C. Both CSMA/CD & CSMA/CA

D. HDLC

Hint

Identify the requested service or delivery guarantee, then distinguish application roles, transport behavior and address configuration.

Answer C: Both CSMA/CD & CSMA/CA

CSMA/CD and CSMA/CA both govern shared-medium access. Legacy half-duplex Ethernet uses collision detection and backoff, while Wi-Fi uses collision avoidance procedures with waiting, backoff and acknowledgments. Selecting only one omits another valid listed mechanism. HDLC is a link framing/control protocol rather than either of these CSMA contention mechanisms, so the combined CSMA option is complete.

Why each choice is right or wrong

A - Incorrect: CSMA/CD is a valid mechanism but omits the other listed CSMA mechanism.

B - Incorrect: CSMA/CA is a valid mechanism but omits the other listed CSMA mechanism.

C - Correct: This includes both listed CSMA contention mechanisms.

D - Incorrect: HDLC is a link framing/control protocol, not a listed CSMA medium-contention mechanism.

Primary note proof

Study-note section NET14

> Random access allows contention: ALOHA sends opportunistically; CSMA senses before sending. In legacy half-duplex Ethernet, CSMA/CD detects collision, sends a jam indication, stops, and retries after random backoff. The jam signals a collision, not its clearance. Wi-Fi 802.11 uses CSMA/CA with waiting/backoff and acknowledgments; sensing does not eliminate hidden-terminal collisions.

Study-note section NET14

> Controlled access uses polling, reservations or a token to grant turns; correctly coordinated access avoids contention collisions. Channelization divides frequency, time or code resources. Stop-and-wait sends one frame and waits for ACK, retransmitting on timeout; sequence bits distinguish duplicates. Sliding windows permit multiple unacknowledged frames. Link reliability/flow control is hop-local; transport reliability/flow control is end-to-end. Ethernet detects corruption but does not itself guarantee reliable delivery.

Study-note section NET13

Question 124 | Q01548

The network layer is concerned with _____ of dat
a.

A. bits

B. frames

C. packets

D. bytes

Hint

Match the requested scope or data unit to the layer duties in the note; distinguish hop delivery from end-to-end process delivery.

Answer C: packets

Despite the broken dat/a line ending, the identifiable concept is the network-layer unit: packets. Evidence: PDF 15, 15, 16, 14.

Why each choice is right or wrong

A - Incorrect: Bits are physical units (PDF 15, 15, 16, 14.)

B - Incorrect: Frames are data-link units (PDF 15, 15, 16, 14.)

C - Correct: Packets are explicitly formed and transmitted by network layer (PDF 15, 15, 16, 14.)

D - Incorrect: Bytes are not the named network PDU (PDF 15, 15, 16, 14.)

Primary note proof

Study-note section NET12

Sending proceeds from application data to transport segment/datagram, network packet, link frame and physical bits/symbols; receiving reverses the order. Each layer serves the layer above. A router removes a received link frame, inspects IP, and creates a new link frame for the next hop. MAC addresses usually change across routed hops; end-to-end IP addresses ordinarily remain until translation.

Physical Layer:
• The Physical Layer provides a standardized interface to physical transmission media, including: Mechanical specification of electrical connectors and cables, for example maximum cable length, Electrical specification of transmission line and Bit-by-bit or symbol-by-symbol delivery.
• Interface: The Physical Layer defines the characteristics of interfaces between the devices & transmission medium.
• Representation of bits: The physical layer is concerned with transmission of signals from one device to another which involves converting data (1_s & 0_s) into signals and vice versa. It is not concerned with the meaning or interpretation of bits.
• Data rate: The physical layer defines the data transmission rate i.e. number of bits sent per second. It is the responsibility of the physical layer to maintain the defined data rate.

Question 125 | Q01549

For IPv4 as described in the note, which listed function is not provided by IP itself? Here “error control” means header checksum error detection.

A. routing

B. inter-networking

C. congestion control

D. error control

Hint

Separate address width, syntax, reserved scope and the supplied prefix or historical classful convention.

Answer C: congestion control

IPv4 supports logical packet delivery across networks, including routing, and checks its header with a checksum. The use of error control therefore refers to detection, not reliable end-to-end recovery. TCP supplies congestion control to protect network capacity; IPv4 itself does not provide TCP’s congestion-control service. The question separates those protocol services instead of denying that the network layer ever detects errors.

Why each choice is right or wrong

A - Incorrect: Routing is explicitly a network-layer function, so it cannot be the requested exception.

B - Incorrect: Forwarding packets between networks is an established network-layer responsibility.

C - Correct: Congestion control of the kind protecting network capacity is a TCP service rather than a service supplied by IPv4 itself.

D - Incorrect: IPv4 detects header corruption with its checksum, so error detection is present under the stated meaning.

Primary note proof

Study-note section NET16

> The IPv4 checksum protects its header; IP does not lack error checking altogether. Identification, flags and offset support fragmentation. IPv4 sources and routers may fragment when allowed; reassembly occurs at the destination. If DF is set and the next MTU is too small, forwarding fails and an ICMP diagnostic may be returned.

Study-note section NET17

TCP offers a reliable ordered byte stream using sequence numbers, acknowledgments, retransmission and windows. Flow control protects the receiver; congestion control protects network capacity. UDP sends independent datagrams with ports and a checksum but no built-in setup, delivery guarantee, retransmission or ordering. Live interactive traffic may choose UDP when late data is less useful than lost data. Application protocols can add reliability over UDP.

Study-note section NET30

Routing computes paths; forwarding chooses a next hop for an individual packet. Select the matching route with the longest prefix, then apply the routing system's tie-breaking criteria. A default /0 matches when nothing more specific does. Static routes are configured; dynamic protocols exchange reachability. Distance vector uses neighbor estimates, while link state distributes link information and computes shortest paths. Interior protocols operate within an autonomous system; BGP exchanges routes between systems.

Question 126 | Q01550

A 4 byte IP address consists of _____

A. only network address

B. only host address

C. network address & host address

D. network address & MAC address

Hint

Separate address width, syntax, reserved scope and the supplied prefix or historical classful convention.

Answer C: network address & host address

The module says an IP address encodes network and host numbers; physical/MAC addresses are separate. Evidence: PDF 18, 19, 17.

Why each choice is right or wrong

A - Incorrect: Only network omits the stated host part (PDF 18, 19, 17.)

B - Incorrect: Only host omits the stated network part (PDF 18, 19, 17.)

C - Correct: Network plus host matches the stated composition (PDF 18, 19, 17.)

D - Incorrect: MAC is a separate physical address, not part of the IP field (PDF 18, 19, 17.)

Primary note proof

Study-note section NET-S06

An IP address identifies a network interface rather than limiting a whole computer to one address. A computer or router can have several interfaces and addresses. Under a supplied IPv4 prefix, leading bits identify the network and the remaining bits identify an address within that network; a MAC address is a separate link-layer identifier.

Study-note section NET22

Write IPv4 as four decimal octets 0-255, or as 32 binary bits. Use weights 128,64,32,16,8,4,2,1 within each octet. Thus 11000001 10000011 00011011 11111111 is 193.131.27.255. A value such as 257 is impossible. Syntactic validity differs from assignability: an address ending .0 or .255 can be a host under some prefixes.

Subnetting: It allows a network to be split into several
parts for internal use but still act like a single network to
the outsideworld.
• To implement subnetting, the router needs a
subnet mask that indicates the split between
network + subnet number and host. Ex.

Question 127 | Q01551

Which single option gives the complete set of listed algorithms or routing approaches usable in network-layer route design?

A. shortest path algorithm

B. distance vector routing

C. link state routing

D. all of the mentioned

Hint

Match the requested scope or data unit to the layer duties in the note; distinguish hop delivery from end-to-end process delivery.

Answer D: all of the mentioned

Distance-vector routing uses estimates received from neighboring routers. Link-state routing distributes link information and uses shortest-path computation to build routes. Therefore each named approach is usable in network-layer routing design. Because the question asks for the complete set, choosing any one named approach would omit other valid members; the combined response is the complete selection.

Why each choice is right or wrong

A - Incorrect: Shortest-path computation is usable, but this choice alone omits the other listed routing approaches.

B - Incorrect: Distance-vector routing is usable, but alone is an incomplete set.

C - Incorrect: Link-state routing is usable, but alone is an incomplete set.

D - Correct: All three approaches can be used, so the inclusive option gives the complete set.

> In general, routing involves the network topology, or the setup of hardware, that can effectively relay data. Standard protocols help to identify the best routes for data and to ensure quality transmission. Individual pieces of hardware such as routers are referred to as —nodes‖ in the network. Different algorithms and protocols can be used to figure out how to best route data packets, and which nodes should be used. For example, some data packets travel according to a distance vector model that primarily uses distance as a factor, whereas others use Link-State Protocol, which involves other aspects of a —best path‖ for data.

Question 128 | Q01552

In a multi-destination scheme that carries an explicit list of multiple selected targets in each packet, which statements are incorrect as general descriptions? Select all that apply.

A. is same as broadcast routing

B. contains the list of all destinations

C. data is not sent by packets

D. there are multiple receivers

Hint

Use the cited note definitions to identify the requested function or scope, then check each alternative against that same rule.

Answer A, C: is same as broadcast routing; data is not sent by packets

A packet can carry a list identifying several selected destinations without addressing every destination in the broadcast scope. That makes universal equivalence with broadcasting false. The scheme is explicitly packet-based, so saying data are not sent by packets is also false. The list of targets and the presence of multiple receivers are true descriptions and therefore are not selected in this negative question.

Why each choice is right or wrong

A - Correct: Multi-destination delivery to listed targets is not necessarily broadcast to every destination in a scope.

B - Incorrect: A list of destinations is a supported multi-destination packet representation, making this statement correct.

C - Correct: NET30 explicitly describes multi-destination packets, contradicting the statement that data is not sent by packets.

D - Incorrect: Multiple targeted receivers are the defining destination-set property, so this statement is not incorrect.

Primary note proof

Study-note section NET30

> Flooding sends copies on eligible outgoing links with duplicate/lifetime controls; random walk picks a neighbor probabilistically. Unicast targets one destination, broadcast all in a scope, multicast a subscribed group and anycast one member sharing an address, normally nearest under routing metrics. Multi-destination packets can list multiple targets; this is not necessarily identical to broadcast. Group multicast trees use mechanisms such as reverse-path checks; Ethernet spanning tree is a different layer-2 mechanism.

ICMP is primarily used for _____

A. error and diagnostic functions

B. addressing

C. forwarding

D. routing

Hint

Use the cited note definitions to identify the requested function or scope, then check each alternative against that same rule.

Answer A: error and diagnostic functions

ICMP provides error reports, echo connectivity checks and timeout-based traceroute. These are error and diagnostic functions. Evidence: PDF 27, 17, 12.

Why each choice is right or wrong

A - Correct: Matches destination-unreachable, echo and timeout examples (PDF 27, 17, 12.)

B - Incorrect: ARP handles address resolution; ICMP is not the addressing scheme (PDF 27, 17, 12.)

C - Incorrect: Routers forward packets; ICMP reports conditions (PDF 27, 17, 12.)

D - Incorrect: A routing algorithm chooses paths; ICMP provides diagnostics rather than route choice (PDF 27, 17, 12.)

Primary note proof

Study-note section NET20

> ARP resolves an on-link IPv4 next hop to a link address, using a broadcast request and normally unicast reply. For an off-subnet target, ARP resolves the gateway, not the remote target's MAC. It bridges the network/link addressing boundary and is often classified at the link layer; calling ARP simply a network protocol uses a loose textbook convention. ARP - Address Resolution Protocol: It is used to resolve thephysical address of a device on a network, where its logical address is known.
Physical address is the 48 bit address that is imprinted on theNIC or LAN card, Logical address is the Internet Address orcommonly known as IP address that is used to uniquely & universally identify a device.
RARP- Reverse Address Resolution Protocol: It is used bya device on the network to find its Internet address when it knows its physical address.

ROUTER: Router is a specialized network device used tointerconnect different types of network that uses different protocol.
Router allows the users to connect several LAN and WAN
• A LAN to another LAN

• A WAN to another WAN
• A LAN to the Internet
Routers use the routing table to determine how to forwardpackets.
• The list of routing tables provides directions to transfer the data to a particular network destination -various paths to forward the data.
• A router analyzes a destination IP address of a givenpacket and compares it with the routing table to decide the packet's next best path

Question 131 | Q01555

At a sending host, transport identifies data from different application endpoints using ports and forms segments or datagrams. To which OSI layer does it pass these units directly?

A. network layer

B. data link layer

C. application layer

D. physical layer

Hint

Match the requested scope or data unit to the layer duties in the note; distinguish hop delivery from end-to-end process delivery.

Answer A: network layer

On the sending path, transport creates segments or datagrams and hands them to the network layer for packet delivery. The network layer then uses the data-link layer, which in turn uses physical signaling. Ports distinguish application endpoints; this multiplexing does not merge unrelated applications into one undifferentiated TCP byte stream. The answer follows the immediate downward interface in the OSI stack.

Why each choice is right or wrong

A - Correct: The network layer immediately receives transport units on the sending path.

B - Incorrect: Data link is below network, not immediately below transport.

C - Incorrect: Application is above transport rather than its downward delivery target.

D - Incorrect: Physical is below both network and data link.

Primary note proof

Study-note section NET12

Sending proceeds from application data to transport segment/datagram, network packet, link frame and physical bits/symbols; receiving reverses the order. Each layer serves the layer above. A router removes a received link frame, inspects IP, and creates a new link frame for the next hop. MAC addresses usually change across routed hops; end-to-end IP addresses ordinarily remain until translation.

Study-note section NET18

TCP setup creates a logical transport connection, not a reserved physical circuit. Ports allow multiplexing separate applications over IP; they do not combine all applications into one TCP byte stream. Do not assign TCP reliability to all layer-4 protocols merely because the reference layer lists reliability as a possible service.

• At the sending side, the transport layer receives data from the session layer, divides it into units called segments and sends it to the network layer.
• To ensure process to process delivery the transport layer makes use of port address to identify the data from the sending and receiving process.
• The data can be transported in a connection oriented or connectionless manner.
• The Transport layer is responsible for segmentation and reassembly of the message into segments which bear sequence numbers.
• The transport layer also carries out flow control and error control functions; but unlike data link layer these are end to end rather than node to node.
• The main responsibility of the transport layer is process to process delivery of the entire message

Network Layer
• The network layer makes sure that the data is deliveredto the receiver despite multiple intermediate devices.
• The network layer at the sending side accepts data from the transport layer, divides it into packets, addsaddressing information in the header and passes it tothe data link layer.
• The network layer is responsible for source todestination of delivery of data.
• The network layer uses logical address commonlyknown as IP address to recognize devices on the network.

• Each packet is independent of the other and may travelusing different routes to reach the receiver hence may arrive out of turn at the receiver (Routing).
• The Network layer does not perform any flow controlor error control
• The main responsibility of Network Layer is transmission of packets from source to destination

Data Communication and Computer Networking module | PDF page 15 | lines 13-40

Data Link Layer
• The Data Link layer adds reliability to the physical layer by providing error detection and correction mechanisms.
• Framing: the Data Link layer receives the data from Network Layer and divides the stream of bits into fixed size manageable units called as Frames and sends it to the physical layer. On the receiver side, the data link layer receives the stream of bits from the physical layer and regroups them into frames and sends them to the Network layer.
• Physical Addressing: The Data link layer appends the physical address in the header of the frame before sending it to physical layer.
• Flow control: The data link layer makes sure that the sender sends the data at a speed at which the receiver canreceive it else if there is an overflow at the receiver sidethe data will be lost.
• Error Control: The data link layer imposes error control mechanism to identify lost or damaged frames, duplicateframes and then retransmit them.
• Access Control: The data link layer imposes access control mechanism to determine which device has right to send data in an multipoint connection setting.
• Main Responsibility: The main responsibility of the data link layer is hop to hop transmission of frames.

Question 132 | Q01556

Which of the following are transport layer protocols used in networking?

A. TCP and FTP

B. UDP and HTTP

C. TCP and UDP

D. HTTP and FTP

Hint

Match the requested scope or data unit to the layer duties in the note; distinguish hop delivery from end-to-end process delivery.

Answer C: TCP and UDP

TCP and UDP are explicitly transport protocols; FTP and HTTP are application services. Evidence: PDF 18, 18.

Why each choice is right or wrong

A - Incorrect: FTP makes this pair include an application protocol (PDF 18, 18.)

B - Incorrect: HTTP makes this pair include an application protocol (PDF 18, 18.)

C - Correct: Both are explicitly transport protocols (PDF 18, 18.)

D - Incorrect: Both are application services, not transport protocols (PDF 18, 18.)

Question 133 | Q01557

User datagram protocol is called connectionless because _____

A. all UDP packets are treated independently by transport layer

B. it sends data as a stream of related packets

C. it is received in the same order as sent order

D. it sends data very quickly

Hint

Identify the requested service or delivery guarantee, then distinguish application roles, transport behavior and address configuration.

Answer A: UDP treats datagrams independently without connection setup

Connectionless UDP sends independent datagrams without establishing a transport connection. NET17 explicitly separates this from TCP’s reliable ordered byte stream. Fast transmission may be desirable but is not the definition of connectionlessness, and UDP itself does not preserve send order or combine datagrams into an ordered related stream.

Why each choice is right or wrong

A - Correct: Independent datagram treatment without built-in setup directly explains why UDP is connectionless.

B - Incorrect: An ordered related byte stream describes TCP's service rather than UDP's independent datagrams.

C - Incorrect: UDP provides no built-in ordering guarantee, so reception need not match transmission order.

D - Incorrect: Speed is not the defining condition; connectionlessness concerns the absence of connection establishment and associated state.

Question 134 | Q01558

For one TCP connection, which single option gives the complete set of correct descriptions?

A. is a connection-oriented protocol

B. uses a three way handshake to establish a connection

C. receives data from application as a single stream

D. all of the mentioned

Hint

Identify the requested service or delivery guarantee, then distinguish application roles, transport behavior and address configuration.

Answer D: all of the mentioned

TCP establishes logical transport connection state through the SYN, SYN+ACK and ACK exchange. It then provides an ordered byte-stream service for that connection rather than preserving individual application message boundaries. All three descriptions apply to one TCP connection. Each individual response is therefore incomplete under the complete-set instruction, while the inclusive option collects all of the valid properties.

Why each choice is right or wrong

A - Incorrect: TCP is connection-oriented, but this choice alone omits its handshake and stream properties.

B - Incorrect: TCP uses a three-way handshake, but that alone is an incomplete set.

C - Incorrect: TCP accepts an application byte stream within a connection, but this alone is incomplete.

D - Correct: Connection orientation, three-way setup and a per-connection byte stream are all valid.

Primary note proof

Study-note section NET18

> TCP establishes state with SYN, SYN+ACK, then ACK. SYN consumes one sequence position even with no application bytes. An acknowledgment states the next expected sequence number. For client ISN=395 and server ISN=260: client sends SYN seq395; server sends SYN+ACK seq260 ack396; client sends ACK seq396 ack261. Later byte counts advance sequence numbers. FIN also consumes one sequence position.

Question 136 | Q01560

Which phrase names the precise transport-layer endpoint-delivery responsibility in the OSI model?

A. application to application communication

B. process to process communication

C. node to node communication

D. man to man communication

Hint

Match the requested scope or data unit to the layer duties in the note; distinguish hop delivery from end-to-end process delivery.

Answer B: process to process communication

Transport provides process-to-process delivery, with ports identifying transport endpoints. Application-to-application communication is a broader description of what that service supports, but it does not name the precise endpoint-delivery term requested here. Hop or node-to-node frame delivery belongs to the data-link layer. Human communication describes an application purpose rather than the protocol endpoint responsibility used to distinguish the OSI layers.

Why each choice is right or wrong

A - Incorrect: Applications use transport, but this broad description does not name the precise process-delivery term requested.

B - Correct: Process-to-process is the precise transport endpoint-delivery responsibility.

C - Incorrect: Hop/node-to-node frame delivery is a link-layer responsibility rather than transport process delivery.

D - Incorrect: Human-to-human interaction is not the protocol endpoint service defining transport.

Question 137 | Q01561

A local telephone network is an example of a _____ network.

A. Packet switched

B. Circuit switched

C. Bit switched

D. Line switched

Hint

Use the cited note definitions to identify the requested function or scope, then check each alternative against that same rule.

Answer B: Circuit switched

Assuming the traditional local circuit telephone network, call setup creates a dedicated circuit and teardown releases it. This identifies circuit switching.

Why each choice is right or wrong

A - Incorrect: Packet switching is discrete packet communication

B - Correct: Circuit switching matches the traditional dedicated-call assumption

C - Incorrect: Bit switched is not a listed switching category

D - Incorrect: Line switched is not a listed switching category

Primary note proof

Study-note section NET31

Circuit switching sets up a path with reserved resources, transfers data, then releases it. Predictable allocated bandwidth trades against setup/blocking and wasted reservation during silence. A traditional telephone call is the standard example. Packet switching divides data into packets that share links statistically; queueing can add variable delay and loss. This does not make modern voice-over-packet impossible: buffering, scheduling and capacity planning manage it.

Circuit Switching: In circuit switching, two
communicating stations are connected by a dedicated
communication path which consists of intermediate
nodes in the network and the links that connect these
nodes.
It involved the following three distinct steps
• Circuit Establishment: To establish an end-to-end
connection before any transfer of data.
• Data transfer: Transfer data is from the source to the
destination. The data may be analog or digital,
depending on the nature of the network. The
connection is generally full-duplex.
• Circuit disconnect: Terminate connection at the end
of data transfer. Signals must be propagated to
deallocate the dedicated resources.

Question 138 | Q01562

Most packet switches use this principle _____

A. Stop and wait

B. Store and forward

C. Store and wait

D. Stop and forward

Hint

Compare signal repetition, frame forwarding, packet routing and policy enforcement using the stated device or traffic assumptions.

Answer B: Store and forward

Packet store-and-forward means receiving the complete packet or frame before forwarding it. That is the switching principle named by B. Stop-and-wait is instead a reliability procedure that sends one frame and waits for acknowledgment. Cut-through alternatives exist, so the answer identifies the conventional principle without claiming every switch must use it.

Why each choice is right or wrong

A - Incorrect: Stop-and-wait is a link reliability/flow procedure involving acknowledgments, not the switching-buffering principle.

B - Correct: Store-and-forward buffers the full packet or frame before sending it on the next link.

C - Incorrect: Store and wait is not the defined switching principle named in NET31.

D - Incorrect: Stop and forward is not the defined receive-complete-then-forward switching procedure.

Primary note proof

Study-note section NET31

Datagram packets are forwarded independently. Virtual circuits establish forwarding state, but resource reservation is optional, not a necessary property of every virtual circuit. Message switching stores a complete message before forwarding, without a dedicated end-to-end path. Packet store-and-forward waits for the full packet/frame; cut-through starts after enough header arrives; fragment-free historically waits through the initial collision-sensitive portion. No routing algorithm guarantees that every packet always takes the geometrically shortest route.

Study-note section NET14

Controlled access uses polling, reservations or a token to grant turns; correctly coordinated access avoids contention collisions. Channelization divides frequency, time or code resources. Stop-and-wait sends one frame and waits for ACK, retransmitting on timeout; sequence bits distinguish duplicates. Sliding windows permit multiple unacknowledged frames. Link reliability/flow control is hop-local; transport reliability/flow control is end-to-end. Ethernet detects corruption but does not itself guarantee reliable delivery.

• Framing: the Data Link layer receives the data from Network Layer and divides the stream of bits into fixed size manageable units called as Frames and sends it to the physical layer. On the receiver side, the data link layer receives the stream of bits from the physical layer and regroups them into frames and sends them to the Network layer.
• Physical Addressing: The Data link layer appends the physical address in the header of the frame before sending it to physical layer.
• Flow control: The data link layer makes sure that the sender sends the data at a speed at which the receiver canreceive it else if there is an overflow at the receiver sidethe data will be lost.
• Error Control: The data link layer imposes error control mechanism to identify lost or damaged frames, duplicateframes and then retransmit them.
• Access Control: The data link layer imposes access control mechanism to determine which device has right to send data in an multipoint connection setting.
• Main Responsibility: The main responsibility of the data link layer is hop to hop transmission of frames.

Network Layer
• The network layer makes sure that the data is deliveredto the receiver despite multiple intermediate devices.
• The network layer at the sending side accepts data from the transport layer, divides it into packets, addsaddressing information in the header and passes it tothe data link layer.
• The network layer is responsible for source todestination of delivery of data.
• The network layer uses logical address commonlyknown as IP address to recognize

devices on the network.
• Each packet is independent of the other and may travelusing different routes to reach the receiver hence may arrive out of turn at the receiver (Routing).
• The Network layer does not perform any flow controlor error control
• The main responsibility of Network Layer is transmission of packets from source to destination

Question 141 | Q01565

Which one of the following is an architecture paradigms?

A. Peer to peer

B. Client-server

C. HTTP

D. Both Peer-to-Peer & Client-Server

Hint

Use the cited note definitions to identify the requested function or scope, then check each alternative against that same rule.

Answer D: Both Peer-to-Peer & Client-Server

The architecture section explicitly describes client-server and peer-to-peer; HTTP is a protocol rather than that resource-service arrangement. Evidence: PDF 24, 18.

Why each choice is right or wrong

A - Incorrect: Peer-to-peer is an architecture, but the combined option includes the other valid architecture (PDF 24, 18.)

B - Incorrect: Client-server is an architecture, but the combined option includes the other valid architecture (PDF 24, 18.)

C - Incorrect: HTTP is a protocol/service, not either listed architecture paradigm (PDF 24, 18.)

D - Correct: Both named architectures are explicitly described (PDF 24, 18.)

Primary note proof

Study-note section NET02

An intranet serves an organization internally; an extranet exposes selected services to approved outsiders. Neither term alone specifies geographic size. A client requests a service; a server

supplies it. Peer systems may perform both roles. Dedicated servers concentrate on service workloads but can still be clients of DNS, backup or update services. A ten-user cutoff is a teaching guideline, not a technical law. Centralization simplifies administration but creates dependencies; peer networks still need security.

Study-note section NET21

HTTP defines web request/response semantics; it is stateless, and a message body may be absent. HTTPS adds TLS protection. FTP transfers files using control and separate data connections; it is not the same protocol as SFTP. SMTP submits and relays mail; POP3 retrieves messages and IMAP accesses/synchronizes server mailboxes. Saying SMTP handles both sending and end-user mailbox retrieval is inaccurate.

Network Architecture: based on the architecture (where do the clients get the shared resources?), networks can be categorized into three:
Client-Server Architecture: There can be one or more systems acting as Server. Other being Client, request the Server to serve requests. Servers take and process request on clients‘ behalf.
Peer-to-Peer (Point-to-point): Two systems can be connected Point-to-Point, or in other words back-to-back fashion. They both reside on same level and called peers.
There can be hybrid network which involves network architecture of both the above types.

Question 142 | Q01566

Application developer has permission to decide the following on transport layer side

A. Transport layer protocol

B. Maximum buffer size

C. Both Transport layer protocol and Maximum buffer size

D. None of the mentioned

Hint

Match the requested scope or data unit to the layer duties in the note; distinguish hop delivery from end-to-end process delivery.

Answer C: Choose transport protocol and request buffer size, subject to OS limits

NET17 permits an application to choose its transport protocol and request socket-buffer sizes. In that application-configuration sense, C combines both choices. “Maximum buffer size” must mean the requested socket limit, not authority to override the operating system’s enforced maximum; the note explicitly makes the request subject to OS limits.

Why each choice is right or wrong

A - Incorrect: Choosing a transport is permitted, but this option omits the also-permitted socket-buffer size request.

B - Incorrect: A buffer limit can be requested subject to OS limits, but this omits transport-protocol choice.

C - Correct: Both settings can be selected/requested by the application, with the buffer size constrained by the operating system.

D - Incorrect: At least transport choice and buffer-size requests are explicitly permitted, so none is false.

Question 143 | Q01567

Using “end-to-end” for application service and “process-to-process” for the transport service beneath it, which service does the application layer offer?

A. End to end

B. Process to process

C. Both End to end and Process to process

D. None of the mentioned

Hint

Match the requested scope or data unit to the layer duties in the note; distinguish hop delivery from end-to-end process delivery.

Answer A: End to end

The question explicitly separates an application service from the underlying transport service. The note describes end-to-end application service as building on process-to-process transport. Under those named scopes, the application layer offers the end-to-end service, while process delivery identifies the transport boundary. Combining both would collapse the distinction being tested; none of the mentioned fails because the application-service term is present.

Why each choice is right or wrong

A - Correct: End-to-end is the stated application-service scope.

B - Incorrect: Process-to-process names the underlying transport service in this question.

C - Incorrect: The combination assigns the underlying transport-service term to the application layer, contrary to the stated distinction.

D - Incorrect: The stated application-service term is offered in A.

d.

A. IP

B. MAC

C. Port

D. None of the mentioned

Hint

Use the cited note definitions to identify the requested function or scope, then check each alternative against that same rule.

Answer C: Port

Port numbers explicitly identify the destination application/process, while IP identifies an interface and MAC a local physical endpoint. Evidence: PDF 28, 18, 17.

Why each choice is right or wrong

Question 145 | Q01572

In TCP connection establishment procedure, if a client chooses Initial Sequence Number of 395, and server chooses 260, then:

A. The 1st segment sent will contain sequence number of 396

B. The 2nd segment sent will contain acknowledgement number of 261

C. The 3rd segment sent will contain sequence number of 261

D. The 2nd segment sent will contain acknowledgement number of 396

E. The 2nd segment sent will contain sequence number of 395

F. The 3rd segment sent will contain acknowledgement number of 396

Hint

Trace the handshake in order, keeping each endpoint’s sequence and acknowledgment fields separate.

Answer D: Second segment acknowledgment number 396

SYN consumes one sequence position. The first segment is client SYN seq395. The server’s second segment is SYN+ACK seq260 ack396, acknowledging the client SYN. The third is client ACK seq396 ack261. Comparing those fields shows only D matches; sequence numbers and acknowledgment numbers must not be swapped between endpoints.

Why each choice is right or wrong

A - Incorrect: The first client SYN uses its initial sequence number 395, not the next position 396.

B - Incorrect: The second segment acknowledges the client SYN with 396; 261 is the later acknowledgment of the server SYN.

C - Incorrect: The third segment’s sequence number is the client’s next position 396, not the server acknowledgment value 261.

D - Correct: The server’s SYN+ACK acknowledges client ISN 395 plus one, giving 396.

E - Incorrect: The second segment is sent by the server with its own sequence number 260.

F - Incorrect: The third segment acknowledges server ISN 260 plus one, giving 261 rather than 396.

Primary note proof

Study-note section NET18

TCP establishes state with SYN, SYN+ACK, then ACK. SYN consumes one sequence position even with no application bytes. An acknowledgment states the next expected sequence number. For client ISN=395 and server ISN=260: client sends SYN seq395; server sends SYN+ACK seq260 ack396; client sends ACK seq396 ack261. Later byte counts advance sequence numbers. FIN also consumes one sequence position.

Question 146 | Q01573

For IPv4 when fragmentation is permitted, which option gives the complete set of nodes that may fragment packets and the location of reassembly?

A. Fragment at the source host; re-assemble at the destination host

B. Fragment at the source host and routers; re-assemble at the destination host

C. Fragment at the source host and routers; re-assemble at the routers and destination host

D. Fragment at the source host; re-assemble at the routers and destination host

E. IP does not support Fragmentation and Re-assembly.

Hint

Separate address width, syntax, reserved scope and the supplied prefix or historical classful convention.

Answer B: Fragment at the source host and routers; re-assemble at the destination host

IPv4 permits both the source and a router to fragment packets when fragmentation is allowed and an outgoing MTU requires it. The destination reassembles the fragments. Source-only fragmentation omits a permitted IPv4 case; it instead resembles the IPv6 restriction. Adding intermediate-router reassembly is incorrect. Naming IPv4 and asking for the complete permitted set makes the version-specific distinction explicit.

Why each choice is right or wrong

A - Incorrect: A source may fragment, but this option omits permitted IPv4 router fragmentation.

B - Correct: IPv4 sources and routers may fragment; only the destination reassembles.

C - Incorrect: Neither cited IP fragmentation rule places reassembly at intermediate routers.

D - Incorrect: Destination reassembly is required; the additional router reassembly claim is unsupported for either version.

E - Incorrect: Both version-specific rules support fragmentation and reassembly, although the allowed fragmenting nodes differ.

Primary note proof

Study-note section NET16

> The IPv4 checksum protects its header; IP does not lack error checking altogether. Identification, flags and offset support fragmentation. IPv4 sources and routers may fragment when allowed; reassembly occurs at the destination. If DF is set and the next MTU is too small, forwarding fails and an ICMP diagnostic may be returned.

Packets in one TCP connection can be distinguished from packets in another TCP connection by:

A. Source port, destination port, protocol number

B. Source IP address, destination IP address, protocol number

C. Source port, destination port, source IP address, destination IP address

D. Source IP address, destination IP address

E. Source port, destination port

F. Protocol number

Hint

Identify the requested service or delivery guarantee, then distinguish application roles, transport behavior and address configuration.

Answer C: Both IP addresses and both port numbers

All packets under discussion are already TCP, so their protocol identity is common. Distinguishing arbitrary simultaneous connections needs the endpoint four-tuple: source IP, destination IP, source port and destination port. Addresses alone cannot distinguish separate applications between the same hosts; ports alone can repeat between different hosts. C supplies all four required fields.

Why each choice is right or wrong

A - Incorrect: Ports and protocol can repeat between different host pairs, so this omits necessary IP addresses.

B - Incorrect: Two hosts can have several simultaneous TCP connections; addresses and TCP protocol alone do not distinguish them.

C - Correct: The source/destination IP addresses and source/destination ports form the TCP connection four-tuple.

D - Incorrect: An IP-address pair cannot distinguish multiple connections between the same two hosts.

E - Incorrect: The same source/destination port pair can be used with different IP-address endpoints.

F - Incorrect: Every connection in the stem uses TCP, so protocol number alone distinguishes none of them.

Question 148 | Q01630

Compared to other common topologies in LANs (such as bus, mesh, ring), which of the following is a disadvantage of using a star topology for LAN?

A. Poor performance due to sharing of point-to-multipoint links between users

B. Failure of a single station results in no stations being able to communicate

C. Failure of a single link results in no stations being able to communicate

D. Each station requires many network interfaces

E. Too many links needed in the network

F. Failure of a special node results in no stations being able to communicate

Hint

Draw the links and identify shared components, alternate paths and the effect of the specified failure or growth requirement.

Answer F: Failure of a special node results in no stations being able to communicate

The star description explicitly calls its hub/switch a single point of failure: failure of that central device brings the whole system down. Ordinary station/link failure is isolated. Evidence: PDF 23, 23, 23, 23.

Why each choice is right or wrong

A - Incorrect: Star has separate central links, not the bus shared-backbone defect (PDF 23, 23, 23, 23.)

B - Incorrect: Failure of an ordinary station does not remove the central device (PDF 23, 23, 23, 23.)

C - Incorrect: The module says a link failure affects only its attached device (PDF 23, 23, 23, 23.)

D - Incorrect: Many interfaces per station is the full-mesh burden (PDF 23, 23, 23, 23.)

E - Incorrect: Star uses more cable than bus/ring but less than mesh, so this is not the distinctive universal comparison (PDF 23, 23, 23, 23.)

F - Correct: The special central node is explicitly a single point of failure (PDF 23, 23, 23, 23.)

Primary note proof

Study-note section NET08

> Bus uses a shared backbone; an unterminated break can disrupt the segment. Star connects endpoints through a central device: one edge failure isolates that endpoint, whereas central failure affects the star. Ring forms a loop; basic single rings are vulnerable to a break, while protected dual rings differ. Token passing is associated with Token Ring but is an access method, not a necessary property of every ring. Tree is hierarchical; hybrid combines arrangements.

Star Topology: in this topology, each node is connected directly to a central device called a hub or a switch. Data on a star network passes through the central device (switch) before continuing to its destination. The central device manages and controls all functions of the network. This configuration is common with twisted pair cable. RJ-45 Connectors are used to connect the cable to the Network Interface Card (NIC) of each computer. Its advantages include, ease of installation and reconfiguration, robust (ease of fault identification and isolation), link failure only affects device(s) connected to that link, and is less expensive than mesh. Its drawbacks include more cable requirements (than bus and ring) and single point of failure (if central device fail, the whole system will be down).

Mesh Topology: in this topology devices are connected with many redundant interconnections between network nodes. In a full mesh topology, every node has a connection to every other node in the network, which makes it the most expensive topology over all the other topologies. The number of cables grows fast as the number of nodes increases, and it can be calculated by using the general formula ((n (n - 1)) /2), where n is the number of nodes in the

Data Communication and Computer Networking module | PDF page 23 | lines 4-18

Bus Topology: in this topology all devices are connected to a central cable, called the bus or backbone, which is terminated at its ends. The purpose of the terminators is to stop the signal from bouncing, thereby clearing the cable so that other computers can send data. Message transmitted along the Bus is visible to all computers connected to the backbone cable. As the message arrives at each workstation, the workstation checks the destination address contained in the message either to process or drop the packet if it matches or not respectively. Its

advantages are, ease of installation and less amount of cable requirement. Its main drawback is, the entire network will be shut down if there is a break in the main cable.

Data Communication and Computer Networking module | PDF page 23 | lines 35-44

Ring Topology: in this topology, all devices are connected to one another in the shape of a closed loop, so that each device is connected directly to two other devices, one on either side of it. Some of its advantages include, easy to install and reconfigure, less expensive (than mesh), and performance is even despite the number of users. Its cons include, break in the ring (such as a disabled station) can disable the entire network, and limitations on media and traffic (limitation on ring length and number of devices).

Question 149 | Q01631

For IPv4 networks, distinguish interface IP addresses, transport port numbers and the IPv4 Protocol header field. Which statement is true?

A. The protocol number commonly used by web server applications is 80

B. Every application must use a well-known port number

C. Each host and router in the Internet has only a single IP address

D. Client applications may dynamically select port numbers

E. A protocol number is used to indicate the version of IP being used

Hint

Identify the requested service or delivery guarantee, then distinguish application roles, transport behavior and address configuration.

Answer D: Client applications may dynamically select port numbers

Client applications commonly use dynamically selected ephemeral ports. Ports identify transport endpoints, whereas the IPv4 Protocol field identifies the carried upper-layer protocol, such as TCP or UDP. The separate Version field identifies the IP version. Port 80 is a usual HTTP service port, not an IP protocol number. Hosts and routers can have multiple addressed interfaces, so they are not restricted to one IP address.

Why each choice is right or wrong

A - Incorrect: 80 is a usual HTTP port number, not the IPv4 Protocol value for HTTP.

B - Incorrect: Clients may use ephemeral ports, so a well-known port is not mandatory for every application.

C - Incorrect: A device can have multiple addressed interfaces and therefore multiple IP addresses.

D - Correct: Clients may dynamically select ephemeral transport ports.

E - Incorrect: The IPv4 Protocol field identifies the upper-layer protocol; the Version field identifies the IP version.

Primary note proof

Study-note section NET-S06

An IP address identifies a network interface rather than limiting a whole computer to one address. A computer or router can have several interfaces and addresses. Under a supplied IPv4 prefix, leading bits identify the network and the remaining bits identify an address within that network; a MAC address is a separate link-layer identifier.

Study-note section NET-S06

TCP and UDP port fields are 16 bits, allowing numbers from 0 through 65535. Well-known ports are 0-1023, registered ports are 1024-49151, and dynamic/private ports are 49152-65535. Client endpoints can use dynamically selected ports instead of every application requiring a well-known assignment. These port numbers are distinct from the IP version and upper-protocol fields.

Study-note section NET16

IP supplies connectionless best-effort packet delivery, not end-to-end ordering or retransmission. IPv4 addresses are 32 bits. Its minimum header is 20 bytes and can grow to 60 bytes; it is not a 32-bit header. IHL counts 32-bit words; total length includes header and payload. TTL limits lifetime across routers; the protocol field identifies TCP, UDP or another upper-layer protocol.

TCP and UDP must use port numbers to communicate
with the upper layers, because they‘re what keep track of
different conversations crossing the network
simultaneously. These port numbers identify the source
and destination application or process in the TCP
segment. There are 216 = 65,536 ports available.
Well-known ports: The port numbers range from 0 to
1,023.
Registered ports: The port numbers range from 1,024 to
49,151. Registered ports are used by applications or
services that need to have consistent port assignments.
Dynamic or private ports: The port numbers range from
49,152 to 65,535.

IP addresses: IP address uniquely identifies a device on the Internet. Every host and router on the Internet has an IP address, which encodes its network number and host number.
• The combination is unique: in principle, no two machines on the Internet have the same IP address.
• An IPv4 address is 32 bits long
• They are used in the Source address and Destination address fields of IP packets.
• An IP address does not refer to a host but it refers to a network interface.

Question 150 | Q01632

If you would like to give IP address to 57 hosts from your IP prefix which subnet mask do you use most effectively?

A. 255.255.255.248

B. 255.255.255.240

C. 255.255.255.224

D. 255.255.255.128

E. 255.255.255.192

Hint

Convert the mask to a prefix, separate network and host bits, and apply the relevant subnet-count or usable-host rule.

Answer E: 255.255.255.192

For 57 hosts choose the smallest offered block with at least 57 total addresses: /26 (192=11000000) has 64. The next smaller /27 has only 32, and /25 wastes twice the space. Even the conventional two reserved addresses leave /26 sufficient. Evidence: PDF 19, 19.

Why each choice is right or wrong

A - Incorrect: 248 gives only eight total addresses (PDF 19, 19.)

B - Incorrect: 240 gives only 16 (PDF 19, 19.)

C - Incorrect: 224 gives only 32 (PDF 19, 19.)

D - Incorrect: 128 gives 128 and uses more space than necessary (PDF 19, 19.)

E - Correct: 192 gives 64, the smallest offered sufficient block (PDF 19, 19.)

Primary note proof

Study-note section NET26

> For H hosts, choose the smallest h satisfying 2^h-2≥H, then p=32-h. For 24 hosts use /27; 52 or 57 use /26; 100 use /25; 500 use /23. For at least six equal subnets choose b=3. A Class C /24 split to /27 yields eight subnets. Always check both the number of subnets and the host capacity.

Which one of the following is NOT correct about POP3 and SMTP?

A. A sender can send email using SMTP

B. Both are application layer protocols

C. A sender can receive emails using POP3

D. Both are network layer protocols

Hint

Use the cited note definitions to identify the requested function or scope, then check each alternative against that same rule.

Answer D: Both are network layer protocols

The application-layer list includes SMTP and POP3; POP3 is explicitly for receiving mail. They are not network-layer protocols. Evidence: PDF 28, 18.

Why each choice is right or wrong

A - Incorrect: SMTP mail transfer supports sending (PDF 28, 18.)

B - Incorrect: Both appear in the application list (PDF 28, 18.)

C - Incorrect: Receiving via POP3 matches the explicit receive-mail statement (PDF 28, 18.)

D - Correct: Calling both network-layer protocols contradicts the layer list (PDF 28, 18.)

Primary note proof

Study-note section NET21

HTTP defines web request/response semantics; it is stateless, and a message body may be absent. HTTPS adds TLS protection. FTP transfers files using control and separate data connections; it is not the same protocol as SFTP. Question 152 | SM0022

A university’s private LANs and WANs provide services only to its staff, students and administrators. Which term best describes this system by its access scope?

A. Local Area Network

B. Intranet

C. Wide Area Network

D. Metropolitan Area Network

Hint

Use the cited note definitions to identify the requested function or scope, then check each alternative against that same rule.

Answer B: Intranet

The relevant distinction is who can access organizational services, rather than how far the links extend. An intranet serves an organization internally, so it can include both local and wide-area components. LAN, WAN and MAN describe geographic reach and cannot replace that access-scope classification. The option identifies an intranet without assuming a particular geographic footprint.

Why each choice is right or wrong

A - Incorrect: LAN describes geographic reach of local components rather than the organizational access scope requested.

B - Correct: An intranet serves the university’s internal members across its constituent networks.

C - Incorrect: WAN describes geographic reach of some components rather than the internal-access scope requested.

D - Incorrect: MAN describes metropolitan geographic reach rather than internal organizational access.

Primary note proof

Study-note section NET02

> PAN connects personal devices, such as Bluetooth accessories. LAN covers a local building or campus; MAN spans a metropolitan region; WAN connects distant regions. Device count alone does not determine the category. The Internet is a global network of networks, commonly the largest example of a WAN.

Study-note section NET02

> An intranet serves an organization internally; an extranet exposes selected services to approved outsiders. Neither term alone specifies geographic size. A client requests a service; a server

supplies it. Peer systems may perform both roles. Dedicated servers concentrate on service workloads but can still be clients of DNS, backup or update services. A ten-user cutoff is a teaching guideline, not a technical law. Centralization simplifies administration but creates dependencies; peer networks still need security.

Client-Server Architecture: There can be one or more systems acting as Server. Other being Client, request the Server to serve requests. Servers take and process request on clients‘ behalf.
Peer-to-Peer (Point-to-point): Two systems can be connected Point-to-Point, or in other words back-to-back fashion. They both reside on same level and called peers.
There can be hybrid network which involves network architecture of both the above types.

Question 153 | SM0025

At which layer of the OSI model are devices such as bridges, switches and Network Interface Cards used?

A. Physical layer

B. Application layer

C. Network layer

D. Data link layer

Hint

Match the requested scope or data unit to the layer duties in the note; distinguish hop delivery from end-to-end process delivery.

Answer D: Data-link forwarding functions, with NICs also implementing PHY

Bridges and ordinary switches inspect MAC frames at layer 2. A NIC commonly implements both physical and data-link functions, as NET09 explains; listing NICs here does not force all NIC work into one layer. D is the common frame/addressing layer for the listed devices' relevant network-interface forwarding functions.

Why each choice is right or wrong

A - Incorrect: A NIC has physical functions, but bridges/switches make layer-2 forwarding decisions beyond signal repetition.

B - Incorrect: These devices' MAC/frame operations are below application-service semantics.

C - Incorrect: Ordinary bridges and Ethernet switches do not route IP prefixes as their defining function.

D - Correct: Bridges/switches operate at layer 2, and NICs also implement link-layer MAC/frame functions.

Primary note proof

Study-note section NET09

> A NIC supplies a computer's network interface and commonly implements both physical and link functions. Calling a NIC a physical interface does not mean all its functions are layer 1. Physical specifications include connectors, signaling, voltage, timing and physical coding/modulation; the PHY interface to MAC handles hardware signaling.

Study-note section NET10

A bridge or ordinary Ethernet switch operates at layer 2. It learns source-MAC-to-port mappings, looks up the destination, forwards a known unicast to its port, filters it if the destination is on the incoming segment, and floods an unknown unicast or broadcast within its VLAN. A switch does not always send only to one destination port. Wireless access points normally bridge wireless and wired link-layer traffic.

Data Link Layer
• The Data Link layer adds reliability to the physical
layer by providing error detection and correction
mechanisms.
• Framing: the Data Link layer receives the data
from Network Layer and divides the stream of bits
into fixed size manageable units called as Frames
and sends it to the physical layer. On the receiver

side, the data link layer receives the stream of bits from the physical layer and regroups them into frames and sends them to the Network layer.
• Physical Addressing: The Data link layer appends the physical address in the header of the frame before sending it to physical layer.
• Flow control: The data link layer makes sure that the sender sends the data at a speed at which the receiver canreceive it else if there is an overflow at the receiver sidethe data will be lost.
• Error Control: The data link layer imposes error control mechanism to identify lost or damaged frames, duplicateframes and then retransmit them.
• Access Control: The data link layer imposes access control mechanism to determine which device has right to send data in an multipoint connection setting.
• Main Responsibility: The main responsibility of the data link layer is hop to hop transmission of frames.

Question 154 | SM0035

Which listed device is an end resource used by clients, rather than an intermediary that forwards, bridges or repeats network traffic?

A. Routers

B. Network printer

C. Wireless access point

D. Hubs

Hint

Use the cited note definitions to identify the requested function or scope, then check each alternative against that same rule.

Answer B: Network printer

A network printer is an endpoint resource that receives client jobs. A router forwards packets between networks, a wireless access point normally bridges wireless and wired link traffic, and a hub repeats physical signals among ports. These are intermediary roles in the comparison. The question classifies their normal function rather than claiming that an intermediary cannot also expose a management endpoint.

Why each choice is right or wrong

A - Incorrect: Routers forward traffic between networks and are intermediaries.

B - Correct: A network printer is the client-facing end resource.

C - Incorrect: A wireless access point normally bridges wireless and wired link traffic.

D - Incorrect: A hub repeats signals between attached devices and is an intermediary.

Primary note proof

Study-note section NET09

> A repeater regenerates layer-1 signals without inspecting destination addresses. An active hub is a multiport repeater: it repeats incoming signals onto other ports, placing half-duplex endpoints in one collision domain. A passive hub is a connector. A hub neither learns MAC addresses nor eliminates collisions. An endpoint such as a network printer consumes services; routers, hubs and access points are intermediary devices.

A network can be defined as two or more computers connected together in such a way that they can share resources. The primary purpose of a network is to share

resources, and a resource could be:
• a file,
• a folder,
• a printer,
• a disk drive, or just about anything else that exists on a computer.
Therefore, a computer network is simply a collection of computers or other hardware devices that are connected together, either physically or logically, using special hardware and software, to allow them to exchange information and cooperate. Networking is the term that describes the processes involved in designing, implementing, upgrading, managing and otherwise working with networks and network technologies.

Which network type is the largest as compared to the rest?

A. Wide Area Network

B. Metropolitan Area Network

C. The Internet

D. Local Area Network

Hint

Use the cited note definitions to identify the requested function or scope, then check each alternative against that same rule.

Answer C: The Internet

The Internet names the particular global network of networks, while WAN, MAN and LAN name scope categories. NET02 explicitly gives the Internet as the largest common WAN example. Thus C is the intended largest actual network in the comparison, even though WAN includes Internet-scale networks rather than being a disjoint smaller category.

Why each choice is right or wrong

A - Incorrect: WAN is a category that includes the Internet, not a separate specific network shown to be larger.

B - Incorrect: MAN spans a metropolitan area rather than the global network of networks.

C - Correct: NET02 identifies the global Internet as the largest common WAN example.

D - Incorrect: LAN covers a local building/campus and is much narrower in geographic scope.

Question 157 | SM0057

Which statement is incorrect when packet switching means connectionless datagram switching?

A. In packet switching, messages are sent in small blocks

B. In packet switching, an end-to-end connection has to be established

C. In circuit switching, a channel is dedicatedly used

D. For bursty traffic, statistical packet sharing can use capacity that dedicated circuits would reserve while idle.

Hint

Compare signal repetition, frame forwarding, packet routing and policy enforcement using the stated device or traffic assumptions.

Answer B: In packet switching, an end-to-end connection has to be established

Datagram switching divides messages into packets and forwards those packets independently without requiring end-to-end connection establishment. Circuit switching reserves resources along a path. Statistical sharing lets bursty packet traffic use capacity that would otherwise remain reserved but idle; this is a conditional utilization advantage, not a universal claim that packets outperform circuits for every workload or metric.

Why each choice is right or wrong

A - Incorrect: Packet switching divides messages into smaller packets.

B - Correct: Connectionless datagrams do not require end-to-end connection setup.

C - Incorrect: Circuit switching reserves channel resources for the connection.

D - Incorrect: For bursty traffic, shared packet links can avoid idle dedicated reservations; the qualified statement is true.

Primary note proof

Study-note section NET31

Circuit switching sets up a path with reserved resources, transfers data, then releases it. Predictable allocated bandwidth trades against setup/blocking and wasted reservation during silence. A traditional telephone call is the standard example. Packet switching divides data into packets that share links statistically; queueing can add variable delay and loss. This does not make modern voice-over-packet impossible: buffering, scheduling and capacity planning manage it.

Study-note section NET31

Datagram packets are forwarded independently. Virtual circuits establish forwarding state, but resource reservation is optional, not a necessary property of every virtual circuit. Message switching stores a complete message before forwarding, without a dedicated end-to-end path. Packet store-and-forward waits for the full packet/frame; cut-through starts after enough header arrives; fragment-free historically waits through the initial collision-sensitive portion. No routing algorithm guarantees that every packet always takes the geometrically shortest route.

Circuit Switching: In circuit switching, two communicating stations are connected by a dedicated communication path which consists of intermediate nodes in the network and the links that connect these nodes.
It involved the following three distinct steps
• Circuit Establishment: To establish an end-to-end connection before any transfer of data.
• Data transfer: Transfer data is from the source to the destination. The data may be analog or digital, depending on the nature of the network. The connection is generally full-duplex.
• Circuit disconnect: Terminate connection at the end of data transfer. Signals must be propagated to deallocate the dedicated resources.

Message Switching:
Packet Switching: Packet switching was designed to

address the shortcomings of circuit switching in dealing with data communication. Unlike circuit switching where communication is continuous along a dedicated circuit, in packet switching, communication is discrete in form of packets.
The three switching modes to choose from are:
• Cut-through
• Store-and-forward
• Fragment-free

Question 158 | SM0062

Which layer uses port number to identify applications?

A. Transport layer

B. Physical layer

C. Network layer

D. Application layer

Hint

Match the requested scope or data unit to the layer duties in the note; distinguish hop delivery from end-to-end process delivery.

Answer A: Transport layer

Ports explicitly identify source and destination processes for transport delivery. Evidence: PDF 16, 28, 14, 15, 16.

Why each choice is right or wrong

A - Correct: Transport uses port addresses for processes (PDF 16, 28, 14, 15, 16.)

B - Incorrect: Physical represents bits and signals (PDF 16, 28, 14, 15, 16.)

C - Incorrect: Network uses logical IP addresses (PDF 16, 28, 14, 15, 16.)

D - Incorrect: Application uses transport services but port addressing is assigned to transport (PDF 16, 28, 14, 15, 16.)

Primary note proof

Study-note section NET17

> Ports identify transport endpoints; the application can choose a transport and request socket buffer sizes, subject to OS limits. A TCP connection is identified by source/destination IP and source/destination port, with TCP understood. IPv4 protocol numbers identify upper protocols; 80 is a usual HTTP port, not an IP protocol number. Clients often use ephemeral ports. SCTP is a reliable message-oriented transport with multiple streams.

Study-note section NET12

> Sending proceeds from application data to transport segment/datagram, network packet, link frame and physical bits/symbols; receiving reverses the order. Each layer serves the layer above. A router removes a received link frame, inspects IP, and creates a new link frame for the next hop. MAC addresses usually change across routed hops; end-to-end IP addresses ordinarily remain until translation.

TCP and UDP must use port numbers to communicate with the upper layers, because they‘re what keep track of different conversations crossing the network simultaneously. These port numbers identify the source and destination application or process in the TCP segment. There are 216 = 65,536 ports available.
Well-known ports: The port numbers range from 0 to 1,023.
Registered ports: The port numbers range from 1,024 to 49,151. Registered ports are used by applications or services that need to have consistent port assignments.
Dynamic or private ports: The port numbers range from 49,152 to 65,535.

Physical Layer:
• The Physical Layer provides a standardized interface to physical transmission media, including: Mechanical specification of electrical connectors and cables, for example maximum cable length, Electrical specification of transmission line and Bit-by-bit or symbol-by-symbol delivery.
• Interface: The Physical Layer defines the characteristics of interfaces between the devices & transmission medium.
• Representation of bits: The physical layer is concerned with transmission of signals from one device to another which involves converting data (1_s & 0_s) into signals and vice versa. It is not concerned with the meaning or interpretation of bits.

• Data rate: The physical layer defines the data transmission rate i.e. number of bits sent per second. It is the responsibility of the physical layer to maintain the defined data rate.

Question 159 | SM0225

In which network topology does a single line cable called a backbone connect all nodes on a network without intervening connected devices?

A. Bus

B. Ring

C. Star

D. Mesh

Hint

Draw the links and identify shared components, alternate paths and the effect of the specified failure or growth requirement.

Answer A: Bus

Bus explicitly connects all devices to a central backbone cable terminated at both ends. Evidence: PDF 23, 23, 23, 23.

Why each choice is right or wrong

A - Correct: Bus has the stated shared backbone (PDF 23, 23, 23, 23.)

B - Incorrect: Ring is a closed neighbor loop (PDF 23, 23, 23, 23.)

C - Incorrect: Star uses a central hub/switch and separate links (PDF 23, 23, 23, 23.)

D - Incorrect: Mesh has many direct node-pair links (PDF 23, 23, 23, 23.)

Primary note proof

Study-note section NET08

> Bus uses a shared backbone; an unterminated break can disrupt the segment. Star connects endpoints through a central device: one edge failure isolates that endpoint, whereas central failure affects the star. Ring forms a loop; basic single rings are vulnerable to a break, while protected dual rings differ. Token passing is associated with Token Ring but is an access method, not a necessary property of every ring. Tree is hierarchical; hybrid combines arrangements.

purpose of the terminators is to stop the signal from bouncing, thereby clearing the cable so that other computers can send data. Message transmitted along the Bus is visible to all computers connected to the backbone cable. As the message arrives at each workstation, the workstation checks the destination address contained in the message either to process or drop the packet if it matches or not respectively. Its advantages are, ease of installation and less amount of cable requirement. Its main drawback is, the entire network will be shut down if there is a break in the main cable.

Star Topology: in this topology, each node is connected directly to a central device called a hub or a switch. Data on a star network passes through the central device (switch) before continuing to its destination. The central device manages and controls all functions of the network. This configuration is common with twisted pair cable. RJ-45 Connectors are used to connect the cable to the Network Interface Card (NIC) of each computer. Its advantages include, ease of installation and reconfiguration, robust (ease of fault identification and isolation), link failure only affects device(s) connected to that link, and is less expensive than mesh. Its drawbacks include more cable requirements (than bus and ring) and single point of failure (if central device fail, the whole system will be down).

Ring Topology: in this topology, all devices are connected to one another in the shape of a closed loop, so that each device is connected directly to two other devices, one on either side of it. Some of its advantages include, easy to install and reconfigure, less expensive (than mesh), and performance is even despite the number of users. Its cons include, break in the ring (such as a disabled station) can disable the entire network, and limitations on media and traffic (limitation on ring length and number of devices).

In computer networking, _____ refers to how various nodes, devices, and connections on your network are physically or logically arranged in relation to each other.

A. Network layer

B. Network installation

C. Network protocol

D. Network topology

Hint

Compare signal repetition, frame forwarding, packet routing and policy enforcement using the stated device or traffic assumptions.

Answer D: Network topology

Network topology is the shape/layout and geometrical relation of links and devices, including physical and logical connectedness. Evidence: PDF 22, 5.

Why each choice is right or wrong

A - Incorrect: Network layer is a protocol responsibility layer (PDF 22, 5.)

B - Incorrect: Installation is the activity of building, not the layout name (PDF 22, 5.)

C - Incorrect: Protocol is a communication rule set (PDF 22, 5.)

D - Correct: Topology is exactly the arrangement concept (PDF 22, 5.)

There are three key elements of a protocol:
Syntax: It means the structure or format of the data. It is the
arrangement of data in a particular order.
Semantics: It tells the meaning of each section of bits and
indicates the interpretation of each section.
Timing: It tells the sender about the readiness of the receiver to

Answer A: Distance

The five components are message, sender, receiver, medium and protocol. Distance is a property of a path, not a component in this definition. Evidence: PDF 5.

In which network topology should every computer have N-1 I/O ports when there are N computers in the network?

A. Star

B. Mesh

C. Bus

D. Ring

Hint

Draw the links and identify shared components, alternate paths and the effect of the specified failure or growth requirement.

Answer B: Mesh

Question 163 | SM0291

In data communication, data rate refers how fast we can send data and is measured in bits per second. Which one of
the following is not a factor for data rate?

A. Travel distance

B. Levels of the signals

[SS

C. Bandwidth available

D. Level of noise

Hint

Use the cited note definitions to identify the requested function or scope, then check each alternative against that same rule.

Answer A: Travel distance is not an explicit channel-capacity formula variable

NET05 gives Nyquist in terms of bandwidth and signal states, and Shannon in terms of bandwidth and signal-to-noise ratio. Distance is not an independent variable in those simplified capacity formulas, so A is the intended comparison. It can still affect practical achievable rate through attenuation and delay. The image confirms travel distance despite noise in another extracted option.

Why each choice is right or wrong

A - Correct: Distance is absent as an independent variable in the simplified formulas, although it affects real links indirectly.

B - Incorrect: The number of signal levels appears explicitly in Nyquist through log2(M).

C - Incorrect: Available bandwidth directly appears as B in both Nyquist and Shannon capacity expressions.

D - Incorrect: Noise affects signal-to-noise ratio and therefore the Shannon capacity limit.

Primary note proof

Study-note section NET05

For an ideal noiseless channel, Nyquist gives R≤2B log2(M). For Gaussian noise, Shannon gives C=B log2(1+S/N), with a linear power ratio; SNR(dB)=10 log10(S/N). Bandwidth, signal levels and noise appear explicitly. Distance affects attenuation, delay and often achievable rate, but is not a separate variable in these simplified capacity formulas.

Study-note section NET06

Transmission delay is packet bits divided by link bit rate; propagation delay is distance divided by signal speed. Processing and queueing add delay. A 1000-byte packet takes 0.8 ms to serialize at 10 Mbit/s; increasing line rate does not reduce propagation time.

BIT LENGTH or Bit Interval (Tb)
It is the time required to send one bit.
It is measured in seconds.
BIT RATE
It is the number of bits transmitted in one second.
It is expressed as bits per second (bps).
Relation between bit rate and bit interval can be as follows
Bit rate = 1 / Bit interval
Baud Rate
It is the rate of Signal Speed, i.e the rate at which the signal

A digital signal with two levels 0_& 1_will have the same
baud rate and bit rate & bit rate.

receiver.There are three causes of impairment:
• Attenuation
• Distortion
• Noise
Attenuation
Attenuation results in loss of energy due to distance.

Whena signal travels through a medium, it loses some of its energy in overcoming the resistance of the medium. The electrical energy in the signal may convert to heat. To compensate for this loss, amplifiers are used to amplify thesignal.
Distortion
Distortion changes the shape of the signal.
Noise
Noise is any unwanted signal that is mixed or combined with the original signal during transmission. Due to noise the original signal is altered and signal received is not sameas the one sent.

Data Communication and Computer Networking module | PDF page 9 | lines 29-49

Transmission of Digital signal: Digital signal can be transmitted in the following two ways:
• Baseband Transmission: The signal is transmitted without making any change to it (i.e. Without modulation)
o In baseband transmission, the bandwidth of the signal to be transmitted has to be less than the bandwidth of the channel.
o Ex. Consider a Baseband channel with lower frequency 0Hz and higher frequency 100Hz, hence its bandwidth is 100 (Bandwidth is calculated by getting the difference between the highest and lowest frequency)
o A channel whose bandwidth is more than the bandwidth of the signal is called Wideband channel
o A channel whose bandwidth is less than the bandwidth of the signal is called Narrowband channel
• Broadband Transmission: Given a bandpass channel, a digital signal cannot be transmitted directly through it
o In broadband transmission we use modulation, i.e. we change the signal to analog signal before transmitting it.

Question 164 | SM0292

Which layer of the OSI model ensures that the whole message (group of packets) arrives at the destination intact and in order?

A. Session layer

B. Transport layer

C. Data link layer

D. Network layer

Hint

Match the requested scope or data unit to the layer duties in the note; distinguish hop delivery from end-to-end process delivery.

Answer B: Transport layer

Transport explicitly makes process-delivered data intact and ordered, using sequence-numbered segments and end-to-end error control. Evidence: PDF 16, 15, 15, 16.

Why each choice is right or wrong

A - Incorrect: Session controls dialogs/checkpoints (PDF 16, 15, 15, 16.)

B - Correct: Transport explicitly ensures intact and ordered whole-message delivery (PDF 16, 15, 15, 16.)

C - Incorrect: Data link controls hop-to-hop frames rather than the entire end-to-end message (PDF 16, 15, 15, 16.)

D - Incorrect: Network packets can arrive out of order (PDF 16, 15, 15, 16.)

Primary note proof

Study-note section NET17

> TCP offers a reliable ordered byte stream using sequence numbers, acknowledgments, retransmission and windows. Flow control protects the receiver; congestion control protects network capacity. UDP sends independent datagrams with ports and a checksum but no built-in setup, delivery guarantee, retransmission or ordering. Live interactive traffic may choose UDP when late data is less useful than lost data. Application protocols can add reliability over UDP.

Study-note section NET14

> Controlled access uses polling, reservations or a token to grant turns; correctly coordinated access avoids contention collisions. Channelization divides frequency, time or code resources. Stop-and-wait sends one frame and waits for ACK, retransmitting on timeout; sequence bits distinguish duplicates. Sliding windows permit multiple unacknowledged frames. Link reliability/flow control is hop-local; transport reliability/flow control is end-to-end. Ethernet detects corruption but does not itself guarantee reliable delivery.

Study-note section NET19

OSI session roles establish/manage dialogs and can coordinate checkpoints so transfer resumes after interruption. Presentation roles translate encodings and handle compression/encryption. Compression reduces representation size; encryption hides content and need not shrink it. Application protocols provide services directly to applications. Practical implementations distribute these functions differently; TLS is not proof of a separate physical presentation-layer device.

Data Link Layer
• The Data Link layer adds reliability to the physical layer by providing error detection and correction mechanisms.
• Framing: the Data Link layer receives the data from Network Layer and divides the stream of bits into fixed size manageable units called as Frames and sends it to the physical layer. On the receiver side, the data link layer receives the stream of bits from the physical layer and regroups them into frames and sends them to the Network layer.
• Physical Addressing: The Data link layer appends the physical address in the header of the frame before sending it to physical layer.
• Flow control: The data link layer makes sure that the sender sends the data at a speed at which the receiver canreceive it else if there is an overflow at the receiver sidethe data will be lost.

• Error Control: The data link layer imposes error control mechanism to identify lost or damaged frames, duplicateframes and then retransmit them.
• Access Control: The data link layer imposes access control mechanism to determine which device has right to send data in an multipoint connection setting.
• Main Responsibility: The main responsibility of the data link layer is hop to hop transmission of frames.

• The network layer is responsible for source todestination of delivery of data.
• The network layer uses logical address commonlyknown as IP address to recognize devices on the network.
• Each packet is independent of the other and may travelusing different routes to reach the receiver hence may arrive out of turn at the receiver (Routing).
• The Network layer does not perform any flow controlor error control
• The main responsibility of Network Layer is transmission of packets from source to destination

Session Layer
• The session layer establishes a session between the communicating devices called dialog and synchronizes their interaction. It is the responsibility of the session layer to establish and synchronize the dialogs. It is also called the network dialog controller.
• The session layer at the sending side accepts data from the presentation layer adds checkpoints to it called sync bits and passes the data to the transport layer. At the receiving end the session layer receives

data from the transport layer removes the checkpoints inserted previously and passes the data to the presentation layer. So, the main responsibility of session layer is dialog control and synchronization.

Which of the following is not a valid host address within the network 172.17.128.0/21 ?

A. 172.17.128.1/21

B. 172.17.135.255 /21

C. 172.17.135.0 /21

D. 172.17.128.255/21

Hint

Convert the mask to a prefix, separate network and host bits, and apply the relevant subnet-count or usable-host rule.

Answer B: 172.17.135.255/21 is broadcast

A /21 groups eight third-octet values, here 128-135. The network is 172.17.128.0 and its broadcast is 172.17.135.255. B sets every host bit to one and cannot be assigned to an ordinary host. The other choices are inside the usable range; ending in .0 or .255 alone does not make an address reserved.

Why each choice is right or wrong

A - Incorrect: 172.17.128.1 is one above the network boundary and is a valid usable host.

B - Correct: 172.17.135.255 sets all eleven host bits to one and is the subnet broadcast address.

C - Incorrect: 172.17.135.0 is inside the /21 block; its host bits are not all zero or all one.

D - Incorrect: 172.17.128.255 is an interior host; the .255 ending alone does not make it /21 broadcast.

Primary note proof

For ordinary broadcast LANs let h=32-p. Total addresses=2^h; usable hosts=2^h-2, reserving network and directed broadcast. Find the changing octet's increment as 256-mask octet, round the address down to a multiple, and extend through the next boundary minus one.

IP addresses: IP address uniquely identifies a device on the
Internet. Every host and router on the Internet has an IP address,
which encodes its network number and host number.
• The combination is unique: in principle, no two
machines on the Internet have the same IP address.
• An IPv4 address is 32 bits long
• They are used in the Source address and Destination
address fields of IP packets.
• An IP address does not refer to a host but it refers to a
network interface.

Data Communication and Computer Networking module | PDF page 19 | lines 2-22

Address Space: An address space is the total
number ofaddresses used by the protocol.
• If a protocol uses N bits to define an address,
the address space is 2N
because each bit can
have twodifferent values (0 or 1) and N bits
can have 2N values.
• IPv4 uses 32-bit addresses, which means that
the address space is 232 or 4,294,967,296
(more than 4billion).
Notations: There are two notations to show an IPv4 address:
• Binary notation: The IPv4 address is displayed
as 32bits. ex. 11000001 10000011 00011011
11111111
• Dotted decimal notation: To make the IPv4
address easier to read, Internet addresses are
usually written in decimal form with a decimal
point (dot) separatingthe bytes. Each byte (octet)
is 8 bits hence each number in dotted-decimal
notation is a value rangingfrom 0 to 255. Ex.
129.11.11.239

Data Communication and Computer Networking module | PDF page 19 | lines 23-36

Classful addressing : In classful addressing, the
addressspace is divided into five classes: A, B, C,
D, and E.
• Netid and Hostid In classful addressing, an IP

addressin class A, B, or C is divided into netid
and hostid.
Subnetting: It allows a network to be split into several
parts for internal use but still act like a single network to
the outsideworld.
• To implement subnetting, the router needs a
subnet mask that indicates the split between
network + subnet number and host. Ex.
255.255.252.0/22. A‖/22‖ to indicate that the
subnet mask is 22 bits long.

Question 166 | SS111

Which of the following is not the function of Cross-over UTP cable?

A. To connect router to pc

B. To connect switch to switch

C. To connect switch to pc

D. To connect pc to pc

Hint

Compare the signal mechanism, medium properties or transmission direction against the definitions and stated physical assumptions.

Answer C: Switch-to-PC normally uses straight-through cable in legacy Ethernet

Under the legacy MDI/MDI-X convention, a switch port and PC have unlike roles and use straight-through cable. PCs and router Ethernet endpoints conventionally share the endpoint role, while two switches share the switch role, so those like-role links use crossover. Auto-MDI-X can remove the practical requirement; the question is testing the conventional cable-role distinction.

Why each choice is right or wrong

A - Incorrect: A legacy router Ethernet endpoint and PC have like interface roles, so crossover is appropriate.

B - Incorrect: Two legacy switch ports have like roles and conventionally require crossover.

C - Correct: Switch and PC have unlike legacy interface roles and normally use straight-through cable.

D - Incorrect: Two PCs have like legacy interface roles; NET07 explicitly names PC-PC as a crossover example.

Primary note proof

Study-note section NET07

Radio, microwave and infrared are unguided media. Ground waves follow Earth, sky waves can reflect from ionized layers, and line-of-sight paths require suitable visibility. Microwaves are radio waves in the broader physical classification. Infrared generally does not penetrate walls. Directionality depends on antennas: omnidirectional means broad azimuth coverage, not equal radiation in every 3-D direction. Legacy Ethernet straight-through cables join unlike MDI/MDI-X roles; crossover joins like roles, such as PC-PC or switch-switch. Auto-MDI-X can remove that requirement.

Study-note section NET-S07

For legacy fixed Ethernet port roles, PCs and router Ethernet endpoints use the same endpoint role, while ordinary switch ports use the opposite role. Thus a direct router-to-PC link uses crossover wiring; PC-to-switch or router-to-switch uses straight-through wiring. Automatic MDI-X can remove the need to choose the crossover manually.

Star Topology: in this topology, each node is connected directly to a central device called a hub or a switch. Data on a star network passes through the central device (switch) before continuing to its destination. The central device manages and controls all functions of the network. This configuration is common with twisted pair cable. RJ-45 Connectors are used to connect the cable to the Network Interface Card (NIC) of each computer. Its advantages include, ease of installation and reconfiguration, robust (ease of fault identification and isolation), link failure only affects device(s) connected to that link, and is less expensive than mesh. Its drawbacks include more

cable requirements (than bus and ring) and single point of failure (if central device fail, the whole system will be down).

Question 167 | SS126

Given a situation two hosts attempt on a half-duplex Ethernet LAN to send data concurrently, resulting in a collision and subsequent to this collision,
what will the hosts do?

A. An electrical pulse indicates that the collision has cleared

B. The router on the segment will signal that the collision has cleared

C. The jam signal indicates that the collision has been cleared

D. The hosts will attempt to resume transmission after a time delay has expired

Hint

Compare the signal mechanism, medium properties or transmission direction against the definitions and stated physical assumptions.

Answer D: Stop and retry after random backoff

NET14 gives the collision sequence: detect, jam, stop and retry after random backoff. The jam indicates the collision itself, not that it has cleared. There is no router-coordinated clearance procedure or electrical clearance pulse in the stated rule. Therefore waiting for a delay and attempting transmission again is the supported host behavior.

Why each choice is right or wrong

A - Incorrect: The defined procedure uses collision indication and backoff; it does not include a collision-cleared electrical pulse.

B - Incorrect: Ethernet collision recovery is performed by the hosts' MAC procedure, not a router clearance signal.

C - Incorrect: A jam announces the collision; it does not certify that the shared medium is clear.

D - Correct: After stopping, hosts retry following random backoff, matching a delay before another transmission attempt.

Primary note proof

Study-note section NET14

Random access allows contention: ALOHA sends opportunistically; CSMA senses before sending. In legacy half-duplex Ethernet, CSMA/CD detects collision, sends a jam indication, stops, and retries after random backoff. The jam signals a collision, not its clearance. Wi-Fi 802.11 uses

CSMA/CA with waiting/backoff and acknowledgments; sensing does not eliminate hidden-terminal collisions.

Study-note section NET14

Controlled access uses polling, reservations or a token to grant turns; correctly coordinated access avoids contention collisions. Channelization divides frequency, time or code resources. Stop-and-wait sends one frame and waits for ACK, retransmitting on timeout; sequence bits distinguish duplicates. Sliding windows permit multiple unacknowledged frames. Link reliability/flow control is hop-local; transport reliability/flow control is end-to-end. Ethernet detects corruption but does not itself guarantee reliable delivery.

Question 168 | SS134

Which of the following is true regarding the use of switches and hubs for network connectivity in the network?

A. Switches increase the number of collision domains in the network

B. Switches take less time to process frames than hubs take

C. Switches do not forward broadcasts

D. Hubs can filter frames

Hint

Compare signal repetition, frame forwarding, packet routing and policy enforcement using the stated device or traffic assumptions.

Answer A: Switch ports separate collision domains

NET10 says each switch port separates collision domains, whereas a half-duplex hub repeats traffic into one shared collision domain. Switches still flood broadcasts within their VLAN, and hubs do not inspect and filter destination frames. The note gives no universal switch-versus-hub processing-time advantage, so A is the supported claim.

Why each choice is right or wrong

A - Correct: Replacing a shared hub segment with separate switch ports divides the network into additional collision domains.

B - Incorrect: The note establishes no universal lower switch processing time; a hub simply repeats signals.

C - Incorrect: Switches flood broadcasts within the VLAN unless another control filters them.

D - Incorrect: Hubs repeat physical signals and neither learn MAC destinations nor filter frames.

Primary note proof

Study-note section NET10

Each switch port separates collision domains; full-duplex point-to-point Ethernet has no collisions and does not use CSMA/CD. Switching permits independent conversations simultaneously. Broadcasts still reach the VLAN unless another control filters them. A layer-3 switch also routes, so device marketing names do not override the function being examined.

Study-note section NET09

A repeater regenerates layer-1 signals without inspecting destination addresses. An active hub is a multiport repeater: it repeats incoming signals onto other ports, placing half-duplex endpoints in one collision domain. A passive hub is a connector. A hub neither learns MAC addresses nor eliminates collisions. An endpoint such as a network printer consumes services; routers, hubs and access points are intermediary devices.

A TCP/IP layer which is responsible for addressing, path selection and routing refers:

A. Transport Layer

B. Network Access Layer

C. Application Layer

D. Internet Layer

Hint

Match the requested scope or data unit to the layer duties in the note; distinguish hop delivery from end-to-end process delivery.

Answer D: Internet Layer

The TCP/IP Internet layer corresponds to OSI network and provides IP addressing/source-to-destination transmission with routing. Evidence: PDF 17, 15, 17.

Why each choice is right or wrong

A - Incorrect: Transport is process delivery (PDF 17, 15, 17.)

B - Incorrect: Network access combines physical/data link (PDF 17, 15, 17.)

C - Incorrect: Application combines OSI upper layers (PDF 17, 15, 17.)

D - Correct: Internet matches network-layer addressing and routing (PDF 17, 15, 17.)

Primary note proof

IP protocol which is a network layer protocol and is responsiblefor source to destination transmission of data.
The Internetworking Protocol (IP) is a connection-less & unreliable protocol.
It is a best effort delivery service. i.e. there is no error checking in IP, it simply sends the data and relies on its underlying layers to get the data transmitted to the destination.Even if it is unreliable IP cannot be considered weak and useless; since it provides only the functionality that is requiredfor transmitting data thereby giving maximum efficiency.
Since there is no mechanism of error detection or correction in IP, there will be no delay introduced on a medium where thereis no error at all.

Which of the following is the correct order of packet data unit as data moved in the OS! reference model from bottom to top?

A. Segment, packet, frame, bit

B. Segment, frame, packet, bit

C. Bit, packet, frame, segment

D. Bit, frame, packet, segment

Hint

Match the requested scope or data unit to the layer duties in the note; distinguish hop delivery from end-to-end process delivery.

Answer D: Bit, frame, packet, segment

Moving bottom to top reverses sending encapsulation: physical bits become data-link frames, then network packets, then transport segments. Evidence: PDF 14, 15, 15, 16.

Why each choice is right or wrong

A - Incorrect: Starts at transport instead of physical and moves downward

B - Incorrect: Starts at transport and misorders frame and packet

C - Incorrect: Skips frame before packet

D - Correct: Bit, frame, packet, segment follows the upward layer order

Primary note proof

Study-note section NET12

Sending proceeds from application data to transport segment/datagram, network packet, link frame and physical bits/symbols; receiving reverses the order. Each layer serves the layer above. A router removes a received link frame, inspects IP, and creates a new link frame for the next hop. MAC addresses usually change across routed hops; end-to-end IP addresses ordinarily remain until translation.

Question 171 | AM0474

Which of the following is not a primary function of the network layer in the OSI model?

A. Routing

B. Addressing

C. Flow control

D. Fragmentation

Hint

Match the requested scope or data unit to the layer duties in the note; distinguish hop delivery from end-to-end process delivery.

Answer C: Flow control is not a primary network-layer duty

The network layer supplies logical addressing/routing and, for IPv4, fragmentation when permitted. Flow control instead protects a receiver in transport or hop-local link procedures, as NET14 and NET17 explain. Thus C is not a primary network-layer function in this layer model, without claiming that all control mechanisms belong exclusively to one layer.

Why each choice is right or wrong

A - Incorrect: Routing is explicitly a main network-layer duty in the NET12 layer table.

B - Incorrect: Logical addressing is explicitly assigned to the network layer.

C - Correct: Receiver flow control is described at link and transport scope rather than as a primary network duty.

D - Incorrect: NET16 supports IPv4 fragmentation by sources and routers, a network-protocol function.

Primary note proof

Study-note section NET16

> The IPv4 checksum protects its header; IP does not lack error checking altogether. Identification, flags and offset support fragmentation. IPv4 sources and routers may fragment when allowed; reassembly occurs at the destination. If DF is set and the next MTU is too small, forwarding fails and an ICMP diagnostic may be returned.

Study-note section NET14

reliability/flow control is hop-local; transport reliability/flow control is end-to-end. Ethernet detects corruption but does not itself guarantee reliable delivery.

Study-note section NET17

TCP offers a reliable ordered byte stream using sequence numbers, acknowledgments, retransmission and windows. Flow control protects the receiver; congestion control protects network capacity. UDP sends independent datagrams with ports and a checksum but no built-in setup, delivery guarantee, retransmission or ordering. Live interactive traffic may choose UDP when late data is less useful than lost data. Application protocols can add reliability over UDP.

Question 172 | AM0475

What is the purpose of a MAC address in computer networking?

A. To identify a device within a local area network (LAN)

B. To identify a device within a wide area network (WAN)

C. To establish a secure connection between two devices

D. To determine the IP address of a device

Hint

Use the cited note definitions to identify the requested function or scope, then check each alternative against that same rule.

Answer A: To identify a device within a local area network (LAN)

The module physical MAC address is imprinted on a NIC and used for local physical delivery; it is not encryption or the IP routing address. Evidence: PDF 17, 15.

Why each choice is right or wrong

A - Correct: MAC identifies the local physical interface for frame delivery (PDF 17, 15.)

B - Incorrect: WAN-wide logical routing uses IP rather than treating MAC as a universal end-to-end address (PDF 17, 15.)

C - Incorrect: A physical identifier does not establish encryption/security (PDF 17, 15.)

D - Incorrect: ARP starts with IP and resolves MAC; MAC itself is not a rule for determining IP (PDF 17, 15.)

Primary note proof

Study-note section NET20

ARP resolves an on-link IPv4 next hop to a link address, using a broadcast request and normally unicast reply. For an off-subnet target, ARP resolves the gateway, not the remote target's MAC. It bridges the network/link addressing boundary and is often classified at the link layer; calling ARP simply a network protocol uses a loose textbook convention. RARP reverses hardware-to-IP lookup; BOOTP/DHCP support boot configuration. ICMP reports errors and diagnostics; IGMP

manages IPv4 multicast membership. These are separate companion protocols, not four pieces whose combination is IP.

Study-note section NET10

A bridge or ordinary Ethernet switch operates at layer 2. It learns source-MAC-to-port mappings, looks up the destination, forwards a known unicast to its port, filters it if the destination is on the incoming segment, and floods an unknown unicast or broadcast within its VLAN. A switch does not always send only to one destination port. Wireless access points normally bridge wireless and wired link-layer traffic.

Study-note section NET12

Sending proceeds from application data to transport segment/datagram, network packet, link frame and physical bits/symbols; receiving reverses the order. Each layer serves the layer above. Question 174 | AM0477

What is the purpose of a firewall in computer networks?

A. To encrypt network traffic for secure communication

B. To manage network resources and allocate bandwidth

C. To filter and control network traffic based on predefined rules

D. To connect two separate networks and enable communication between them

Hint

Use the cited note definitions to identify the requested function or scope, then check each alternative against that same rule.

Answer C: To filter and control network traffic based on predefined rules

The module firewall example permits only authorized systems to access internal computers, supporting selective traffic filtering/control. Evidence: PDF 48, 12, 16.

Why each choice is right or wrong

A - Incorrect: Encryption is a distinct presentation function (PDF 48, 12, 16.)

B - Incorrect: Bandwidth allocation is not the firewall access-control function described (PDF 48, 12, 16.)

C - Correct: Rules permitting authorized access match firewall filtering (PDF 48, 12, 16.)

D - Incorrect: Connecting networks is the router/gateway function, not the defining firewall policy (PDF 48, 12, 16.)

Primary note proof

Study-note section NET11

> A firewall allows, rejects or inspects traffic under a security policy; it does not necessarily encrypt. A VPN, Virtual Private Network, provides a logical private connection over another network; a secure VPN authenticates/encrypts its tunnel. A modem modulates outgoing and demodulates incoming carrier signals. These functions may coexist in one home router but remain conceptually distinct.

Study-note section NET11

> Network Address Translation (NAT)
> NAT translates the IP addresses of computers in a local network to a single IP address. This address is often used by the router that connects the computers to the Internet. The router can be connected to a DSL modem, cable modem, T1 line, or even a dial-up modem. When other computers on the Internet attempt to access computers within the local network, they only see the IP address of the router. This adds an extra level of security, since the router can be configured as a firewall, only allowing

authorized systems to access the computers within the network.

Question 175 | AM0478

Which of the following network topologies provides the highest fault tolerance?

A. Bus topology

B. Ring topology

C. Star topology

D. Mesh topology

Hint

Draw the links and identify shared components, alternate paths and the effect of the specified failure or growth requirement.

Answer D: Mesh topology

Mesh has redundant interconnections and a single link failure does not affect the entire network. Bus backbone, ring break and star center failure are explicit vulnerabilities. Evidence: PDF 23, 24, 23, 23, 23.

Why each choice is right or wrong

A - Incorrect: A broken backbone can shut down bus (PDF 23, 24, 23, 23, 23.)

B - Incorrect: A break/disabled station can disable a ring (PDF 23, 24, 23, 23, 23.)

C - Incorrect: Central device failure can shut down star (PDF 23, 24, 23, 23, 23.)

D - Correct: Redundant mesh paths support the strongest listed fault tolerance (PDF 23, 24, 23, 23, 23.)

Primary note proof

Study-note section NET08

> Bus uses a shared backbone; an unterminated break can disrupt the segment. Star connects endpoints through a central device: one edge failure isolates that endpoint, whereas central failure affects the star. Ring forms a loop; basic single rings are vulnerable to a break, while protected dual rings differ. Token passing is associated with Token Ring but is an access method, not a necessary property of every ring. Tree is hierarchical; hybrid combines arrangements.

Study-note section NET08

> A full undirected mesh of n nodes needs n(n-1)/2 links and n-1 interfaces per node. For 50 nodes: 50×49/2=1225 links. Redundant paths improve fault tolerance at greater cable and interface cost.

network. It has several benefits, such as: dedicated links between devices, robust (single link failure don‘t affect entire network), privacy/security (direct communication between communicating devices), and ease of fault identification and isolation. Its drawbacks include, installation and reconnection are difficult (large number of cables), huge amount of cables consumes a lot of space, and it is the most expensive of all.

Data Communication and Computer Networking module | PDF page 23 | lines 19-34

Star Topology: in this topology, each node is connected directly to a central device called a hub or a switch. Data on a star network passes through the central device (switch) before continuing to its destination. The central device manages and controls all functions of the network. This configuration is common with twisted pair cable. RJ-45 Connectors are used to connect the cable to the Network Interface Card (NIC) of each computer. Its advantages include, ease of installation and reconfiguration, robust (ease of fault identification and isolation), link failure only affects device(s) connected to that link, and is less expensive than mesh. Its drawbacks include more cable requirements (than bus and ring) and single point of failure (if central device fail, the whole system will be down).

Data Communication and Computer Networking module | PDF page 23 | lines 35-44

Ring Topology: in this topology, all devices are connected to one another in the shape of a closed loop, so that each device is connected directly to two other devices, one on either side of it. Some of its advantages include, easy to install and reconfigure, less expensive (than mesh), and performance is even despite the number of users. Its cons include, break in the ring (such as a disabled station) can disable the entire network, and limitations on media and traffic (limitation on ring length and number of devices).

Data Communication and Computer Networking module | PDF page 23 | lines 4-18

Bus Topology: in this topology all devices are connected to a central cable, called the bus or backbone, which is terminated at its ends. The purpose of the terminators is to stop the signal from bouncing, thereby clearing the cable so that other computers can send data. Message transmitted along

the Bus is visible to all computers connected to the backbone cable. As the message arrives at each workstation, the workstation checks the destination address contained in the message either to process or drop the packet if it matches or not respectively. Its advantages are, ease of installation and less amount of cable requirement. Its main drawback is, the entire network will be shut down if there is a break in the main cable.

Question 176 | AM0479

Which listed terms describe IPv6’s flexible-prefix addressing or operations supported by that approach? Select all that apply.

A. Classful addressing

B. Classless addressing

C. Subnetting

D. CIDR (Classless Inter-Domain Routing)

Hint

Identify the requested service or delivery guarantee, then distinguish application roles, transport behavior and address configuration.

Answer B, C, D: Classless addressing; Subnetting; CIDR (Classless Inter-Domain Routing)

IPv6 uses flexible network prefixes rather than historical IPv4 address classes. Classless addressing describes this approach, subnetting divides prefixes into smaller networks, and CIDR terminology expresses classless prefixes and aggregation. These are compatible descriptions or operations rather than mutually exclusive schemes. The selection instruction therefore permits all three while excluding the classful A/B/C allocation model associated with historical IPv4.

Why each choice is right or wrong

A - Incorrect: Historical classful A/B/C IPv4 defaults are not the IPv6 flexible-prefix scheme.

B - Correct: IPv6 uses flexible prefixes rather than fixed historical address classes.

C - Correct: IPv6 prefixes can be subdivided into subnets; the term overlaps the broad scheme wording.

D - Correct: Classless prefix/CIDR terminology applies to flexible-prefix allocation and routing rather than historical class boundaries.

Primary note proof

Study-note section NET23

IPv6 has 128-bit hexadecimal addresses, flexible prefixes and no IPv4-style broadcast. Sources, not routers, fragment IPv6 packets. IPv6 does not automatically encrypt traffic or make authentication unnecessary. Compare IPv6's larger 128-bit address space and encryption support separately; specify the property being evaluated.

Study-note section NET28

CIDR, Classless Inter-Domain Routing, replaces rigid class allocation and supports aggregation. Combine contiguous aligned blocks sharing leading bits; unrelated adjacent-looking labels may not aggregate cleanly. Four consecutive /26 blocks covering a /24 summarize to /24. More-specific routes must remain available where the aggregate would otherwise send traffic to the wrong next hop.

Study-note section NET26

To split parent /a into equal /p blocks, borrow b=p-a bits and obtain 2^b subnets. Do not subtract two subnets under modern practice. For a Class B /16 parent split to /19, b=3 gives eight subnets, each with 8192 addresses and 8190 conventional hosts. A /19 alone does not state its parent.

Question 177 | AM0480

Which protocol is responsible for translating domain names into IP addresses?

A. DHCP (Dynamic Host Configuration Protocol)

B. DNS (Domain Name System)

C. ARP (Address Resolution Protocol)

D. ICMP (Internet Control Message Protocol)

Hint

Identify the requested service or delivery guarantee, then distinguish application roles, transport behavior and address configuration.

Answer B: DNS (Domain Name System)

DNS is the domain naming service and external name/address service contrasted with hosts entries. Evidence: PDF 18, 65, 28, 17, 17.

Why each choice is right or wrong

A - Incorrect: DHCP is named host configuration, not domain naming

B - Correct: DNS matches the named domain service

C - Incorrect: ARP resolves known IP to MAC

D - Incorrect: ICMP reports packet problems

Primary note proof

Study-note section NET20

> DNS resolves names to records, including IPv4 A and IPv6 AAAA addresses; it can use UDP or TCP port 53. DHCP dynamically leases IPv4 settings, commonly address, mask, gateway and DNS server. Its basic exchange is discover, offer, request, acknowledge. IP itself does not assign addresses.

Study-note section NET20

> ARP resolves an on-link IPv4 next hop to a link address, using a broadcast request and normally unicast reply. For an off-subnet target, ARP resolves the gateway, not the remote target's MAC. It bridges the network/link addressing boundary and is often classified at the link layer; calling ARP simply a network protocol uses a loose textbook convention. RARP reverses hardware-to-IP lookup; BOOTP/DHCP support boot configuration. ICMP reports errors and diagnostics; IGMP manages IPv4 multicast membership. These are separate companion protocols, not four pieces whose combination is IP.

Question 178 | AM0481

What is the purpose of NAT (Network Address Translation) in computer networks?

A. To secure network communications through encryption

B. To provide redundancy and fault tolerance

C. To translate private IP addresses to public IP addresses

D. To manage network resources and allocate bandwidth

Hint

Convert the mask to a prefix, separate network and host bits, and apply the relevant subnet-count or usable-host rule.

Answer C: To translate private IP addresses to public IP addresses

NAT explicitly translates an organization private IP address to a public IP address. It is not an encryption, redundancy or bandwidth-allocation mechanism. Evidence: PDF 19, 48, 16.

Why each choice is right or wrong

A - Incorrect: Encryption is a separate representation/security transformation (PDF 19, 48, 16.)

B - Incorrect: Redundancy is not the address translation definition (PDF 19, 48, 16.)

C - Correct: Private-to-public translation is the exact NAT definition (PDF 19, 48, 16.)

D - Incorrect: Bandwidth allocation is not the NAT definition (PDF 19, 48, 16.)

Primary note proof

Study-note section NET29

Static NAT gives a fixed address mapping; dynamic NAT allocates mappings from a pool. PAT/NAPT maps address-plus-port combinations so multiple private clients share a public address. It is translation, not ARP resolution and not encryption. Return traffic must match the translation state or a configured inbound mapping.

Study-note section NET29

A private host such as 10.0.0.1 commonly reaches the public Internet through NAT at a gateway, together with valid routing and a public external address. NAT alone does not supply a physical

connection or DNS. A public address does not automatically grant permission to use it; both public and private unicast addresses can be used on a LAN under the correct allocation and subnet.

Study-note section NET11

A firewall allows, rejects or inspects traffic under a security policy; it does not necessarily encrypt. A. To encrypt network traffic for secure communication

B. To assign unique IP addresses to hosts in a network

C. To provide a firewall for network security

D. To translate private IP addresses to public IP addresses

Answer D: To translate private IP addresses to public IP addresses

Apply the same study-note rule to this alternative source set; the choice contrasts below show the derivation.

Why each choice is right or wrong

A - Incorrect: Encryption changes data protection; NAT changes addresses (PDF19,48).

B - Incorrect: Assigning initial unique host addresses is different from translating already-used internal addresses (PDF19,48).

C - Incorrect: PDF48 says a router can additionally be a firewall; optional access control is not the NAT translation definition.

D - Correct: This variant moves the explicit private-to-public translation definition to D (PDF19).

Question 179 | AM0482

Which listed protocol is a connectionless transport-layer protocol, sending independent datagrams without built-in connection setup?

A. TCP (Transmission Control Protocol)

B. UDP (User Datagram Protocol)

C. HTTP (Hypertext Transfer Protocol)

D. FTP (File Transfer Protocol)

Hint

Identify the requested service or delivery guarantee, then distinguish application roles, transport behavior and address configuration.

Answer B: UDP (User Datagram Protocol)

UDP is a transport protocol that sends independent datagrams without a built-in setup handshake, ordering or retransmission service. TCP instead establishes a connection and supplies an ordered reliable byte stream. HTTP and FTP are application protocols, so they are outside the requested transport-layer category. HTTP being stateless at the application level does not make it a connectionless transport protocol.

Why each choice is right or wrong

A - Incorrect: TCP is connection-oriented transport with reliable ordered byte-stream delivery.

B - Correct: UDP is the connectionless datagram transport described.

C - Incorrect: HTTP is an application protocol; application statelessness is distinct from connectionless transport.

D - Incorrect: FTP is an application file-transfer protocol, not a transport protocol.

Primary note proof

Study-note section NET17

> TCP offers a reliable ordered byte stream using sequence numbers, acknowledgments, retransmission and windows. Flow control protects the receiver; congestion control protects network capacity. UDP sends independent datagrams with ports and a checksum but no built-in setup, delivery guarantee, retransmission or ordering. Live interactive traffic may choose UDP when late data is less useful than lost data. Application protocols can add reliability over UDP.

Study-note section NET21

FTP transfers files using control and separate data connections; it is not the same protocol as SFTP. Question 180 | AM0483

Which listed devices ordinarily forward frames at OSI layer 2? Select all that apply.

A. Hub

B. Switch

C. Router

D. Bridge

Hint

Match the requested scope or data unit to the layer duties in the note; distinguish hop delivery from end-to-end process delivery.

Answer B, D: Switch; Bridge

A bridge and an ordinary Ethernet switch both inspect link-layer frames and use MAC-address information in forwarding. A hub regenerates and repeats physical signals without that address inspection. A router forwards IP packets between networks using network-layer destinations. The explicit multiple-selection instruction preserves both correct layer-2 devices and avoids implying that only one kind of device can operate at a layer.

Why each choice is right or wrong

A - Incorrect: A hub repeats layer-1 signals rather than making MAC/frame forwarding decisions.

B - Correct: An ordinary Ethernet switch is explicitly a layer-2 forwarding device.

C - Incorrect: A router's defining forwarding function is network-layer IP routing.

D - Correct: A bridge is explicitly a layer-2 device, like an ordinary Ethernet switch.

Primary note proof

Study-note section NET10

> A bridge or ordinary Ethernet switch operates at layer 2. It learns source-MAC-to-port mappings, looks up the destination, forwards a known unicast to its port, filters it if the destination is on the incoming segment, and floods an unknown unicast or broadcast within its VLAN. A switch does not always send only to one destination port. Wireless access points normally bridge wireless and wired link-layer traffic.

Study-note section NET09

> A repeater regenerates layer-1 signals without inspecting destination addresses. An active hub is a multiport repeater: it repeats incoming signals onto other ports, placing half-duplex endpoints in one collision domain. A passive hub is a connector. A hub neither learns MAC addresses nor eliminates collisions. An endpoint such as a network printer consumes services; routers, hubs and access points are intermediary devices.

Study-note section NET11

> Routers forward IP packets between networks using destination prefixes and next hops. They separate broadcast domains and normally do not forward local link broadcasts. A default gateway is usually a router, while a protocol gateway can translate application formats; therefore a gateway is not inherently a device that implements every OSI layer.

Data Link Layer
• The Data Link layer adds reliability to the physical layer by providing error detection and correction mechanisms.
• Framing: the Data Link layer receives the data from Network Layer and divides the stream of bits into fixed size manageable units called as Frames and sends it to the physical layer. On the receiver side, the data link layer receives the stream of bits from the physical layer and regroups them into frames and sends them to the Network layer.
• Physical Addressing: The Data link layer appends the physical address in the header of the frame before sending it to physical layer.
• Flow control: The data link layer makes sure that the sender sends the data at a speed at which the receiver canreceive it else if there is an overflow at the receiver sidethe data will be lost.
• Error Control: The data link layer imposes error control mechanism to identify lost or damaged frames, duplicateframes and then retransmit them.
• Access Control: The data link layer imposes

access control mechanism to determine which device has right to send data in an multipoint connection setting.
• Main Responsibility: The main responsibility of the data link layer is hop to hop transmission of frames.

Network Address Translation (NAT)
NAT translates the IP addresses of computers in a local
network to a single IP address. This address is often used
by the router that connects the computers to the Internet.
The router can be connected to a DSL modem, cable
modem, T1 line, or even a dial-up modem. When other
computers on the Internet attempt to access computers
within the local network, they only see the IP address of
the router. This adds an extra level of security, since the

Question 182 | AM0486

Which of the following is a network device that operates at the Physical layer of the OSI model?

A. Switch

B. Hub

C. Router

D. Bridge

Hint

Match the requested scope or data unit to the layer duties in the note; distinguish hop delivery from end-to-end process delivery.

Answer B: Hub

An active hub is explicitly a multiport repeater, and repeaters operate at physical layer. Evidence: PDF 12, 11, 12, 12, 12.

Why each choice is right or wrong

A - Incorrect: Switch forwards by MAC at data-link scope (PDF 12, 11, 12, 12, 12.)

B - Correct: Active hub repeats physical signals (PDF 12, 11, 12, 12, 12.)

Question 183 | AM0487

Which network component is responsible for converting digital data into analog signals for transmission over telephone lines?

A. Modem

B. Router

C. Switch

D. Firewall

Hint

Compare the signal mechanism, medium properties or transmission direction against the definitions and stated physical assumptions.

Answer A: Modem

The stem asks about conversion for a telephone-line carrier, which is modem modulation. NET11 separates this signal-conversion function from routing IP packets, switching link frames and applying firewall traffic policy. These functions can coexist in one appliance, but the functional component asked for remains the modem.

Why each choice is right or wrong

A - Correct: A modem modulates outgoing carrier signals and demodulates incoming ones, supplying the requested conversion.

B - Incorrect: A router selects next hops between networks; that role is distinct from telephone-carrier modulation.

C - Incorrect: A switch forwards link-layer frames and is not the component defined by carrier modulation.

D - Incorrect: A firewall applies security policy to traffic rather than converting data onto a telephone-line carrier.

Question 184 | AM0488

Which protocol submits and relays email messages, including acceptance by a receiving mail server? Select one.

A. SMTP

B. HTTP

C. FTP

D. DNS

Hint

Identify the requested service or delivery guarantee, then distinguish application roles, transport behavior and address configuration.

Answer A: SMTP

SMTP is used for mail submission and relay, including a mail server accepting an incoming message. End-user access to stored mail is a separate operation supplied by POP3 or IMAP. HTTP handles web exchanges, FTP transfers files, and DNS resolves records. Specifying server receipt and relay makes the mail-system role clear without assigning mailbox retrieval to the transfer protocol.

Why each choice is right or wrong

A - Correct: SMTP submits and relays mail, including server acceptance of incoming messages.

B - Incorrect: HTTP defines web request/response exchanges rather than the mail submission and relay protocol requested.

C - Incorrect: FTP transfers files and is not the mail submission/relay or mailbox access protocol in the note.

D - Incorrect: DNS resolves records; it does not transport or retrieve the user’s messages.

What is the purpose of DNS (Domain Name System) in computer networks?

A. To encrypt network traffic for secure communication

B. To manage network resources and allocate bandwidth

C. To convert domain names into IP addresses

D. To provide firewall protection

Hint

Answer C: To convert domain names into IP addresses

The domain naming service is contrasted with explicit host-address entries, supporting resolving a name into the corresponding address. Evidence: PDF 18, 65.

Why each choice is right or wrong

A - Incorrect: Encryption is not DNS naming (PDF 18, 65.)

B - Incorrect: Bandwidth allocation is not DNS naming (PDF 18, 65.)

Which listed application protocol has the name File Transfer Protocol?

A. HTTP

B. FTP

C. SMTP

D. TCP

Hint

Identify the requested service or delivery guarantee, then distinguish application roles, transport behavior and address configuration.

Answer B: FTP

FTP is the named application protocol File Transfer Protocol. HTTP also transfers resource bodies and can download files, so generic file transfer alone does not distinguish them. SMTP is a mail-transfer application protocol, while TCP supplies an underlying reliable byte-stream transport. The explicit protocol name identifies the intended service without claiming that FTP is the only way to transfer a file.

Why each choice is right or wrong

A - Incorrect: HTTP is Hypertext Transfer Protocol and can carry files, but is not the stated protocol name.

B - Correct: FTP expands to File Transfer Protocol.

C - Incorrect: SMTP sends and relays email rather than bearing the stated protocol name.

TCP - Transmission Control Protocol: TCP is a reliable connection-oriented, reliable protocol. i.e. a connection is established between the sender and receiver before the data can be transmitted. It divides the data it receives from the upper layer into segments and tags a sequence number to each segment which is used at the receiving end for reordering of data.
UDP - User Datagram Protocol: UDP is a simple protocol used for process to process transmission. It is an unreliable, connectionless protocol for applications that do not require flow control or error control. It simply adds port address, checksum and length information to the data it receives from the upper layer.

Question 187 | AM0491

Which device connects multiple Ethernet LAN endpoints and learns MAC-to-port mappings to forward known unicast frames selectively?

A. Hub

B. Router

C. Switch

D. Modem

Hint

Compare signal repetition, frame forwarding, packet routing and policy enforcement using the stated device or traffic assumptions.

Answer C: Switch

Both hubs and switches can connect LAN endpoints, but their forwarding behavior differs. A hub repeats incoming signals to its other ports without learning addresses. An ordinary Ethernet switch learns source MAC-to-port mappings and uses the destination MAC address to forward known unicasts. Routers instead forward IP packets between networks, while modems convert carrier signals. The added forwarding requirement distinguishes the intended device.

Why each choice is right or wrong

A - Incorrect: A hub connects endpoints but repeats signals without learning MAC-to-port mappings.

B - Incorrect: A router's defining function is connecting/routing between IP networks rather than this shared LAN-device role.

C - Correct: A switch learns MAC-to-port mappings and forwards known unicasts selectively.

Which protocol is responsible for assigning IP addresses to devices on a network automatically?

A. HTTP

B. DNS

C. DHCP

Hint

Answer C: DHCP

Why each choice is right or wrong

A - Incorrect: HTTP provides web request/response semantics rather than automatic IP-address leases.

B - Incorrect: DNS resolves names into records, including addresses, but does not lease the host's own address.

Question 190 | AM0494

Which OSI layer establishes and manages application dialogs, including checkpoints for recovery after an interruption?

A. Physical layer

B. Data Link layer

C. Transport layer

D. Session layer

Hint

Match the requested scope or data unit to the layer duties in the note; distinguish hop delivery from end-to-end process delivery.

Answer D: Session layer

Session-layer roles include establishing and managing dialogs and coordinating checkpoints so a transfer can resume after an interruption. TCP transport connections are a different form of connection state and do not make every reference to a dialog a transport function. Physical signaling and hop-local link delivery likewise have different scopes. The revised stem identifies dialog and checkpoint management as the lifecycle being classified.

Why each choice is right or wrong

A - Incorrect: Physical signaling does not perform application-dialog management or checkpoint coordination.

B - Incorrect: Data link handles hop-local frames and link procedures rather than application dialogs and checkpoints.

C - Incorrect: Transport handles process delivery and TCP connection state, not the session-dialog role specified.

D - Correct: Session manages dialogs and can coordinate checkpoints for recovery.

Primary note proof

Study-note section NET19

OSI session roles establish/manage dialogs and can coordinate checkpoints so transfer resumes after interruption. Presentation roles translate encodings and handle compression/encryption. Compression reduces representation size; encryption hides content and need not shrink it. Application protocols provide services directly to applications. Practical implementations

distribute these functions differently; TLS is not proof of a separate physical presentation-layer device.

Study-note section NET18

TCP establishes state with SYN, SYN+ACK, then ACK. SYN consumes one sequence position even with no application bytes. An acknowledgment states the next expected sequence number. For client ISN=395 and server ISN=260: client sends SYN seq395; server sends SYN+ACK seq260 ack396; client sends ACK seq396 ack261. Later byte counts advance sequence numbers. FIN also consumes one sequence position.

Study-note section NET14

Controlled access uses polling, reservations or a token to grant turns; correctly coordinated access avoids contention collisions. Channelization divides frequency, time or code resources. Stop-and-wait sends one frame and waits for ACK, retransmitting on timeout; sequence bits distinguish duplicates. Sliding windows permit multiple unacknowledged frames. Link reliability/flow control is hop-local; transport reliability/flow control is end-to-end. Ethernet detects corruption but does not itself guarantee reliable delivery.

Session Layer
• The session layer establishes a session between the communicating devices called dialog and synchronizes their interaction. It is the responsibility of the session layer to establish and synchronize the dialogs. It is also called the network dialog controller.
• The session layer at the sending side accepts data from the presentation layer adds checkpoints to it called sync bits and passes the data to the transport layer. At the receiving end the session layer receives data from the transport layer removes the checkpoints inserted previously and passes the data to the presentation layer. So, the main responsibility of session layer is dialog control and synchronization.

Physical Layer:
• The Physical Layer provides a standardized interface to physical transmission media, including: Mechanical specification of electrical connectors and cables, for example maximum cable length, Electrical specification of transmission line and Bit-by-bit or symbol-by-symbol delivery.
• Interface: The Physical Layer defines the characteristics of interfaces between the devices & transmission medium.
• Representation of bits: The physical layer is concerned with transmission of signals from one device to another which involves converting data (1_s & 0_s) into signals and vice versa. It is not concerned with the meaning or interpretation of bits.
• Data rate: The physical layer defines the data transmission rate i.e. number of bits sent per second. It is the responsibility of the physical layer to maintain the defined data rate.

Data Link Layer
• The Data Link layer adds reliability to the physical layer by providing error detection and correction mechanisms.
• Framing: the Data Link layer receives the data from Network Layer and divides the stream of bits into fixed size manageable units called as Frames and sends it to the physical layer. On the receiver side, the data link layer receives the stream of bits from the physical layer and regroups them into frames and sends them to the Network layer.
• Physical Addressing: The Data link layer appends the physical address in the header of the frame before sending it to physical layer.
• Flow control: The data link layer makes sure that the sender sends the data at a speed at which the

receiver canreceive it else if there is an overflow at the receiver sidethe data will be lost.
• Error Control: The data link layer imposes error control mechanism to identify lost or damaged frames, duplicateframes and then retransmit them.
• Access Control: The data link layer imposes access control mechanism to determine which device has right to send data in an multipoint connection setting.
• Main Responsibility: The main responsibility of the data link layer is hop to hop transmission of frames.

Question 191 | AM0495

Which protocol is used for reliable data delivery at the transport layer in the TCP/IP protocol suite?

A. UDP

B. IP

C. FTP

D. TCP

Hint

Match the requested scope or data unit to the layer duties in the note; distinguish hop delivery from end-to-end process delivery.

Answer D: TCP

TCP is explicitly reliable and connection-oriented at transport, unlike UDP and network-layer IP. Evidence: PDF 18, 17, 18.

Why each choice is right or wrong

A - Incorrect: UDP is explicitly unreliable (PDF 18, 17, 18.)

B - Incorrect: IP is network-layer best effort (PDF 18, 17, 18.)

C - Incorrect: FTP is application file transfer (PDF 18, 17, 18.)

D - Correct: TCP is the explicitly reliable transport protocol (PDF 18, 17, 18.)

Primary note proof

Study-note section NET17

TCP offers a reliable ordered byte stream using sequence numbers, acknowledgments, retransmission and windows. Flow control protects the receiver; congestion control protects network capacity. UDP sends independent datagrams with ports and a checksum but no built-in setup, delivery guarantee, retransmission or ordering. Live interactive traffic may choose UDP when late data is less useful than lost data. Application protocols can add reliability over UDP.

Study-note section NET16

IP supplies connectionless best-effort packet delivery, not end-to-end ordering or retransmission. IPv4 addresses are 32 bits. Its minimum header is 20 bytes and can grow to 60 bytes; it is not a 32-bit header. IHL counts 32-bit words; total length includes header and payload. TTL limits lifetime across routers; the protocol field identifies TCP, UDP or another upper-layer protocol.

Study-note section NET21

HTTP defines web request/response semantics; it is stateless, and a message body may be absent. HTTPS adds TLS protection. FTP transfers files using control and separate data connections; it is not the same protocol as SFTP. SMTP submits and relays mail; POP3 retrieves messages and IMAP accesses/synchronizes server mailboxes. Saying SMTP handles both sending and end-user mailbox retrieval is inaccurate.

TCP - Transmission Control Protocol: TCP is a reliable connection-oriented, reliable protocol. i.e. a connection is established between the sender and receiver before the data can be transmitted. It divides the data it receives from the upper layer into segments and tags a sequence number to each segment which is used at the receiving end for reordering of data.
UDP - User Datagram Protocol: UDP is a simple protocol used for process to process transmission. It is an unreliable, connectionless protocol for applications that do not require flow control or error control. It simply adds port address, checksum and length information to the data it receives from the upper layer.

Network Layer or IP
Also called as the Internetwork Layer (IP). It holds the IP protocol which is a network layer protocol and is responsiblefor source to destination transmission of data.
The Internetworking Protocol (IP) is a connection-less & unreliable protocol.
It is a best effort delivery service. i.e. there is no error checking in IP, it simply sends the data and relies on its

underlying layers to get the data transmitted to the destination.Even if it is unreliable IP cannot be considered weak and useless; since it provides only the functionality that is requiredfor transmitting data thereby giving maximum efficiency.
Since there is no mechanism of error detection or correction in IP, there will be no delay introduced on a medium where thereis no error at all.

Question 192 | AM0496

Which layer of the OSI reference model is responsible for addressing and routing data packets across different networks?

A. Network layer

B. Data Link layer

C. Transport layer

D. Physical layer

Hint

Match the requested scope or data unit to the layer duties in the note; distinguish hop delivery from end-to-end process delivery.

Answer A: Network layer

Network explicitly adds logical addressing and routes packets from source to destination across intermediate devices. Evidence: PDF 15, 15, 16, 14.

Why each choice is right or wrong

A - Correct: Network has addressing and routing responsibilities (PDF 15, 15, 16, 14.)

B - Incorrect: Data link handles physical addresses and one-hop frames (PDF 15, 15, 16, 14.)

C - Incorrect: Transport delivers to processes with ports (PDF 15, 15, 16, 14.)

D - Incorrect: Physical delivers bits/signals (PDF 15, 15, 16, 14.)

Primary note proof

Study-note section NET30

Routing computes paths; forwarding chooses a next hop for an individual packet. Select the matching route with the longest prefix, then apply the routing system's tie-breaking criteria. A default /0 matches when nothing more specific does. Static routes are configured; dynamic protocols exchange reachability. Distance vector uses neighbor estimates, while link state distributes link information and computes shortest paths. Interior protocols operate within an autonomous system; BGP exchanges routes between systems.

Study-note section NET12

Sending proceeds from application data to transport segment/datagram, network packet, link frame and physical bits/symbols; receiving reverses the order. Each layer serves the layer above. A router removes a received link frame, inspects IP, and creates a new link frame for the next hop. MAC addresses usually change across routed hops; end-to-end IP addresses ordinarily remain until translation.

Study-note section NET17

Ports identify transport endpoints; the application can choose a transport and request socket buffer sizes, subject to OS limits. A TCP connection is identified by source/destination IP and source/destination port, with TCP understood. IPv4 protocol numbers identify upper protocols; 80 is a usual HTTP port, not an IP protocol number. Clients often use ephemeral ports. SCTP is a reliable message-oriented transport with multiple streams.

Question 193 | AM0497

Which OSI layer supplies hop-local frame acknowledgments and retransmission when a reliable-link protocol is used, rather than end-to-end transport recovery?

A. Network layer

B. Transport layer

C. Data Link layer

D. Application layer

Hint

Match the requested scope or data unit to the layer duties in the note; distinguish hop delivery from end-to-end process delivery.

Answer C: Data Link layer

Reliable data-link protocols can acknowledge frames and retransmit missing or damaged frames across a single hop. Transport recovery instead covers the end-to-end communication between processes. Network-layer IPv4 includes a header checksum but remains best-effort and does not supply this frame ARQ service. The link-layer role is protocol-dependent: Ethernet error detection alone does not guarantee reliable local delivery.

Why each choice is right or wrong

A - Incorrect: IP routing and its header checksum are not the requested hop-local frame ARQ service.

B - Incorrect: Transport reliability has end-to-end rather than one-link scope.

C - Correct: Data link implements the specified hop-local frame acknowledgment/retransmission procedure.

D - Incorrect: Application services are above the specified link-frame recovery mechanism.

Primary note proof

Study-note section NET14

> Controlled access uses polling, reservations or a token to grant turns; correctly coordinated access avoids contention collisions. Channelization divides frequency, time or code resources. Stop-and-wait sends one frame and waits for ACK, retransmitting on timeout; sequence bits distinguish duplicates. Sliding windows permit multiple unacknowledged frames. Link reliability/flow control is hop-local; transport reliability/flow control is end-to-end. Ethernet detects corruption but does not itself guarantee reliable delivery.

Study-note section NET13

> Detection adds redundancy but does not guarantee correction. Even parity adds a bit so the total number of ones is even: 1011 needs parity 1. It detects every odd number of bit flips but misses even counts. CRC treats bits as a polynomial and appends the XOR-division remainder; the receiver repeats the division. Internet checksums add words with end-around carry and complement the sum. A burst spans from the first corrupted bit through the last, including unchanged interior bits. Retransmission or sufficient forward-error-correcting redundancy is needed for recovery.

Study-note section NET16

> The IPv4 checksum protects its header; IP does not lack error checking altogether. Identification, flags and offset support fragmentation. IPv4 sources and routers may fragment when allowed; reassembly occurs at the destination. If DF is set and the next MTU is too small, forwarding fails and an ICMP diagnostic may be returned.

Question 194 | AM0498

Which protocol submits and relays email messages, including acceptance by a receiving mail server? Select one.

A. SMTP

B. FTP

C. HTTP

D. DNS

Hint

Identify the requested service or delivery guarantee, then distinguish application roles, transport behavior and address configuration.

Answer A: SMTP

SMTP is used for mail submission and relay, including a mail server accepting an incoming message. End-user access to stored mail is a separate operation supplied by POP3 or IMAP. HTTP handles web exchanges, FTP transfers files, and DNS resolves records. Specifying server receipt and relay makes the mail-system role clear without assigning mailbox retrieval to the transfer protocol.

Why each choice is right or wrong

A - Correct: SMTP submits and relays mail, including server acceptance of incoming messages.

B - Incorrect: FTP transfers files through a separate protocol rather than the mail flow defined here.

C - Incorrect: HTTP defines web request/response exchanges rather than the mail submission and relay protocol requested.

D - Incorrect: DNS supplies records such as mail-exchanger names rather than delivering or retrieving message contents.

Question 195 | AM0499

Which layer of the OSI reference model is responsible for converting data into a format suitable for transmission over a network?

A. Presentation layer

B. Session layer

C. Physical layer

D. Application layer

Hint

Match the requested scope or data unit to the layer duties in the note; distinguish hop delivery from end-to-end process delivery.

Answer A: Presentation layer for representation/format translation

The word format identifies representation translation rather than routing or connection management. NET19 assigns encoding translation and other representation work to presentation. Physical signaling maps bits to medium symbols, but does not supply the application-data format translation asked for. Thus A matches the intended formatting responsibility.

Why each choice is right or wrong

A - Correct: Presentation translates representations/encodings into suitable data formats.

B - Incorrect: Session manages dialogs and checkpoints rather than data representation formats.

C - Incorrect: Physical maps bits/symbols to signals, a different responsibility from representation-format translation.

D - Incorrect: Application supplies network services to applications rather than the distinct presentation-format function.

Primary note proof

Study-note section NET19

OSI session roles establish/manage dialogs and can coordinate checkpoints so transfer resumes after interruption. Presentation roles translate encodings and handle compression/encryption. Compression reduces representation size; encryption hides content and need not shrink it. Application protocols provide services directly to applications. Practical implementations distribute these functions differently; TLS is not proof of a separate physical presentation-layer device.

Study-note section NET09

A NIC supplies a computer's network interface and commonly implements both physical and link functions. Calling a NIC a physical interface does not mean all its functions are layer 1. Physical specifications include connectors, signaling, voltage, timing and physical coding/modulation; the PHY interface to MAC handles hardware signaling.

A file-transfer client uses one connection for protocol commands and a separate connection for file data. Which listed application protocol uses this control/data separation?

A. SMTP

B. HTTP

C. FTP

D. TCP

Hint

Identify the requested service or delivery guarantee, then distinguish application roles, transport behavior and address configuration.

Answer C: FTP

FTP separates its control conversation from the data connection used for transfers. That architectural feature distinguishes it from the broad ability to download files, which HTTP also provides. SMTP handles mail submission and relay. TCP is the transport service on which an application protocol can build connections; it does not itself define FTP commands or the application's separate control and data roles.

Why each choice is right or wrong

A - Incorrect: SMTP defines mail transfer, not the described FTP control/data arrangement.

B - Incorrect: HTTP can transfer files, but does not define the described separate FTP control and data connections.

C - Correct: FTP uses separate control and data connections.

D - Incorrect: TCP provides transport connections; the application protocol defines their command/data roles.

HTTP defines web request/response semantics; it is stateless, and a message body may be absent. HTTPS adds TLS protection. FTP transfers files using control and separate data connections; it is not the same protocol as SFTP. SMTP submits and relays mail; POP3 retrieves messages and IMAP accesses/synchronizes server mailboxes. Saying SMTP handles both sending and end-user mailbox retrieval is inaccurate.

Study-note section NET17

TCP offers a reliable ordered byte stream using sequence numbers, acknowledgments, retransmission and windows. Flow control protects the receiver; congestion control protects network capacity. UDP sends independent datagrams with ports and a checksum but no built-in setup, delivery guarantee, retransmission or ordering. Live interactive traffic may choose UDP when late data is less useful than lost data. Application protocols can add reliability over UDP.

Application Layer
The Application Layer is a combination of Session,
Presentation & Application Layers of OSI models and defines
high level protocols like File Transfer (FTP), Electronic Mail
(SMTP), Virtual Terminal (TELNET), Domain Name Service
(DNS), etc.

Data Communication and Computer Networking module | PDF page 18 | lines 9-21

TCP - Transmission Control Protocol: TCP is a reliable
connection-oriented, reliable protocol. i.e. a connection is
established between the sender and receiver before the data can
be transmitted. It divides the data it receives from the upper
layer into segments and tags a sequence number to each
segment which is used at the receiving end for reordering of
data.
UDP - User Datagram Protocol: UDP is a simple protocol
used for process to process transmission. It is an unreliable,
connectionless protocol for applications that do not require flow
control or error control. It simply adds port address, checksum
and length information to the data it receives from the upper
layer.

Question 199 | AM0503

Which layer of the OSI reference model is responsible for providing services directly to the end-user applications?

A. Presentation layer

B. Session layer

C. Transport layer

D. Application layer

Hint

Match the requested scope or data unit to the layer duties in the note; distinguish hop delivery from end-to-end process delivery.

Answer D: Application layer

Application explicitly provides user access to network resources; the other layers perform representation, dialog and process-delivery work. Evidence: PDF 16, 16, 16, 16.

Why each choice is right or wrong

A - Incorrect: Presentation translates/encrypts/compresses (PDF 16, 16, 16, 16.)

B - Incorrect: Session establishes and synchronizes dialogs (PDF 16, 16, 16, 16.)

C - Incorrect: Transport segments and delivers between processes (PDF 16, 16, 16, 16.)

D - Correct: Application explicitly exposes network resources to users (PDF 16, 16, 16, 16.)

Primary note proof

Study-note section NET19

> OSI session roles establish/manage dialogs and can coordinate checkpoints so transfer resumes after interruption. Presentation roles translate encodings and handle compression/encryption. Compression reduces representation size; encryption hides content and need not shrink it. Application protocols provide services directly to applications. Practical implementations distribute these functions differently; TLS is not proof of a separate physical presentation-layer device.

Application Layer
• The application layer enables the user to communicate its data to the receiver by providing certain services.
• The main Responsibility of Application layer is to provide the user access to network resources.

Data Communication and Computer Networking module | PDF page 16 | lines 33-42

Presentation Layer
• The communicating devices may be having different platforms. The presentation layer performs translation, encryption and compression of data.
• The presentation layer receives the data from the application layer adds header which contains information related to encryption and compression and sends it to the session layer.
• So, the main responsibility of the Presentation layer is translation, compression and encryption.

Data Communication and Computer Networking module | PDF page 16 | lines 18-32

Session Layer
• The session layer establishes a session between the communicating devices called dialog and synchronizes their interaction. It is the responsibility of the session layer to establish and synchronize the dialogs. It is also called the network dialog controller.
• The session layer at the sending side accepts data from the presentation layer adds checkpoints to it called sync bits and passes the data to the transport layer. At the receiving end the session layer receives data from the transport layer removes the checkpoints inserted previously and passes the data to the presentation layer. So, the main responsibility of session layer is dialog control and synchronization.

Data Communication and Computer Networking module | PDF page 16 | lines 2-17

• At the sending side, the transport layer receives data from the session layer, divides it into units called segments and sends it to the network layer.
• To ensure process to process delivery the transport layer makes use of port address to identify the data from the sending and receiving process.
• The data can be transported in a connection oriented or connectionless manner.
• The Transport layer is responsible for segmentation and reassembly of the message into segments which bear sequence numbers.

• The transport layer also carries out flow control and error control functions; but unlike data link layer these are end to end rather than node to node.
• The main responsibility of the transport layer is process to process delivery of the entire message

Question 200 | AM0504

Which subnet mask represents a Class C network?

A. 255.0.0.0

B. 255.255.0.0

C. 255.255.255.0

D. 255.255.255.255

Hint

Convert the mask to a prefix, separate network and host bits, and apply the relevant subnet-count or usable-host rule.

Answer C: 255.255.255.0, the historical Class C default

In the classful convention requested, Class C has a /24 default. Twenty-four leading one bits give three full 255 octets followed by zero: 255.255.255.0. This is a historical default rather than a restriction that every modern address in that range must use /24; CIDR can specify another prefix.

Why each choice is right or wrong

A - Incorrect: 255.0.0.0 is /8, the historical Class A default rather than Class C.

B - Incorrect: 255.255.0.0 is /16, the historical Class B default.

C - Correct: 255.255.255.0 is /24, matching the historical Class C default prefix.

D - Incorrect: 255.255.255.255 is /32, identifying one address rather than the Class C default network.

Primary note proof

Study-note section NET22

Historical classes use leading patterns: A 0 with /8, B 10 with /16, C 110 with /24; D 1110 is multicast and E 1111 reserved. Ordinary class-A first octets are 1-126 because 0 and 127 have special uses. B spans 128-191 and C 192-223. Default usable counts are 2^24-2, 2^16-2 and 254. Modern CIDR requires the actual prefix and overrides class defaults.

Study-note section NET24

A /p IPv4 prefix has p leading one bits followed by 32-p zeros. Partial octet masks are 128,192,224,240,248,252,254. /19 is 255.255.224.0; /20 is 255.255.240.0; /21 is 255.255.248.0, correcting the study guide's 255.248.0.0 mistake.

CIDR: A class B address is far too large for most organizationsand a class C network, with 256 addresses is too small. This leads to granting Class B address to organizations who do not require all. This is resulting in depletion of Address space. A solution is CIDR (Classless InterDomain Routing) The basic idea behind CIDR, is to allocate the remaining IP addresses in variable-sized blocks, without regard to the classes.

Question 201 | AM0505

What is the maximum number of hosts in a subnet with a subnet mask of 255.255.255.224?

A. 8

B. 16

C. 30

D. 62

Hint

Convert the mask to a prefix, separate network and host bits, and apply the relevant subnet-count or usable-host rule.

Answer C: 30 usable hosts

The mask 255.255.255.224 has 27 one bits and five host bits. Five bits yield 32 total addresses; reserving the subnet identifier and directed broadcast leaves 30 assignable ordinary hosts. This is an ordinary broadcast-subnet calculation, so the special /31 point-to-point exception is not relevant.

Why each choice is right or wrong

A - Incorrect: Eight does not equal the usable count from five host bits and two reserved addresses.

B - Incorrect: Sixteen is not the /27 usable-host count; this block has 32 total addresses.

C - Correct: A /27 has 32 total addresses and 30 ordinary assignable host addresses.

D - Incorrect: Sixty-two usable hosts requires six host bits, corresponding to /26 rather than /27.

Primary note proof

Which IP address belongs to the loopback network?

A. 127.0.0.1

B. 192.168.0.1

C. 10.0.0.1

D. 172.16.0.1

Hint

Separate address width, syntax, reserved scope and the supplied prefix or historical classful convention.

Answer A: 127.0.0.1

The module explicitly identifies 127.0.0.1 as localhost for interprocess communication. This supports the loopback instance, without needing an unprovided full 127/8 range rule. Evidence: PDF 65, 19.

Why each choice is right or wrong

A - Correct: 127.0.0.1 is explicitly localhost (PDF 65, 19.)

B - Incorrect: 192.168.0.1 is not the cited localhost address (PDF 65, 19.)

C - Incorrect: 10.0.0.1 is not the cited localhost address (PDF 65, 19.)

A LAN may also use legitimately assigned public addresses; private is common, not mandatory. 127.0.0.0/8 is IPv4 loopback, commonly 127.0.0.1, for local protocol access without an external link. 255.255.255.255 is limited broadcast; 0.0.0.0 can identify an unconfigured source. Question 203 | AM0507

How many subnets can be created from a Class B network with a subnet mask of 255.255.240.0?

A. 8

B. 16

C. 32

D. 64

Hint

Convert the mask to a prefix, separate network and host bits, and apply the relevant subnet-count or usable-host rule.

Answer B: 16 subnets

The question explicitly supplies a Class B parent, so use its historical /16. The given mask 255.255.240.0 is /20. Borrowing 20−16=4 bits yields 2^4=16 equal subnets under modern practice. The note says not to subtract two subnets; host capacity is a different calculation.

Why each choice is right or wrong

A - Incorrect: Eight subnets would borrow three bits and produce /19 from a /16 parent.

B - Correct: The /20 mask borrows four bits from /16, yielding sixteen equal subnets.

C - Incorrect: Thirty-two subnets would borrow five bits and require /21 from the Class B parent.

D - Incorrect: Sixty-four subnets would borrow six bits and require /22 rather than /20.

Primary note proof

Study-note section NET26

> To split parent /a into equal /p blocks, borrow b=p-a bits and obtain 2^b subnets. Do not subtract two subnets under modern practice. For a Class B /16 parent split to /19, b=3 gives eight subnets, each with 8192 addresses and 8190 conventional hosts. A /19 alone does not state its parent.

What is the default subnet mask for a Class A network?

A. 255.0.0.0

B. 255.255.0.0

C. 255.255.255.0

D. 255.255.255.255

Hint

Convert the mask to a prefix, separate network and host bits, and apply the relevant subnet-count or usable-host rule.

Answer A: 255.0.0.0

The historical Class A default is /8. Eight leading mask ones fill only the first octet, giving 255.0.0.0. The other choices correspond to /16, /24 and /32; they can be explicit CIDR prefixes, but they are not the historical default asked for.

Why each choice is right or wrong

A - Correct: 255.0.0.0 contains eight leading ones and is the historical Class A default.

B - Incorrect: 255.255.0.0 is /16, the historical default for Class B.

C - Incorrect: 255.255.255.0 is /24, the historical default for Class C.

Question 205 | AM0509

For a conventional IPv4 link needing two usable endpoints and reserving network/broadcast addresses, which offered mask allocates the smallest sufficient block?

A. 255.255.255.0

B. 255.255.255.128

C. 255.255.255.192

D. 255.255.255.252

Hint

Separate address width, syntax, reserved scope and the supplied prefix or historical classful convention.

Answer D: 255.255.255.252

The offered masks correspond to /24, /25, /26 and /30 blocks. A conventional /30 contains four addresses, leaving two usable endpoints after reserving network and broadcast addresses. The other choices allocate more addresses than this link needs. Supported /31 point-to-point links are a separate exception, so the question limits the comparison to the conventional model and the masks actually offered.

Why each choice is right or wrong

A - Incorrect: /24 is sufficient but allocates 256 addresses, more than the smallest offered sufficient block.

B - Incorrect: /25 allocates 128 addresses and is not the smallest sufficient offered block.

C - Incorrect: /26 allocates 64 addresses and is not the smallest sufficient offered block.

D - Correct: /30 allocates four addresses and two conventional usable endpoints, the smallest sufficient offered block.

Primary note proof

Study-note section NET28

> A conventional /30 has four addresses and two usable endpoints; check the link and addressing assumptions when selecting a WAN prefix. RFC3021 permits /31 on supported point-to-point links: both addresses are endpoints, so the subtract-two rule does not apply. /32 identifies one address/host route. Question 206 | AM0510

How many bits are in the host portion of an IPv4 address with a subnet mask of 255.255.255.192?

A. 6

B. 8

C. 10

D. 14

Hint

Convert the mask to a prefix, separate network and host bits, and apply the relevant subnet-count or usable-host rule.

Answer A: 6

192=11000000 leaves six zero mask bits; the full mask is /26. Hence 32-26=6 host bits. Evidence: PDF 18, 19, 19.

Why each choice is right or wrong

A - Correct: Six is the calculated count (PDF 18, 19, 19.)

B - Incorrect: Eight would correspond to /24 (PDF 18, 19, 19.)

C - Incorrect: Ten would correspond to /22 (PDF 18, 19, 19.)

D - Incorrect: Fourteen would correspond to /18 (PDF 18, 19, 19.)

Primary note proof

Study-note section NET24

A /p IPv4 prefix has p leading one bits followed by 32-p zeros. Partial octet masks are 128,192,224,240,248,252,254. /19 is 255.255.224.0; /20 is 255.255.240.0; /21 is 255.255.248.0, correcting the study guide's 255.248.0.0 mistake.

Study-note section NET25

For ordinary broadcast LANs let h=32-p. Total addresses=2^h; usable hosts=2^h-2, reserving network and directed broadcast. Find the changing octet's increment as 256-mask octet, round the address down to a multiple, and extend through the next boundary minus one.

Question 207 | AM0511

What is the network address for the IP address 192.168.10.25/28?

A. 192.168.10.0

B. 192.168.10.16

C. 192.168.10.24

D. 192.168.10.25

Hint

Convert the mask to a prefix, separate network and host bits, and apply the relevant subnet-count or usable-host rule.

Answer B: 192.168.10.16

/28 mask last octet is 240. 25=00011001 AND 240=11110000 gives 16=00010000. Therefore network address is 192.168.10.16. Evidence: PDF 18, 19, 19.

Why each choice is right or wrong

A - Incorrect: 0 is the preceding /28 block (PDF 18, 19, 19.)

B - Correct: 16 is the correct masked boundary (PDF 18, 19, 19.)

C - Incorrect: 24 retains host bits and is not a 16-step boundary (PDF 18, 19, 19.)

D - Incorrect: 25 is the given host address, not the masked network (PDF 18, 19, 19.)

Primary note proof

Study-note section NET24

Compute network=address AND mask. Host bits zero identify the block start; host bits one give broadcast. With 172.16.28.252/20, the third octet is grouped in blocks of 16, so the network is 172.16.16.0 and broadcast 172.16.31.255. A written host/prefix such as 172.105.180.0/21 need not be an aligned block label: masking yields 172.105.176.0/21.

Study-note section NET25

192.168.2.64/26 spans .64-.127; usable .65-.126 gives 62 hosts. 192.168.10.25/28 spans .16-.31, so its network is .16. 172.17.128.0/21 spans 172.17.128.0-172.17.135.255; .128.255 and .135.0 are valid interior hosts, but .135.255 is broadcast. /27 gives 32 total and 30 usable, not 32 usable.

Question 208 | AM0512

How many usable host addresses are available in a subnet with a subnet mask of 255.255.255.224?

A. 6

B. 14

C. 30

D. 62

Hint

Convert the mask to a prefix, separate network and host bits, and apply the relevant subnet-count or usable-host rule.

Answer C: 30 usable host addresses

224 in the final mask octet is 11100000. That yields /27 and h=5. Computing 2^5−2 gives 30 ordinary usable host addresses after network and directed-broadcast reservations. The distractors correspond to different host-bit counts; none changes the explicit mask in this question.

Why each choice is right or wrong

A - Incorrect: Six usable hosts would use three host bits, normally /29 rather than /27.

B - Incorrect: Fourteen usable hosts would use four host bits, normally /28.

C - Correct: Five host bits give 32 addresses minus two reservations, yielding 30 usable hosts.

D - Incorrect: Sixty-two usable hosts would use six host bits and a /26 mask.

Question 209 | AM0513

Which address category is defined for internal reuse by RFC1918 rather than global public routing?

A. Public IP address

B. Private IP address

C. Reserved IP address

D. Dynamic IP address

Hint

Use the cited note definitions to identify the requested function or scope, then check each alternative against that same rule.

Answer B: Private IP address

RFC1918 defines private blocks that organizations can reuse internally and that are not globally routed as public destinations. Public addresses can also be used on a LAN when legitimately assigned, so local communication alone would not distinguish the categories. Dynamic describes an assignment method such as a DHCP lease, not an address scope. The revised scope identifies the category by its defined allocation purpose.

Why each choice is right or wrong

A - Incorrect: Public addresses are globally allocated unicast space rather than RFC1918 internal-reuse space.

B - Correct: Private addresses are the RFC1918 blocks defined for internal reuse.

C - Incorrect: Reserved addresses have specific purposes and are not a generic ordinary-LAN host address category.

D - Incorrect: Dynamic describes how an address is assigned, not whether it belongs to RFC1918 space.

Primary note proof

Study-note section NET23

RFC1918 private blocks are 10.0.0.0/8, 172.16.0.0/12 (through 172.31.255.255), and 192.168.0.0/16. They can be reused internally but are not globally routed as public destinations. A LAN may also use legitimately assigned public addresses; private is common, not mandatory. 127.0.0.0/8 is IPv4 loopback, commonly 127.0.0.1, for local protocol access without an external link. 255.255.255.255 is limited broadcast; 0.0.0.0 can identify an unconfigured source. Link-local/APIPA uses 169.254.0.0/16, with edge /24 blocks excluded from normal automatic selection.

Study-note section NET20

DNS resolves names to records, including IPv4 A and IPv6 AAAA addresses; it can use UDP or TCP port 53. DHCP dynamically leases IPv4 settings, commonly address, mask, gateway and DNS server. Its basic exchange is discover, offer, request, acknowledge. IP itself does not assign addresses.

NAT (Network Address Translation): The scarcity of
network addresses in IPv4 led to the development of IPv6.
Due to this, we need to use private IP address inside the
organization and translate it to public IP address using
NAT.

Data Communication and Computer Networking module | PDF page 48 | lines 29-40

Network Address Translation (NAT)
NAT translates the IP addresses of computers in a local
network to a single IP address. This address is often used
by the router that connects the computers to the Internet.
The router can be connected to a DSL modem, cable
modem, T1 line, or even a dial-up modem. When other
computers on the Internet attempt to access computers
within the local network, they only see the IP address of
the router. This adds an extra level of security, since the
router can be configured as a firewall, only allowing
authorized systems to access the computers within the
network.

Question 210 | AM0514

Which of the following is not a valid IP address?

A. 192.168.0.1

B. 10.0.0.256

C. 172.16.0.0

D. 255.255.255.0

Hint

Separate address width, syntax, reserved scope and the supplied prefix or historical classful convention.

Answer B: 10.0.0.256

Each IPv4 decimal octet must be 0-255. 10.0.0.256 violates that constraint; the other strings are syntactically valid IPv4 values regardless of host-assignability restrictions. Evidence: PDF 19.

Why each choice is right or wrong

A - Incorrect: All four octets satisfy the syntax rule (PDF 19.)

B - Correct: 256 exceeds the eight-bit maximum (PDF 19.)

C - Incorrect: All octets are syntactically valid; a network-address role is a separate issue (PDF 19.)

D - Incorrect: All octets are syntactically valid; use as a mask does not make the bit string invalid (PDF 19.)

Primary note proof

Study-note section NET22

> Write IPv4 as four decimal octets 0-255, or as 32 binary bits. Use weights 128,64,32,16,8,4,2,1 within each octet. Thus 11000001 10000011 00011011 11111111 is 193.131.27.255. A value such as 257 is impossible. Syntactic validity differs from assignability: an address ending .0 or .255 can be a host under some prefixes.

What is the default subnet mask for a Class B IP address?

A. 255.0.0.0

B. 255.255.0.0

C. 255.255.255.0

D. 255.255.255.255

Hint

Convert the mask to a prefix, separate network and host bits, and apply the relevant subnet-count or usable-host rule.

Answer B: 255.255.0.0

NET22 gives historical Class B a /16 default. The first sixteen mask bits are ones, producing 255.255.0.0. This answers the requested default-mask question; it does not imply that a modern Class B-range address cannot have a different explicit CIDR prefix.

Why each choice is right or wrong

A - Incorrect: 255.0.0.0 is /8, the historical default for Class A.

B - Correct: 255.255.0.0 has sixteen leading ones and is the historical Class B default.

C - Incorrect: 255.255.255.0 is /24, the historical default for Class C.

D - Incorrect: 255.255.255.255 is /32, a single-address prefix rather than a Class B default.

Primary note proof

Study-note section NET22

Historical classes use leading patterns: A 0 with /8, B 10 with /16, C 110 with /24; D 1110 is multicast and E 1111 reserved. Ordinary class-A first octets are 1-126 because 0 and 127 have special uses. B spans 128-191 and C 192-223. Default usable counts are 2^24-2, 2^16-2 and 254. Modern CIDR requires the actual prefix and overrides class defaults.

Question 213 | AM0517

Given a subnet mask of 255.255.255.224, how many host addresses are available in each subnet?

A. 6

B. 14

C. 30

D. 62

Hint

Convert the mask to a prefix, separate network and host bits, and apply the relevant subnet-count or usable-host rule.

Answer C: 30 host addresses per ordinary subnet

The mask 255.255.255.224 is /27, leaving five host bits. A block therefore contains 32 addresses. Because the question asks addresses available to hosts, exclude its network and broadcast addresses, leaving 30. Treating all 32 as usable would confuse block size with conventional broadcast-LAN host capacity.

Why each choice is right or wrong

A - Incorrect: Six usable addresses corresponds to /29, not the stated /27 mask.

B - Incorrect: Fourteen usable addresses corresponds to /28 and four host bits.

C - Correct: The /27 block has five host bits and 32−2=30 conventional usable addresses.

D - Incorrect: Sixty-two usable addresses would require /26 and six host bits.

A /p IPv4 prefix has p leading one bits followed by 32-p zeros. Partial octet masks are 128,192,224,240,248,252,254. /19 is 255.255.224.0; /20 is 255.255.240.0; /21 is 255.255.248.0, correcting the study guide’s 255.248.0.0 mistake.

Address Space: An address space is the total
number ofaddresses used by the protocol.
• If a protocol uses N bits to define an address,
the address space is 2N
because each bit can
have twodifferent values (0 or 1) and N bits
can have 2N values.
• IPv4 uses 32-bit addresses, which means that
the address space is 232 or 4,294,967,296
(more than 4billion).
Notations: There are two notations to show an IPv4 address:
• Binary notation: The IPv4 address is displayed
as 32bits. ex. 11000001 10000011 00011011
11111111
• Dotted decimal notation: To make the IPv4
address easier to read, Internet addresses are
usually written in decimal form with a decimal
point (dot) separatingthe bytes. Each byte (octet)
is 8 bits hence each number in dotted-decimal
notation is a value rangingfrom 0 to 255. Ex.

Classful addressing : In classful addressing, the
addressspace is divided into five classes: A, B, C,
D, and E.
• Netid and Hostid In classful addressing, an IP
addressin class A, B, or C is divided into netid
and hostid.
Subnetting: It allows a network to be split into several
parts for internal use but still act like a single network to
the outsideworld.
• To implement subnetting, the router needs a
subnet mask that indicates the split between
network + subnet number and host. Ex.

Question 214 | AM0518

What is the network address for the IP address 192.168.1.65/26?

A. 192.168.1.0

B. 192.168.1.64

C. 192.168.1.65

D. 192.168.1.128

Hint

Convert the mask to a prefix, separate network and host bits, and apply the relevant subnet-count or usable-host rule.

Answer B: 192.168.1.64

/26 makes the fourth-octet mask192=11000000. 65=01000001 AND192=11000000 gives64=01000000, so the network is 192.168.1.64. Evidence: PDF 18, 19, 19.

Why each choice is right or wrong

A - Incorrect: 0 is the preceding 64-address block (PDF 18, 19, 19.)

B - Correct: 64 is the masked network boundary (PDF 18, 19, 19.)

C - Incorrect: 65 retains the nonzero host bit (PDF 18, 19, 19.)

D - Incorrect: 128 is the next block boundary (PDF 18, 19, 19.)

Primary note proof

Study-note section NET24

> Compute network=address AND mask. Host bits zero identify the block start; host bits one give broadcast. With 172.16.28.252/20, the third octet is grouped in blocks of 16, so the network is 172.16.16.0 and broadcast 172.16.31.255. A written host/prefix such as 172.105.180.0/21 need not be an aligned block label: masking yields 172.105.176.0/21.

Question 215 | AM0519

How many subnets can be created from a Class C network with a subnet mask of 255.255.255.192?

A. 2

B. 4

C. 8

D. 16

Hint

Convert the mask to a prefix, separate network and host bits, and apply the relevant subnet-count or usable-host rule.

Answer B: 4 subnets

A historical Class C parent is /24. The supplied 255.255.255.192 mask is /26, borrowing two bits. Modern counting gives 2^2=4 equal subnets, not two: NET26 explicitly rejects subtracting two subnets under modern practice. Here the parent is given, unlike the under-specified standalone-prefix questions.

Why each choice is right or wrong

A - Incorrect: Two would incorrectly exclude two subnets under an obsolete unstated convention; modern counting gives four.

B - Correct: Borrowing two bits from /24 to /26 produces four equal subnets.

C - Incorrect: Eight subnets requires borrowing three bits, producing /27 rather than /26.

D - Incorrect: Sixteen subnets requires four borrowed bits and a /28 prefix.

Primary note proof

Study-note section NET26

To split parent /a into equal /p blocks, borrow b=p-a bits and obtain 2^b subnets. Do not subtract two subnets under modern practice. For a Class B /16 parent split to /19, b=3 gives eight subnets, each with 8192 addresses and 8190 conventional hosts. A /19 alone does not state its parent.

Study-note section NET22

Historical classes use leading patterns: A 0 with /8, B 10 with /16, C 110 with /24; D 1110 is multicast and E 1111 reserved. Ordinary class-A first octets are 1-126 because 0 and 127 have

special uses. B spans 128-191 and C 192-223. Default usable counts are 2^24-2, 2^16-2 and 254. Modern CIDR requires the actual prefix and overrides class defaults.

Question 216 | AM0520

What is the maximum number of IP addresses that can be assigned to hosts in a subnet with a /27 subnet mask?

A. 14

B. 30

C. 62

D. 126

Hint

Convert the mask to a prefix, separate network and host bits, and apply the relevant subnet-count or usable-host rule.

Answer B: 30 assignable host IP addresses

With /27, 32−27=5 host bits produce 2^5=32 addresses. For an ordinary subnet, network and broadcast are reserved, so 30 can be assigned to hosts. The alternative values are usable-host counts for /28, /26 and /25, rather than the supplied /27.

Why each choice is right or wrong

A - Incorrect: Fourteen usable hosts requires /28, leaving only four host bits.

B - Correct: A /27 leaves five host bits and therefore 30 assignable ordinary host addresses.

C - Incorrect: Sixty-two usable hosts is the /26 result, not /27.

D - Incorrect: 126 usable hosts requires /25 and seven host bits.

Question 217 | AM0521

Which IP address range is reserved for Automatic Private IP Addressing (APIPA)?

A. 10.0.0.0 - 10.255.255.255

B. 127.0.0.0 - 127.255.255.255

C. 169.254.0.0 - 169.254.255.255

D. 192.168.0.0 - 192.168.255.255

Hint

Separate address width, syntax, reserved scope and the supplied prefix or historical classful convention.

Answer C: 169.254.0.0/16 link-local/APIPA range

NET23 assigns link-local/APIPA to 169.254.0.0/16, the range printed in C. That identifies the reserved overall block; the first and last /24 blocks are excluded from normal automatic selection. The private RFC1918 blocks and loopback block offered elsewhere have different purposes and are not the APIPA range.

Why each choice is right or wrong

A - Incorrect: 10/8 is RFC1918 private space, not the link-local/APIPA allocation.

B - Incorrect: 127/8 is loopback for local protocol access, not automatic link-local addressing.

C - Correct: 169.254/16 is the APIPA block; normal automatic host selection excludes its edge /24 blocks.

D - Incorrect: 192.168/16 is RFC1918 private space rather than the APIPA block.

Primary note proof

Study-note section NET23

RFC1918 private blocks are 10.0.0.0/8, 172.16.0.0/12 (through 172.31.255.255), and 192.168.0.0/16. They can be reused internally but are not globally routed as public destinations. A LAN may also use legitimately assigned public addresses; private is common, not mandatory. 127.0.0.0/8 is IPv4 loopback, commonly 127.0.0.1, for local protocol access without an external link. 255.255.255.255 is limited broadcast; 0.0.0.0 can identify an unconfigured source. Link-local/APIPA uses 169.254.0.0/16, with edge /24 blocks excluded from normal automatic selection.

Question 218 | AM0523

Which of the following protocols is responsible for assigning IP addresses to hosts dynamically?

A. DNS

B. DHCP

C. HTTP

D. FTP

Hint

Identify the requested service or delivery guarantee, then distinguish application roles, transport behavior and address configuration.

Answer B: DHCP

DHCP is the address-configuration service in NET20, dynamically leasing an address together with other settings. DNS resolves names rather than assigning a client's host address. HTTP and FTP handle web exchanges and file transfers. Therefore B matches dynamic assignment rather than name resolution or application-data transfer.

Why each choice is right or wrong

A - Incorrect: DNS resolves names to records and does not perform the dynamic lease assignment asked about.

B - Correct: DHCP dynamically leases host addresses and related network configuration.

C - Incorrect: HTTP provides web request/response exchanges rather than dynamic IP-address allocation.

D - Incorrect: FTP transfers files and is not a host-address lease protocol.

Primary note proof

Study-note section NET20

DNS resolves names to records, including IPv4 A and IPv6 AAAA addresses; it can use UDP or TCP port 53. DHCP dynamically leases IPv4 settings, commonly address, mask, gateway and DNS server. Its basic exchange is discover, offer, request, acknowledge. IP itself does not assign addresses.

Study-note section NET21

HTTP defines web request/response semantics; it is stateless, and a message body may be absent. HTTPS adds TLS protection. FTP transfers files using control and separate data connections; it is not the same protocol as SFTP. SMTP submits and relays mail; POP3 retrieves messages and IMAP accesses/synchronizes server mailboxes. Saying SMTP handles both sending and end-user mailbox retrieval is inaccurate.

Which TCP/IP-suite protocols listed below are connectionless? Select all that apply.

A. User Datagram Protocol (UDP)

B. Internet Protocol

C. Transmission Control Protocol

D. The OSI reference protocol

Hint

Identify the requested service or delivery guarantee, then distinguish application roles, transport behavior and address configuration.

Answer A, B: User Datagram Protocol (UDP); Internet Protocol

UDP sends independent datagrams without built-in connection setup, ordering or retransmission. IP likewise provides connectionless best-effort packet delivery at the network layer. TCP instead establishes transport connection state and supplies a reliable ordered stream. OSI is a reference model rather than a protocol in the TCP/IP suite. The multiple-selection instruction therefore permits both connectionless protocols across the two layers.

Why each choice is right or wrong

A - Correct: UDP has no built-in connection setup and treats datagrams independently.

B - Correct: IP also supplies connectionless best-effort packet delivery at the network layer.

C - Incorrect: TCP establishes logical transport connection state before its reliable stream transfer.

D - Incorrect: OSI is a reference model, not a connectionless TCP/IP-suite protocol.

Primary note proof

Study-note section NET17

> TCP offers a reliable ordered byte stream using sequence numbers, acknowledgments, retransmission and windows. Flow control protects the receiver; congestion control protects network capacity. UDP sends independent datagrams with ports and a checksum but no built-in setup, delivery guarantee, retransmission or ordering. Live interactive traffic may choose UDP when late data is less useful than lost data. Application protocols can add reliability over UDP.

Study-note section NET16

> IP supplies connectionless best-effort packet delivery, not end-to-end ordering or retransmission. IPv4 addresses are 32 bits. Question 220 | CS0156

Which statements describe capabilities or properties of IPv6? Select all that apply. Encryption support in D means capability, not automatic confidentiality or exclusivity to IPv6.

A. Handle more addresses

B. Use 128-bits

C. Route slower and is memory intensive

D. Support encryptions

Hint

Identify the requested service or delivery guarantee, then distinguish application roles, transport behavior and address configuration.

Answer A, B, D: Handle more addresses; Use 128-bits; Support encryptions

IPv6 uses 128-bit addresses, giving it a much larger address space than IPv4's 32-bit addresses. It can support encryption, but that capability does not mean every IPv6 packet is encrypted or that IPv4 cannot support encryption. Routing speed and memory requirements depend on implementation and workload; they are not inherently fixed by the protocol version. Thus the three capability/property statements qualify.

Why each choice is right or wrong

A - Correct: A 128-bit address space can represent far more addresses than IPv4's 32-bit space.

B - Correct: NET23 explicitly states that IPv6 addresses contain 128 bits.

C - Incorrect: Slower routing and greater memory use are not inherent requirements of every IPv6 implementation.

D - Correct: Encryption is supported, but IPv6 does not automatically encrypt traffic and this is not unique to IPv6.

Primary note proof

Study-note section NET23

IPv6 has 128-bit hexadecimal addresses, flexible prefixes and no IPv4-style broadcast. Sources, not routers, fragment IPv6 packets. IPv6 does not automatically encrypt traffic or make authentication unnecessary. Compare IPv6's larger 128-bit address space and encryption support separately; specify the property being evaluated.

Study-note section NET16

IP supplies connectionless best-effort packet delivery, not end-to-end ordering or retransmission. IPv4 addresses are 32 bits. Question 221 | CS0157

Which one does NOT describe a loopback address?

A. It helps to refer to the host itself

B. It allows programs to access network protocols for local services

C. It is an external pseudo address

D. It is denoted by the IP address: 127.0.0.1

Hint

Separate address width, syntax, reserved scope and the supplied prefix or historical classful convention.

Answer C: Loopback is local self-reference, not an external address

Loopback lets a host address itself and access local services through networking protocols without an external link. NET23 identifies 127/8 and common 127.0.0.1 for that purpose. Describing it as external contradicts this local scope, whereas the remaining choices all describe supported loopback uses or notation.

Why each choice is right or wrong

A - Incorrect: Referring to the host itself is precisely the loopback function, so this statement does describe it.

B - Incorrect: Local programs can use networking protocols to access local services through loopback.

C - Correct: External contradicts loopback's local self-reference without an external network link.

D - Incorrect: 127.0.0.1 is explicitly given as the common IPv4 loopback address.

Primary note proof

Study-note section NET23

> RFC1918 private blocks are 10.0.0.0/8, 172.16.0.0/12 (through 172.31.255.255), and 192.168.0.0/16. They can be reused internally but are not globally routed as public destinations. A LAN may also use legitimately assigned public addresses; private is common, not mandatory. 127.0.0.0/8 is IPv4 loopback, commonly 127.0.0.1, for local protocol access without an external link. 255.255.255.255 is limited broadcast; 0.0.0.0 can identify an unconfigured source. Link-local/APIPA uses 169.254.0.0/16, with edge /24 blocks excluded from normal automatic selection.

Question 222 | CS0164

In data communication, which of the following is NOT a factor for data rate?

A. Travel distance

B. Bandwidth available

C. Level of noise

D. Levels of the signals

Hint

Use the cited note definitions to identify the requested function or scope, then check each alternative against that same rule.

Answer A: Travel distance is not explicit in the simplified capacity formulas

In the simplified capacity comparison taught in NET05, Nyquist uses bandwidth and signal levels, while Shannon uses bandwidth and signal-to-noise ratio. Travel distance is not a separate formula parameter, making A the intended choice. The qualification matters: distance can affect attenuation, delay and real achievable rates, so the answer is not physical independence from distance.

Why each choice is right or wrong

A - Correct: Travel distance is absent as an independent variable in the taught formulas, despite indirect real-link effects.

B - Incorrect: Bandwidth appears directly in both Nyquist and Shannon expressions and limits channel capacity.

C - Incorrect: Noise enters Shannon capacity through the signal-to-noise ratio.

D - Incorrect: Signal levels enter Nyquist capacity through the number of bits represented per symbol.

Primary note proof

Study-note section NET05

> For an ideal noiseless channel, Nyquist gives $R \leq 2B \log_2(M)$. For Gaussian noise, Shannon gives $C = B \log_2(1+S/N)$, with a linear power ratio; $SNR(dB) = 10 \log_{10}(S/N)$. Bandwidth, signal levels and noise appear explicitly. Distance affects attenuation, delay and often achievable rate, but is not a separate variable in these simplified capacity formulas.

Study-note section NET06

> Transmission delay is packet bits divided by link bit rate; propagation delay is distance divided by signal speed. Processing and queueing add delay. A 1000-byte packet takes 0.8 ms to serialize at 10 Mbit/s; increasing line rate does not reduce propagation time.

BIT LENGTH or Bit Interval (Tb)
It is the time required to send one bit.
It is measured in seconds.
BIT RATE
It is the number of bits transmitted in one second.
It is expressed as bits per second (bps).
Relation between bit rate and bit interval can be as follows
Bit rate = 1 / Bit interval
Baud Rate
It is the rate of Signal Speed, i.e the rate at which the signal changes.
A digital signal with two levels 0_& 1_will have the same baud rate and bit rate & bit rate.

receiver.There are three causes of impairment:
• Attenuation
• Distortion
• Noise
Attenuation
Attenuation results in loss of energy due to distance.
Whena signal travels through a medium, it loses some of its energy in overcoming the resistance of the medium. The electrical energy in the signal may convert to heat. To compensate for this loss, amplifiers are used to amplify thesignal.
Distortion
Distortion changes the shape of the signal.
Noise
Noise is any unwanted signal that is mixed or combined with the original signal during transmission.
Due to noise the original signal is altered and signal received is not sameas the one sent.

Data Communication and Computer Networking module | PDF page 9 | lines 29-49

Transmission of Digital signal: Digital signal can be transmitted in the following two ways:
• Baseband Transmission: The signal is transmitted without making any change to it (i.e. Without modulation)
o In baseband transmission, the bandwidth of the signal to be transmitted has to be less than the bandwidth of the channel.
o Ex. Consider a Baseband channel with lower frequency 0Hz and higher frequency 100Hz, hence its bandwidth is 100 (Bandwidth is calculated by getting the difference between the highest and lowest frequency)
o A channel whose bandwidth is more than the bandwidth

of the signal is called Wideband channel
o A channel whose bandwidth is less than the bandwidth of the signal is called Narrowband channel
• Broadband Transmission: Given a bandpass channel, a digital signal cannot be transmitted directly through it
o In broadband transmission we use modulation, i.e. we change the signal to analog signal before transmitting it.

Question 223 | NS0334

Which of the following OSI layers is NOT correctly matched to its corresponding data Units (PDU)?

A. Application layer ---> Data

B. Transport layer ---> Segment

C. Physical layer ---> Bit

D. Network layer ---> Frame

Hint

Match the requested scope or data unit to the layer duties in the note; distinguish hop delivery from end-to-end process delivery.

Answer D: Network-layer PDU is packet, not frame

The PDUs are: application data, transport segment/datagram, network packet, link frame and physical bits. D assigns the link-layer frame to the network layer, making it the mismatch. Transport segment is appropriate for TCP, so B remains a valid conventional example rather than a claim about every transport protocol.

Why each choice is right or wrong

A - Incorrect: Application data is the conventional PDU designation, so this match is valid.

B - Incorrect: TCP uses transport segments; this is a valid conventional transport PDU example.

C - Incorrect: Bits/symbols belong to physical transport, making this match valid.

D - Correct: A frame is link-layer; the network-layer unit is a packet.

Primary note proof

Study-note section NET12

> Sending proceeds from application data to transport segment/datagram, network packet, link frame and physical bits/symbols; receiving reverses the order. Each layer serves the layer above. A router removes a received link frame, inspects IP, and creates a new link frame for the next hop. MAC addresses usually change across routed hops; end-to-end IP addresses ordinarily remain until translation.

Question 224 | NS0341

Which of the following layers is responsible for encryption, translation and compression?

A. Presentation layer

B. Data link layer

C. Transport layer

D. Network layer

Hint

Match the requested scope or data unit to the layer duties in the note; distinguish hop delivery from end-to-end process delivery.

Answer A: Presentation layer

The three listed operations are representation functions: encoding translation, compression and encryption. NET19 groups them under the OSI presentation role. Link handles frames, transport process delivery and network logical routing; none is the named OSI representation layer. Real implementations may distribute these functions, but the reference-model answer is presentation.

Why each choice is right or wrong

A - Correct: Presentation explicitly covers encoding translation, compression and encryption roles.

B - Incorrect: Data link handles hop frames/access rather than the OSI representation-function grouping.

C - Incorrect: Transport delivers between process endpoints, not the named presentation representation roles.

D - Incorrect: Network handles logical addressing/routing rather than compression/encoding translation.

Primary note proof

Study-note section NET19

> OSI session roles establish/manage dialogs and can coordinate checkpoints so transfer resumes after interruption. Presentation roles translate encodings and handle compression/encryption. Compression reduces representation size; encryption hides content and need not shrink it. Application protocols provide services directly to applications. Practical implementations distribute these functions differently; TLS is not proof of a separate physical presentation-layer device.

Study-note section NET12

> Sending proceeds from application data to transport segment/datagram, network packet, link frame and physical bits/symbols; receiving reverses the order. Each layer serves the layer above. A router removes a received link frame, inspects IP, and creates a new link frame for the next hop. Question 225 | NS0352

Assume that you have IPv4 addresses in binary notation 11000001 10000011 00011011 11111111 and you are requested to change into dotted decimal notation. What is the equivalent IP address in decimal dotted notation?

A. 192.174.27.255

B. 192.134.67.254

C. 193.130.28.254

D. 193.131.27.255

Hint

Sum the eight bit weights in each octet independently, then preserve their order in dotted-decimal notation.

Answer D: 193.131.27.255

Using octet weights 128,64,32,16,8,4,2,1 gives 11000001=193, 10000011=131, 00011011=27 and 11111111=255. Combining the four decimal octets gives 193.131.27.255. This is a notation conversion, not a claim about whether that address is assignable as a host under an unspecified prefix.

Why each choice is right or wrong

A - Incorrect: The first octet should be 193 and the second 131, not 192 and 174.

B - Incorrect: All four printed octets differ from the binary-derived values 193,131,27,255.

C - Incorrect: Only the first octet matches; the correct remaining values are 131,27,255.

D - Correct: Each decimal octet matches its eight-bit sum: 193, 131, 27 and 255.

Primary note proof

Study-note section NET22

> Write IPv4 as four decimal octets 0-255, or as 32 binary bits. Use weights 128,64,32,16,8,4,2,1 within each octet. Thus 11000001 10000011 00011011 11111111 is 193.131.27.255. A value such as 257 is impossible. Syntactic validity differs from assignability: an address ending .0 or .255 can be a host under some prefixes.

Question 226 | NS0573

A company has 500 computers distributed across 10 floors of a single building. Which network type BEST describes this setup?

A. WAN

B. MAN

C. LAN

D. Internet

Hint

Use the cited note definitions to identify the requested function or scope, then check each alternative against that same rule.

Answer C: LAN

All computers are in one building, the geographic scope of a LAN in NET02. The count of 500 devices or ten floors does not itself make a MAN/WAN; the note explicitly separates device count from geographic category. No metropolitan or distant-region interconnection is supplied.

Why each choice is right or wrong

A - Incorrect: WAN concerns distant regions, not simply many devices on floors of one building.

B - Incorrect: MAN requires metropolitan scope rather than a single-building deployment.

C - Correct: A single building falls within the LAN scope defined by NET02.

D - Incorrect: The Internet is the global network of networks, not the building network described.

Primary note proof

Study-note section NET02

> PAN connects personal devices, such as Bluetooth accessories. LAN covers a local building or campus; MAN spans a metropolitan region; WAN connects distant regions. Device count alone does not determine the category. The Internet is a global network of networks, commonly the largest example of a WAN.

Question 227 | NS0574

In which OSI layer does the MAC address operate?

A. Network Layer (Layer 3)

B. Physical Layer (Layer 1)

C. Data Link Layer (Layer 2)

D. Transport Layer (Layer 4)

Hint

Match the requested scope or data unit to the layer duties in the note; distinguish hop delivery from end-to-end process delivery.

Answer C: Data link, layer 2

MAC addressing identifies link-layer frame endpoints and forwarding scope. NET13 assigns medium-dependent addressing/access to MAC in the data-link layer. Physical transports signals, network uses logical IP prefixes and transport identifies process endpoints by ports. The word physical in physical address must not be confused with a layer-1 functional assignment.

Why each choice is right or wrong

A - Incorrect: Network-layer addressing uses logical IP addresses rather than the link MAC address.

B - Incorrect: Physical transports signals; the conventional physical-address nickname does not move MAC addressing to layer 1.

C - Correct: MAC addressing and frame delivery are data-link functions at layer 2.

D - Incorrect: Transport identifies process endpoints by ports rather than MAC frame addresses.

Primary note proof

Study-note section NET13

> Link-layer LLC identifies or multiplexes upper-layer protocols and may supply link control; MAC handles medium-dependent addressing/access and frame delivery. Network addressing belongs to layer 3. Ethernet, PPP and HDLC are link protocols. Frame headers may carry addresses and control/type fields; synchronization and exact framing depend on the protocol.

Study-note section NET17

> Ports identify transport endpoints; the application can choose a transport and request socket buffer sizes, subject to OS limits. A TCP connection is identified by source/destination IP and source/destination port, with TCP understood. IPv4 protocol numbers identify upper protocols; 80 is a usual HTTP port, not an IP protocol number. Clients often use ephemeral ports. SCTP is a reliable message-oriented transport with multiple streams.

Study-note section NET16

> IP supplies connectionless best-effort packet delivery, not end-to-end ordering or retransmission. IPv4 addresses are 32 bits. Its minimum header is 20 bytes and can grow to 60 bytes; it is not a 32-bit header. IHL counts 32-bit words; total length includes header and payload. TTL limits lifetime across routers; the protocol field identifies TCP, UDP or another upper-layer protocol.

Question 228 | NS0575

Which of the following correctly describes attenuation in data transmission?

A. The delay caused by different frequencies traveling at different speeds

B. The loss of signal strength as it travels over a distance

C. Interference from adjacent communication channels

D. The maximum data rate of a transmission medium

Hint

Compare the signal mechanism, medium properties or transmission direction against the definitions and stated physical assumptions.

Answer B: Loss of signal strength

NET06 defines attenuation as reduced signal strength. Different delays among frequency components describe distortion, adjacent-channel leakage describes crosstalk and maximum rate concerns capacity. B gives the strength-loss mechanism rather than those separate impairments or performance measures.

Why each choice is right or wrong

A - Incorrect: Different component delays change waveform shape, describing distortion rather than attenuation.

B - Correct: A reduction in signal strength during propagation is attenuation.

C - Incorrect: Adjacent-channel interference is crosstalk, a separate noise source.

D - Incorrect: Maximum data rate is channel capacity, not signal-strength loss.

Primary note proof

Study-note section NET06

> Attenuation reduces signal strength. Distortion changes shape, often because frequencies have different delays. Noise adds unwanted energy: thermal noise comes from random thermal motion, crosstalk leaks from nearby channels, and impulse noise is a short disturbance. Amplifiers amplify noise too; digital repeaters regenerate decisions but cannot reconstruct every corrupted bit.

Study-note section NET05

> For an ideal noiseless channel, Nyquist gives $R \leq 2B \log_2(M)$. For Gaussian noise, Shannon gives $C = B \log_2(1+S/N)$, with a linear power ratio; $SNR(dB) = 10 \log_{10}(S/N)$. Bandwidth, signal levels and noise appear explicitly. Distance affects attenuation, delay and often achievable rate, but is not a separate variable in these simplified capacity formulas.

Question 229 | NS0576

A network administrator wants to divide the Class C network 192.168.10.0 into 6 subnets. What is the minimum number of bits that must be borrowed from the host portion?

A. 2 bits

B. 3 bits

C. 4 bits

D. 6 bits

Hint

Convert the mask to a prefix, separate network and host bits, and apply the relevant subnet-count or usable-host rule.

Answer B: Borrow 3 bits to obtain at least six equal subnets

For equal-sized subnets of a /24 parent, borrowing b bits yields 2^b blocks. Two bits give only four; three give eight, the minimum power-of-two count that accommodates six required subnets. The resulting mask is /27 with 30 conventional hosts per block. Exactly six equal blocks would not fill the parent; two blocks remain unused.

Why each choice is right or wrong

A - Incorrect: Two borrowed bits yield only four blocks, fewer than the six required.

B - Correct: Three borrowed bits yield eight blocks and are the minimum satisfying at least six.

C - Incorrect: Four bits yield sixteen blocks and are not the minimum required.

D - Incorrect: Six bits yield sixty-four blocks, substantially more than the minimum.

Primary note proof

Study-note section NET26

> To split parent /a into equal /p blocks, borrow b=p-a bits and obtain 2^b subnets. Do not subtract two subnets under modern practice. For a Class B /16 parent split to /19, b=3 gives eight subnets, each with 8192 addresses and 8190 conventional hosts. A /19 alone does not state its parent.

Study-note section NET26

> For H hosts, choose the smallest h satisfying 2^h-2≥H, then p=32-h. For 24 hosts use /27; 52 or 57 use /26; 100 use /25; 500 use /23. For at least six equal subnets choose b=3. A Class C /24 split to /27 yields eight subnets. Always check both the number of subnets and the host capacity.

Question 230 | NS0577

Which topology provides the HIGHEST level of redundancy?

A. Star

B. Ring

C. Bus

D. Mesh

Hint

Draw the links and identify shared components, alternate paths and the effect of the specified failure or growth requirement.

Answer D: Full mesh among the conventional topology choices

A full mesh connects every pair of nodes, offering multiple alternate paths compared with the basic star, single ring and shared bus. NET08 explains the additional links/interfaces and improved fault tolerance. D assumes the conventional full-mesh interpretation; actual protected rings or partial mesh designs would require more detail for a quantitative comparison.

Why each choice is right or wrong

A - Incorrect: A basic star depends on its central device and lacks the full mesh's many alternate paths.

B - Incorrect: A basic single ring is vulnerable to a break, unlike a full mesh's multiple paths.

C - Incorrect: A shared bus depends on one backbone rather than redundant pairwise paths.

D - Correct: A full mesh supplies pairwise links and multiple alternate paths, at increased cable/interface cost.

Primary note proof

Study-note section NET08

> Bus uses a shared backbone; an unterminated break can disrupt the segment. Star connects endpoints through a central device: one edge failure isolates that endpoint, whereas central failure affects the star. Ring forms a loop; basic single rings are vulnerable to a break, while protected dual rings differ. Token passing is associated with Token Ring but is an access method, not a necessary property of every ring. Tree is hierarchical; hybrid combines arrangements.

Study-note section NET08

> A full undirected mesh of n nodes needs n(n-1)/2 links and n-1 interfaces per node. For 50 nodes: 50×49/2=1225 links. Redundant paths improve fault tolerance at greater cable and interface cost.

Question 231 | NS0578

What is the broadcast address of the network 192.168.17.0/24?

A. 192.168.17.0

B. 192.168.17.254

C. 192.168.17.255

D. 192.168.16.255

Hint

Use the cited note definitions to identify the requested function or scope, then check each alternative against that same rule.

Answer C: 192.168.17.255

A /24 prefix fixes the first three octets and leaves eight host bits. Setting them all to one gives final octet 255, so the broadcast is 192.168.17.255. The .0 address is the network boundary and .254 is the last ordinary host; 192.168.16.255 belongs outside the specified /24.

Why each choice is right or wrong

A - Incorrect: 192.168.17.0 has all host bits zero and identifies the network, not broadcast.

B - Incorrect: 192.168.17.254 is the last ordinary host, one below broadcast.

C - Correct: The final eight host bits are all one, giving the /24 broadcast .255.

D - Incorrect: The third octet 16 lies outside network 192.168.17.0/24.

Primary note proof

Study-note section NET24

> Compute network=address AND mask. Host bits zero identify the block start; host bits one give broadcast. With 172.16.28.252/20, the third octet is grouped in blocks of 16, so the network is 172.16.16.0 and broadcast 172.16.31.255. A written host/prefix such as 172.105.180.0/21 need not be an aligned block label: masking yields 172.105.176.0/21.

Study-note section NET25

> For ordinary broadcast LANs let h=32-p. Total addresses=2^h; usable hosts=2^h-2, reserving network and directed broadcast. Find the changing octet's increment as 256-mask octet, round the address down to a multiple, and extend through the next boundary minus one.

Question 232 | NS0579

Which device operates at Layer 3 of the OSI model and uses IP addresses to forward data?

A. Hub

B. Bridge

C. Switch

D. Router

Hint

Match the requested scope or data unit to the layer duties in the note; distinguish hop delivery from end-to-end process delivery.

Answer D: Router

IP destination-prefix forwarding between networks is the router function in NET11. Hubs repeat signals and bridges/ordinary switches forward MAC frames at layer 2. Some marketed switches include routing, but the unqualified ordinary switch function in this option set is layer 2; router is the explicit matching device.

Why each choice is right or wrong

A - Incorrect: A hub repeats layer-1 signals rather than forwarding on IP prefixes.

B - Incorrect: A bridge makes layer-2 frame-forwarding decisions using MAC addresses.

C - Incorrect: An ordinary switch is layer 2; a specifically layer-3 switch would require the missing routing qualifier.

D - Correct: Routers inspect destination IP prefixes and choose next hops at layer 3.

Primary note proof

Study-note section NET11

> Routers forward IP packets between networks using destination prefixes and next hops. They separate broadcast domains and normally do not forward local link broadcasts. A default gateway is usually a router, while a protocol gateway can translate application formats; therefore a gateway is not inherently a device that implements every OSI layer.

Study-note section NET10

> A bridge or ordinary Ethernet switch operates at layer 2. It learns source-MAC-to-port mappings, looks up the destination, forwards a known unicast to its port, filters it if the destination is on the incoming segment, and floods an unknown unicast or broadcast within its VLAN. A switch does not always send only to one destination port. Wireless access points normally bridge wireless and wired link-layer traffic.

Study-note section NET09

> A repeater regenerates layer-1 signals without inspecting destination addresses. An active hub is a multiport repeater: it repeats incoming signals onto other ports, placing half-duplex endpoints in one collision domain. A passive hub is a connector. A hub neither learns MAC addresses nor

eliminates collisions. An endpoint such as a network printer consumes services; routers, hubs and access points are intermediary devices.

Question 233 | NS0580

UDP is described as a 'connectionless protocol' because it:

A. Cannot transmit video data

B. Does not establish a dedicated connection before sending data and provides no delivery guarantee

C. Only transmits in simplex mode

D. Operates exclusively at the Network Layer

Hint

Identify the requested service or delivery guarantee, then distinguish application roles, transport behavior and address configuration.

Answer B: No setup and no built-in delivery guarantee

UDP's connectionlessness means independent datagrams without built-in setup, not an inability to carry video or an enforced physical duplex mode. It is a transport protocol. B correctly combines no connection establishment with absence of built-in reliable delivery; applications may add their own recovery mechanisms.

Why each choice is right or wrong

A - Incorrect: UDP can carry live media; connectionlessness does not forbid video data.

B - Correct: UDP sends independent datagrams without setup or built-in delivery guarantees.

C - Incorrect: UDP does not impose simplex physical transmission; transport service and physical duplex mode are distinct.

D - Incorrect: UDP is transport-layer, not exclusively a network-layer protocol.

Primary note proof

Study-note section NET17

TCP offers a reliable ordered byte stream using sequence numbers, acknowledgments, retransmission and windows. Flow control protects the receiver; congestion control protects network capacity. UDP sends independent datagrams with ports and a checksum but no built-in setup, delivery guarantee, retransmission or ordering. Live interactive traffic may choose UDP when late data is less useful than lost data. Application protocols can add reliability over UDP.

Study-note section NET06

Simplex is one way, half duplex alternates directions, and full duplex permits simultaneous sending/receiving. A walkie-talkie is half duplex; a telephone conversation uses full duplex. Serial sends sequential bits; parallel uses multiple conductors and may suffer skew. Character-oriented asynchronous serial adds start/stop bits; synchronous framing uses ongoing clock recovery. Neither is synonymous with browser asynchronous requests.

Question 234 | NS0581

Assume historical classful addressing and an ordinary broadcast network. A host has address 185.28.17.9. How many usable host addresses are in its default classful network?

A. 254

B. 65,534

C. 16,777,214

D. 65,536

Hint

Convert the mask to a prefix, separate network and host bits, and apply the relevant subnet-count or usable-host rule.

Answer B: 65,534

The first octet 185 lies in the historical Class B range, whose default prefix is /16. That leaves sixteen host bits, yielding 2^16 = 65,536 total addresses. Reserving the network and directed-broadcast addresses gives 65,534 usable hosts. The explicit classful assumption permits deriving the default prefix; modern CIDR would require a stated prefix instead of inferring it from the address.

Why each choice is right or wrong

A - Incorrect: 254 is the usable count for /24, not the Class B default /16.

B - Correct: Class B defaults to /16, giving 2^16−2 = 65,534 usable hosts.

C - Incorrect: 16,777,214 belongs to /8 rather than the Class B default.

D - Incorrect: 65,536 is the /16 total before network and broadcast reservations.

Primary note proof

Study-note section NET22

> Historical classes use leading patterns: A 0 with /8, B 10 with /16, C 110 with /24; D 1110 is multicast and E 1111 reserved. Ordinary class-A first octets are 1-126 because 0 and 127 have special uses. B spans 128-191 and C 192-223. Default usable counts are 2^24-2, 2^16-2 and 254. Modern CIDR requires the actual prefix and overrides class defaults.

Study-note section NET25

> For ordinary broadcast LANs let h=32-p. Total addresses=2^h; usable hosts=2^h-2, reserving network and directed broadcast. Find the changing octet’s increment as 256-mask octet, round the address down to a multiple, and extend through the next boundary minus one.

Question 235 | NS0582

Which transmission mode allows simultaneous bidirectional communication?

A. Simplex

B. Half-Duplex

C. Full-Duplex

D. Multipoint

Hint

Use the cited note definitions to identify the requested function or scope, then check each alternative against that same rule.

Answer C: Full duplex

The decisive condition is simultaneous communication in both directions. NET06 defines full duplex exactly that way. Half duplex permits both directions at different times and simplex only one. Multipoint describes sharing a medium among endpoints, not whether two endpoints can send and receive at the same instant.

Why each choice is right or wrong

A - Incorrect: Simplex permits communication in one direction only.

B - Incorrect: Half duplex alternates directions and does not permit simultaneous transmission both ways.

C - Correct: Full duplex supports sending and receiving simultaneously.

D - Incorrect: Multipoint describes medium sharing among endpoints rather than a bidirectional timing mode.

Primary note proof

Study-note section NET06

> Simplex is one way, half duplex alternates directions, and full duplex permits simultaneous sending/receiving. A walkie-talkie is half duplex; a telephone conversation uses full duplex. Serial sends sequential bits; parallel uses multiple conductors and may suffer skew. Character-oriented asynchronous serial adds start/stop bits; synchronous framing uses ongoing clock recovery. Neither is synonymous with browser asynchronous requests.

Study-note section NET08

> Physical topology describes link layout; logical topology describes communication/access relationships. Point-to-point links join two endpoints; multipoint links share a medium. A full mesh consists of point-to-point links.

Question 236 | NS0583

The OSI Presentation Layer is primarily responsible for:

A. Routing packets between networks

B. Establishing and ending communication sessions

C. Data compression, encryption, and format translation

D. Physical transmission of raw bits

Hint

Match the requested scope or data unit to the layer duties in the note; distinguish hop delivery from end-to-end process delivery.

Answer C: Compression, encryption and representation translation

NET19 assigns these three representation functions to the OSI presentation layer. Routing belongs to network, dialogs to session and raw bit signaling to physical. Real software can combine roles, but within the stated OSI model C is the specific matching responsibility set.

Why each choice is right or wrong

A - Incorrect: Routing between networks is the network-layer responsibility.

B - Incorrect: Session setup/ending belongs to the session role rather than presentation representation handling.

C - Correct: Compression, encryption and format translation are the presentation roles explicitly listed in NET19.

D - Incorrect: Physical signaling transports bits/symbols rather than translating data representations.

Primary note proof

Study-note section NET19

> OSI session roles establish/manage dialogs and can coordinate checkpoints so transfer resumes after interruption. Presentation roles translate encodings and handle compression/encryption. Compression reduces representation size; encryption hides content and need not shrink it. Application protocols provide services directly to applications. Practical implementations distribute these functions differently; TLS is not proof of a separate physical presentation-layer device.

Study-note section NET30

> Routing computes paths; forwarding chooses a next hop for an individual packet. Select the matching route with the longest prefix, then apply the routing system’s tie-breaking criteria. A default /0 matches when nothing more specific does. Static routes are configured; dynamic protocols exchange reachability. Distance vector uses neighbor estimates, while link state distributes link information and computes shortest paths. Interior protocols operate within an autonomous system; BGP exchanges routes between systems.

Study-note section NET12

Sending proceeds from application data to transport segment/datagram, network packet, link frame and physical bits/symbols; receiving reverses the order. Each layer serves the layer above. A router removes a received link frame, inspects IP, and creates a new link frame for the next hop. MAC addresses usually change across routed hops; end-to-end IP addresses ordinarily remain until translation.

Question 237 | NS0584

Which statements are not valid universal guarantees for fiber-optic cable? Select all that apply. Interpret B as a capability with suitable optics and installation, and D as a claim of automatic security.

A. Immunity to electromagnetic interference

B. High bandwidth and long transmission distance

C. Lower initial cost than copper cables

D. High data security due to difficulty of tapping

Hint

Compare the signal mechanism, medium properties or transmission direction against the definitions and stated physical assumptions.

Answer C, D: Lower initial cost than copper cables; High data security due to difficulty of tapping

Fiber guides light, resists electromagnetic interference and can support high capacity over long distances when suitable optics and installation are used. Material alone does not determine a universal installed-cost advantage over copper. Nor does physical tapping difficulty automatically ensure data security: fiber can still be tapped. The selected statements are therefore the unsupported universal guarantees about cost and security, rather than the supported transmission capabilities.

Why each choice is right or wrong

A - Incorrect: EMI resistance follows from light-guided transmission, so this is not a rejected guarantee under the stated scope.

B - Incorrect: With suitable optics and installation, high capacity and long reach are supported capabilities, so this is not selected.

C - Correct: Initial cost depends on optics, reach and installation; lower cost than copper is not universal.

D - Correct: Fiber can be tapped, so automatic high security does not follow from the medium.

Primary note proof

Study-note section NET07

> Twisted pairs reduce coupled interference; UTP has no added shield and STP adds shielding. Coax has an inner conductor and outer shield sharing an axis. Fiber guides light and resists electromagnetic interference; it supports high capacity and long reach, but requires suitable optics and installation. Exact speed, cost and reach depend on the specification, not the material alone. Fiber can still be tapped.

Question 238 | NS0585

Which option best defines a dedicated server by its primary workload?

A. A server that also acts as a client

B. A machine whose primary workload is supplying services, even though it may use DNS, backup or update services as a client.

C. A server that handles only file storage

D. Any computer in a peer-to-peer network

Hint

Use the cited note definitions to identify the requested function or scope, then check each alternative against that same rule.

Answer B: A machine whose primary workload is supplying services, even though it may use DNS, backup or update services as a client.

A dedicated server concentrates on supplying services, rather than requiring an absolute prohibition on making any client requests. It may still request DNS resolution, backups or software updates. Merely acting as a client does not define dedication, and dedicated workloads are not limited to file storage. The choice identifies the defining workload while allowing ordinary supporting client activity.

Why each choice is right or wrong

A - Incorrect: A dedicated server may act as a DNS/backup client, but that incidental capability is not its defining dedicated workload.

B - Correct: Concentration on service workloads is the defining dedicated-server characteristic.

C - Incorrect: Dedicated service workloads need not be limited to file storage.

D - Incorrect: An arbitrary peer computer is not thereby a dedicated service-workload server.

Primary note proof

Study-note section NET02

> An intranet serves an organization internally; an extranet exposes selected services to approved outsiders. Neither term alone specifies geographic size. A client requests a service; a server supplies it. Peer systems may perform both roles. Dedicated servers concentrate on service workloads but can still be clients of DNS, backup or update services. A ten-user cutoff is a teaching guideline, not a technical law. Centralization simplifies administration but creates dependencies; peer networks still need security.

Question 239 | NS0586

Which protocol operates at the Application Layer of the TCP/IP model and is responsible for translating domain names to IP addresses?

A. SMTP

B. FTP

C. HTTP

D. DNS

Hint

Match the requested scope or data unit to the layer duties in the note; distinguish hop delivery from end-to-end process delivery.

Answer D: DNS

DNS is the name-resolution application protocol in NET20. A/AAAA records provide address data for names. SMTP submits/relays mail, FTP transfers files and HTTP serves web requests; none provides the requested general domain-name record service. Its lookup role is separate from DHCP address assignment.

Why each choice is right or wrong

A - Incorrect: SMTP submits and relays mail rather than resolving hostnames to addresses.

B - Incorrect: FTP transfers files and does not supply the name-resolution record service.

C - Incorrect: HTTP defines web exchanges, not the general hostname-to-address service.

D - Correct: DNS resolves names into records such as A and AAAA address records.

Primary note proof

Study-note section NET20

> DNS resolves names to records, including IPv4 A and IPv6 AAAA addresses; it can use UDP or TCP port 53. DHCP dynamically leases IPv4 settings, commonly address, mask, gateway and DNS server. Its basic exchange is discover, offer, request, acknowledge. IP itself does not assign addresses.

Study-note section NET21

> HTTP defines web request/response semantics; it is stateless, and a message body may be absent. HTTPS adds TLS protection. FTP transfers files using control and separate data connections; it is not the same protocol as SFTP. SMTP submits and relays mail; POP3 retrieves messages and IMAP accesses/synchronizes server mailboxes. Saying SMTP handles both sending and end-user mailbox retrieval is inaccurate.

Question 240 | NS0587

Crosstalk is best described as:

A. Loss of signal strength over distance

B. Signals from one communication channel leaking into an adjacent channel

C. Random electron motion causing electrical noise

D. Delay caused by varying signal frequencies

Hint

Compare the signal mechanism, medium properties or transmission direction against the definitions and stated physical assumptions.

Answer B: Leakage from an adjacent communication channel

Crosstalk is unwanted coupling from a neighboring communication channel, directly matching B. Strength loss is attenuation, random thermal motion creates thermal noise and differential frequency delay produces distortion. These impairments can coexist but their definitions are distinct, so the question's mechanism identifies crosstalk specifically.

Why each choice is right or wrong

A - Incorrect: Signal-strength loss is attenuation rather than coupling from a neighboring channel.

B - Correct: Signals leaking into an adjacent channel are crosstalk.

C - Incorrect: Random electron/thermal motion describes thermal noise.

D - Incorrect: Different component-frequency delays distort waveform shape rather than defining crosstalk.

Primary note proof

Study-note section NET06

> Attenuation reduces signal strength. Distortion changes shape, often because frequencies have different delays. Noise adds unwanted energy: thermal noise comes from random thermal motion, crosstalk leaks from nearby channels, and impulse noise is a short disturbance. Amplifiers amplify noise too; digital repeaters regenerate decisions but cannot reconstruct every corrupted bit.

Question 241 | NS0588

How many usable host addresses are available in the subnet 192.168.2.64/26?

A. 32

B. 64

C. 62

D. 30

Hint

Convert the mask to a prefix, separate network and host bits, and apply the relevant subnet-count or usable-host rule.

Answer C: 62 usable hosts

A /26 leaves six host bits, so the block has 64 addresses. In the specified block, .64 is the network and .127 the broadcast; usable hosts span .65-.126 inclusive, totaling 62. The question asks usable hosts, not block size, and /31 point-to-point exceptions do not apply.

Why each choice is right or wrong

A - Incorrect: Thirty-two is not the usable count of this /26 block; /26 has 64 total addresses.

B - Incorrect: Sixty-four is the total block size before network/broadcast reservations.

C - Correct: Six host bits give 64 total addresses minus two reservations, leaving 62 usable hosts.

D - Incorrect: Thirty usable hosts is the /27 result, not /26.

Primary note proof

Study-note section NET25

> For ordinary broadcast LANs let h=32-p. Total addresses=2^h; usable hosts=2^h-2, reserving network and directed broadcast. Find the changing octet's increment as 256-mask octet, round the address down to a multiple, and extend through the next boundary minus one.

Study-note section NET25

> 192.168.2.64/26 spans .64-.127; usable .65-.126 gives 62 hosts. 192.168.10.25/28 spans .16-.31, so its network is .16. 172.17.128.0/21 spans 172.17.128.0-172.17.135.255; .128.255 and .135.0 are valid interior hosts, but .135.255 is broadcast. /27 gives 32 total and 30 usable, not 32 usable.

Question 242 | NS0589

Which OSI layer is responsible for establishing, maintaining, and ending communication sessions?

A. Transport Layer

B. Session Layer

C. Application Layer

D. Presentation Layer

Hint

Match the requested scope or data unit to the layer duties in the note; distinguish hop delivery from end-to-end process delivery.

Answer B: Session layer

The stem explicitly specifies communication sessions, matching the OSI session role rather than merely a TCP connection. NET19 assigns dialog management and checkpoints to that layer. Transport serves process endpoints, application supplies services and presentation handles representations. B is therefore the specific reference-model lifecycle role.

Why each choice is right or wrong

A - Incorrect: Transport connection state is distinct from the explicitly named OSI session/dialog lifecycle.

B - Correct: Session manages dialogs and their setup, maintenance and recovery/end lifecycle.

C - Incorrect: Application supplies user/application network services rather than the distinct session-layer lifecycle.

D - Incorrect: Presentation translates/compresses/encrypts representations instead of managing dialogs.

Primary note proof

Study-note section NET19

> OSI session roles establish/manage dialogs and can coordinate checkpoints so transfer resumes after interruption. Presentation roles translate encodings and handle compression/encryption. Compression reduces representation size; encryption hides content and need not shrink it. Application protocols provide services directly to applications. Practical implementations distribute these functions differently; TLS is not proof of a separate physical presentation-layer device.

Study-note section NET18

> TCP establishes state with SYN, SYN+ACK, then ACK. SYN consumes one sequence position even with no application bytes. An acknowledgment states the next expected sequence number. For client ISN=395 and server ISN=260: client sends SYN seq395; server sends SYN+ACK seq260 ack396; client sends ACK seq396 ack261. Later byte counts advance sequence numbers. FIN also consumes one sequence position.

Question 243 | NS0590

A bus topology network has 20 nodes. If the main cable breaks, what happens?

A. Only the two nodes nearest the break are affected

B. The network continues to function normally

C. The entire network goes down

D. Only the node that caused the break is disconnected

Hint

Draw the links and identify shared components, alternate paths and the effect of the specified failure or growth requirement.

Answer C: A main-backbone break can disrupt the whole basic bus segment

In the conventional single-backbone bus assumed by these options, a main-cable break disrupts the shared segment, affecting the network rather than just one endpoint. NET08 qualifies the physical mechanism as an unterminated break. Redundant segmentation or protected designs are not specified, so C expresses the standard basic-bus failure consequence.

Why each choice is right or wrong

A - Incorrect: A main-backbone fault affects shared signaling, not merely the two closest nodes.

B - Incorrect: A broken unterminated backbone does not preserve normal basic-bus operation.

C - Correct: The shared basic bus segment can fail as a whole when its main backbone is broken.

D - Incorrect: A backbone break differs from an isolated endpoint spur failure and need not be limited to one node.

Primary note proof

Study-note section NET08

> Bus uses a shared backbone; an unterminated break can disrupt the segment. Star connects endpoints through a central device: one edge failure isolates that endpoint, whereas central failure affects the star. Ring forms a loop; basic single rings are vulnerable to a break, while protected dual rings differ. Token passing is associated with Token Ring but is an access method, not a necessary property of every ring. Tree is hierarchical; hybrid combines arrangements.

Question 244 | NS0591

Synchronous data transmission differs from asynchronous in that synchronous transmission:

A. Uses start and stop bits for each data chunk

B. Sends data continuously with sender and receiver using the same clock

C. Is always slower than asynchronous

D. Cannot transmit binary data

Hint

Use the cited note definitions to identify the requested function or scope, then check each alternative against that same rule.

Answer B: Ongoing synchronized clock recovery rather than per-character start/stop

NET06 contrasts character start/stop framing with ongoing clock recovery in synchronous transmission. B is the intended synchronized-transfer description; “same clock” should mean synchronized timing, not necessarily a single physical clock device. The note gives no universal speed ordering, and both methods can transmit digital/binary data.

Why each choice is right or wrong

A - Incorrect: Per-character start/stop bits describe character-oriented asynchronous serial transmission.

B - Correct: Synchronous transfer maintains coordinated timing through ongoing clock recovery rather than character start/stop framing.

C - Incorrect: No universal slower-than-asynchronous rule follows from the timing method.

D - Incorrect: Synchronous framing can carry binary data; the timing convention does not prohibit it.

Primary note proof

Study-note section NET06

> Simplex is one way, half duplex alternates directions, and full duplex permits simultaneous sending/receiving. A walkie-talkie is half duplex; a telephone conversation uses full duplex. Question 245 | NS0592

What is the PRIMARY function of the Network Layer (Layer 3)?

A. Providing physical transmission of bits

B. Error detection and MAC addressing

C. End-to-end routing of data between different networks using IP addresses

D. Establishing communication sessions between applications

Hint

Match the requested scope or data unit to the layer duties in the note; distinguish hop delivery from end-to-end process delivery.

Answer C: Logical IP addressing and routing across networks

NET12 gives network-layer logical addressing and routing; NET11 explains forwarding IP packets among networks by destination prefixes. C directly states that responsibility. The other options assign physical signaling, link MAC/error detection and session-dialog management, which belong to different model layers.

Why each choice is right or wrong

A - Incorrect: Transporting raw physical bits/symbols is the physical-layer function.

B - Incorrect: MAC addressing and hop frame error detection are data-link responsibilities.

C - Correct: Network-layer logical addressing and routing carry IP packets between networks.

D - Incorrect: Establishing application dialogs is a session-layer role rather than IP routing.

Primary note proof

Study-note section NET11

> Routers forward IP packets between networks using destination prefixes and next hops. They separate broadcast domains and normally do not forward local link broadcasts. A default gateway is usually a router, while a protocol gateway can translate application formats; therefore a gateway is not inherently a device that implements every OSI layer.

Study-note section NET12

> Sending proceeds from application data to transport segment/datagram, network packet, link frame and physical bits/symbols; receiving reverses the order. Each layer serves the layer above. A router removes a received link frame, inspects IP, and creates a new link frame for the next hop. MAC addresses usually change across routed hops; end-to-end IP addresses ordinarily remain until translation.

Study-note section NET19

Question 246 | NS0593

Which of the following IPv4 addresses is INVALID?

A. 192.168.0.1

B. 10.0.0.255

C. 172.16.254.1

D. 10.256.0.1

Hint

Separate address width, syntax, reserved scope and the supplied prefix or historical classful convention.

Answer D: 10.256.0.1 has an impossible octet

An IPv4 decimal octet must fit eight bits, from 0 through 255. D has 256 and is therefore syntactically invalid. A-C each meet that range condition. B's .255 ending alone does not establish a broadcast without a prefix, so it cannot be rejected merely by its last octet.

Why each choice is right or wrong

A - Incorrect: All four octets are within 0-255, so this notation is valid.

B - Incorrect: Every octet is valid; a .255 ending alone does not determine broadcast status without a prefix.

C - Incorrect: All four values fit eight-bit octets and form valid dotted-decimal notation.

D - Correct: The second octet 256 exceeds the maximum representable eight-bit value 255.

Primary note proof

Study-note section NET22

Write IPv4 as four decimal octets 0-255, or as 32 binary bits. Use weights 128,64,32,16,8,4,2,1 within each octet. Thus 11000001 10000011 00011011 11111111 is 193.131.27.255. A value such as 257 is impossible. Syntactic validity differs from assignability: an address ending .0 or .255 can be a host under some prefixes.

Question 247 | NS0594

In IPv6, addresses are how many bits long?

A. 32 bits

B. 64 bits

C. 96 bits

D. 128 bits

Hint

Separate address width, syntax, reserved scope and the supplied prefix or historical classful convention.

Answer D: 128 bits

NET23 explicitly gives IPv6 addresses a 128-bit width. IPv4 uses 32 bits; 64 may describe a common subnet interface boundary but is not the whole IPv6 address length. Ninety-six bits is likewise not the full width. D therefore answers the requested address size.

Why each choice is right or wrong

A - Incorrect: Thirty-two bits is the IPv4 address width, not IPv6.

B - Incorrect: Sixty-four bits is not the complete IPv6 address width.

C - Incorrect: Ninety-six bits does not match the specified 128-bit IPv6 address length.

D - Correct: IPv6 addresses contain 128 bits as explicitly stated in NET23.

Primary note proof

Study-note section NET23

> IPv6 has 128-bit hexadecimal addresses, flexible prefixes and no IPv4-style broadcast. Sources, not routers, fragment IPv6 packets. IPv6 does not automatically encrypt traffic or make authentication unnecessary. Compare IPv6's larger 128-bit address space and encryption support separately; specify the property being evaluated.

Study-note section NET16

> IP supplies connectionless best-effort packet delivery, not end-to-end ordering or retransmission. IPv4 addresses are 32 bits. Its minimum header is 20 bytes and can grow to 60 bytes; it is not a 32-bit header. IHL counts 32-bit words; total length includes header and payload. TTL limits lifetime across routers; the protocol field identifies TCP, UDP or another upper-layer protocol.

Study-note section NET-S06

> A common IPv6 unicast subnet uses a 64-bit subnet prefix and a 64-bit interface identifier. This split does not make the complete address 64 bits: it remains 128 bits. Special uses and explicitly different prefix lengths must be considered separately.

Question 248 | NS0595

A bridge decides whether to forward a frame to another network segment by examining the:

A. IP address in the packet header

B. Port number in the segment header

C. Source and destination MAC addresses

D. TTL (Time to Live) field

Hint

Compare signal repetition, frame forwarding, packet routing and policy enforcement using the stated device or traffic assumptions.

Answer C: Learn source MACs and forward according to destination MAC

A bridge learns which sources are reachable through each port and consults the destination MAC when forwarding/filtering a frame. C names the relevant link addresses. IP, transport ports and TTL belong to higher-layer packet/segment processing, not the ordinary bridge forwarding decision. Unknown destinations may be flooded, so learning does not imply always-one-port forwarding.

Why each choice is right or wrong

A - Incorrect: Destination IP prefixes drive routing, not ordinary layer-2 bridge frame forwarding.

B - Incorrect: Transport ports identify process endpoints and are not the bridge MAC-table lookup key.

C - Correct: Source MAC informs learning and destination MAC informs forwarding/filtering to the appropriate segment.

D - Incorrect: TTL is an IP header field used in routed packet lifetime, not ordinary bridging.

Primary note proof

Study-note section NET10

> A bridge or ordinary Ethernet switch operates at layer 2. It learns source-MAC-to-port mappings, looks up the destination, forwards a known unicast to its port, filters it if the destination is on the incoming segment, and floods an unknown unicast or broadcast within its VLAN. A switch does not always send only to one destination port. Wireless access points normally bridge wireless and wired link-layer traffic.

Study-note section NET17

> Ports identify transport endpoints; the application can choose a transport and request socket buffer sizes, subject to OS limits. A TCP connection is identified by source/destination IP and source/destination port, with TCP understood. IPv4 protocol numbers identify upper protocols; 80 is a usual HTTP port, not an IP protocol number. Clients often use ephemeral ports. SCTP is a reliable message-oriented transport with multiple streams.

Study-note section NET16

IP supplies connectionless best-effort packet delivery, not end-to-end ordering or retransmission. IPv4 addresses are 32 bits. Its minimum header is 20 bytes and can grow to 60 bytes; it is not a 32-bit header. IHL counts 32-bit words; total length includes header and payload. Data Communication & Networking review questions · Question 24

Question 249 | NS0596

Circuit switching guarantees bandwidth for the duration of a call. What is the main DISADVANTAGE of this?

A. High latency during transmission

B. Bandwidth is wasted when no data is actively being transmitted

C. Packets may arrive out of order

D. It cannot support voice communication

Hint

Compare signal repetition, frame forwarding, packet routing and policy enforcement using the stated device or traffic assumptions.

Answer B: Reserved bandwidth can be wasted during silence

Circuit switching holds resources for the call even while endpoints are silent, so unused reservation cannot be statistically shared as packet traffic would be. B gives that cost. Circuit switching does not inherently deliver packets out of order or prevent voice transmission; traditional telephone calls are a standard example.

Why each choice is right or wrong

A - Incorrect: Reserved circuits can offer predictable transfer behavior; setup cost is distinct from universally high transfer latency.

B - Correct: Capacity remains reserved during silence and can be wasted when no data is sent.

C - Incorrect: Independent out-of-order packet routing is not the defining reserved-circuit disadvantage.

D - Incorrect: Traditional telephone calls are the note's standard circuit-switching example, so voice is supported.

Primary note proof

Study-note section NET31

> Circuit switching sets up a path with reserved resources, transfers data, then releases it. Predictable allocated bandwidth trades against setup/blocking and wasted reservation during silence. A traditional telephone call is the standard example. Packet switching divides data into packets that share links statistically; queueing can add variable delay and loss. This does not make modern voice-over-packet impossible: buffering, scheduling and capacity planning manage it.

Question 250 | NS0597

Under the textbook direct line-of-sight wireless-link convention, which option gives the most complete set of listed technologies whose direct path can be blocked by buildings or terrain? Treat radio waves as the broad category rather than assuming every radio propagation mode needs line of sight.

A. Radio waves

B. Microwaves

C. Infrared

D. Both B and C

Hint

Compare the signal mechanism, medium properties or transmission direction against the definitions and stated physical assumptions.

Answer D: Microwave and infrared under the conventional line-of-sight assumption

Conventional directional microwave links need suitable path visibility, and infrared generally does not penetrate walls. Obstacles can therefore interrupt the direct links specified here. Both individual technologies fit, so the combined option is the complete response. Radio waves is a broader physical category that includes microwave but also other propagation modes; the question does not assert that all radio links share the same line-of-sight restriction.

Why each choice is right or wrong

A - Incorrect: The broad radio category includes propagation modes beyond the specified line-of-sight comparison.

B - Incorrect: Microwave fits the stated direct-link case, but this alone omits infrared.

C - Incorrect: Infrared fits the stated obstructed-direct-path case, but this alone omits microwave.

D - Correct: Both microwave and infrared fit the specified comparison, making this the complete set.

Primary note proof

Study-note section NET07

> Radio, microwave and infrared are unguided media. Ground waves follow Earth, sky waves can reflect from ionized layers, and line-of-sight paths require suitable visibility. Microwaves are radio waves in the broader physical classification. Infrared generally does not penetrate walls. Directionality depends on antennas: omnidirectional means broad azimuth coverage, not equal radiation in every 3-D direction. Legacy Ethernet straight-through cables join unlike MDI/MDI-X roles; crossover joins like roles, such as PC-PC or switch-switch. Auto-MDI-X can remove that requirement.

Question 251 | NS0598

What does CIDR stand for, and what problem did it solve?

A. Classless Inter-Domain Routing; it solved address wastage in classful addressing

B. Classful Internet Domain Routing; it solved packet loss

C. Centralized IP Domain Routing; it solved routing loops

D. Classless Internet Data Routing; it solved latency in WANs

Hint

Apply the cited definitions to the stated scope; for calculations, derive the result from the supplied prefix, bit count or resource rule.

Answer A: Classless Inter-Domain Routing; flexible prefixes reduce rigid class allocation waste

CIDR replaces rigid class allocation. Flexible prefixes allow blocks sized to requirements and aggregation of aligned blocks, addressing waste from fixed historical class sizes. The other expansions are incorrect and their proposed packet-loss, loop or latency cures are not the defined purpose.

Why each choice is right or wrong

A - Correct: This gives the correct expansion and relates flexible prefix allocation to avoiding rigid class-size waste.

B - Incorrect: Classful Internet Domain Routing is the wrong expansion, and CIDR is not defined as a packet-loss cure.

C - Incorrect: Centralized IP Domain Routing is not the acronym expansion or the stated mechanism.

D - Incorrect: Classless Internet Data Routing is incorrect; CIDR is not defined as a general WAN-latency cure.

Primary note proof

Study-note section NET28

> CIDR, Classless Inter-Domain Routing, replaces rigid class allocation and supports aggregation. Combine contiguous aligned blocks sharing leading bits; unrelated adjacent-looking labels may not aggregate cleanly. Four consecutive /26 blocks covering a /24 summarize to /24. More-specific routes must remain available where the aggregate would otherwise send traffic to the wrong next hop.

Study-note section NET26

> For H hosts, choose the smallest h satisfying 2^h-2≥H, then p=32-h. For 24 hosts use /27; 52 or 57 use /26; 100 use /25; 500 use /23. For at least six equal subnets choose b=3. A Class C /24 split to /27 yields eight subnets. Always check both the number of subnets and the host capacity.

Question 252 | NS0599

How many subnets are created when you borrow 5 bits from the host portion of a Class B network?

A. 5

B. 16

C. 32

D. 64

Hint

Apply the cited definitions to the stated scope; for calculations, derive the result from the supplied prefix, bit count or resource rule.

Answer C: 32 subnets

Borrowing five bits yields 2^5=32 equal subnets under modern counting. The parent Class B /16 would become /21, but the direct subnet count only needs the specified five borrowed bits. NET26 says not to subtract two subnets under modern practice.

Why each choice is right or wrong

A - Incorrect: Five is the number of borrowed bits, not the exponential number of resulting subnet combinations.

B - Incorrect: Sixteen subnets would use four borrowed bits rather than five.

C - Correct: Five borrowed bits have 32 distinct combinations and therefore produce 32 subnets.

D - Incorrect: Sixty-four subnets would require six borrowed bits.

Primary note proof

Study-note section NET26

> To split parent /a into equal /p blocks, borrow b=p-a bits and obtain 2^b subnets. Do not subtract two subnets under modern practice. For a Class B /16 parent split to /19, b=3 gives eight subnets, each with 8192 addresses and 8190 conventional hosts. A /19 alone does not state its parent.

Question 253 | NS0600

The 'forwarding table' in a bridge is also known as the:

A. Routing table

B. ARP table

C. MAC table

D. IP table

Hint

Apply the cited definitions to the stated scope; for calculations, derive the result from the supplied prefix, bit count or resource rule.

Answer C: MAC table

The bridge forwarding database records MAC-to-port associations learned from source addresses and used for destination lookups. MAC table is therefore the matching name. A routing table maps IP prefixes to next hops; ARP associates on-link IPv4 addresses with link addresses. Those are different tables even if one device maintains several of them.

Why each choice is right or wrong

A - Incorrect: Routing tables describe destination IP prefixes and next hops rather than bridge MAC-to-port mappings.

B - Incorrect: ARP caches associate IPv4 next hops with link addresses, not MAC addresses with bridge ports.

C - Correct: The bridge's learned source-MAC-to-port forwarding database is its MAC table.

D - Incorrect: IP table does not name the layer-2 learned MAC forwarding database described in NET10.

Primary note proof

Study-note section NET-S06

> A bridge or switch's MAC address table is its learned forwarding database: it associates MAC addresses with ports for frame forwarding. It differs from an ARP cache, which associates an IPv4 next hop with a link address, and from a routing table, which selects next hops for IP prefixes.

Study-note section NET10

> A bridge or ordinary Ethernet switch operates at layer 2. It learns source-MAC-to-port mappings, looks up the destination, forwards a known unicast to its port, filters it if the destination is on the incoming segment, and floods an unknown unicast or broadcast within its VLAN. A switch does not always send only to one destination port. Wireless access points normally bridge wireless and wired link-layer traffic.

Question 254 | NS0601

Which layer of the OSI model is responsible for defining voltage levels, cable specifications, and how bits are physically transmitted?

A. Data Link Layer

B. Network Layer

C. Physical Layer

D. Transport Layer

Hint

Apply the cited definitions to the stated scope; for calculations, derive the result from the supplied prefix, bit count or resource rule.

Answer C: Physical layer

Voltage, cable/interface characteristics and signal transport are the physical-layer scope in NET09. Data-link functions operate on frames and MAC access, network handles IP routing and transport handles process delivery. The wording explicitly asks how bits are physically represented and carried, so C is the corresponding layer.

Why each choice is right or wrong

A - Incorrect: Data link manages frames/access rather than defining the physical voltage and cable interface.

B - Incorrect: Network manages logical addressing/routing rather than electrical signal specifications.

C - Correct: Physical-layer specifications include connectors, signaling, voltage and timing.

D - Incorrect: Transport supplies process delivery rather than cable and voltage definitions.

Primary note proof

Study-note section NET09

> A NIC supplies a computer’s network interface and commonly implements both physical and link functions. Calling a NIC a physical interface does not mean all its functions are layer 1. Physical specifications include connectors, signaling, voltage, timing and physical coding/modulation; the PHY interface to MAC handles hardware signaling.

Study-note section NET12

> Sending proceeds from application data to transport segment/datagram, network packet, link frame and physical bits/symbols; receiving reverses the order. Each layer serves the layer above. A router removes a received link frame, inspects IP, and creates a new link frame for the next hop. MAC addresses usually change across routed hops; end-to-end IP addresses ordinarily remain until translation.

Question 255 | NS0602

In a star topology, what happens if the central hub fails?

A. Only the hub's nearest neighbor is affected

B. The entire network fails

C. The network continues operating in bus mode

D. Nodes automatically reconnect in ring topology

Hint

Apply the cited definitions to the stated scope; for calculations, derive the result from the supplied prefix, bit count or resource rule.

Answer B: The dependent star loses connectivity when its center fails

In a basic star every endpoint depends on the central hub for communication with other endpoints. Failure of that common center therefore affects the whole star. No alternate center or automatic topology reconfiguration is specified; the network does not become a bus or ring merely because the hub stops functioning.

Why each choice is right or wrong

A - Incorrect: The center serves all star endpoints, so its failure is not limited to the nearest neighbor.

B - Correct: All endpoints depend on the central hub, so the basic star loses inter-endpoint connectivity.

C - Incorrect: A hub failure does not physically or logically rewire the star into an operational bus.

D - Incorrect: No automatic ring reconnection mechanism follows from the basic star topology.

Primary note proof

Study-note section NET08

> Bus uses a shared backbone; an unterminated break can disrupt the segment. Star connects endpoints through a central device: one edge failure isolates that endpoint, whereas central failure affects the star. Ring forms a loop; basic single rings are vulnerable to a break, while protected dual rings differ. Token passing is associated with Token Ring but is an access method, not a necessary property of every ring. Tree is hierarchical; hybrid combines arrangements.

Question 256 | NS0603

What type of noise CANNOT be completely eliminated because it is caused by the random motion of electrons due to temperature?

A. Crosstalk

B. Impulse noise

C. Thermal noise

D. Intermodulation noise

Hint

Apply the cited definitions to the stated scope; for calculations, derive the result from the supplied prefix, bit count or resource rule.

Answer C: Thermal noise

The stated cause-random motion associated with temperature-is thermal noise in NET06. Crosstalk is neighboring-channel coupling and impulse noise is a short disturbance. D names a different noise phenomenon not defined by random thermal motion. The cause identifies C without requiring a claim that all other real noise can be perfectly eliminated.

Why each choice is right or wrong

A - Incorrect: Crosstalk arises from coupling between nearby communication channels, not the stated thermal-motion cause.

B - Incorrect: Impulse noise is a short disturbance rather than persistent random thermal motion.

C - Correct: Thermal noise is explicitly caused by random thermal motion, matching the temperature-dependent clue.

D - Incorrect: This option does not match the random thermal-motion definition supplied in NET06.

Primary note proof

Study-note section NET06

> Attenuation reduces signal strength. Distortion changes shape, often because frequencies have different delays. Noise adds unwanted energy: thermal noise comes from random thermal motion, crosstalk leaks from nearby channels, and impulse noise is a short disturbance. Amplifiers amplify noise too; digital repeaters regenerate decisions but cannot reconstruct every corrupted bit.

Study-note section NET-S07

> Intermodulation distortion occurs when multiple signals interact through a nonlinear component and generate unwanted combination-frequency products. Its mechanism differs from random thermal motion, adjacent-channel leakage and an isolated impulse disturbance.

Question 257 | NS0604

Which IP address class has a first-octet range of 128-191?

A. Class A

B. Class B

C. Class C

D. Class D

Hint

Apply the cited definitions to the stated scope; for calculations, derive the result from the supplied prefix, bit count or resource rule.

Answer B: Class B

NET22 gives first-octet 128-191 for historical Class B, corresponding to leading bits 10. Ordinary Class A is 1-126, Class C is 192-223 and Class D uses leading 1110 for multicast. Since the question explicitly asks classes, the historical categorization is appropriate rather than inferring a current CIDR prefix.

Why each choice is right or wrong

A - Incorrect: Ordinary historical Class A uses first octets 1-126 rather than 128-191.

B - Correct: Historical Class B spans first octets 128-191, with leading bits 10.

C - Incorrect: Historical Class C spans 192-223, above the supplied interval.

D - Incorrect: Class D multicast begins with 1110, outside the Class B 128-191 interval.

Primary note proof

Study-note section NET22

> Historical classes use leading patterns: A 0 with /8, B 10 with /16, C 110 with /24; D 1110 is multicast and E 1111 reserved. Ordinary class-A first octets are 1-126 because 0 and 127 have special uses. B spans 128-191 and C 192-223. Default usable counts are 2^24-2, 2^16-2 and 254. Modern CIDR requires the actual prefix and overrides class defaults.

Question 258 | NS0605

The Session Layer's 'checkpointing' feature means that it:

A. Encrypts data to protect it from interception

B. Compresses data to reduce transmission time

C. Saves the state of a communication session at regular intervals so it can be resumed after interruption

D. Translates data between different character encoding formats

Hint

Apply the cited definitions to the stated scope; for calculations, derive the result from the supplied prefix, bit count or resource rule.

Answer C: Checkpoint state supports resuming after interruption

A checkpoint records recoverable progress/state so interrupted work can resume from an agreed point. NET19 assigns such coordination to the session role. Encryption, compression and encoding translation belong to representation handling and do not by themselves preserve resumable dialog progress. C matches the checkpoint recovery purpose.

Why each choice is right or wrong

A - Incorrect: Encryption conceals content and does not define saving resumable session progress.

B - Incorrect: Compression reduces representation size rather than recording recovery checkpoints.

C - Correct: Saving agreed progress/state enables continuation after interruption rather than restarting from the beginning.

D - Incorrect: Encoding translation changes representation format, not checkpoint recovery state.

Primary note proof

Study-note section NET19

> OSI session roles establish/manage dialogs and can coordinate checkpoints so transfer resumes after interruption. Presentation roles translate encodings and handle compression/encryption. Compression reduces representation size; encryption hides content and need not shrink it. Application protocols provide services directly to applications. Practical implementations distribute these functions differently; TLS is not proof of a separate physical presentation-layer device.

Question 259 | NS0606

Which of the following is a De Jure standard?

A. A manufacturer's proprietary cable format adopted industry-wide

B. A standard officially approved by ISO or IEEE

C. A standard developed by a single corporation without regulatory approval

D. A protocol widely used but never formally documented

Hint

Apply the cited definitions to the stated scope; for calculations, derive the result from the supplied prefix, bit count or resource rule.

Answer B: A formally approved standard

NET03 defines de jure by formal approval. B directly states official approval, while industry adoption without that approval is de facto. Corporate origin does not alone decide status, but C specifically lacks formal approval and D emphasizes informal use. Therefore B is the option establishing the defining approval condition.

Why each choice is right or wrong

A - Incorrect: Widespread adoption alone demonstrates de facto use rather than formal de jure approval.

B - Correct: Official approval matches the defining de jure criterion in NET03.

C - Incorrect: A corporate format without the stated formal approval does not meet the offered de jure definition.

D - Incorrect: Widespread informal use without formal approval is de facto rather than de jure.

Primary note proof

Study-note section NET03

> Protocol syntax defines message structure, semantics defines field meanings, and timing defines when/how fast exchanges occur. A standard supports interoperability. De facto means established through use; de jure means formally approved. ISO develops international standards; IEEE develops LAN standards such as 802.3 and 802.11; ITU-T develops telecommunications standards. ANSI coordinates US standards, EIA is associated with interface standards, and FCC is a regulator.

Question 260 | NS0607

Parallel data transmission sends multiple bits simultaneously. Its key DISADVANTAGE compared to serial transmission is:

A. It is always slower

B. It cannot be used for digital data

C. It requires more transmission lines and can suffer from interference between lines

D. It only works over fiber-optic cable

Hint

Apply the cited definitions to the stated scope; for calculations, derive the result from the supplied prefix, bit count or resource rule.

Answer C: More conductors and interline impairments

Parallel transfer needs several conductors to carry simultaneous bits. Those paths can experience skew and neighboring-channel coupling, as NET06's impairment definitions explain. C states the extra-line and interference burden. No universal slower-speed claim, inability to carry digital data or fiber-only restriction follows from parallel transmission.

Why each choice is right or wrong

A - Incorrect: Parallel is not universally slower; performance depends on implementation, distance and synchronization.

B - Incorrect: Parallel transmission can carry digital bits simultaneously, exactly as the stem states.

C - Correct: Multiple conductors add wiring and can suffer skew or coupled interference between adjacent lines.

D - Incorrect: Parallel transmission is not restricted to fiber and commonly concerns multiple electrical conductors.

Primary note proof

Study-note section NET06

> Simplex is one way, half duplex alternates directions, and full duplex permits simultaneous sending/receiving. A walkie-talkie is half duplex; a telephone conversation uses full duplex. Serial sends sequential bits; parallel uses multiple conductors and may suffer skew. Character-oriented asynchronous serial adds start/stop bits; synchronous framing uses ongoing clock recovery. Neither is synonymous with browser asynchronous requests.

Study-note section NET06

> Attenuation reduces signal strength. Distortion changes shape, often because frequencies have different delays. Noise adds unwanted energy: thermal noise comes from random thermal motion, crosstalk leaks from nearby channels, and impulse noise is a short disturbance. Amplifiers amplify noise too; digital repeaters regenerate decisions but cannot reconstruct every corrupted bit.

Question 261 | NS0608

A packet-switching network may be UNSUITABLE for real-time voice communication because:

A. It requires a dedicated circuit

B. Variable latency and possible packet loss can disrupt real-time audio

C. It cannot carry voice signals

D. All bandwidth is reserved, leaving none for voice

Hint

Apply the cited definitions to the stated scope; for calculations, derive the result from the supplied prefix, bit count or resource rule.

Answer B: Variable delay and packet loss can disturb real-time audio

Real-time audio is sensitive to late or missing data. Packet networks may introduce variable queueing delay and loss, so B gives a plausible suitability issue. Modern voice over packets remains possible with buffering, scheduling and capacity planning; it is not intrinsically prohibited or dependent on reserved circuits.

Why each choice is right or wrong

A - Incorrect: Datagram packet switching does not require a dedicated circuit before every communication.

B - Correct: Variable queueing latency and loss can make audio arrive late or incomplete.

C - Incorrect: NET31 explicitly allows voice over packets with suitable engineering.

D - Incorrect: Statistical link sharing differs from reserving all bandwidth for established circuits.

Primary note proof

Study-note section NET31

> Circuit switching sets up a path with reserved resources, transfers data, then releases it. Predictable allocated bandwidth trades against setup/blocking and wasted reservation during silence. A traditional telephone call is the standard example. Packet switching divides data into packets that share links statistically; queueing can add variable delay and loss. This does not make modern voice-over-packet impossible: buffering, scheduling and capacity planning manage it.

Study-note section NET17

> TCP offers a reliable ordered byte stream using sequence numbers, acknowledgments, retransmission and windows. Flow control protects the receiver; congestion control protects network capacity. UDP sends independent datagrams with ports and a checksum but no built-in

setup, delivery guarantee, retransmission or ordering. Live interactive traffic may choose UDP when late data is less useful than lost data. Application protocols can add reliability over UDP.

Question 262 | NS0609

For a Class C network subnetted to /27, how many usable hosts per subnet are available?

A. 32

B. 30

C. 28

D. 62

Hint

Apply the cited definitions to the stated scope; for calculations, derive the result from the supplied prefix, bit count or resource rule.

Answer B: 30 usable hosts

A /27 leaves five host bits regardless of the historical class of its parent. Those bits provide 32 total addresses. On an ordinary broadcast subnet, network and broadcast reserve two, leaving 30 usable host addresses. Parent classification matters for subnet counting, not this explicit-prefix host calculation.

Why each choice is right or wrong

A - Incorrect: Thirty-two is the total address count before reserving network and broadcast.

B - Correct: Five host bits give 32−2=30 ordinary usable hosts.

C - Incorrect: Twenty-eight does not follow from the stated five host bits and two standard reservations.

D - Incorrect: Sixty-two usable hosts corresponds to /26 rather than the supplied /27.

Primary note proof

Study-note section NET25

For ordinary broadcast LANs let h=32-p. Total addresses=2^h; usable hosts=2^h-2, reserving network and directed broadcast. Find the changing octet’s increment as 256-mask octet, round the address down to a multiple, and extend through the next boundary minus one.

Question 263 | NS0610

Which routing type sends data to the NEAREST of multiple hosts sharing the same IP address?

A. Multicast

B. Broadcast

C. Unicast

D. Anycast

Hint

Apply the cited definitions to the stated scope; for calculations, derive the result from the supplied prefix, bit count or resource rule.

Answer D: Anycast

Anycast routes to one member of a set sharing the address, typically the nearest by routing metrics. That is not necessarily geographic distance. Multicast targets a subscribed group, broadcast all in scope and ordinary unicast a single designated destination. D uniquely matches the shared-address nearest-member rule.

Why each choice is right or wrong

A - Incorrect: Multicast targets a subscribed group rather than selecting only one nearest shared-address member.

B - Incorrect: Broadcast targets all destinations within its scope, not the nearest member.

C - Incorrect: Ordinary unicast targets one designated destination without the shared-address nearest-member semantics.

D - Correct: Anycast selects one shared-address member, normally nearest according to routing metrics.

Primary note proof

Study-note section NET30

> Flooding sends copies on eligible outgoing links with duplicate/lifetime controls; random walk picks a neighbor probabilistically. Unicast targets one destination, broadcast all in a scope, multicast a subscribed group and anycast one member sharing an address, normally nearest under routing metrics. Multi-destination packets can list multiple targets; this is not necessarily identical to broadcast. Group multicast trees use mechanisms such as reverse-path checks; Ethernet spanning tree is a different layer-2 mechanism.

Question 264 | NS0611

The term 'coaxial' refers to the fact that the cable's inner conductor and outer shield:

A. Are made of the same conductive material

B. Share the same central axis

C. Carry signals in opposite directions

D. Are both covered in plastic insulation

Hint

Apply the cited definitions to the stated scope; for calculations, derive the result from the supplied prefix, bit count or resource rule.

Answer B: The conductor and shield share an axis

The name coaxial refers to a common geometric axis for the inner conductor and surrounding shield. NET07 states this directly. Neither identical material, opposite signal directions nor a particular insulation covering defines the term; those are separate construction or usage details rather than the shared-axis relationship.

Why each choice is right or wrong

A - Incorrect: The definition concerns geometric arrangement, not whether both conductive parts use the same material.

B - Correct: The inner conductor and outer shield share a central axis, giving the coaxial name.

C - Incorrect: Opposite signal directions are not the defining common-axis geometry.

D - Incorrect: Insulation details do not define coaxial; sharing an axis does.

Primary note proof

Study-note section NET07

> Twisted pairs reduce coupled interference; UTP has no added shield and STP adds shielding. Coax has an inner conductor and outer shield sharing an axis. Fiber guides light and resists electromagnetic interference; it supports high capacity and long reach, but requires suitable optics and installation. Exact speed, cost and reach depend on the specification, not the material alone. Fiber can still be tapped.

Question 265 | NS0612

Which option best describes a protocol-translating gateway joining unlike networked systems?

A. A device that boosts signal strength over long distances

B. A device that connects networks using the same protocol

C. A device that connects two or more networks using different protocols, topologies, or architectures

D. A device that filters traffic based on MAC addresses

Hint

Apply the cited definitions to the stated scope; for calculations, derive the result from the supplied prefix, bit count or resource rule.

Answer C: A device that connects two or more networks using different protocols, topologies, or architectures

Gateway has several networking meanings. A default IP gateway is commonly a router, while a protocol gateway translates between unlike protocols or application formats. The question asks for that translating role, so the option joining unlike systems fits. Signal regeneration belongs to repeaters, same-protocol routing does not require translation, and MAC-based filtering describes bridging or switching rather than protocol conversion.

Why each choice is right or wrong

A - Incorrect: Signal regeneration/strength extension is a repeater function rather than either gateway meaning defined here.

B - Incorrect: Connecting networks using the same protocol describes routing without the required protocol translation.

C - Correct: A protocol gateway joins unlike systems through the translation required by the stated scope.

D - Incorrect: MAC-address frame filtering describes bridging/switching rather than the gateway distinction in NET11.

Primary note proof

Study-note section NET11

> Routers forward IP packets between networks using destination prefixes and next hops. They separate broadcast domains and normally do not forward local link broadcasts. A default gateway is usually a router, while a protocol gateway can translate application formats; therefore a gateway is not inherently a device that implements every OSI layer.

Study-note section NET10

> A bridge or ordinary Ethernet switch operates at layer 2. It learns source-MAC-to-port mappings, looks up the destination, forwards a known unicast to its port, filters it if the destination is on the incoming segment, and floods an unknown unicast or broadcast within its VLAN. A switch does

not always send only to one destination port. Wireless access points normally bridge wireless and wired link-layer traffic.

Study-note section NET09

A repeater regenerates layer-1 signals without inspecting destination addresses. An active hub is a multiport repeater: it repeats incoming signals onto other ports, placing half-duplex endpoints in one collision domain. A passive hub is a connector. A hub neither learns MAC addresses nor eliminates collisions. An endpoint such as a network printer consumes services; routers, hubs and access points are intermediary devices.

An organization is assigned the Class A IP address 10.200.240.4. What is the network address?

A. 10.0.0.0

B. 10.200.0.0

C. 10.200.240.0

D. 0.0.0.0

Hint

Apply the cited definitions to the stated scope; for calculations, derive the result from the supplied prefix, bit count or resource rule.

Answer A: 10.0.0.0 under the explicitly requested Class A default

Because the question explicitly assigns Class A, its historical default /8 supplies the intended network/host boundary. Keep first octet 10 and zero the remaining 24 host bits to obtain 10.0.0.0. If a different CIDR prefix were supplied it would override the default, but none is given in this class-specific question.

Why each choice is right or wrong

A - Correct: The Class A /8 default keeps first octet 10 and clears the remaining three octets.

B - Incorrect: This assumes a /16 boundary instead of the explicitly invoked Class A /8 default.

C - Incorrect: This assumes /24, retaining host bits that the Class A default would clear.

D - Incorrect: Clearing the network octet too loses the assigned Class A network identifier 10.

Primary note proof

Study-note section NET22

> Historical classes use leading patterns: A 0 with /8, B 10 with /16, C 110 with /24; D 1110 is multicast and E 1111 reserved. Ordinary class-A first octets are 1-126 because 0 and 127 have special uses. B spans 128-191 and C 192-223. Default usable counts are 2^24-2, 2^16-2 and 254. Modern CIDR requires the actual prefix and overrides class defaults.

Study-note section NET24

> Compute network=address AND mask. Host bits zero identify the block start; host bits one give broadcast. With 172.16.28.252/20, the third octet is grouped in blocks of 16, so the network is 172.16.16.0 and broadcast 172.16.31.255. A written host/prefix such as 172.105.180.0/21 need not be an aligned block label: masking yields 172.105.176.0/21.

Question 267 | NS0614

UTP cable is most susceptible to which type of interference?

A. Thermal noise only

B. Electromagnetic interference (EMI) and crosstalk

C. Infrared interference

D. Gamma radiation

Hint

Apply the cited definitions to the stated scope; for calculations, derive the result from the supplied prefix, bit count or resource rule.

Answer B: EMI and crosstalk

UTP is unshielded copper: twisting reduces coupled interference but does not remove all electromagnetic coupling. NET06 identifies crosstalk as leakage from nearby channels. B names the relevant ordinary interference types, whereas thermal-only excludes other sources and infrared/gamma are not the note's cabling-susceptibility mechanism.

Why each choice is right or wrong

A - Incorrect: Thermal noise is not the only impairment; unshielded pairs can experience coupled electromagnetic interference.

B - Correct: EMI and adjacent-pair/channel crosstalk are relevant to unshielded copper, though twisting reduces coupling.

C - Incorrect: Infrared is an optical/unguided signaling category rather than the stated ordinary copper-coupling issue.

D - Incorrect: Gamma radiation is not the interference mechanism identified for UTP in the supplied note.

Primary note proof

Study-note section NET07

> Twisted pairs reduce coupled interference; UTP has no added shield and STP adds shielding. Coax has an inner conductor and outer shield sharing an axis. Question 268 | NS0615

For a known unicast whose destination is on a different learned switch port in the same VLAN, what is the main forwarding difference between an active hub and an ordinary Ethernet switch?

A. Hubs operate at Layer 3; switches operate at Layer 2

B. Hubs send data to all connected devices; switches send data only to the intended device

C. Hubs use IP addresses; switches use MAC addresses

D. Hubs support fiber-optic; switches do not

Hint

Apply the cited definitions to the stated scope; for calculations, derive the result from the supplied prefix, bit count or resource rule.

Answer B: Hubs send data to all connected devices; switches send data only to the intended device

An active hub repeats incoming signals onto its other ports without examining addresses. A switch learns MAC-to-port mappings and, for the specified known unicast on another port, forwards the frame only to that destination port. Unknown unicasts and broadcasts are different cases and can be flooded. The scope restriction makes the intended contrast accurate without treating selective forwarding as a universal rule for all switch traffic.

Why each choice is right or wrong

A - Incorrect: Hubs are layer-1 repeaters, not layer-3 routers; ordinary switches are layer 2.

B - Correct: In this known-unicast case the hub repeats to other ports, while the switch sends only to the learned destination port.

C - Incorrect: Hubs do not use IP addresses to decide forwarding; they repeat signals without address inspection.

D - Incorrect: Hub versus switch is a signal-repetition versus frame-forwarding distinction; it does not impose the claimed prohibition on optical switch links.

Primary note proof

Study-note section NET10

> A bridge or ordinary Ethernet switch operates at layer 2. It learns source-MAC-to-port mappings, looks up the destination, forwards a known unicast to its port, filters it if the destination is on the incoming segment, and floods an unknown unicast or broadcast within its VLAN. A switch does not always send only to one destination port. Wireless access points normally bridge wireless and wired link-layer traffic.

Study-note section NET-S07

Ethernet switches can have fiber-optic interfaces with suitable optical transceivers. A forwarding role therefore does not impose a copper-only restriction: distinguish what the device does with frames from the physical medium used by its ports.

In multicast routing, data is sent to:

A. All devices on the network regardless of interest

B. A single specific destination

C. The nearest host among multiple hosts sharing an address

D. Only the devices that have expressed interest in receiving the data

Hint

Apply the cited definitions to the stated scope; for calculations, derive the result from the supplied prefix, bit count or resource rule.

Answer D: A subscribed/interested receiver group

NET30 distinguishes multicast group delivery from unicast, broadcast and anycast. Receivers express membership/interest in a group, rather than every network device receiving by definition or only one nearest destination being selected. D matches that destination-set meaning. Delivery still depends on the deployed network's forwarding and membership mechanisms.

Why each choice is right or wrong

A - Incorrect: All devices regardless of interest describes broadcast scope rather than multicast group selection.

B - Incorrect: One specific destination is ordinary unicast rather than a receiver group.

C - Incorrect: One nearest shared-address member is anycast.

D - Correct: Multicast targets a subscribed group of receivers that expressed interest.

Primary note proof

Study-note section NET30

> Flooding sends copies on eligible outgoing links with duplicate/lifetime controls; random walk picks a neighbor probabilistically. Unicast targets one destination, broadcast all in a scope, multicast a subscribed group and anycast one member sharing an address, normally nearest under routing metrics. Multi-destination packets can list multiple targets; this is not necessarily identical to broadcast. Group multicast trees use mechanisms such as reverse-path checks; Ethernet spanning tree is a different layer-2 mechanism.

What IPv4 address class is designed for multicast addressing?

A. Class A

B. Class B

C. Class C

D. Class D

Hint

Apply the cited definitions to the stated scope; for calculations, derive the result from the supplied prefix, bit count or resource rule.

Answer D: Class D

Historical IPv4 Class D begins with bits 1110 and is designated for multicast. Classes A, B and C describe historical unicast network allocations, with differing default prefixes. The question explicitly asks that historical class designation, so D is supported independently of how modern unicast prefixes are allocated.

Why each choice is right or wrong

A - Incorrect: Class A is historical unicast network space rather than the multicast class.

B - Incorrect: Class B is historical unicast space with a /16 default, not multicast.

C - Incorrect: Class C is historical unicast space with a /24 default.

D - Correct: Class D, identified by leading 1110, is designated for IPv4 multicast.

Primary note proof

Study-note section NET22

> Historical classes use leading patterns: A 0 with /8, B 10 with /16, C 110 with /24; D 1110 is multicast and E 1111 reserved. Ordinary class-A first octets are 1-126 because 0 and 127 have special uses. B spans 128-191 and C 192-223. Default usable counts are 2^24-2, 2^16-2 and 254. Modern CIDR requires the actual prefix and overrides class defaults.

Question 271 | NS0618

Which OSI layer provides sequencing, acknowledgments and receiver flow control for end-to-end reliable process delivery, as in TCP?

A. Network Layer

B. Data Link Layer

C. Transport Layer

D. Session Layer

Hint

Apply the cited definitions to the stated scope; for calculations, derive the result from the supplied prefix, bit count or resource rule.

Answer C: Transport Layer

TCP uses sequence numbers, acknowledgments and windows to provide reliable ordered delivery between transport endpoints. Reliable link protocols can use similar mechanisms, but their scope is a single hop. The explicit end-to-end process requirement therefore selects transport. IP supplies best-effort network delivery, while session coordinates dialogs and checkpoints rather than defining TCP's ordered-byte-stream reliability and receiver flow control.

Why each choice is right or wrong

A - Incorrect: IP is best effort and does not supply the listed reliable acknowledgment/retransmission service.

B - Incorrect: Data-link reliability is hop-local rather than the required end-to-end process service.

C - Correct: Transport supplies TCP's end-to-end sequencing, acknowledgments and receiver flow control.

D - Incorrect: Session manages dialogs/checkpoints rather than the specifically listed link/TCP reliability machinery.

Primary note proof

Study-note section NET17

> TCP offers a reliable ordered byte stream using sequence numbers, acknowledgments, retransmission and windows. Flow control protects the receiver; congestion control protects network capacity. UDP sends independent datagrams with ports and a checksum but no built-in setup, delivery guarantee, retransmission or ordering. Live interactive traffic may choose UDP when late data is less useful than lost data. Application protocols can add reliability over UDP.

Study-note section NET14

> Controlled access uses polling, reservations or a token to grant turns; correctly coordinated access avoids contention collisions. Channelization divides frequency, time or code resources. Stop-and-wait sends one frame and waits for ACK, retransmitting on timeout; sequence bits distinguish duplicates. Sliding windows permit multiple unacknowledged frames. Link reliability/flow control is hop-local; transport reliability/flow control is end-to-end. Ethernet detects corruption but does not itself guarantee reliable delivery.

Study-note section NET19

> OSI session roles establish/manage dialogs and can coordinate checkpoints so transfer resumes after interruption. Presentation roles translate encodings and handle compression/encryption. Compression reduces representation size; encryption hides content and need not shrink it. Application protocols provide services directly to applications. Practical implementations

distribute these functions differently; TLS is not proof of a separate physical presentation-layer device.

Question 272 | NS0619

For the IP address 192.168.2.64/26, what is the broadcast address?

A. 192.168.2.65

B. 192.168.2.126

C. 192.168.2.127

D. 192.168.2.255

Hint

Apply the cited definitions to the stated scope; for calculations, derive the result from the supplied prefix, bit count or resource rule.

Answer C: 192.168.2.127

A /26 has blocks of 64 addresses. Starting at .64, this block runs through .127; the final address has all six host bits one and is broadcast. .65 and .126 are ordinary first/last hosts. .255 belongs to another /26 block, so it is not this subnet's broadcast.

Why each choice is right or wrong

A - Incorrect: 192.168.2.65 is the first usable host, not the all-host-bits-one address.

B - Incorrect: 192.168.2.126 is the last usable host, one address below broadcast.

C - Correct: The .64-.127 /26 block ends at .127, its directed broadcast.

D - Incorrect: The .255 address is outside this .64-.127 subnet block.

Primary note proof

Study-note section NET25

> 192.168.2.64/26 spans .64-.127; usable .65-.126 gives 62 hosts. 192.168.10.25/28 spans .16-.31, so its network is .16. 172.17.128.0/21 spans 172.17.128.0-172.17.135.255; .128.255 and .135.0 are valid interior hosts, but .135.255 is broadcast. /27 gives 32 total and 30 usable, not 32 usable.

Study-note section NET24

> Compute network=address AND mask. Host bits zero identify the block start; host bits one give broadcast. With 172.16.28.252/20, the third octet is grouped in blocks of 16, so the network is 172.16.16.0 and broadcast 172.16.31.255. A written host/prefix such as 172.105.180.0/21 need not be an aligned block label: masking yields 172.105.176.0/21.

Question 273 | NS0620

Which of the following CORRECTLY describes the role of SMTP?

A. Translates domain names to IP addresses

B. Governs how web pages are requested and delivered

C. Governs how email messages are sent from a client to a mail server

D. Enables file transfer between devices over the internet

Hint

Apply the cited definitions to the stated scope; for calculations, derive the result from the supplied prefix, bit count or resource rule.

Answer C: SMTP submits and relays email

NET21 assigns SMTP mail submission and relay. A client sending a message to a mail server is therefore a correct SMTP role. DNS resolves names, HTTP serves web requests and FTP transfers files. This does not assign end-user mailbox retrieval to SMTP; POP3/IMAP serve that separate task.

Why each choice is right or wrong

A - Incorrect: DNS resolves domain names to address records rather than SMTP.

B - Incorrect: HTTP governs web requests/responses, not SMTP.

C - Correct: SMTP submits mail from a client to a server and relays messages between mail servers.

D - Incorrect: File transfer is the FTP service role in this comparison, not SMTP's defining mail role.

Primary note proof

Study-note section NET21

> HTTP defines web request/response semantics; it is stateless, and a message body may be absent. HTTPS adds TLS protection. FTP transfers files using control and separate data connections; it is not the same protocol as SFTP. SMTP submits and relays mail; POP3 retrieves messages and IMAP accesses/synchronizes server mailboxes. Saying SMTP handles both sending and end-user mailbox retrieval is inaccurate.

Study-note section NET20

> DNS resolves names to records, including IPv4 A and IPv6 AAAA addresses; it can use UDP or TCP port 53. DHCP dynamically leases IPv4 settings, commonly address, mask, gateway and DNS server. Its basic exchange is discover, offer, request, acknowledge. IP itself does not assign addresses.

Question 274 | NS0621

An omnidirectional antenna transmits signals in which pattern?

A. A narrow beam toward a specific target

B. Only vertically upward

C. In all directions simultaneously, creating 360-degree coverage

D. In a focused line-of-sight path only

Hint

Apply the cited definitions to the stated scope; for calculations, derive the result from the supplied prefix, bit count or resource rule.

Answer C: 360-degree azimuth coverage, with a nonuniform vertical pattern

NET07 defines omnidirectional as broad azimuth coverage. C is correct when its 360 degrees refers to the horizontal plane, not equal power in every three-dimensional direction. Directional beams or upward-only radiation do not describe this pattern. Antenna elevation patterns can still have lobes/nulls, so the answer retains that scope qualification.

Why each choice is right or wrong

A - Incorrect: A narrow targeted beam is directional rather than omnidirectional azimuth coverage.

B - Incorrect: Upward-only radiation does not provide the broad around-the-antenna azimuth pattern.

C - Correct: 360-degree azimuth coverage is the intended meaning, without asserting equal power in all three-dimensional directions.

D - Incorrect: A single focused path describes a directional antenna pattern.

Primary note proof

Study-note section NET07

> Radio, microwave and infrared are unguided media. Ground waves follow Earth, sky waves can reflect from ionized layers, and line-of-sight paths require suitable visibility. Microwaves are radio waves in the broader physical classification. Infrared generally does not penetrate walls. Directionality depends on antennas: omnidirectional means broad azimuth coverage, not equal radiation in every 3-D direction. Legacy Ethernet straight-through cables join unlike MDI/MDI-X roles; crossover joins like roles, such as PC-PC or switch-switch. Auto-MDI-X can remove that requirement.

Question 1 | Q00012

When we use a hash table data structure, our hash function should map the expected inputs (keys) as evenly as possible over its output range(indexes). This property of good hash function is known as_____.

A. Uniformity

B. Determinism

C. Continuity

D. Data normalization

Hint

Trace the initial state and each executed operation in order, preserving the requested output layout.

Answer A: Uniformity

DSA25 defines uniformity as spreading expected keys evenly among addresses. That directly matches the question's wording. Determinism is a different obligation: repeated equal keys receive the same address for the chosen function. Continuity and data normalization do not name this distribution property, so only Uniformity answers the literal stem.

Why each choice is right or wrong

A - Correct: Uniformity describes spreading expected input keys evenly across the output address range, exactly as the stem requires.

B - Incorrect: Determinism requires repeated equal keys to map identically; it does not require an even address distribution.

C - Incorrect: Continuity is not the key-distribution property defined for hash functions in DSA25.

D - Incorrect: Data normalization does not name the even-distribution requirement of a hash function.

Primary note proof

Study-note section DSA25

> Determinism means repeated equal keys get the same address for the chosen function. Uniformity means expected keys spread evenly. Universal hashing chooses one function randomly from a suitable family for the table, independently of a fixed key set; it does not choose a fresh unrelated function for each lookup. Random choice controls collision probability, not a promise of zero collisions.

Question 2 | Q00013

In a one-based array representation of a binary heap, the root is at index 1. If a node at index i has a right child, at which index is that child stored?

A. 2*i+1

B. i/2

C. (i+1)/2

D. 2*i

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer A: A. 2*i+1

Heap child formulas depend on whether indexing begins at zero or one. With the explicitly stated one-based convention, the two children of node i occupy positions 2i and 2i+1. The latter is the right child. Integer division by two instead identifies a parent in this convention. The existence condition matters because an index computed beyond the current heap size does not designate an actual child.

Why each choice is right or wrong

A - Correct: 2i+1 is the one-based right-child index.

B - Incorrect: floor(i/2) computes the parent for nonroot nodes.

C - Incorrect: (i+1)/2 does not compute the right child.

D - Incorrect: 2i is the one-based left child.

Primary note proof

Study-note section DSA23

> Zero-based array representation: root index 0, left=2i+1, right=2i+2, parent=floor((i-1)/2) for i>0. One-based representation uses children 2i,2i+1 and parent floor(i/2). A child exists only if its index is inside the current heap size.

Question 3 | Q00014

Use iterative sequential search and iterative binary search on random-access arrays, with constant-size indices. For binary search, reverse comparisons on descending arrays. Compare tight asymptotic auxiliary space and worst-case element probes as n grows. Which statement is false?

A. Binary searching algorithm can work on list of data which is stored in descending order

B. Sequential and binary searching algorithm are not equal in terms of memory efficiency

C. Sequential searching algorithm can work on sorted and unsorted list of data

D. Binary search has a smaller tight worst-case probe order than sequential search on sorted random-access arrays.

Hint

Fix the input case and cost model, then count dominant work or simultaneously live storage.

Answer B: B. Sequential and binary searching algorithm are not equal in terms of memory efficiency

Both iterative algorithms keep only a fixed number of indices and temporary values, giving constant auxiliary space. Their worst-case probe counts differ: sequential search can inspect every element, whereas binary search halves the ordered interval each time. Binary search can also handle descending order with reversed comparisons, and sequential search does not require sorted input. Under these specified implementations, the unequal-memory claim is the false statement.

Why each choice is right or wrong

A - Incorrect: Descending binary search works with reversed comparisons.

B - Correct: Both iterative implementations use constant auxiliary space, so this inequality claim is false.

C - Incorrect: A sequential scan works with either input ordering.

D - Incorrect: Binary search has logarithmic rather than linear worst-case probes.

Primary note proof

Study-note section DSA28

> Compare the target with successive elements until equal or exhausted. Unsorted data is allowed; sorted data is allowed too. A first-element match costs Theta(1). An absent target or last-position match needs n comparisons, giving Theta(n) worst time. Uniformly likely successful positions average (n+1)/2 comparisons, still linear.

Study-note section DSA29

> Worst probes are floor($\log_2 n$)+1 for n>0: seven for 100 keys, about twenty for one million. Iteration uses constant space; recursion uses logarithmic stack depth. Linked midpoint traversal loses logarithmic total time. Boundary variants retain a candidate rather than stopping at equality.

Question 4 | Q00045

For ordinary array sorting implementations, which listed algorithm uses a temporary element buffer proportional to n rather than only a fixed number of saved elements? Count recursive call frames separately from auxiliary element storage.

A. Insertion sort

B. Selection sort

C. Merge sort

D. Quick sort

Hint

Fix the input case and cost model, then count dominant work or simultaneously live storage.

Answer C: C. Merge sort

Ordinary array mergesort merges two sorted halves through a temporary buffer that can hold a number of elements proportional to n. Insertion sort retains one item while shifting, and selection sort needs fixed temporary storage for a minimum position and an exchange. Ordinary quicksort partitions inside the original array. Its recursive stack is counted separately here, so the linear element-buffer requirement uniquely identifies mergesort.

Why each choice is right or wrong

A - Incorrect: Insertion saves one item and shifts within the same array.

B - Incorrect: Selection retains a minimum position and a fixed-size swap temporary.

C - Correct: Ordinary array merging needs a linear auxiliary element buffer.

D - Incorrect: In-array partitioning needs no full merge buffer; recursive frames are excluded by the stated convention.

A. Insertion Sort
The most instinctive type of sorting algorithm; it finds the location for an element and move all others up, and insert the element to its right position. It starts with the left most two items and put
them in order. Then add 3rd
item to the relatively sorted portion and find its correct location
(relative to each other) swapping adjacent elements if they are out of order. In such it sorts all item

Question 5 | Q00066

Which data structure is the most appropriate for sharing a printer in a network environment?

A. Stack

B. Binary search tree

C. Full binary tree

D. Queue

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer D: Queue

The module explicitly identifies print-server jobs as a queue application. FIFO preserves arrival order among pending jobs. Evidence: assigned PDF pages 8, 6, 9.

Why each choice is right or wrong

A - Incorrect: A stack would give the most recent print request priority. See assigned PDF 8, 6, 9.

B - Incorrect: BST ordering by key is not arrival-order service. See assigned PDF 8, 6, 9.

C - Incorrect: A full tree shape does not specify job service order. See assigned PDF 8, 6, 9.

D - Correct: The print server maintains a queue of print jobs. See assigned PDF 8, 6, 9.

Primary note proof

Study-note section DSA14

> FIFO suits equal-priority printer jobs, shared-resource waiting, asynchronous buffers and level-order exploration. A play sequence can also use a queue. Distinguish airline seat records from waiting requests; an application name alone does not force one representation.

Question 6 | Q00076

Which one of the following is true about Queue data structure?

A. Queue data structure applies first come first served policy

B. Queue data structure uses last in first out rule

C. Queue data structure does not have efficient basic operations

D. Queue data structure cannot be implemented using linked list

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer A: Queue data structure applies first come first served policy

FIFO serves the first arrival first; the module also explicitly gives linked-list enqueue and dequeue. Therefore A is true and the supplied D key contradicts page 8. Evidence: assigned PDF pages 7, 8.

Why each choice is right or wrong

A - Correct: First come first served is stated under queue applications. See assigned PDF 7, 8, 8.

B - Incorrect: LIFO describes the stack, whereas queue deletion is at the front. See assigned PDF 7, 8, 8.

C - Incorrect: A blanket inefficiency claim is unsupported; front removal and rear insertion can use fixed pointer updates. See assigned PDF 7, 8, 8.

D - Incorrect: The module expressly implements the queue as a linked list. See assigned PDF 7, 8, 8.

Primary note proof

Study-note section DSA14

An ordinary queue enqueues at rear, dequeues at front, and peeks at front. This is FIFO or first-come, first-served. A linked implementation with head and tail supports both operations in constant time: append at tail, remove at head. The first insertion sets both pointers; removing the last item clears both. With head alone, insertion must traverse to the tail.

Question 7 | Q00148

An unsorted singly linked list maintains only its head pointer. Which option gives the complete set of listed operations with tight worst-case constant time? There is no cached tail, predecessor index or positional index.

A. Insertion at the front of the linked list

B. Insertion at the end of the linked list

C. Deletion of the front node of the linked list

D. Deletion of the last node of the linked list

E. A&C

Hint

Fix the input case and cost model, then count dominant work or simultaneously live storage.

Answer E: E. A&C

Inserting at the head links the new node to the old head and updates head. Deleting the head advances head and releases one node. Both use constant work. Appending requires traversal to find the tail, and deleting the tail requires its predecessor, also found by traversal. The complete constant-time set is therefore insertion at the front together with deletion of the front, which is option E.

Why each choice is right or wrong

A - Incorrect: Front insertion is constant, but this alone omits the also-constant front deletion.

B - Incorrect: Head-only append traverses the list to find its tail.

C - Incorrect: Front deletion is constant, but this alone omits the also-constant front insertion.

D - Incorrect: Tail deletion must locate its predecessor by traversal.

E - Correct: This combines exactly the two listed constant-time operations.

Primary note proof

Study-note section DSA09

> Prepend with new.next=head; head=new. To insert after a known predecessor p, set new.next=p.next before p.next=new. Appending with only head requires a tail traversal; maintaining tail avoids it. Delete the head by saving old=head, advancing head=head.next and releasing old in C++.

Study-note section DSA09

> Deleting the tail of a singly linked list requires its predecessor, even when tail itself is known. Handle empty and single-node lists separately; after removing the only node, set both head and

tail to null. To remove a known successor, bypass it before deallocation. Clearing an owned n-node chain visits and releases every node.

1. Single Linked lists
It is a self-referential structure (Structures can hold pointers to instances of themselves), that allow
to create a chain of structs/Nodes with related data. Each node in the list contains data items and pointer to next node.
Basic Operations on Single Linked List
I. Creating Linked Lists
Structure definition of a single linked list need to contain both data items declaration and next node
pointer. In addition the first node pointer is essential to keep track of the list to perform various operations on the list. Thus, it is initialized to NULL first as the list is empty before any node added
to the chain.

Data Structure and Algorithms module | PDF page 5 | lines 13-24

Step 3: Then add the node at the end of the list. For this we need to check whether the list is empty or not. If list is empty the new node will be the first (Start) node, otherwise navigate forward starting form the first node till last node found and add it next to this node which make the new node the last node.
if (start == NULL) // If list is empty, then new node become start node
start = temp;
else {
temp2 = start; // list not empty! Thus temp2 starts from first node
while (temp2->next!= NULL) { // till the current last node found navigates forward
temp2 = temp2->next; // Move to next link in chain
}
temp2->next = temp; // new node (temp) appended at the end of the list

Data Structure and Algorithms module | PDF page 6 | lines 4-13

2. Make temp1 point to whatever the start pointer is pointing to.
3. If the next pointer of what temp1 indicates is NULL, then we've found the last node of the list, so
jump to step 7.
4. Make another pointer, temp2, point to the current node in the list.
5. Make temp1 point to the next item in the list.
6. Go to step 3.
7. If you get this far, then the temporary pointer, temp1, should point to the last item in the list and
the other temporary pointer, temp2, should point to the last-but-one item.

8. Delete the node pointed to by temp1.
9. Mark the next pointer of the node pointed to by temp2 as NULL - it is the new last node.

Question 8 | Q00150

Which of the following data structure is more appropriate to represent a heap tree?

A. Two dimensional array

B. Doubly linked list

C. Linear array

D. Single linked list

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer C: Linear array

The heap algorithm directly maps tree nodes to Data indices and uses arithmetic child indices, establishing the linear array representation. Evidence: assigned PDF pages 11.

Why each choice is right or wrong

A - Incorrect: A second array dimension is unnecessary for one index per node. See assigned PDF 11.

B - Incorrect: A doubly linked list lacks the given direct child-index arithmetic. See assigned PDF 11.

C - Correct: Data[0] and children 2*i+1, 2*i+2 use a one-dimensional array. See assigned PDF 11.

D - Incorrect: A singly linked chain does not directly represent the two children by these indices. See assigned PDF 11.

Primary note proof

Study-note section DSA23

Zero-based array representation: root index 0, left=2i+1, right=2i+2, parent=floor((i-1)/2) for i>0. One-based representation uses children 2i,2i+1 and parent floor(i/2). A child exists only if its index is inside the current heap size.

iii. Heap Sort
Heap sort operates by first converting the list in to a heap tree. Heap tree is a binary tree in which
each node has a value greater than both its children (if any). It uses a process called "adjust to accomplish its task (building a heap tree) whenever a value is larger than its parent. The time complexity of heap sort is O(nlogn).
Algorithm:
1. Construct a binary tree
• The root node corresponds to Data[0].
• If we consider the index associated with a particular node to be i, then the left child of this node corresponds to the element with index 2*i+1 and the right child corresponds to the element with index 2*i+2. If any or both of these elements do not exist in the array, then the corresponding child node does not exist either.
2. Construct the heap tree from initial binary tree using "adjust" process.
Sort by swapping the root value with the lowest, right most value and deleting the lowest, right most value and inserting the deleted value in the array in it proper position.

Question 9 | Q00151

Linear search is highly inefficient compare to binary search when dealing with_____?

A. Small, unsorted arrays

B. Large, sorted arrays

C. Small, sorted arrays

D. Large, unsorted arrays

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer B: Large, sorted arrays

The comparison n versus log2 n becomes substantial for large n, and binary searching requires ordering. Thus both size and sortedness matter. Evidence: assigned PDF pages 3.

Why each choice is right or wrong

A - Incorrect: Unsorted input does not satisfy binary-search prerequisites. See assigned PDF 3, 3.

B - Correct: Large sorted arrays provide both the prerequisite and the asymptotic advantage. See assigned PDF 3, 3.

C - Incorrect: Sorting permits binary search, but small size does not produce the large growth-rate difference requested. See assigned PDF 3, 3.

D - Incorrect: Large unsorted arrays still cannot be binary-searched without preprocessing. See assigned PDF 3, 3.

Primary note proof

Study-note section DSA28

> Compare the target with successive elements until equal or exhausted. Unsorted data is allowed; sorted data is allowed too. A first-element match costs Theta(1). An absent target or last-position match needs n comparisons, giving Theta(n) worst time. Uniformly likely successful positions average (n+1)/2 comparisons, still linear.

Study-note section DSA29

> Worst probes are floor($\log_2 n$)+1 for n>0: seven for 100 keys, about twenty for one million. Iteration uses constant space; recursion uses logarithmic stack depth. Linked midpoint traversal loses logarithmic total time. Boundary variants retain a candidate rather than stopping at equality.

Considering the array elements (independently for this question):
int a[6]={11,13,15,17,19,21}
Implementing stack, the elements after pop(); push(9); are:

A. 9, 11, 13, 15, 17, 19

B. 13, 15, 17, 19, 21, 9

C. 11, 13, 15, 17, 19, 9

D. 9, 13, 15, 17, 19, 21

Hint

Trace the initial state and each executed operation in order, preserving the requested output layout.

Answer C: 11, 13, 15, 17, 19, 9

Take the listed array in bottom-to-top order, with 21 at top. Pop removes 21; push appends 9 at the same top slot, leaving 11,13,15,17,19,9. Evidence: assigned PDF pages 6.

Why each choice is right or wrong

A - Incorrect: This puts 9 at the bottom and shifts surviving data. See assigned PDF 6, 6.

B - Incorrect: This removes 11, which is a queue-style front removal. See assigned PDF 6, 6.

C - Correct: Only the final top entry changes from 21 to 9. See assigned PDF 6, 6.

D - Incorrect: This replaces the bottom entry 11 rather than the top. See assigned PDF 6, 6.

Question 11 | Q00153

A capacity-six circular queue uses all six slots with front=0 and size=6. Its physical array is [11,13,15,17,19,21]. After dequeue() and enqueue(9), what is the logical front-to-rear sequence?

A. 9, 11, 13, 15, 17, 19

B. 13, 15, 17, 19, 21, 9

C. 11, 13, 15, 17, 19, 9

D. Queue overflow

Hint

Trace the initial state and each executed operation in order, preserving the requested output layout.

Answer B: B. 13, 15, 17, 19, 21, 9

The initial front element is 11, so dequeue removes it and advances front to the slot containing 13. The queue now has five items. Circular insertion reuses the freed physical slot zero for 9 and restores size six. Reading from the new front around to the rear gives 13,15,17,19,21,9. Physical slot order differs from this requested logical service order.

Why each choice is right or wrong

A - Incorrect: This would remove 21 and prepend 9 rather than remove the front.

B - Correct: This is the front-to-rear order after removing 11 and appending 9.

C - Incorrect: This incorrectly retains 11 and removes the rear 21.

D - Incorrect: Circular reuse makes room for the insertion after the removal.

Primary note proof

Study-note section DSA15

> A simple noncircular array queue may report overflow when rear reaches the final index despite released slots at the front. A circular queue reuses slots with modulo arithmetic. Use a count convention: front points to the next removal, size counts items, and insertion slot is (front+size)%C. Empty means size==0; full means size==C.

Question 12 | Q00154

A circular queue has capacity six, front=0 and size=6, using physical slots [11,13,15,17,19,21]. It can use all six slots. After dequeue() and enqueue(9), list the physical array in index order 0 through 5.

A. 9, 11, 13, 15, 17, 19

B. 13, 15, 17, 19, 21, 9

C. 11, 13, 15, 17, 19, 9

D. 9, 13, 15, 17, 19, 21

Hint

Trace the initial state and each executed operation in order, preserving the requested output layout.

Answer D: D. 9, 13, 15, 17, 19, 21

Dequeue reads 11 at index zero, advances front to index one and reduces size to five. The count-based insertion formula then gives (front+size)%6=(1+5)%6=0. Enqueue therefore writes 9 into the freed slot zero. All other physical slots retain their old values. The logical service order begins at 13, but the requested physical index order begins at the newly stored 9.

Why each choice is right or wrong

A - Incorrect: This drops 21 and retains the removed 11.

B - Incorrect: This is logical front-to-rear order, not physical index order.

C - Incorrect: This overwrites 21 instead of reusing slot zero.

D - Correct: Slot zero receives 9 and slots 1-5 remain unchanged.

Primary note proof

Question 13 | Q00171

The data structure used in the standard implementation of Breadth First Search is ?

A. Stack

B. Array

C. Linked List

D. Queue

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer D: Queue

Breadth-first search repeatedly dequeues a vertex and enqueues its undiscovered neighbors. FIFO ordering ensures earlier distance layers are processed before later ones. Arrays or linked nodes can store this frontier, but Queue names its required access discipline. A stack instead serves latest pending work.

Why each choice is right or wrong

A - Incorrect: A stack serves the latest pending vertex first and does not preserve BFS distance-layer order.

B - Incorrect: An array can store a queue, but an array alone specifies no FIFO frontier discipline.

C - Incorrect: Linked nodes can represent a queue, but Linked List alone does not specify breadth-first processing.

D - Correct: A FIFO queue processes discovered vertices by distance layer, the standard BFS frontier rule.

Primary note proof

Study-note section DSA41

Mark the source when enqueuing it. Repeatedly dequeue a vertex, examine its neighbours, and enqueue each unvisited neighbour while marking it. Store predecessor[v] when discovering v if a path must be reconstructed. FIFO ensures vertices at distance d are explored before later distance layers.

Question 14 | Q00214

Suppose we define a static method totalEvenLoc() that returns the total for even-index items of an integer list as shown, on the right, below. What is the Big O running time of the method if lst is a LinkedList of size N?

```
public static int totalEvenLoc(List<Integer> lst) {
int sum = 0;
for(int i = 0; i < lst.size(); i += 2)
sum += lst.get(i);
return sum;
}
```

A. O(N)

B. O(1)

C. O(N^2)

D. O(logN)

E. O(NlogN)

Hint

Fix the input case and cost model, then count dominant work or simultaneously live storage.

Answer C: O(N^2), tightly Θ(N^2)

The loop visits about N/2 even indices, but LinkedList.get(i) walks from the nearer endpoint. A linear number of those indices lie near the middle, each requiring linear traversal. DSA07 analyzes exactly this access pattern and obtains Θ(N^2) total work. Incrementing by two changes a constant factor, not the quadratic order.

Why each choice is right or wrong

A - Incorrect: O(N) would require constant-cost indexed access; LinkedList.get(i) instead traverses nodes.

B - Incorrect: A growing number of accesses and additions prevents a constant bound on total work.

C - Correct: A linear number of middle-index accesses each traverse a linear number of nodes, yielding quadratic time.

D - Incorrect: Neither the iteration count nor the accumulated linked-node traversal has logarithmic growth.

E - Incorrect: Quadratic traversal grows faster than N log N, so this is not a valid upper bound.

Primary note proof

Study-note section DSA07

> Indexed access is not constant for every List implementation. Java LinkedList.get(i) walks from the nearer endpoint. Summing get(0), get(2), get(4), ... over a length-N list still gives Theta(N^2), because a linear number of middle indices each require linear traversal. An iterator scans once in linear time. An exact executable runtime requires valid code and an explicit cost convention.

Think of a reference implementation of a classical queue with front and rear pointing to the appropriate locations in the queue. Which of these references will change during an insertion into a possibly empty queue?

A. Neither change

B. Only front changes

C. None of the choices is correct

D. Both may change.

E. Only rear changes

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer D: Both may change.

Insertion into an empty linked queue makes the new node both front and rear. Insertion into a nonempty queue changes rear while front remains. Consequently both references may change across the allowed cases. Evidence: assigned PDF pages 7, 8, 5.

Why each choice is right or wrong

A - Incorrect: Insertion must update at least rear to include the new node. See assigned PDF 7, 8, 5.

B - Incorrect: Rear changes too; front alone is insufficient. See assigned PDF 7, 8, 5.

C - Incorrect: D describes the empty-queue case correctly. See assigned PDF 7, 8, 5.

D - Correct: Both change when the first node is inserted. See assigned PDF 7, 8, 5.

E - Incorrect: Rear alone changes only in the nonempty case. See assigned PDF 7, 8, 5.

Primary note proof

Question 17 | Q00217

Binary search is to operate on an already ordered sequence of comparable keys through an indexed-access interface. Which listed property is required of its search domain, rather than being a particular physical array representation or allocation policy?

A. The array must hold elements of the same data type.

B. All are additional requirements.

C. The array must be contiguous.

D. The search interval must have valid finite bounds.

E. The array must fix its size a prior to population.

F. None is an additional requirement.

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer D: D. The search interval must have valid finite bounds.

Binary search maintains an interval of candidate indices and repeatedly shrinks it until a match or an empty interval is obtained. That operation requires valid finite bounds. Homogeneous physical storage and contiguity are properties of ordinary array representations, rather than requirements of the abstract interval-halving procedure. Fixing capacity before population is unnecessary: a resizable sequence can be populated first and searched afterward. Hence not all listed properties are requirements.

Why each choice is right or wrong

A - Incorrect: Comparable keys are assumed; identical physical data types are not the abstract domain requirement.

B - Incorrect: All fails because prior fixed allocation is unnecessary.

C - Incorrect: Contiguity is a representation choice rather than the abstract search-domain requirement.

D - Correct: The candidate index domain needs valid finite bounds.

E - Incorrect: A resizable sequence may be populated before searching.

F - Incorrect: Valid finite bounds are a required condition among these choices.

Primary note proof

> An ordinary queue enqueues at rear, dequeues at front, and peeks at front. This is FIFO or first-come, first-served. A linked implementation with head and tail supports both operations in constant time: append at tail, remove at head. The first insertion sets both pointers; removing the last item clears both. With head alone, insertion must traverse to the tail.

> “A queue is an ordered list in which all insertions at one end called REAR and deletions are made at another end called FRONT”. Queues are sometimes referred to as First in First out (FIFO) lists. The two basic operations are:
> Enqueue - Inserts an item / element at the rear end of the queue. An overflow error occurs if the queue is full.
> Dequeue - Removes an item / element from the front end of the queue, and returns it to the user. An underflow error occurs if the queue is empty.

> “A stack is an ordered list in which all insertions and deletions are made at one end, called the top”. Stacks are sometimes referred to as Last in First out (LIFO) lists. Stacks have some useful terminology associated with them:
> • Push To add an element to the stack
> • Pop To remove an element from the stock
> • Peek To look at elements in the stack without removingthem
> • LIFO Refers to the last in, first out behavior of thestack
> • FILO (First in Last Out) : equivalent to LIFO

Question 19 | Q00286

What is the tightest listed worst-case time bound for constructing an optimal binary search tree using the standard interval dynamic program that tries every key as root of every interval?

A. O(n)

B. $O(n^3)$

C. O(logn)

D. O (n!)

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer B: B. $O(n^3)$

This asks about constructing an optimal BST, rather than searching a tree after construction. The standard dynamic program considers quadratically many key intervals. For each interval it tries up to a linear number of candidate roots, combining the relevant subproblem costs. Multiplying those counts gives cubic construction time. The cubic option states that bound; the linear, logarithmic and factorial alternatives do not give the tight construction order.

Why each choice is right or wrong

A - Incorrect: Linear time does not cover all intervals and root candidates.

B - Correct: Quadratic intervals times linear root trials give cubic time.

C - Incorrect: Logarithmic time concerns balanced search paths, not this construction.

D - Incorrect: Factorial is a loose upper bound rather than the tight listed order.

Primary note proof

Study-note section DSA19

> Standard optimal-BST dynamic programming tries each possible root for each key interval: $O(n^2)$ intervals times $O(n)$ roots gives $O(n^3)$ construction.

Question 20 | Q00288

Which of the following is the best case time complexity of linear search algorithm?

A. O(n'2)

B. O(n)

C. O(1)

D. O(log n)

Hint

Fix the input case and cost model, then count dominant work or simultaneously live storage.

Answer C: O(1)

A match at the very first inspected element ends scanning after one comparison, independent of n. Interpret the options as tight growth orders rather than arbitrary loose Big-O upper bounds. Evidence: assigned PDF pages 3.

Why each choice is right or wrong

A - Incorrect: Quadratic is not the tight best-case count. See assigned PDF 3.

B - Incorrect: Linear is the complete-scan bound, not the immediate-match cost. See assigned PDF 3.

C - Correct: One first-element comparison is constant. See assigned PDF 3.

D - Incorrect: Logarithmic describes halving, not immediate linear-search success. See assigned PDF 3.

Primary note proof

Study-note section DSA28

> Compare the target with successive elements until equal or exhausted. Unsorted data is allowed; sorted data is allowed too. A first-element match costs Theta(1). An absent target or last-position match needs n comparisons, giving Theta(n) worst time. Uniformly likely successful positions average (n+1)/2 comparisons, still linear.

Question 21 | Q00289

If the elements '1', '2', '3' and '4' are inserted in a queue, what would be order for the removal?

A. 4321

B. 3241

C. 1234

D. None of the above

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer C: 1234

FIFO removes the four insertions in their original order: 1 then 2 then 3 then 4. Evidence: assigned PDF pages 7.

Why each choice is right or wrong

A - Incorrect: 4321 reverses arrival order. See assigned PDF 7.

B - Incorrect: 3241 puts later arrivals before 1 and 2. See assigned PDF 7.

C - Correct: 1234 preserves insertion order. See assigned PDF 7.

D - Incorrect: C already supplies the FIFO result. See assigned PDF 7.

Question 22 | Q00290

What is the disadvantage of array data structure?

A. The amount of memory to be allocated should be known beforehand.

B. Elements of an array can be accessed in constant time.

C. Elements are stored in contiguous memory blocks.

D. Multiple other data structures can be implemented using arrays.

Hint

Compare the required access order and representation constraints with the defining operations of each option.

Answer A: The amount of memory to be allocated should be known beforehand.

The module calls array storage static and contrasts it with dynamically allocated nodes. A fixed array requires a capacity in advance; constant access and reuse as a storage implementation are benefits, while contiguous storage alone is not the capacity drawback. Evidence: assigned PDF pages 6, 7, 5.

Why each choice is right or wrong

A - Correct: Preallocated fixed capacity is the disadvantage illustrated by static array implementations. See assigned PDF 6, 7, 5.

B - Incorrect: Constant indexed access is an advantage, not a disadvantage. See assigned PDF 6, 7, 5.

C - Incorrect: Contiguity itself does not state the capacity limitation. See assigned PDF 6, 7, 5.

D - Incorrect: Supporting other structures is useful rather than a disadvantage. See assigned PDF 6, 7, 5.

Primary note proof

Study-note section DSA02

> A fixed array has a chosen capacity; the choice need not occur at compile time. A resizable array allocates a larger block and copies when needed. Inserting in the middle shifts later elements, so it costs linear time. Appending into spare capacity is constant; a resizing append can be linear, though repeated geometric growth gives amortized constant append cost.
