> • Example: If a company has antivirus software but does not use an anti-virus and keep the virus signatures up-to-date, this is vulnerability. The company is vulnerable to virus attacks. Similarly, if you fail to routinely update your operating systems or application software, these will remain vulnerable to software problems ("bugs") that have been identified and patched

Question sources

Computer Science MCQ practice collection · Question 543

Question 87 | AM0544

What are the basic requirements for a trusted operating system?

A. Authentication, encryption, and firewall protection

B. User-friendly interface, multitasking, and device driver support

C. Confidentiality, integrity, availability, and accountability

D. User access control, software updates, and system backup

Hint

Separate security-policy enforcement and assurance from ordinary OS features.

Answer C: Confidentiality, integrity, availability and accountability

SEC28 connects trust to enforcement of a stated policy through identity, isolation, access enforcement, protected auditing and safe recovery. Those mechanisms support the broad confidentiality, integrity, availability and accountability requirements in C. The other options list selected mechanisms or ordinary usability features; they do not state the overall security requirements as completely.

Why each choice is right or wrong

A - Incorrect: Authentication/encryption/firewalls are selected controls and do not cover the overall trust requirements.

B - Incorrect: A GUI and multitasking do not establish security trust, as SEC28 explicitly warns.

C - Correct: These broad protection/accountability goals are supported by the trusted OS enforcement and auditing mechanisms.

D - Incorrect: Access controls, updates and backups contribute mechanisms but omit the complete high-level requirement set.

Primary note proof

Study-note section SEC28

A trusted OS is relied on to enforce a stated security policy. Relevant mechanisms include identification/authentication, process and memory isolation, controlled privileges, object access enforcement, protected auditing, safe resource reuse, trusted boot/update paths and recovery behavior. The trusted computing base comprises components whose failure can violate policy; smaller, analyzable boundaries simplify assurance.

Study-note section SEC28

A GUI or multitasking support alone does not establish trust.

Study-note section SEC01

Accountability links actions to responsible entities through reliable identity and protected logs.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Security module | PDF page 2 | lines 84-90

• Computer Security: (W. Stallings)
o Protection to an automated information system in order to attain the applicable objectives of preserving the confidentiality, integrity, and availability (CIA) of information system resources (includes hardware, software, firmware, information/data, and telecommunications).

Computer Security module | PDF page 4 | lines 28-35

• Accountability
o Ensuring an entity’s action is traceable uniquely to that entity.
o Ascertains the responsibility of an entity (like a person) for its actions and decisions.
o All relevant activities events and operations on a system, e.g., failed and successful authentication attempts, are recorded in a log.

Computer Security module | PDF page 11 | lines 74-79

• Most OS authentication is handled through user names and passwords. Biometric (e.g. voice, face, retina, iris, fingerprint) and physical token-based (swipe cards, pin-generating cards) authentication are sometimes used to augment simple passwords, but the costs and accuracy of the technology limit their adoption.

Question sources

Computer Science MCQ practice collection · Question 544

Question 88 | AM0545

What is the purpose of independent evaluation in computer security?

A. To certify that a system is immune to all security threats

B. To assess the effectiveness of security controls and mechanisms

C. To perform regular system backups and data recovery tests

D. To ensure compliance with industry standards and regulations

Hint

Distinguish requirements, technical evaluation, evidence and certification decisions.

Answer B: Assess security controls against stated claims

Independent evaluation examines evidence and tests controls against the product's specified functional and assurance claims. B captures that assessment purpose. SEC29 explicitly rejects immunity to all attacks and universal regulatory conclusions. Backups are an operational recovery practice rather than the evaluation's defining task.

Why each choice is right or wrong

A - Incorrect: A scoped evaluation cannot certify immunity to every present and future security threat.

B - Correct: Examining evidence and testing controls assesses whether their stated security claims are met.

C - Incorrect: Routine backups and restore tests are operational recovery tasks, not the defining independent-evaluation purpose.

D - Incorrect: Evaluation assesses specified security claims; it does not automatically establish every industry/regulatory obligation.

Primary note proof

Study-note section SEC29

> Under Common Criteria, define the Target of Evaluation (TOE), its configuration and environment. A Security Target (ST) states threats, assumptions, objectives, functional requirements and assurance requirements; a Protection Profile describes reusable requirements for a product category. Evaluators examine developer evidence, test and analyze vulnerabilities against those claims. A certification body oversees/reviews the evaluation and issues the certification decision; sponsors commission work and developers supply product/evidence.

Study-note section SEC29

> A certificate applies to a specified product/configuration and claims, not immunity to all future attacks.

Study-note section SEC29

An Evaluation Assurance Level packages assurance requirements; EAL1-7 express increasing evaluation rigor, not a universal ranking of security functions.

Computer Security module | PDF page 10 | lines 56-62

✓ Vulnerability Assessment: the process of scanning (locating & reporting) vulnerabilities to provide a way to detect and resolve security problems by ranking the vulnerabilities.
✓ Penetration Testing: an authorized simulated attack on a computer system, performed to evaluate the security of the system.

Computer Security module | PDF page 10 | lines 85-90

o Penetration Test (pen test):
✓ To identify both weaknesses (vulnerabilities) & strengths, to enable a full risk assessment.
✓ Determine whether a system is vulnerable, defenses were sufficient and which defenses (if any) the test defeated.

Question sources

Computer Science MCQ practice collection · Question 545

Question 89 | AM0546

What are the evaluation criteria used in the independent evaluation of operating systems?

A. User interface design and performance metrics

B. Compliance with international security standards

C. Vulnerability scanning and penetration testing results

D. Security functionality, assurance, and vulnerabilities

Hint

Distinguish requirements, technical evaluation, evidence and certification decisions.

Answer D: Security functionality, assurance and vulnerability analysis

SEC29 gives functional and assurance requirements in the Security Target, along with evaluator vulnerability analysis. D captures those evaluation dimensions. User-interface/performance measures are not the security criteria at issue; standards compliance is too broad, and scan/penetration results are evidence rather than the complete requirements framework.

Why each choice is right or wrong

A - Incorrect: Interface design and generic performance metrics do not state the security functional/assurance criteria.

B - Incorrect: Generic standards compliance omits the scoped Security Target's concrete functionality and assurance requirements.

C - Incorrect: Testing results can be evidence but do not replace the requirements and assurance criteria themselves.

D - Correct: Functionality, assurance and vulnerability analysis match the evaluation dimensions described in SEC29.

Primary note proof

Study-note section SEC29

> Under Common Criteria, define the Target of Evaluation (TOE), its configuration and environment. A Security Target (ST) states threats, assumptions, objectives, functional requirements and assurance requirements; a Protection Profile describes reusable requirements for a product category. Evaluators examine developer evidence, test and analyze vulnerabilities against those claims. A certification body oversees/reviews the evaluation and issues the certification decision; sponsors commission work and developers supply product/evidence.

Study-note section SEC27

> Vulnerability assessment finds and prioritizes weaknesses; authorized penetration testing attempts to demonstrate consequences.

Study-note section SEC27

> Static analysis inspects code, dynamic testing executes it, and fuzzing varies inputs.

Question sources

Computer Science MCQ practice collection · Question 546

Question 90 | AM0547

What is the evaluation process for trusted operating systems?

A. Development, testing, and deployment

B. Risk assessment, vulnerability scanning, and patching

C. Security requirements analysis, design, and implementation

D. Independent evaluation, testing, and certification

Hint

Distinguish requirements, technical evaluation, evidence and certification decisions.

Answer D: Independent evaluation, testing and certification

SEC29 separates developer product/evidence work, evaluator examination/testing and the certification body's review/decision. D names that evaluation-and-certification process. Development/deployment, patching and security design are related lifecycle activities but do not themselves constitute independent examination and the subsequent scoped certification decision.

Why each choice is right or wrong

A - Incorrect: Development/testing/deployment is a general software lifecycle and omits independent certification review.

B - Incorrect: Risk assessment and patching are administration/security operations rather than the full independent evaluation process.

C - Incorrect: Requirements/design/implementation are development activities that supply evidence, not the independent evaluation decision.

D - Correct: Independent examination/testing followed by certification review matches the process and roles in SEC29.

Primary note proof

Study-note section SEC29

Under Common Criteria, define the Target of Evaluation (TOE), its configuration and environment. A Security Target (ST) states threats, assumptions, objectives, functional

requirements and assurance requirements; a Protection Profile describes reusable requirements for a product category. Evaluators examine developer evidence, test and analyze vulnerabilities against those claims. A certification body oversees/reviews the evaluation and issues the certification decision; sponsors commission work and developers supply product/evidence.

Study-note section SEC29

An Evaluation Assurance Level packages assurance requirements; EAL1-7 express increasing evaluation rigor, not a universal ranking of security functions.

Study-note section SEC29

CCRA is a mutual-recognition arrangement, not a single worldwide testing laboratory.

Question sources

Computer Science MCQ practice collection · Question 547

Question 91 | AM0548

Under Common Criteria, which role oversees and reviews an independent product evaluation and issues the certification decision?

A. International Organization for Standardization (ISO)

B. National Security Agency (NSA)

C. National Institute of Standards and Technology (NIST)

D. The certification body of the applicable evaluation scheme

Hint

Distinguish requirements, technical evaluation, evidence and certification decisions.

Answer D: The certification body of the applicable evaluation scheme

Evaluators examine evidence, test the target and analyze vulnerabilities against its stated claims. The applicable scheme's certification body oversees or reviews that evaluation and issues the certification decision. CCRA concerns mutual recognition rather than acting as a worldwide testing laboratory. The answer names the responsible scheme role instead of assigning a universal responsibility to one national organization without a jurisdiction or scheme being specified.

Why each choice is right or wrong

A - Incorrect: ISO's name alone does not identify the applicable scheme certification body.

B - Incorrect: NSA's name alone does not identify the applicable scheme certification body.

C - Incorrect: NIST's name alone does not identify the applicable scheme certification body.

D - Correct: This is the oversight and certification-decision role specified here.

Primary note proof

Study-note section SEC29

> Under Common Criteria, define the Target of Evaluation (TOE), its configuration and environment. A Security Target (ST) states threats, assumptions, objectives, functional requirements and assurance requirements; a Protection Profile describes reusable requirements for a product category. > ✓ Penetration Testing: an authorized simulated attack on a computer system, performed to evaluate the security of the system.

Question sources

Computer Science MCQ practice collection · Question 548

Question 92 | AM0549

What is the goal of security functionality evaluation in trusted operating systems?

A. To assess the system's resistance to external attacks

B. To evaluate the system's ability to protect sensitive information

C. To analyze the system's performance and resource utilization

D. To identify potential vulnerabilities and weaknesses in the system

Hint

Separate security-policy enforcement and assurance from ordinary OS features.

Answer B: Evaluate claimed protection of sensitive information

Functionality evaluation addresses whether claimed security behavior performs its intended protection, while assurance concerns confidence in that implementation. B most directly states that protection capability. External-attack resistance is narrower, performance is not security functionality, and weakness discovery is the vulnerability-analysis aspect rather than the complete functional goal.

Why each choice is right or wrong

A - Incorrect: Resistance to external attacks is only a subset and omits internal threats and broader claimed security behavior.

B - Correct: Assessing the ability to protect sensitive information matches evaluation of claimed security functionality.

C - Incorrect: Generic performance/resource use is not the security-functionality goal described.

D - Incorrect: Weakness identification is vulnerability analysis, a related evaluation activity rather than the overall functionality goal.

Primary note proof

Study-note section SEC28

> A trusted OS is relied on to enforce a stated security policy. Relevant mechanisms include identification/authentication, process and memory isolation, controlled privileges, object access enforcement, protected auditing, safe resource reuse, trusted boot/update paths and recovery behavior. The trusted computing base comprises components whose failure can violate policy; smaller, analyzable boundaries simplify assurance.

Study-note section SEC29

> A Security Target (ST) states threats, assumptions, objectives, functional requirements and assurance requirements; a Protection Profile describes reusable requirements for a product category.

Study-note section SEC28

Assurance is justified confidence that controls implement the claims; functionality is what controls claim to do.

Question sources

Computer Science MCQ practice collection · Question 549

Question 93 | AM0550

What is the assurance level in the evaluation of trusted operating systems?

A. The level of protection provided by the system's security controls

B. The level of confidence in the system's security claims and implementation

C. The level of user satisfaction with the system's performance

D. The level of compliance with industry standards and regulations

Hint

Separate security-policy enforcement and assurance from ordinary OS features.

Answer B: Confidence in security claims and implementation

Assurance describes justified confidence that controls implement their claims; SEC28 states that distinction and SEC29 describes increasing evaluation rigor. B matches confidence in implementation. It must not be confused with the number or strength of functions, user satisfaction or generic compliance. Products with different scopes cannot be ranked automatically by assurance number alone.

Why each choice is right or wrong

A - Incorrect: Protection functionality is what controls do; assurance is confidence in the evidence and implementation.

B - Correct: Assurance is justified confidence in security claims and their implementation.

C - Incorrect: User satisfaction with performance is not security assurance.

D - Incorrect: Generic compliance is not the defined confidence measure or evaluation rigor represented by assurance.

Primary note proof

Study-note section SEC28

> A trusted OS is relied on to enforce a stated security policy. Relevant mechanisms include identification/authentication, process and memory isolation, controlled privileges, object access enforcement, protected auditing, safe resource reuse, trusted boot/update paths and recovery behavior. The trusted computing base comprises components whose failure can violate policy; smaller, analyzable boundaries simplify assurance.

Study-note section SEC28

> Assurance is justified confidence that controls implement the claims; functionality is what controls claim to do.

> • IA: measures that protect and defend information and ISs by ensuring their availability, integrity, authentication, confidentiality, and non-repudiation.
> • Information protection or InfoSec: protection of information and ISs from unauthorized access, use, disclosure, disruption, modification, perusal, inspection, recording or destruction.

Computer Security module | PDF page 10 | lines 56-62

> ✓ Vulnerability Assessment: the process of scanning (locating & reporting) vulnerabilities to provide a way to detect and resolve security problems by ranking the vulnerabilities.
> ✓ Penetration Testing: an authorized simulated attack on a computer system, performed to evaluate the security of the system.

Question sources

Computer Science MCQ practice collection · Question 550

Question 94 | AM0551

What is the role of vulnerability analysis in the independent evaluation of operating systems?

A. To identify potential weaknesses and vulnerabilities in the system

B. To analyze the system's performance and resource utilization

C. To assess the system's resistance to external attacks

D. To evaluate the system's ability to protect sensitive information

Hint

Trace timing over shared state or distinguish finding a weakness from demonstrating consequences.

Answer A: To identify potential weaknesses and vulnerabilities in the system

Vulnerability assessment explicitly locates and reports vulnerabilities and pen testing identifies weaknesses/strengths (PDF p.10). Thus identifying weaknesses is the directly supported purpose of vulnerability analysis, including when used within an evaluation.

Why each choice is right or wrong

A - Correct: Locating weaknesses directly matches the stated assessment task. See PDF p.10.

B - Incorrect: Performance/resource utilization is not the stated vulnerability-finding task. See PDF p.10.

C - Incorrect: Attack resistance is a broader test concern; locating weaknesses is the direct analysis function asked. See PDF p.10.

D - Incorrect: Protecting sensitive information is the broader security goal, not the immediate vulnerability-analysis output. See PDF p.10.

Primary note proof

Study-note section SEC27

> Vulnerability assessment finds and prioritizes weaknesses; authorized penetration testing attempts to demonstrate consequences. Static analysis inspects code, dynamic testing executes it, and fuzzing varies inputs. Host/network/database scanners see different exposures and have false results. Correct findings, patch, test and recheck; testing is not proof of absence. Build threat modeling, review, least privilege, dependency management and safe error handling into development.

Study-note section SEC29

> An Evaluation Assurance Level packages assurance requirements; EAL1-7 express increasing evaluation rigor, not a universal ranking of security functions.

Study-note section SEC29

> Evaluators examine developer evidence, test and analyze vulnerabilities against those claims.

Question sources

Computer Science MCQ practice collection · Question 551

Question 95 | AM0552

What is the purpose of certification in the evaluation of trusted operating systems?

A. To ensure compliance with industry standards and regulations

B. To guarantee absolute security and protection against all threats

C. To provide a warranty for the system's performance and reliability

D. To demonstrate that the system meets specific security requirements

Hint

Distinguish requirements, technical evaluation, evidence and certification decisions.

Answer D: Demonstrate conformance to specified security requirements

Certification records a reviewed decision about a scoped product/configuration meeting specified claims. D fits that purpose. The decision is not an unlimited guarantee against attacks, a performance warranty or proof of every industry/regulatory requirement. SEC29's scope qualification is essential to interpreting what the certificate actually establishes.

Why each choice is right or wrong

A - Incorrect: Generic industry/regulatory compliance exceeds the specific scoped security claims established by certification.

B - Incorrect: Certification does not guarantee absolute security or protection against all threats.

C - Incorrect: A security certificate is not a warranty of general performance and reliability.

D - Correct: Certification demonstrates satisfaction of specified security requirements within the evaluated scope/configuration.

Primary note proof

Study-note section SEC29

> Under Common Criteria, define the Target of Evaluation (TOE), its configuration and environment. A Security Target (ST) states threats, assumptions, objectives, functional requirements and assurance requirements; a Protection Profile describes reusable requirements for a product category. Evaluators examine developer evidence, test and analyze vulnerabilities against those claims. A certification body oversees/reviews the evaluation and issues the certification decision; sponsors commission work and developers supply product/evidence.

Study-note section SEC29

> A certificate applies to a specified product/configuration and claims, not immunity to all future attacks.

Study-note section SEC29

> A higher number does not make a product with different scope automatically safer.

Question sources

Computer Science MCQ practice collection · Question 552

Question 96 | AM0553

What is the significance of independent evaluation in trusted operating systems?

A. It guarantees absolute security and protection against all threats.

B. It ensures compliance with industry standards and regulations.

C. It provides assurance that the system is immune to all vulnerabilities.

D. It increases confidence in the system's security and reliability.

Hint

Distinguish requirements, technical evaluation, evidence and certification decisions.

Answer D: Increase justified confidence in security and reliability

Independent examination and testing add evidence supporting confidence in stated security behavior and reliability within scope. D gives that qualified benefit. SEC29 rejects the inference that certification makes a product immune to future attacks; it also does not establish every unrelated regulatory obligation. Confidence increases through evidence, rather than becoming an absolute guarantee.

Why each choice is right or wrong

A - Incorrect: Independent evaluation cannot guarantee absolute security against every threat.

B - Incorrect: It does not automatically establish compliance with all industry standards and regulations.

C - Incorrect: Tests and evidence cannot prove immunity to every possible vulnerability.

D - Correct: Independent scrutiny increases justified confidence in the product’s scoped security and dependable operation.

Primary note proof

Study-note section SEC29

> Under Common Criteria, define the Target of Evaluation (TOE), its configuration and environment. A Security Target (ST) states threats, assumptions, objectives, functional requirements and assurance requirements; a Protection Profile describes reusable requirements for a product category. Evaluators examine developer evidence, test and analyze vulnerabilities against those claims. A certification body oversees/reviews the evaluation and issues the certification decision; sponsors commission work and developers supply product/evidence.

Study-note section SEC29

> A certificate applies to a specified product/configuration and claims, not immunity to all future attacks.

Question sources

Computer Science MCQ practice collection · Question 553

Question 97 | AM0554

Which listed properties are fundamental database-security goals, rather than operational growth or transaction-execution capabilities? Select all that apply.

A. Availability

B. Concurrency

C. Scalability

D. Confidentiality

Hint

Match the control's scope to the disclosure or access path.

Answer A, D: Availability; Confidentiality

Database security includes confidentiality, integrity, availability and accountability together. Availability and confidentiality are both present in the choices and must be selected. Concurrency concerns overlapping transactions and can require integrity-preserving control, while scalability concerns capacity growth. These capabilities matter to a database system but do not replace the named security goals. The revised selection wording preserves both valid goals instead of choosing confidentiality arbitrarily.

Why each choice is right or wrong

A - Correct: Availability is explicitly part of database security.

B - Incorrect: Concurrency is an execution capability, not a named security goal in this taxonomy.

C - Incorrect: Scalability describes growth capability rather than a named security goal.

D - Correct: Confidentiality is explicitly part of database security.

Primary note proof

Study-note section SEC30

> Database security needs confidentiality, integrity, availability and accountability together. Authenticate connections, give roles only necessary table/column/row privileges, restrict views and audit sensitive changes. A user allowed to read a report need not read the underlying full table. Check application-level authorization as well as database rights.

Study-note section SEC01

> One event can harm several goals.

Study-note section SEC01

> Information assurance includes confidence, risk management, protection, detection, response and restoration across the information lifecycle.

> • Confidentiality: Data confidentiality and Privacy
> o is the prevention of unauthorized disclosure of information.

o In other words, confidentiality means keeping information private or safe.
o it may be important for military, business or personal reasons.
o it may also be known as privacy or secrecy.

Computer Security module | PDF page 3 | lines 87-91

• Availability:
o Assures that systems work promptly and service is not denied to authorized users.
o Information should be accessible and usable upon appropriate demand by an authorized user.

Question sources

Computer Science MCQ practice collection · Question 554

Question 98 | AM0555

Which technique ensures the reliability of a database system?

A. Data encryption

B. Data replication

C. Role-based access control

D. Intrusion detection system

Hint

Separate valid data states, permission to update and recovery.

Answer B: Data replication can improve service availability

Among these options replication supplies alternate service capacity, supporting database reliability/availability when failover and failure domains are properly handled. It does not guarantee correctness or replace backups; malicious changes can replicate too. Encryption, RBAC and IDS serve confidentiality, access restriction and detection rather than redundant database service capacity.

Why each choice is right or wrong

A - Incorrect: Encryption primarily protects confidentiality rather than providing alternate database service capacity.

B - Correct: Replication can supply alternate service capacity, with reliability dependent on failover and independent failure handling.

C - Incorrect: RBAC controls permitted operations; it does not itself provide redundant database capacity or crash recovery.

D - Incorrect: An IDS detects suspicious activity and does not itself maintain database availability after component failure.

Primary note proof

Study-note section SEC31

> Write-ahead logging persists recovery records before dependent data-file changes, supporting recovery after a crash. Backups, restore tests and separately protected logs recover from deletion/corruption; replication provides alternate service capacity but does not replace backups. Redundancy improves availability only with appropriate failover and independent failure handling. Distinguish confidentiality controls from reliability controls and from integrity constraints.

Study-note section SEC30

> Strong access controls, encryption and protected transmission can all contribute to secrecy; compare their roles and assumptions.

Study-note section SEC30

> Replication is useful for availability but also copies malicious updates unless separate recovery controls exist.

> • The secret key shared by both sender and receiver.
> • All classical encryption algorithms are private-key.
> o Use the same key (shared key) for encryption and
> decryption process.
> • If this key is disclosed communications are compromised.

Computer Security module | PDF page 11 | lines 80-87

> 6. Access control
> • Since many systems (such as router access control lists)

define which packets may and which packets may not pass based on the sender's IP address
• An access enforcement mechanism authorizes requests from multiple subjects (e.g. users, processes, etc.) to perform operations (e.g., read, write, etc.) on objects (e.g., files, sockets, etc.).

Computer Security module | PDF page 4 | lines 89-99

o Encryption: primary control that protects CIA, by which Cleartext scambled into ciphertext.
o Software controls: password checker, virus scanner, IDS (intrusion detection system)
o Hardware controls: provide higher degree of security; Locks, Smart cards, dongles, hadware keys...
o Policies and procedures: Alignment with users' legal and ethical standards; eg. password policy
o Physical controls: natural and man-made disaster protection; walls, locks, guards, security, cameras, backup copies and archives

Question sources

Computer Science MCQ practice collection · Question 555

Question 99 | AM0556

Which option gives the most direct definition of database integrity as a property of stored data, rather than a broader recovery activity, confidentiality control or monitoring activity?

A. Ensuring data consistency and accuracy

B. Protecting data from unauthorized access

C. Preventing data loss or corruption

D. Monitoring and detecting security breaches

Hint

Separate valid data states, permission to update and recovery.

Answer A: Ensuring data consistency and accuracy

Integrity concerns valid, accurate and consistent data and valid state transitions. A states that property directly. Preventing corruption can contribute to integrity, but the combined loss-or-corruption wording also includes availability and recovery concerns, so it is a broader activity rather than the most direct definition requested. Access protection can serve confidentiality, and monitoring detects events; neither describes the data-validity property as precisely as A.

Why each choice is right or wrong

A - Correct: Accuracy and consistency directly characterize the requested integrity property.

B - Incorrect: Generic access protection is broader and does not directly define data validity.

C - Incorrect: Preventing loss or corruption is a broader protection/recovery activity, though preventing corruption contributes to integrity.

D - Incorrect: Monitoring is a detection activity rather than the property of valid data.

Primary note proof

Study-note section SEC31

> Integrity requires valid data and valid transitions. NOT NULL rejects missing mandatory values; UNIQUE/primary keys prevent duplicate identifiers; foreign keys preserve references; CHECK enforces declared predicates. Transactions group a transfer's debit and credit atomically; concurrency control prevents unsafe interleavings. Roles/ACLs limit who may update, but constraints and transaction logic determine whether an authorized update is valid.

Study-note section SEC01

> Information assurance includes confidence, risk management, protection, detection, response and restoration across the information lifecycle.

Study-note section SEC01

> Availability supplies timely, usable service to authorized users: crashes, resource starvation and denied access violate it.

Question sources

Computer Science MCQ practice collection · Question 556

Question 100 | AM0557

Which controls directly restrict disclosure of database contents in their applicable scopes, rather than primarily reviewing evidence after activity? Select all that apply.

A. Using strong access controls

B. Implementing encryption techniques

C. Enforcing secure data transmission protocols

D. Conducting regular security audits

Hint

Match the control's scope to the disclosure or access path.

Answer A, B, C: Using strong access controls; Implementing encryption techniques; Enforcing secure data transmission protocols

Access controls restrict which subjects can read data. Encryption at rest protects stolen storage when keys remain separate, and protected transmission secures data on the connection. All three can directly contribute to secrecy in their respective scopes, though none prevents every disclosure. Audits principally inspect evidence and reveal problems rather than themselves concealing contents or enforcing every access. The stated direct-control distinction makes A, B and C the valid selection.

Why each choice is right or wrong

A - Correct: Access rules can directly restrict unauthorized readers.

B - Correct: Encryption protects content in its applicable scope when keys are properly separated.

C - Correct: Protected transport restricts disclosure on the communication channel.

D - Incorrect: Audits primarily review evidence rather than directly concealing content or enforcing each read.

Primary note proof

Study-note section SEC30

> Database security needs confidentiality, integrity, availability and accountability together. Authenticate connections, give roles only necessary table/column/row privileges, restrict views and audit sensitive changes. A user allowed to read a report need not read the underlying full table. Check application-level authorization as well as database rights.

Study-note section SEC30

> Encryption at rest protects stolen storage/backups when keys remain separate; transport encryption protects the connection.

Study-note section SEC30

Strong access controls, encryption and protected transmission can all contribute to secrecy; compare their roles and assumptions.

o A cryptographic protocol for operating NW services securely over an unsecured NW.
o Best-known application: for remote login to computer systems by users.
o Common applications: remote command-line login and execution.

Question sources

Computer Science MCQ practice collection · Question 557

Question 101 | AM0558

What is inference control in database security?

A. Controlling the flow of information within a database

B. Enforcing access controls based on user roles

C. Preventing unauthorized data leakage through inference

D. Detecting and mitigating security breaches in real-time

Hint

Consider what can be inferred from allowed outputs as well as direct access.

Answer C: Prevent protected facts being inferred from allowed outputs

Inference control addresses indirect disclosure, such as subtracting a known salary from a two-person total to learn the protected value. SEC32 describes restricting/coarsening outputs and tracking queries to reduce that leakage. C names the specific purpose, while generic information flow, roles and real-time detection do not identify inference from combinations of permitted results.

Why each choice is right or wrong

A - Incorrect: Information-flow control is broader; this option omits inference from permitted outputs and auxiliary knowledge.

B - Incorrect: Role-based access alone does not prevent inference from otherwise permitted query results.

C - Correct: Inference control limits indirect disclosure of protected facts through combinations of outputs and outside knowledge.

D - Incorrect: Real-time breach detection is a separate incident-monitoring function rather than inference control.

Primary note proof

Study-note section SEC32

Inference reveals protected facts by combining individually permitted outputs with other knowledge. If a report gives a two-person salary total and one salary is known, subtraction

reveals the other. Blocking direct SELECT of a salary column does not stop that inference. Restrict small groups and overlapping queries, track query history, coarsen/suppress results, or introduce carefully designed noise; each trades utility against leakage.

Computer Security module | PDF page 11 | lines 80-87

6. Access control
• Since many systems (such as router access control lists) define which packets may and which packets may not pass based on the sender's IP address
• An access enforcement mechanism authorizes requests from multiple subjects (e.g. users, processes, etc.) to perform operations (e.g., read, write, etc.) on objects (e.g., files, sockets, etc.).

Question sources

Computer Science MCQ practice collection · Question 558

Question 102 | AM0559

How can multi-level databases ensure data confidentiality?

A. By using data encryption techniques

B. By implementing mandatory access controls

C. By conducting regular security audits

D. By employing intrusion detection systems

Hint

Consider what can be inferred from allowed outputs as well as direct access.

Answer B: Mandatory label/clearance access controls

SEC32 distinguishes multilevel databases by mandatory label/clearance restrictions, including controlled read/write flows. B names that mechanism. Encryption, audits and IDS can support security, but none alone enforces the multilevel policy. Even mandatory controls need consideration of inference and covert channels rather than a blanket confidentiality guarantee.

Why each choice is right or wrong

A - Incorrect: Encryption can protect stored/transmitted content but does not itself enforce multilevel classification/clearance rules.

B - Correct: Mandatory controls compare clearances/classifications and enforce the multilevel disclosure policy.

C - Incorrect: Audits review activity and controls; they do not themselves enforce every multilevel access decision.

D - Incorrect: IDS detects suspicious activity but does not implement the database's mandatory label policy.

Primary note proof

Study-note section SEC32

> A multilevel database stores items at different labels and enforces mandatory policy using subject clearances, classifications and compartments. Bell-LaPadula-style read/write restrictions prevent direct downward confidentiality flow; trusted declassification is a separate controlled action. Views alone are not proof of multilevel isolation. Covert channels, query results and error messages may still reveal information, so evaluate both direct access and indirect inference.

Study-note section SEC24

> An IDS observes and alerts; an IPS can enforce blocking, usually inline.

Study-note section SEC30

> Strong access controls, encryption and protected transmission can all contribute to secrecy; compare their roles and assumptions.

o it may also be known as privacy or secrecy.

Question sources

Computer Science MCQ practice collection · Question 559

Question 103 | AM0560

Which security requirement is critical for protecting sensitive data in a database?

A. Availability

B. Scalability

C. Confidentiality

D. Concurrency

Hint

Identify the property harmed: disclosure, improper change, unavailable service or lack of reliable attribution.

Answer C: Confidentiality

Protecting sensitive data from disclosure requires confidentiality, which the module also calls privacy or secrecy (PDF p.3). Other system properties do not specifically express that disclosure restriction.

Why each choice is right or wrong

A - Incorrect: Availability protects timely authorized access rather than secrecy. See PDF p.3.

B - Incorrect: Scalability is not the disclosed-data protection goal. See PDF p.3.

C - Correct: Confidentiality is the stated secrecy/disclosure protection goal. See PDF p.3.

D - Incorrect: Concurrency is not the stated secrecy/disclosure protection goal. See PDF p.3.

Primary note proof

Study-note section SEC01

Confidentiality restricts disclosure: copying a credit-card database violates secrecy even if the original stays intact. Integrity restricts unauthorized or improper changes: altering a balance or inserting a false message damages correctness. Availability supplies timely, usable service to

authorized users: crashes, resource starvation and denied access violate it. One event can harm several goals.

Study-note section SEC30

Database security needs confidentiality, integrity, availability and accountability together.

Study-note section SEC01

Data security protects information at rest, in use and in transit, including accidental corruption as well as intentional attacks.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Science MCQ practice collection · Question 560

Question 104 | AM0561

What is the purpose of data encryption in database security?

A. To ensure data availability

B. To protect data integrity

C. To achieve data secrecy

D. To control data access

Hint

Match the control's scope to the disclosure or access path.

Answer C: To achieve data secrecy

The module equates confidentiality with secrecy (PDF p.3) and explains shared-key encryption so an adversary cannot understand the contents (p.7). Applying that transformation to database contents protects their secrecy.

Why each choice is right or wrong

A - Incorrect: Encryption alone does not ensure that data remains accessible on time. See PDF p.3, PDF p.7.

B - Incorrect: Plain encryption is not, by itself, the unauthorized-modification definition of integrity. See PDF p.3, PDF p.7.

C - Correct: Rendering data unintelligible without the key serves secrecy. See PDF p.3, PDF p.7.

D - Incorrect: Access-control permission decisions are a separate subject/object mechanism. See PDF p.3, PDF p.7.

Primary note proof

Study-note section SEC30

> Database security needs confidentiality, integrity, availability and accountability together. Authenticate connections, give roles only necessary table/column/row privileges, restrict views and audit sensitive changes. A user allowed to read a report need not read the underlying full table. Check application-level authorization as well as database rights.

Study-note section SEC30

> Strong access controls, encryption and protected transmission can all contribute to secrecy; compare their roles and assumptions.

Question sources

Computer Science MCQ practice collection · Question 561

Question 105 | AM0562

Which permission mechanisms can prevent unauthorized database updates, while constraints and transaction logic separately enforce the validity of authorized changes? Select all that apply.

A. Access control lists

B. Data replication

C. Intrusion detection systems

D. Role-based access control

Hint

Identify subject, object and permitted operation before comparing policy models.

Answer A, D: Access control lists; Role-based access control

ACLs associate objects with allowed subjects or actions, while RBAC assigns update permissions through roles. Both can prevent updates by unauthorized subjects and therefore contribute to integrity. They do not by themselves establish that every authorized state change satisfies business rules; constraints and transaction logic address that separate requirement. Replication may copy bad updates, and intrusion detection reveals activity rather than serving as the requested permission mechanism.

Why each choice is right or wrong

A - Correct: ACLs can deny update permission to unauthorized subjects.

B - Incorrect: Replication copies state and is not an update-permission mechanism.

C - Incorrect: Intrusion detection observes or alerts rather than defining update permissions.

D - Correct: RBAC can restrict update permission through role assignments.

Primary note proof

Study-note section SEC09

Subjects request operations on objects. An ACL associates an object/resource with allowed subjects or actions; a network ACL matches traffic such as address, protocol and port. Classification and filtering are direct effects; high availability or malware detection is not guaranteed by an ACL.

Study-note section SEC31

Roles/ACLs limit who may update, but constraints and transaction logic determine whether an authorized update is valid.

Study-note section SEC09

Allowing SELECT but denying UPDATE is an access-control decision that helps integrity; it does not by itself enforce all valid business-state transitions.

Related reading (context, not primary note proof)

Question sources

Computer Science MCQ practice collection · Question 562

Question 106 | AM0563

What is the primary purpose of inference control in database security?

A. To prevent unauthorized data modification

B. To enforce secure data transmission

C. To detect and prevent unauthorized data leakage

D. To control data access based on user roles

Hint

Consider what can be inferred from allowed outputs as well as direct access.

Answer C: Prevent unauthorized information leakage through inference

Inference control concerns disclosure derived from combinations of permitted outputs and outside knowledge rather than direct unauthorized writes or merely role membership. SEC32's salary example shows why direct column restrictions are insufficient. C states this leakage-prevention goal; secure transmission and role-based decisions address different channels or controls.

Why each choice is right or wrong

A - Incorrect: Unauthorized modification concerns integrity, whereas inference control targets indirect disclosure.

B - Incorrect: Secure transport protects a connection but does not prevent inference from authorized query results.

C - Correct: Detecting/reducing unauthorized information leakage from combined results is the inference-control goal.

D - Incorrect: Role permissions alone do not stop users inferring protected facts from outputs they may access.

Primary note proof

Study-note section SEC32

> Inference reveals protected facts by combining individually permitted outputs with other knowledge. If a report gives a two-person salary total and one salary is known, subtraction reveals the other. Blocking direct SELECT of a salary column does not stop that inference. Restrict small groups and overlapping queries, track query history, coarsen/suppress results, or introduce carefully designed noise; each trades utility against leakage.

Question sources

Computer Science MCQ practice collection · Question 563

Question 107 | CS0174

XYZ Company is attacked by intruders causing system crashes, slowing down of services and denying services to targeted users. The company is attacked by?

A. Access attack

B. Viruses

C. Information gathering

D. Denial of Services (DoS)

Hint

Match the resource bottleneck or wireless mechanism to the relevant protection layer.

Answer D: Denial of Services (DoS)

The decisive symptom is denial of service to intended users; that is the module's DoS definition (PDF pp.3,5). Crashes and slowing can implement that outcome without uniquely identifying malware.

Why each choice is right or wrong

A - Incorrect: Access attacks concern gaining control, not the specific denial outcome. See PDF p.3, PDF p.5.

B - Incorrect: A virus could be a cause, but no virus evidence is stated. See PDF p.3, PDF p.5.

C - Incorrect: Information gathering does not by itself deny users service. See PDF p.3, PDF p.5.

D - Correct: Denial of Services directly names the reported blocked access. See PDF p.3, PDF p.5.

Primary note proof

Study-note section SEC06

DoS exhausts or disables a resource; distributed DoS uses multiple sources, often bots or reflected/amplified responses. A SYN flood leaves many incomplete TCP handshakes occupying state. DNS flooding targets query capacity; NXDOMAIN attacks generate queries for nonexistent names to stress resolvers. Fragment floods abuse reassembly or packet-processing resources. Rate limits, SYN cookies, filtering and upstream capacity controls address different bottlenecks.

Study-note section SEC06

Rogue access points imitate or bypass approved wireless service.

Study-note section SEC04

Malware is the umbrella term, not a specific replication method.

These source passages provide context; the primary note proof is identified separately above.

Computer Security module | PDF page 5 | lines 42-47

• Denial of Service (DoS) Attack: Blocking access from legitimate users
• Distributed DoS Attack: is accomplished by tricking routers into attacking a target or using Zombie hosts to simultaneously attack a given target with large number of packets.

Computer Security module | PDF page 3 | lines 87-91

• Availability:
o Assures that systems work promptly and service is not denied to authorized users.
o Information should be accessible and usable upon appropriate demand by an authorized user.

Question sources

Computer Science Exit Exam practice collection · Question 174

Question 108 | CS0175

Which one of the following is wrongly coupled about passive (offline) and active (online) attacks?

A. Active attack -> add or delete messages

B. Active attack -> traffic analysis

C. Passive attack -> monitoring traffic

D. Passive attack -> obtain message contents

Hint

Classify the action actually described and distinguish observation, alteration, disruption and identity claims.

Answer B: Active attack -> traffic analysis

PDF p.4 defines passive attacks as learning information without affecting resources and active attacks as alteration/effect on operation. Merely analyzing observed traffic fits passive learning, so B is the wrong pairing.

Why each choice is right or wrong

A - Incorrect: Adding/deleting messages changes resources and is active. See PDF p.4.

B - Correct: Traffic analysis, when only observing, is passive rather than active. See PDF p.4.

C - Incorrect: Monitoring without interference is passive. See PDF p.4.

D - Incorrect: Obtaining contents without changing resources is passive. See PDF p.4.

Primary note proof

Study-note section SEC03

> Interception copies or observes data, modification alters it, interruption blocks it, and fabrication inserts false material. The 4D classification uses disclosure, deception, disruption and usurpation, the last meaning unauthorized control. DoS primarily demonstrates disruption/availability loss; it need not give control of the victim.

Study-note section SEC03

> Passive attacks observe without changing the target exchange: sniffing and traffic analysis.

Study-note section SEC03

> These are not synonyms for offline and online.

Module passages - related reading

> • We can distinguish two types of attacks: (W. Stallings)
> o Active attack: an attempt to alter/affect system

resources or their operation.
o Passive attack: an attempt to learn/make use of information from the system that does not affect system resources.

Computer Security module | PDF page 4 | lines 50-61

• Types of Attacks on Data CIA (W. Stallings)
o Disclosure/Interception: unauthorized party snooping, or getting access to a resource, Attack on data confidentiality:
o Modification / Deception: unauthorized party modifying a resource, acceptance of false data, E.g., providing wrong data (attack on data integrity)
o Disruption/Interruption: destroyed/unavailable services/resources, DoS (attack on data availability)
o Fabrication: unauthorized party inserts a fake asset/resource, loss of confidentiality, authenticity and integrity of the message

Question sources

Computer Science Exit Exam practice collection · Question 175

Question 109 | CS0176

Which one of the following is NOT correct about symmetric key?

A. It requires sender and receiver to share a common secret key

B. Previous key cannot be used for a new key

C. Trusted third party can generate and deliver keys

D. Repetitive key change is encouraged to limit data being compromised

Hint

Distinguish shared-key architecture, key distribution and bulk-data use.

Answer B: Previous key cannot be used for a new key

PDF p.8 explicitly permits use of a previous key to encrypt a new key, so B contradicts a stated symmetric key-distribution alternative. A and C are explicit, while session-key disposal supports limiting reuse.

Why each choice is right or wrong

A - Incorrect: Sharing a common secret is explicitly required. See PDF p.7, PDF p.8.

B - Correct: B denies prior-key use that p.8 explicitly allows for distributing a new key. See PDF p.7, PDF p.8.

C - Incorrect: A third party can select and deliver keys to both participants. See PDF p.7, PDF p.8.

D - Incorrect: Discarding session keys after one session supports limiting key reuse and exposure. See PDF p.7, PDF p.8.

Primary note proof

Study-note section SEC16

Symmetric encryption uses a shared secret and efficiently protects bulk data. Pairwise independent keys for n users require n(n-1)/2 shared keys; a trusted key distribution center changes that architecture. A session key is temporary for a communication context; a master/key-encryption key protects subordinate keys. Distribute keys physically, via an authenticated protected channel, or through a trusted third party. An uncompromised old key can protect a new key, although this does not restore secrecy after the old key is stolen.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Security module | PDF page 7 | lines 48-54

Symmetric key cryptography
• Uses conventional / secret-key / single-key.
• The secret key shared by both sender and receiver.
• All classical encryption algorithms are private-key.
o Use the same key (shared key) for encryption and
decryption process.
• If this key is disclosed communications are compromised.

Computer Security module | PDF page 8 | lines 4-20

• Given parties A and B have various key distribution
alternatives:
o A can select key and physically deliver to B.
o Third party can select & deliver key to A & B.
o If A & B have communicated previously can use
previous key to encrypt a new key.
o If A & B have secure communications with a third-
party C, C can relay key between A & B.
• Key Hierarchy
o session key
✓ temporary key
✓ used for encryption of data between users
✓ for one logical session then discarded
o master key
✓ used to encrypt session keys
✓ shared by user & key distribution center
• Advantage: Simpler and faster

Question sources

Computer Science Exit Exam practice collection · Question 176

Question 110 | CS0177

Which one of the following is NOT a wireless attack?

A. Bluesnarfing

B. Phishing

C. Rogue access point

D. Bluejacking

Hint

Identify the trust claim or communication mapping being abused.

Answer B: Phishing is not specifically a wireless attack

SEC06 defines Bluetooth information theft as bluesnarfing, unsolicited Bluetooth messages as bluejacking and rogue access points as wireless service impersonation/bypass. Phishing is social deception across many media, not a wireless-specific mechanism. It can be delivered over a wireless connection, but that transport does not make its defining attack category wireless.

Why each choice is right or wrong

A - Incorrect: Bluesnarfing steals information over Bluetooth and is specifically a wireless attack mechanism.

B - Correct: Phishing is medium-independent trusted-source deception rather than a wireless-specific mechanism.

C - Incorrect: A rogue access point imitates or bypasses approved wireless service.

D - Incorrect: Bluejacking sends unsolicited Bluetooth messages, making it a wireless-specific attack category.

Primary note proof

Study-note section SEC05

> Phishing impersonates a trusted source to obtain secrets or induce an unsafe action; spear phishing targets a specific person. Verify a request through an independently known channel. Shoulder surfing observes entry; pretexting invents a reason for disclosure. Monitoring software used with authorization is not necessarily an attack merely because it records activity.

Study-note section SEC06

> Bluesnarfing steals Bluetooth information; bluejacking sends unsolicited Bluetooth messages.

Study-note section SEC06

> Rogue access points imitate or bypass approved wireless service.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Security module | PDF page 5 | lines 65-74

• Reconnaissance: The hackers first identifies a target to launch an attack, extract maximum information regarding this target, understand its vulnerabilities, and then only explore the best ways to exploit it.
o Examples: Credential Theft using Keyloggers and Spyware; Identity Theft using spam e-mail, phishing attack and social engineering attack
• Access: Ones the attacker Reconnaissance the target, S/he starts a successful exploitation and continued access to the system. Then, the attacker is in control of the target.

Question sources

Computer Science Exit Exam practice collection · Question 177

Question 111 | CS0178

Considering a vulnerability shared by identically configured components, which statement is NOT correct? Interpret diversity's benefits as possible reductions in common-mode compromise, not guarantees of minimum loss.

A. Non-uniform configurations may reduce loss from a vulnerability shared by one configuration

B. Uniform configurations can increase predictability

C. A vulnerability in the identical shared configuration cannot affect the other identically configured components

D. Diverse configurations may avoid exposing every resource to the same configuration-specific vulnerability

Hint

Start with the stated attacker path or physical hazard and the limits of each control.

Answer C: A vulnerability in the identical shared configuration cannot affect the other identically configured components

Uniform configurations simplify prediction and administration, but a vulnerability in the shared configuration can create correlated failures across components. Diversity may reduce that common-mode exposure, although it increases administrative cost and does not guarantee minimum loss. Option C wrongly denies the possibility of the same configuration vulnerability affecting peers. The other statements now describe qualified benefits rather than absolute guarantees.

Why each choice is right or wrong

A - Incorrect: Diversity can reduce exposure to a vulnerability limited to one configuration.

B - Incorrect: Uniformity can simplify prediction and administration.

C - Correct: Identical shared vulnerabilities can affect peer components, so this denial is false.

D - Incorrect: Diversity can reduce common-mode exposure without guaranteeing immunity.

Primary note proof

Study-note section SEC11

> Protect equipment against theft, unauthorized connections, heat, humidity, water, electrical surges and fire. A UPS supplies temporary conditioned power; it is normally protective, but faulty installation/battery failure can itself be hazardous. A disconnected machine loses many network attack paths yet remains exposed to insiders, removable media, supply-chain attacks and physical access. There is no universal “most secure computer” without a threat model.

Study-note section SEC11

> Uniform configurations simplify patching and prediction but create correlated failures; diversity may reduce common-mode compromise while raising administration cost.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Security module | PDF page 5 | lines 2-10

> • Principles of Least Privilege: —Do not give any more privileges than absolutely necessary to do/perform the required job‖.
> • Defense in Depth: having more than one layer or type of defense
> • Minimization: —do not run any software, or applications that are not strictly required to do the entrusted job.‖
> • Compartmentalization: limits the damage in other compartments when one compartment is compromised.

Question sources

Computer Science Exit Exam practice collection · Question 178

Question 112 | CS0184

_____ is a system that monitors traffic into and out of a network and automatically alerts personnel when suspicious traffic patterns occur.

A. Anti-virus Software

B. IDS

C. Firewall

D. Router

Hint

Separate observation from blocking and sensor placement from detection method.

Answer B: Intrusion detection system

Traffic observation followed by alerts about suspicious patterns is the IDS function in SEC24. The stem does not require inline blocking. Antivirus, firewalls and routers have different primary functions, though products can combine capabilities. B identifies the functional system described without assuming a firewall always detects every intrusion.

Why each choice is right or wrong

A - Incorrect: Antivirus targets malicious software and is not the generic traffic-pattern alerting system named in the note.

B - Correct: An IDS observes traffic/activity and alerts personnel to suspected intrusion patterns.

C - Incorrect: A firewall primarily enforces traffic policy; observation-and-alerting specifically identifies intrusion detection.

D - Incorrect: Routing selects packet next hops rather than defining suspicious-pattern detection and alerts.

Primary note proof

Study-note section SEC24

> An IDS observes and alerts; an IPS can enforce blocking, usually inline. Host-based sensors examine host events, network-based sensors inspect traffic. Signature detection recognizes known patterns; anomaly detection compares with a baseline and may detect novel behavior. Neither guarantees every attack is detected; anomaly detection can raise many false positives, and signatures can sometimes match variants.

Study-note section SEC23

> A firewall enforces traffic policy.

Study-note section SEC-S03

> A router forwards IP packets between networks; forwarding alone is different from detecting suspicious behavior or enforcing a firewall's security policy.

o Detect attack: accept that an attack will occur; the goal is to determine that an attack is under way, or has occurred, and report it.

Computer Security module | PDF page 11 | lines 22-34

3. Firewall
• a program or network devices (e.g. router) which filters access to a protected network from the internet connection.
• protects a local or network of systems from network-based security threats,
• monitors & controls incoming & outgoing network traffic based on predetermined security rules.
• Firewall Objectives
o Keep intruders, malicious code and unwanted traffic out
o Keep private and sensitive information in
o security wall b/n private (protected) NW & outside word.

Question sources

Computer Science Exit Exam practice collection · Question 184

Question 113 | NS0327

Suppose Mr. Negesa might act as Mr. Dereje and send message to Registrar X, the registrar might be lead to believe that message indeed come from Mr. Dereje. What types of attack Mr. Negesa has committed?

A. Denial of service

B. Modification of message

C. Masquerade

D. Replay

Hint

Identify the trust claim or communication mapping being abused.

Answer C: Masquerade

Negesa presents the message as coming from Dereje, so the registrar attributes it to the wrong person. SEC05 defines that false identity claim as masquerade. No service exhaustion, alteration of a prior message or reuse of an old valid message is stated; those attack mechanisms must not be inferred from impersonation alone.

Why each choice is right or wrong

A - Incorrect: The scenario does not deny service or exhaust resources.

B - Incorrect: No prior message is modified; the central behavior is a false sender identity.

C - Correct: Claiming Dereje's identity to fool the registrar is masquerade.

D - Incorrect: Replay requires reusing a valid old message, which the scenario does not describe.

Primary note proof

Study-note section SEC05

> Masquerade claims another identity. ARP spoofing poisons local IPv4-to-MAC associations; DNS spoofing/cache poisoning supplies false name resolutions; IP spoofing falsifies a source address. An intermediary attack intercepts and can alter exchanges. A replay reuses a valid old message; nonces, timestamps and sequence checks can reject it. Session hijacking steals or predicts a valid session token. Protect transport, regenerate session IDs after login, restrict cookies and check authorization server-side on every sensitive request.

Study-note section SEC06

> Rogue access points imitate or bypass approved wireless service.

Study-note section SEC06

> Fragment floods abuse reassembly or packet-processing resources.

Related reading (context, not primary note proof)

Question sources

Computer Science Exit Exam · 2018 · Question 54

Question 114 | NS0343

Which one of following monitors incoming and outgoing network traffic and decides whether to allow or block specific traffic based on a defined set of security rules?

A. Intrusion detection system (IDS)

B. Proxy server

C. Virtual Private network

D. Firewall

Hint

Identify which traffic is mediated and what information drives the device's decisions.

Answer D: Firewall

The described allow/block decisions follow a defined traffic policy, the firewall function in SEC23. IDS observes/alerts, a proxy mediates application requests and a VPN supplies logical private connectivity. A proxy may implement policy in some deployments, but the generic boundary traffic-policy device directly named by the definition is a firewall.

Why each choice is right or wrong

A - Incorrect: An IDS observes and alerts rather than being defined by enforcing allow/block rules.

B - Incorrect: A proxy mediates application exchanges; the general traffic-policy enforcement definition specifically names a firewall.

C - Incorrect: A VPN extends private connectivity and is not inherently a generic rule-based traffic filter.

D - Correct: A firewall enforces allow/block traffic policy based on configured rules.

Primary note proof

Study-note section SEC23

> A firewall enforces traffic policy. Stateless packet filtering matches headers such as source/destination, protocol and ports. Stateful inspection tracks permitted connection context; application proxies terminate and relay application exchanges and can inspect their content. A circuit gateway relays connections, commonly SOCKS, without full application-content interpretation; textbooks associate it with session/transport functions. Such a gateway need not encrypt and is not automatically a VPN.

Study-note section SEC22

> A VPN is a logical private connection; its actual security depends on the chosen authenticated tunnel.

Study-note section SEC24

> An IDS observes and alerts; an IPS can enforce blocking, usually inline.

Question sources

Computer Science Exit Exam · 2018 · Question 76

Question 115 | NS0361

What is the difference between confidentiality, integrity, and availability? Give an example of a breach of each.

Hint

Identify the property harmed: disclosure, improper change, unavailable service or lack of reliable attribution.

Answer: Confidentiality limits disclosure: copying a private credit-card database breaches it. Integrity preserves correctness: changing an account balance improperly breaches it. Availability provides timely usable service: crashing a server or starving resources breaches it.

SEC01 defines the three goals by the property harmed, not by one fixed attack label. Copying can breach secrecy without changing the original; alteration harms correctness; denied service harms availability. One incident can violate several goals, so these examples illustrate the primary property rather than mutually exclusive incident classes.

Primary note proof

Study-note section SEC01

> Confidentiality restricts disclosure: copying a credit-card database violates secrecy even if the original stays intact. Integrity restricts unauthorized or improper changes: altering a balance or inserting a false message damages correctness. Availability supplies timely, usable service to authorized users: crashes, resource starvation and denied access violate it. One event can harm several goals.

Question sources

Computer Security review questions · Question 1

Question 116 | NS0362

Why is multi-factor authentication more secure than passwords alone?

Hint

Separate identity claims from proof, and factor type from factor count.

Answer: MFA requires independent factor classes, such as a password plus a possessed card or biometric. Stealing the password alone then does not satisfy the other proof. Password plus PIN is still knowledge-only, not two independent factors.

SEC07 distinguishes knowledge, possession and inherence. Combining classes adds a separate proof rather than merely another secret from the same class. That reduces dependence on a password alone, although implementation, recovery channels and compromise of the additional factor still matter; MFA is not a guarantee against every attack.

Primary note proof

Study-note section SEC07

> Knowledge is a password/PIN, possession is a token/card, and inherence is a biometric such as a fingerprint. Behavioral biometrics include typing rhythm or handwriting; some textbooks call these “something one does.” A body characteristic is not “three-factor authentication”: one biometric is one factor. Password plus PIN remains one factor class; card plus PIN is two. An OTP’s factor depends on its delivery/generation mechanism.

Study-note section SEC08

> Use unique long secrets and password managers, rate limiting and suitable MFA; store salted slow password hashes, not reversible plaintext passwords.

Study-note section SEC08

> OAuth alone does not define a complete end-user login identity protocol; OpenID Connect adds an identity layer.

Question sources

Computer Security review questions · Question 2

Question 117 | NS0363

What is the difference between symmetric and asymmetric encryption? Why do we use both?

Hint

Identify the intended recipient or signer and separate confidentiality from verification.

Answer: Symmetric encryption shares a secret key and efficiently protects bulk data. Asymmetric encryption uses a recipient public/private pair: encrypt to the authenticated public key and decrypt with the private key. Hybrid systems use public-key mechanisms to establish a symmetric secret, then symmetric protection for content.

SEC16 supplies the efficient shared-secret model; SEC18 supplies recipient key direction and hybrid composition. Public keys ease distribution only with authentic identity bindings. Combining them addresses distribution/authentication and bulk-data efficiency without claiming either family is inherently more secure or assigning fixed speed ratios.

Primary note proof

Study-note section SEC18

> For confidentiality to B, encrypt with B's authenticated public encryption key; B decrypts with B's private key. Do not encrypt to A's public key if only B should read it, and never assume A possesses B's private key. For a signature, A signs with A's private signing key and others verify with A's public key. These are distinct operations; not every public-key algorithm supports encryption.

Study-note section SEC16

> Symmetric encryption uses a shared secret and efficiently protects bulk data.

Study-note section SEC18

> Hybrid systems establish or encapsulate a symmetric secret with public-key mechanisms, then protect bulk data symmetrically.

Question sources

Computer Security review questions · Question 3

Question 118 | NS0364

What is a DDoS attack and how does it differ from a DoS attack?

Hint

Match the resource bottleneck or wireless mechanism to the relevant protection layer.

Answer: DoS exhausts or disables a resource so authorized users lose usable service. DDoS is DoS launched through multiple distributed sources, often bots or reflected/amplified responses. The distinction is source distribution, not a different security goal: both primarily harm availability.

SEC06 defines the resource-exhaustion/disabling mechanism and distributed sources. Multiple sources can stress different bottlenecks, so appropriate responses include rate limits, filtering and upstream capacity controls. The number of sources does not imply the attacker obtained control of the victim; the demonstrated harm is unavailable service.

Primary note proof

Study-note section SEC06

> DoS exhausts or disables a resource; distributed DoS uses multiple sources, often bots or reflected/amplified responses. A SYN flood leaves many incomplete TCP handshakes occupying state. DNS flooding targets query capacity; NXDOMAIN attacks generate queries for nonexistent names to stress resolvers. Fragment floods abuse reassembly or packet-processing resources. Rate limits, SYN cookies, filtering and upstream capacity controls address different bottlenecks.

Study-note section SEC03

> DoS primarily demonstrates disruption/availability loss; it need not give control of the victim.

Study-note section SEC06

> Rogue access points imitate or bypass approved wireless service.

Question sources

Computer Security review questions · Question 4

Question 119 | NS0365

Why is SQL injection dangerous? How is it prevented?

Hint

Locate where untrusted data can become instructions and where they execute.

Answer: SQL injection lets untrusted input alter SQL syntax through unsafe string construction, changing query behavior or affected rows. Use prepared statements with bound data values, allow-list nonparameterizable identifiers, and give the application account minimal privileges. Stored procedures/ORMs must also avoid unsafe dynamic SQL.

The danger is crossing the data-versus-query-syntax boundary, not merely accepting an unusual string. Parameter binding keeps supplied values as data, while identifier allow-lists handle structure that cannot be bound. Restricting database rights limits impact. SEC26 warns that a procedure or ORM name alone does not make dynamically concatenated SQL safe.

Primary note proof

Study-note section SEC26

> SQL injection occurs when untrusted values alter SQL syntax through unsafe string construction. A tautology can change which rows match. Bind data values in prepared statements, allow-list identifiers that cannot be parameters, and restrict the application's database account. Stored procedures/ORMs are safe only when they avoid unsafe dynamic SQL.

Study-note section SEC26

> Stored content persists; reflected content returns in a response; DOM-based XSS can arise from unsafe browser sinks.

Question sources

Computer Security review questions · Question 5

Question 120 | NS0366

What is the difference between IDS and IPS?

Hint

Separate observation from blocking and sensor placement from detection method.

Answer: An IDS observes activity and alerts about suspected attacks. An IPS can actively block traffic, usually inline. Detection can use signatures or anomaly baselines; neither system guarantees every attack is detected or every alert represents a real attack.

The key distinction in SEC24 is observation/alerting versus enforcement. Host sensors examine host events and network sensors inspect traffic, independently of that IDS/IPS action distinction. Inline prevention adds a blocking decision; false positives can then deny legitimate activity, so detection context and policy remain important.

Primary note proof

Study-note section SEC24

> An IDS observes and alerts; an IPS can enforce blocking, usually inline. Host-based sensors examine host events, network-based sensors inspect traffic. Signature detection recognizes known patterns; anomaly detection compares with a baseline and may detect novel behavior. Neither guarantees every attack is detected; anomaly detection can raise many false positives, and signatures can sometimes match variants.

Study-note section SEC24

> A true positive is a real attack detected, false negative is a missed attack, false positive is innocent activity flagged, and true negative is innocent activity accepted.

Question sources

Computer Security review questions · Question 6

Question 121 | NS0417

What are the three primary security goals known as the CIA triad?

Hint

Identify the property harmed: disclosure, improper change, unavailable service or lack of reliable attribution.

Answer: The CIA triad is confidentiality, integrity and availability: restrict unauthorized disclosure, prevent improper changes, and provide timely usable service to authorized users.

SEC01 defines each goal by a separate property. Secrecy concerns who learns information, integrity concerns correct information/changes, and availability concerns usable service. These goals can be harmed together; satisfying one does not establish the others. Authentication and authorization support protection but are not replacements for the three CIA goals.

Primary note proof

Study-note section SEC01

> Confidentiality restricts disclosure: copying a credit-card database violates secrecy even if the original stays intact. Integrity restricts unauthorized or improper changes: altering a balance or inserting a false message damages correctness. Availability supplies timely, usable service to authorized users: crashes, resource starvation and denied access violate it. One event can harm several goals.

Study-note section SEC01

> Authentication establishes an identity or other claim; authorization decides permitted actions.

Study-note section SEC01

> Data security protects information at rest, in use and in transit, including accidental corruption as well as intentional attacks.

Question sources

Computer Security review questions · Question 1

Question 122 | NS0418

What is a 'vulnerability' in the context of computer security?

Hint

Distinguish weaknesses, potential harmful events, actual attempts and the effect of a control.

Answer: A vulnerability is an exploitable weakness in a system or its protection. It differs from a threat, which is a potentially harmful circumstance, and an attack, which is an actual attempt to cause harm.

SEC02 separates weakness, potential harm and attempted exploitation. A software flaw can exist without an attack taking place; controls reduce likelihood or impact. Calling every flaw an active attack would erase that distinction and misstate what a vulnerability finding actually proves.

Primary note proof

Study-note section SEC02

> An asset is something valuable: data, software, hardware, service or reputation. A threat is a potentially harmful circumstance; a vulnerability is an exploitable weakness; an attack is an actual attempt; a control reduces likelihood or impact. A software flaw is not automatically an active attack. Risk concerns likelihood and consequence, not a universally meaningful numeric product of two unmeasured labels.

Question sources

Computer Security review questions · Question 2

Question 123 | NS0419

What is the difference between 'prevention' and 'detection' in computer security?

Hint

Distinguish weaknesses, potential harmful events, actual attempts and the effect of a control.

Answer: Prevention attempts to block a harmful event; detection reveals that an event or suspicious activity has occurred. Encryption can prevent disclosure, while audit logs supply detective/accountability evidence. Recovery is a further function that restores safe operation after damage.

SEC02 classifies controls by effect rather than by whether they are physical or technical. A preventive control can fail, and a detective control may then expose the event. Detection does not itself imply blocking; combining these stages supports a fuller protection and response process.

Primary note proof

Study-note section SEC02

> Preventive controls block events, detective controls reveal them, corrective/recovery controls restore safe operation, and deterrents discourage attempts. Encryption is preventive for disclosure; an audit log is principally detective/accountability evidence. Physical, technical and administrative are control categories, not competing stages. An external firewall cannot replace a written policy or a locked equipment room.

Question sources

Computer Security review questions · Question 3

Question 124 | NS0420

Which security property ensures that a message was not altered by unauthorized individuals?

Hint

Identify the property harmed: disclosure, improper change, unavailable service or lack of reliable attribution.

Answer: Integrity is the property that protects a message against unauthorized or improper alteration. A suitable keyed MAC or digital signature can provide integrity evidence under the relevant key/trust assumptions.

SEC01 defines integrity by correctness of content and changes. SEC20 explains that an unkeyed hash alone requires a trusted reference because an attacker can recompute it after modification. Therefore the property is integrity, while the mechanism used to establish it must be selected with an appropriate trust model.

Primary note proof

Study-note section SEC01

> Confidentiality restricts disclosure: copying a credit-card database violates secrecy even if the original stays intact. Integrity restricts unauthorized or improper changes: altering a balance or inserting a false message damages correctness. Availability supplies timely, usable service to authorized users: crashes, resource starvation and denied access violate it. One event can harm several goals.

Study-note section SEC20

> An attacker can recompute an unkeyed hash of modified data, so a hash alone needs a trusted reference.

Study-note section SEC20

> Verification checks origin/integrity under key-identity and key-custody assumptions; it does not conceal content.

Question sources

Computer Security review questions · Question 4

Question 125 | NS0421

What is Data Security focused on protecting?

Hint

Identify the property harmed: disclosure, improper change, unavailable service or lack of reliable attribution.

Answer: Data security protects information at rest, in use and in transit against unauthorized disclosure, improper changes and loss of usable access. It includes accidental corruption as well as deliberate attacks.

SEC01 explicitly covers the information lifecycle and accidental as well as intentional harm. Protection is broader than encrypting network traffic: storage, processing and access/recovery controls also matter. The CIA goals describe complementary properties, so secrecy alone is not the whole of data security.

Primary note proof

Study-note section SEC01

> Authentication establishes an identity or other claim; authorization decides permitted actions. Accountability links actions to responsible entities through reliable identity and protected logs. Non-repudiation supplies evidence supporting origin or receipt; signatures do not make denial physically impossible. Information assurance includes confidence, risk management, protection, detection, response and restoration across the information lifecycle. Data security protects information at rest, in use and in transit, including accidental corruption as well as intentional attacks.

Question sources

Computer Security review questions · Question 5

Question 126 | NS0422

What are the '4D's' of security threats?

Hint

Classify the action actually described and distinguish observation, alteration, disruption and identity claims.

Answer: The four are disclosure, deception, disruption and usurpation. Disclosure exposes information; deception supplies false material or beliefs; disruption harms service; usurpation means unauthorized control.

SEC03 explicitly names this classification and distinguishes disruption from control. A denial-of-service event demonstrates disruption and availability loss, but does not by itself prove the attacker usurped the victim. The categories describe kinds of harm rather than requiring every attack to produce all four.

Primary note proof

Study-note section SEC03

> Interception copies or observes data, modification alters it, interruption blocks it, and fabrication inserts false material. The 4D classification uses disclosure, deception, disruption and usurpation, the last meaning unauthorized control. DoS primarily demonstrates disruption/availability loss; it need not give control of the victim.

Question sources

Computer Security review questions · Question 6

Question 127 | NS0423

What is the key difference between passive and active attacks?

Hint

Classify the action actually described and distinguish observation, alteration, disruption and identity claims.

Answer: Passive attacks observe without changing the exchange, such as sniffing or traffic analysis. Active attacks inject, modify, replay or disrupt communications or service. Passive/active does not mean offline/online.

The distinction is intervention in the target exchange, as SEC03 explains. Traffic analysis can infer relationships from timing and sizes even with encrypted content, so passive observation still creates risk. Neither category is universally easy to detect or prevent; those claims depend on the mechanism and deployed controls.

Primary note proof

Study-note section SEC03

> Interception copies or observes data, modification alters it, interruption blocks it, and fabrication inserts false material. The 4D classification uses disclosure, deception, disruption and usurpation, the last meaning unauthorized control. DoS primarily demonstrates disruption/availability loss; it need not give control of the victim.

Study-note section SEC03

> Passive attacks observe without changing the target exchange: sniffing and traffic analysis.

Study-note section SEC03

> Traffic analysis can infer relationships from timing/size even when content is encrypted.

Question sources

Computer Security review questions · Question 7

Question 128 | NS0424

What is a Denial of Service (DoS) attack?

Hint

Match the resource bottleneck or wireless mechanism to the relevant protection layer.

Answer: A denial-of-service attack exhausts or disables a resource so authorized users cannot obtain timely usable service. Examples include incomplete-handshake state exhaustion or resolver query flooding. Distributed DoS uses multiple sources.

SEC06 identifies the mechanism as service exhaustion/disabling. SEC01 connects unavailable or unusable service to availability loss. The attacker need not alter stored data or gain control of the target; the resource bottleneck and service effect distinguish this attack from other harms.

Primary note proof

Study-note section SEC06

> DoS exhausts or disables a resource; distributed DoS uses multiple sources, often bots or reflected/amplified responses. A SYN flood leaves many incomplete TCP handshakes occupying state. DNS flooding targets query capacity; NXDOMAIN attacks generate queries for nonexistent names to stress resolvers. Fragment floods abuse reassembly or packet-processing resources. Rate limits, SYN cookies, filtering and upstream capacity controls address different bottlenecks.

Study-note section SEC01

> Availability supplies timely, usable service to authorized users: crashes, resource starvation and denied access violate it.

Study-note section SEC06

> Rogue access points imitate or bypass approved wireless service.

Question sources

Computer Security review questions · Question 8

Question 129 | NS0425

What does 'snooping' refer to in network security?

Hint

Classify the action actually described and distinguish observation, alteration, disruption and identity claims.

Answer: Snooping is unauthorized observation or interception of information, such as reading captured network traffic. When it only observes the exchange without modifying it, it is a passive attack against confidentiality.

SEC03 groups interception with observing/copying data and lists sniffing among passive attacks. This differs from modification or fabrication, which change or inject material. Encryption can hide content while traffic timing/size still supports traffic analysis, so observing communication metadata can remain informative.

Primary note proof

Study-note section SEC03

> Interception copies or observes data, modification alters it, interruption blocks it, and fabrication inserts false material. The 4D classification uses disclosure, deception, disruption and usurpation, the last meaning unauthorized control. DoS primarily demonstrates disruption/availability loss; it need not give control of the victim.

Study-note section SEC03

> Passive attacks observe without changing the target exchange: sniffing and traffic analysis.

Study-note section SEC03

> Traffic analysis can infer relationships from timing/size even when content is encrypted.

Question sources

Computer Security review questions · Question 9

Question 130 | NS0426

What is 'repudiation' in computer security?

Hint

Identify the property harmed: disclosure, improper change, unavailable service or lack of reliable attribution.

Answer: Repudiation is denying involvement, such as denying having sent or received a message. Non-repudiation supplies evidence supporting origin or receipt under identity/key-custody assumptions; it does not make a person physically unable to deny an action.

SEC01 frames non-repudiation as evidentiary support rather than an absolute ban on denial. SEC20 explains why signatures can support origin/integrity while shared-key MACs limit third-party attribution because both holders can create them. The strength of the evidence depends on trustworthy identities, keys and records.

Primary note proof

Study-note section SEC01

> Authentication establishes an identity or other claim; authorization decides permitted actions. Accountability links actions to responsible entities through reliable identity and protected logs. Non-repudiation supplies evidence supporting origin or receipt; signatures do not make denial physically impossible. Information assurance includes confidence, risk management, protection, detection, response and restoration across the information lifecycle. Data security protects information at rest, in use and in transit, including accidental corruption as well as intentional attacks.

Study-note section SEC20

> A keyed MAC provides integrity and shared-secret authentication; both holders can create it, limiting third-party non-repudiation.

Study-note section SEC20

> Verification checks origin/integrity under key-identity and key-custody assumptions; it does not conceal content.

Question sources

Computer Security review questions · Question 10

Question 131 | NS0427

What distinguishes a worm from a computer virus?

Hint

Separate propagation, disguise and payload when classifying malicious software.

Answer: A virus attaches to a host program/document and spreads when the infected host executes. A worm replicates independently, commonly across networks. The distinction is host dependency, not a universal ranking of speed or required user action.

SEC04 defines propagation mechanisms separately from payloads and disguise. A malware package may contain several components, so a worm can also carry another malicious function. That does not change the independent-replication distinction or justify assuming every worm always spreads faster than every virus.

Primary note proof

Study-note section SEC04

> A virus replicates by attaching to a host program or document; execution of the infected host spreads it. A worm replicates independently, commonly across networks. A Trojan disguises malicious behavior as something useful and does not require self-replication. These labels describe different properties, so a malware package may contain several components.

Study-note section SEC04

> Adware displays unwanted advertising and may also track users.

Study-note section SEC04

> Malware is the umbrella term, not a specific replication method.

Question sources

Computer Security review questions · Question 11

Question 132 | NS0428

What is a Trojan Horse in cybersecurity?

Hint

Separate propagation, disguise and payload when classifying malicious software.

Answer: A Trojan horse presents apparently useful or legitimate behavior while hiding malicious activity. Unlike virus/worm labels, the definition concerns disguise and does not require self-replication.

SEC04 distinguishes propagation, disguise and payload properties. A Trojan may contain other malware components, but merely looking useful while concealing harmful behavior is the identifying clue. It should not be defined as a worm simply because its payload might later spread.

Primary note proof

Study-note section SEC04

> A virus replicates by attaching to a host program or document; execution of the infected host spreads it. A worm replicates independently, commonly across networks. A Trojan disguises malicious behavior as something useful and does not require self-replication. These labels describe different properties, so a malware package may contain several components.

Study-note section SEC04

> A backdoor bypasses ordinary access paths; a rootkit hides malicious presence or privileged activity.

Study-note section SEC04

> Malware is the umbrella term, not a specific replication method.

Question sources

Computer Security review questions · Question 12

Question 133 | NS0429

What is a Logic Bomb?

Hint

Separate propagation, disguise and payload when classifying malicious software.

Answer: A logic bomb is malicious code that waits for a specified trigger before activating its payload. The defining feature is conditional activation, rather than a particular replication method or inevitable immediate execution.

SEC04 identifies the trigger dependency. Other malware terms describe independent replication, host attachment, disguise or hidden access; those properties can coexist with a triggered payload. Thus the answer identifies when the harmful behavior activates without inventing a particular date, event or payload not supplied by the question.

Primary note proof

Study-note section SEC04

> A virus replicates by attaching to a host program or document; execution of the infected host spreads it. A worm replicates independently, commonly across networks. A Trojan disguises malicious behavior as something useful and does not require self-replication. These labels describe different properties, so a malware package may contain several components.

Study-note section SEC04

> A logic bomb waits for a trigger.

Study-note section SEC04

> Malware is the umbrella term, not a specific replication method.

Question sources

Computer Security review questions · Question 13

Question 134 | NS0430

What is the difference between a White Hat and Black Hat hacker?

Hint

Classify the action actually described and distinguish observation, alteration, disruption and identity claims.

Answer: White-hat security testing is authorized and stays within agreed scope. Black-hat activity is malicious or unauthorized. Technical skill or the word hacker alone does not establish legality.

SEC03 makes authorization and scope the decisive distinction. Good claimed intentions do not create permission to test another system, and insider/outsider status describes a different dimension. An authorized tester must remain within the approved activity; the label alone cannot excuse actions outside that scope.

Primary note proof

Study-note section SEC03

> White-hat testing requires authorization and scope; black-hat activity is malicious or unauthorized. A competitor may seek commercial secrets; hacktivists pursue a cause. “Hacker” alone does not establish legality. Insider versus outsider describes origin/trust position, not the specific mechanism.

Study-note section SEC27

> In a check-then-open file operation, another actor may replace the file between the check and use.

Study-note section SEC27

> Correct findings, patch, test and recheck; testing is not proof of absence.

Question sources

Computer Security review questions · Question 14

Question 135 | NS0431

What is phishing?

Hint

Identify the trust claim or communication mapping being abused.

Answer: Phishing impersonates a trusted source to trick someone into revealing secrets or performing an unsafe action. Spear phishing targets a particular person. Verify suspicious requests using an independently known channel.

SEC05 defines the deception mechanism and the targeted variant. It is a human-trust attack, not necessarily a wireless mechanism or direct password-guessing algorithm. Independent verification matters because replying through the attacker-supplied contact path can preserve the impersonation rather than test it.

Primary note proof

Study-note section SEC05

> Phishing impersonates a trusted source to obtain secrets or induce an unsafe action; spear phishing targets a specific person. Verify a request through an independently known channel. Shoulder surfing observes entry; pretexting invents a reason for disclosure. Monitoring software used with authorization is not necessarily an attack merely because it records activity.

Question sources

Computer Security review questions · Question 15

Question 136 | NS0432

What is the primary goal of cryptography?

Hint

Trace message transformations and separate data, keys, algorithms and codebreaking.

Answer: Cryptography protects information using key-based mathematical mechanisms. Encryption primarily conceals meaning; suitable MACs/signatures or authenticated encryption additionally support integrity and authenticity. There is no single confidentiality-only description that captures every cryptographic service.

SEC12 defines encryption/decryption, while SEC20 distinguishes hashes, MACs and signatures. These mechanisms address different goals and assumptions: a signature does not conceal content, and an unkeyed hash alone does not establish authentic origin. The goal must be matched to the mechanism rather than treating all cryptography as encryption.

Primary note proof

Study-note section SEC12

> Plaintext is the original message, ciphertext its encrypted representation, a key is input to an algorithm, encryption computes C=E_k(P), and decryption recovers P=D_k(C). The five conventional symmetric ingredients are plaintext, encryption algorithm, secret key, ciphertext and decryption algorithm. Cryptanalysis seeks recovery or other breaks without the authorized secret; cryptology includes cryptography and cryptanalysis. Steganography hides that a message exists; encryption hides its meaning.

Study-note section SEC20

> Verification checks origin/integrity under key-identity and key-custody assumptions; it does not conceal content.

Study-note section SEC20

> An attacker can recompute an unkeyed hash of modified data, so a hash alone needs a trusted reference.

Related reading (context, not primary note proof)

Study-note section SEC16

Question sources

Computer Security review questions · Question 16

Question 137 | NS0433

What is the difference between symmetric and asymmetric key cryptography?

Hint

Identify the intended recipient or signer and separate confidentiality from verification.

Answer: Symmetric cryptography uses a shared secret between parties. Asymmetric confidentiality uses an authenticated public encryption key and corresponding private decryption key; signatures instead use a private signing key and public verification key. Not every public-key algorithm supports encryption.

SEC16 gives the shared-secret model and SEC18 the asymmetric key directions. Symmetric keys require secure distribution and can efficiently protect bulk data. Public keys simplify distribution only when their identity bindings are authentic; hybrid protocols combine these advantages instead of assuming one family is inherently stronger.

Primary note proof

Study-note section SEC18

> For confidentiality to B, encrypt with B's authenticated public encryption key; B decrypts with B's private key. Do not encrypt to A's public key if only B should read it, and never assume A possesses B's private key. For a signature, A signs with A's private signing key and others verify with A's public key. These are distinct operations; not every public-key algorithm supports encryption.

Study-note section SEC16

> Symmetric encryption uses a shared secret and efficiently protects bulk data.

Study-note section SEC18

> Public keys ease distribution but require authentic bindings to identities.

Computer Security review questions · Question 17

Question 138 | NS0434

In Caesar's cipher with a shift of 3, what does the letter 'A' become?

Hint

Separate symbol replacement from position changes and apply the alphabet and modular direction.

Answer: A becomes D. With A=0 and shift k=3, C=(0+3) mod26=3, which is D.

SEC13 specifies the A=0 through Z=25 convention and forward addition for Caesar encryption. Applying that convention avoids confusing encryption with the reverse decryption shift or using a different numeric alphabet. No wraparound is needed for A, but the modulo rule handles letters near the alphabet end.

Primary note proof

Study-note section SEC13

> With A=0 through Z=25, Caesar encryption is C=(P+k) mod26 and decryption P=(C-k) mod26. A shift of 3 maps A→D and HELLO→KHOOR. Key25 moves back one: ATTACK→ZSSZBJ. Ensure negative results wrap into 0-25. A multiplicative cipher uses C=kP mod26 with gcd(k,26)=1; decryption uses k's modular inverse. Affine uses C=aP+b mod26 and requires gcd(a,26)=1. The inverse-key relation, not simply the same numeric multiplication, recovers plaintext.

Question sources

Computer Security review questions · Question 18

Question 139 | NS0435

What formula is used for encryption in the Caesar cipher?

Hint

Separate symbol replacement from position changes and apply the alphabet and modular direction.

Answer: Using A=0 through Z=25, Caesar encryption is C=(P+k) mod26. Here P is the plaintext letter number, k the shift and C the ciphertext letter number. Decryption subtracts the same shift modulo 26.

SEC13 fixes both the numeric alphabet and the direction. Modulo 26 wraps results into the letter range, including negative intermediate values in decryption. A stated shift of 3 therefore maps A to D; reversing the sign would describe decryption instead of the requested encryption formula.

Primary note proof

Study-note section SEC13

> With A=0 through Z=25, Caesar encryption is C=(P+k) mod26 and decryption P=(C-k) mod26. A shift of 3 maps A→D and HELLO→KHOOR. Key25 moves back one: ATTACK→ZSSZBJ. Ensure negative results wrap into 0-25. A multiplicative cipher uses C=kP mod26 with gcd(k,26)=1; decryption uses k's modular inverse. Affine uses C=aP+b mod26 and requires gcd(a,26)=1. The inverse-key relation, not simply the same numeric multiplication, recovers plaintext.

Computer Security review questions · Question 19

Question 140 | NS0436

Why is the One-Time Pad considered the most secure cipher?

Hint

Check the precise ordering or key-use assumptions rather than relying on a cipher's name.

Answer: A genuine one-time pad has perfect secrecy when its key is independent, uniformly random, secret, at least as long as the message and never reused. Without every condition, a Vernam/XOR construction is not automatically a one-time pad.

SEC15 makes the guarantee conditional, not a blanket ranking of every cipher implementation. Pad reuse exposes C1 XOR C2=P1 XOR P2 and leaks relationships between plaintexts. Key delivery and storage are substantial practical costs even though the ideal construction supplies perfect secrecy under its assumptions.

Primary note proof

Study-note section SEC15

> A one-time pad XORs bits with an independent uniformly random secret key at least as long as the message and never reused. Its perfect secrecy depends on every condition. Reusing a pad leaks C1 XOR C2=P1 XOR P2. A Vernam XOR construction is not automatically a one-time pad: a predictable/reused keystream loses that guarantee. Key delivery and storage remain substantial costs.

Computer Security review questions · Question 20

Question 141 | NS0437

What is the main weakness of a monoalphabetic substitution cipher?

Hint

Separate symbol replacement from position changes and apply the alphabet and modular direction.

Answer: One fixed substitution throughout a message preserves letter-frequency patterns, enabling statistical analysis despite a large nominal key space. This is the main weakness of monoalphabetic substitution.

SEC13 distinguishes symbol replacement from transposition and stresses that fixed mappings leak patterns. Increasing the nominal number of possible substitution alphabets does not erase language statistics. Classical substitution therefore serves teaching purposes rather than providing modern data protection, even if exhaustive enumeration of every alphabet is impractical.

Primary note proof

Study-note section SEC13

> Substitution replaces symbols; transposition changes their positions. A monoalphabetic substitution preserves one mapping throughout the message and leaks frequency patterns despite a large nominal key space. Classical ciphers are teaching devices, not modern data protection.

Question sources

Computer Security review questions · Question 21

Question 142 | NS0438

How does the Vigenere cipher improve on monoalphabetic ciphers?

Hint

Identify the cipher's unit, key structure and assumptions before judging its strength.

Answer: Vigenère applies position-dependent shifts from a key, so the same plaintext letter can encrypt differently at different positions. That reduces the single fixed-substitution frequency pattern, but repeating a short key still leaks periodic structure.

SEC14 gives C_i=(P_i+K_i) mod26 and explains the position dependence. The improvement is multiple mappings rather than a guarantee of modern security. A periodic key allows related positions to share the same shift, preserving exploitable regularities instead of eliminating statistical structure altogether.

Primary note proof

Study-note section SEC14

> Vigenère repeats or otherwise supplies shifts K_i and computes C_i=(P_i+K_i) mod26. The same plaintext letter may encrypt differently by position; repeated short keys still leak periodic structure. An autokey scheme extends its initial key using message material.

Computer Security review questions · Question 22

Question 143 | NS0439

What is steganography and how does it differ from cryptography?

Hint

Trace message transformations and separate data, keys, algorithms and codebreaking.

Answer: Steganography conceals the existence of a message by hiding it within other data. Encryption conceals its meaning by transforming plaintext into ciphertext. Cryptography also includes integrity/authenticity mechanisms; it is broader than just encryption.

SEC12 states the existence-versus-meaning distinction. Discovering a hidden carrier can defeat concealment of existence without necessarily revealing separately encrypted content. SEC20's MAC/signature roles further explain why cryptography cannot be reduced to steganography or to secrecy of the communication's existence.

Primary note proof

Study-note section SEC12

> Plaintext is the original message, ciphertext its encrypted representation, a key is input to an algorithm, encryption computes C=E_k(P), and decryption recovers P=D_k(C). The five conventional symmetric ingredients are plaintext, encryption algorithm, secret key, ciphertext and decryption algorithm. Cryptanalysis seeks recovery or other breaks without the authorized secret; cryptology includes cryptography and cryptanalysis. Steganography hides that a message exists; encryption hides its meaning.

Study-note section SEC20

> Verification checks origin/integrity under key-identity and key-custody assumptions; it does not conceal content.

Study-note section SEC20

> A keyed MAC provides integrity and shared-secret authentication; both holders can create it, limiting third-party non-repudiation.

Question sources

Computer Security review questions · Question 23

Question 144 | NS0440

What are the five ingredients of cryptography?

Hint

Trace message transformations and separate data, keys, algorithms and codebreaking.

Answer: For the conventional symmetric-encryption model, the five ingredients are plaintext, encryption algorithm, secret key, ciphertext and decryption algorithm. This is not a universal inventory of every cryptographic construction.

SEC12 supplies this five-part teaching model. Plaintext enters encryption with a secret key, producing ciphertext; decryption recovers the plaintext with the appropriate secret. The qualifier symmetric matters because signature, hash and public-key constructions have different interfaces and cannot all be reduced to this particular five-item list.

Primary note proof

Study-note section SEC12

> Plaintext is the original message, ciphertext its encrypted representation, a key is input to an algorithm, encryption computes C=E_k(P), and decryption recovers P=D_k(C). The five conventional symmetric ingredients are plaintext, encryption algorithm, secret key, ciphertext and decryption algorithm. Cryptanalysis seeks recovery or other breaks without the authorized secret; cryptology includes cryptography and cryptanalysis. Steganography hides that a message exists; encryption hides its meaning.

Study-note section SEC12

> Symmetric cryptography is not inherently less secure than public-key cryptography, and speed ratios are not fixed constants.

Study-note section SEC12

> Security depends on algorithm, key size, randomness, mode and implementation.

Question sources

Computer Security review questions · Question 24

Question 145 | NS0441

In DES, what is the block size and key size?

Hint

Track block width, effective key bits and the transformations within a round.

Answer: DES uses 64-bit data blocks and 56 effective key bits. A commonly stored 64-bit key representation includes eight parity bits, which do not increase the effective key space. DES has 16 Feistel rounds and is a legacy algorithm.

SEC17 distinguishes block width from effective key entropy and parity representation. Calling DES a 64-bit-key security level would count nonsecret parity bits as independent choices. The note also warns that DES/triple DES are legacy mechanisms rather than recommendations for new protection.

Primary note proof

Study-note section SEC17

> DES has a 64-bit block, 56 effective key bits (eight other bits serve parity), and 16 Feistel rounds. After initial permutation, each round computes L_i=R_(i-1), R_i=L_(i-1) XOR f(R_(i-1),K_i). Its right-half expansion makes 48 bits, XOR mixes a 48-bit subkey, eight S-boxes each map six bits to four, and permutation rearranges the 32 output bits. The outer S-box input bits select a row and the inner four select a column.

Study-note section SEC17

> DES and triple DES are legacy algorithms, not choices for new protection.

Study-note section SEC17

> Triple DES repeats DES operations but does not provide 168-bit effective security merely because three 56-bit keys are supplied.

Question sources

Computer Security review questions · Question 25

Question 146 | NS0442

Why does DES divide the plaintext into left and right halves?

Hint

Track block width, effective key bits and the transformations within a round.

Answer: DES splits its 64-bit block into two 32-bit halves for Feistel rounds: L_i=R_(i-1) and R_i=L_(i-1) XOR f(R_(i-1),K_i). This permits inversion using the same overall structure with reversed round keys, without requiring f to be invertible.

SEC17 gives the round equations and inversion property. The old right half becomes the new left half; the old left is mixed with a keyed transformation of the old right. Keeping those relationships allows recovery by reversing the key order rather than independently inverting every S-box/transformation.

Primary note proof

Study-note section SEC17

> DES has a 64-bit block, 56 effective key bits (eight other bits serve parity), and 16 Feistel rounds. After initial permutation, each round computes L_i=R_(i-1), R_i=L_(i-1) XOR f(R_(i-1),K_i). Its right-half expansion makes 48 bits, XOR mixes a 48-bit subkey, eight S-boxes each map six bits to four, and permutation rearranges the 32 output bits. The outer S-box input bits select a row and the inner four select a column.

Study-note section SEC17

> Feistel inversion uses the same overall structure with reversed round keys; f need not itself be invertible.

Study-note section SEC17

> Triple DES repeats DES operations but does not provide 168-bit effective security merely because three 56-bit keys are supplied.

Question sources

Computer Security review questions · Question 26

Question 147 | NS0443

What is the purpose of the S-box in DES?

Hint

Track block width, effective key bits and the transformations within a round.

Answer: DES S-boxes provide nonlinear substitution: each of eight boxes maps six input bits to four output bits. The outer two bits select the row and the inner four select the column, giving 32 output bits altogether.

SEC17 identifies the S-boxes as the nonlinear component that resists simple linear descriptions. Their six-to-four mapping follows expansion and key mixing, then a permutation rearranges the outputs. They are not merely a reversible bit permutation; Feistel structure supplies overall invertibility without requiring each S-box itself to be invertible.

Primary note proof

Study-note section SEC17

> DES has a 64-bit block, 56 effective key bits (eight other bits serve parity), and 16 Feistel rounds. After initial permutation, each round computes L_i=R_(i-1), R_i=L_(i-1) XOR f(R_(i-1),K_i). Its right-half expansion makes 48 bits, XOR mixes a 48-bit subkey, eight S-boxes each map six bits to four, and permutation rearranges the 32 output bits. The outer S-box input bits select a row and the inner four select a column.

Study-note section SEC17

> The nonlinear S-boxes resist simple linear descriptions.

Study-note section SEC17

> Feistel inversion uses the same overall structure with reversed round keys; f need not itself be invertible.

Question sources

Computer Security review questions · Question 27

Question 148 | NS0444

In RSA, what are the formulas for encryption and decryption?

Hint

Check key-generation conditions as well as modular arithmetic.

Answer: Textbook RSA encrypts c=m^e mod n and decrypts m=c^d mod n, for 0≤m<n. Here n=pq, e is coprime to φ=(p−1)(q−1), and d=e^−1 mod φ. Real RSA additionally requires appropriate standardized padding.

SEC19 supplies the formulas and their key-generation preconditions. The modular-inverse condition is necessary for a valid key pair, so arbitrary e values are not acceptable. These arithmetic expressions teach RSA operations; raw unpadded modular exponentiation is not a complete secure deployment recipe.

Primary note proof

Study-note section SEC19

> For textbook RSA choose distinct primes p,q; n=pq and φ=(p-1)(q-1). Choose 1<e<φ with gcd(e,φ)=1, then compute d=e^-1 modφ. Public key is (n,e), private includes d. Encrypt 0≤m<n by c=m^e modn; decrypt by m=c^d modn. Use modular repeated squaring for large exponents. Real RSA requires appropriate standardized padding; raw arithmetic is not a secure deployment recipe.

Study-note section SEC19

> With p=3,q=13,e=3,m=5, 5^3 mod39=8 arithmetically, but gcd(3,24)=3, so e has no inverse and this is not a valid RSA key.

Study-note section SEC19

> Check key validity before treating arithmetic results as a working encryption/decryption pair.

Question sources

Computer Security review questions · Question 28

Question 149 | NS0445

In textbook RSA key generation with p=7, q=19 and φ=108, choose the smallest integer e greater than 1 satisfying 1<e<φ and gcd(e,φ)=1. What is e?

Hint

Check key-generation conditions as well as modular arithmetic.

Answer: e = 5

The exponent must be greater than one, below 108 and coprime to 108. Testing candidates in increasing order, 2 shares factor 2, 3 shares factor 3 and 4 shares factor 2 with 108. Five shares neither prime factor of 108, so gcd(5,108)=1. It is therefore the smallest admissible exponent. Other values can also be admissible, but the explicit smallest-value rule makes this open-ended answer unique.

Primary note proof

Study-note section SEC19

> For textbook RSA choose distinct primes p,q; n=pq and φ=(p-1)(q-1). Choose 1<e<φ with gcd(e,φ)=1, then compute d=e^-1 modφ. Public key is (n,e), private includes d. Encrypt 0≤m<n by c=m^e modn; decrypt by m=c^d modn. Use modular repeated squaring for large exponents. Real RSA requires appropriate standardized padding; raw arithmetic is not a secure deployment recipe.

Study-note section SEC19

> With p=7,q=19, n=133 and φ=108, e=5 is the smallest admissible e>1, but 7 and other coprime choices also work.

Study-note section SEC19

> With p=3,q=13,e=3,m=5, 5^3 mod39=8 arithmetically, but gcd(3,24)=3, so e has no inverse and this is not a valid RSA key.

Question sources

Computer Security review questions · Question 29

Question 150 | NS0446

What is the Playfair cipher and what unique element does its grid contain?

Hint

Identify the cipher's unit, key structure and assumptions before judging its strength.

Answer: Playfair is a digraph substitution cipher using a keyed 5×5 letter grid, commonly combining I and J into one cell. It encrypts pairs by same-row, same-column or rectangle rules; fillers and padding must be specified.

SEC14 explains the 25-cell grid and letter-pair operations. Combining I/J is the conventional element that fits the alphabet into the grid, not a claim about numeric cells. Repeated-letter fillers and final padding affect actual ciphertext, so computations require those conventions rather than guessing them.

Primary note proof

Study-note section SEC14

> Playfair uses a keyed 5×5 grid, commonly combining I/J, and encrypts letter pairs. Specify duplicate-letter fillers and padding. Same row moves right, same column moves down, and rectangle pairs take the other column in their original row; decryption reverses shifts.

Question sources

Computer Security review questions · Question 30

Question 151 | NS0447

What is ARP Spoofing and which OSI layer does it target?

Hint

Identify the trust claim or communication mapping being abused.

Answer: ARP spoofing supplies false local IPv4-to-MAC associations, directing traffic toward an unintended link endpoint. It targets local link-address resolution at the network/data-link boundary and is commonly treated as a data-link-layer attack.

SEC05 identifies the poisoned association rather than DNS names or transport state. Its scope is local IPv4-to-MAC resolution, so describing it simply as arbitrary IP routing would miss the mechanism. The layer answer refers to manipulating the local link mapping, while ARP connects network and link addressing.

Primary note proof

Study-note section SEC05

> Masquerade claims another identity. ARP spoofing poisons local IPv4-to-MAC associations; DNS spoofing/cache poisoning supplies false name resolutions; IP spoofing falsifies a source address. An intermediary attack intercepts and can alter exchanges. A replay reuses a valid old message; nonces, timestamps and sequence checks can reject it. Session hijacking steals or predicts a valid session token. Protect transport, regenerate session IDs after login, restrict cookies and check authorization server-side on every sensitive request.

Question sources

Computer Security review questions · Question 31

Question 152 | NS0448

What three primary services does IPSec provide?

Hint

Match the communication task to the protocol and trace key handling separately from signing.

Answer: The principal IPsec services are confidentiality, integrity and origin authentication for IP traffic. They depend on the chosen protocol/association: AH supplies integrity/authentication without encryption, while ESP can supply confidentiality and integrity; IKE negotiates associations and keys.

IPsec operates at the network layer, with distinct AH, ESP and IKE roles. Listing the service set must not imply every IPsec packet is encrypted or that IKE itself carries protected application content. Transport/tunnel mode describes coverage/encapsulation rather than replacing the service-selection and key assumptions.

Primary note proof

Study-note section SEC22

> SSH protects remote login, commands and file transfer such as SFTP; it supports host keys and several client-authentication methods. IPsec protects IP traffic at network layer. AH provides integrity/origin authentication, not encryption; ESP can provide confidentiality and integrity; IKE negotiates security associations and keys. Transport mode protects upper-layer payload; tunnel mode encapsulates an inner IP packet inside an outer header. A VPN is a logical private connection; its actual security depends on the chosen authenticated tunnel.

Question sources

Computer Security review questions · Question 32

Question 153 | NS0449

How does a TCP SYN flood attack work?

Hint

Match the resource bottleneck or wireless mechanism to the relevant protection layer.

Answer: A TCP SYN flood creates many incomplete connection handshakes, occupying server state and exhausting resources needed for legitimate connections. Rate limits, SYN cookies, filtering or upstream controls address different parts of that resource bottleneck.

SEC06 defines the attack by incomplete-handshake state consumption. The goal is denial of usable service, not necessarily gaining control of the target. Defenses must match the constrained resource and traffic path; no single listed measure guarantees resistance to every distributed load or bandwidth bottleneck.

Primary note proof

Study-note section SEC06

> DoS exhausts or disables a resource; distributed DoS uses multiple sources, often bots or reflected/amplified responses. A SYN flood leaves many incomplete TCP handshakes occupying state. DNS flooding targets query capacity; NXDOMAIN attacks generate queries for nonexistent names to stress resolvers. Fragment floods abuse reassembly or packet-processing resources. Rate limits, SYN cookies, filtering and upstream capacity controls address different bottlenecks.

Study-note section SEC03

> Passive attacks observe without changing the target exchange: sniffing and traffic analysis.

Study-note section SEC06

> Rogue access points imitate or bypass approved wireless service.

Question sources

Computer Security review questions · Question 33

Question 154 | NS0450

What is the difference between SSL and TLS?

Hint

Distinguish peer identity, channel protection and risks outside that channel.

Answer: TLS is the successor to obsolete SSL and provides an authenticated protected channel. Handshakes negotiate parameters, authenticate peers as required and establish keys; symmetric authenticated record protection carries data. Exact handshake messages depend on TLS version.

SEC21 warns against treating an old SSL/ChangeCipherSpec narrative as the universal TLS1.3 sequence. The useful distinction is protocol succession and version-specific behavior, not a claim that the names are interchangeable or that every deployment of either is automatically secure.

Primary note proof

Study-note section SEC21

> A certificate binds a public key to a named subject through an issuer signature. Validate the chain to a trusted root, intended hostname, time validity and applicable key usage/revocation policy. A genuine certificate is not proof that a business is honest.

Study-note section SEC21

> Exact messages depend on TLS version: the old ChangeCipherSpec narrative is not a universal TLS1.3 sequence.

Study-note section SEC21

> TLS succeeds obsolete SSL and supplies an authenticated protected channel.

Question sources

Computer Security review questions · Question 34

Question 155 | NS0451

What does HTTPS stand for and what security does it add over HTTP?

Hint

Distinguish peer identity, channel protection and risks outside that channel.

Answer: HTTPS is secure HTTP: HTTP over TLS. It adds authenticated channel protection for HTTP paths, headers and content. It does not conceal all metadata, such as endpoint IPs/timing, or protect plaintext after a compromised endpoint decrypts it.

SEC21 identifies the composition and coverage. Protection depends on authentication and certificate validation rather than the mere appearance of the URL scheme. It concerns the communication channel; endpoint compromise and visible traffic metadata remain outside that confidentiality boundary.

Primary note proof

Study-note section SEC21

> A certificate binds a public key to a named subject through an issuer signature. Validate the chain to a trusted root, intended hostname, time validity and applicable key usage/revocation policy. A genuine certificate is not proof that a business is honest.

Study-note section SEC21

> It protects HTTP paths, headers and content on the channel, but does not hide all metadata such as IP endpoints and traffic timing, nor protect data after a compromised endpoint decrypts it.

Study-note section SEC21

> HTTPS is HTTP over TLS.

Question sources

Computer Security review questions · Question 35

Question 156 | NS0452

What is DNS Spoofing?

Hint

Identify the trust claim or communication mapping being abused.

Answer: DNS spoofing provides false name-resolution data, potentially redirecting a requested domain to an attacker-chosen destination. Cache poisoning is a form that places false answers in a resolver cache. DNSSEC authenticates DNS data when appropriately deployed and validated.

SEC05 distinguishes false DNS mapping from ARP/IP spoofing. SEC06 separates DNS flooding, which consumes query capacity, from answer authenticity. A successful-looking name lookup can still be maliciously wrong; checking that a response exists is different from establishing its trusted origin and integrity.

Primary note proof

Study-note section SEC05

> Masquerade claims another identity. ARP spoofing poisons local IPv4-to-MAC associations; DNS spoofing/cache poisoning supplies false name resolutions; IP spoofing falsifies a source address. An intermediary attack intercepts and can alter exchanges. A replay reuses a valid old message; nonces, timestamps and sequence checks can reject it. Session hijacking steals or predicts a valid session token. Protect transport, regenerate session IDs after login, restrict cookies and check authorization server-side on every sensitive request.

Study-note section SEC06

> DNS flooding targets query capacity; NXDOMAIN attacks generate queries for nonexistent names to stress resolvers.

Study-note section SEC06

> Match a defense to its layer: authenticated IPsec can resist IP impersonation, DNSSEC authenticates DNS data, TLS authenticates/protects application transport, and bounds-safe code prevents overflows.

Question sources

Computer Security review questions · Question 36

Question 157 | NS0453

What is the purpose of SSH (Secure Shell)?

Hint

Match the communication task to the protocol and trace key handling separately from signing.

Answer: SSH (Secure Shell) protects remote login, command execution and file transfer such as SFTP. It uses host keys and supports several client-authentication methods. Correct host-key validation and restricted management access remain important.

SEC22 states the protected remote-administration functions. SSH is not merely encryption of a password; it protects the session and requires authentic peer identity. File transfer through SFTP is related to SSH rather than being ordinary FTP with a new name.

Primary note proof

Study-note section SEC22

> SSH protects remote login, commands and file transfer such as SFTP; it supports host keys and several client-authentication methods. IPsec protects IP traffic at network layer. AH provides integrity/origin authentication, not encryption; ESP can provide confidentiality and integrity; IKE negotiates security associations and keys. Transport mode protects upper-layer payload; tunnel mode encapsulates an inner IP packet inside an outer header. A VPN is a logical private connection; its actual security depends on the chosen authenticated tunnel.

Study-note section SEC-S03

> SSH expands to Secure Shell and provides secure remote login and related network services.

Study-note section SEC-S03

> AAA names authentication, authorization and accounting functions, rather than a particular remote-shell channel.

Question sources

Computer Security review questions · Question 37

Question 158 | NS0454

What is a Man-in-the-Middle (MITM) attack?

Hint

Identify the trust claim or communication mapping being abused.

Answer: A man-in-the-middle attack places an attacker between communicating parties to intercept and potentially alter their exchange. Authentication of the intended peer and a protected channel are needed; encryption without authentic key binding can still allow intermediary substitution.

SEC05 gives the interception/alteration mechanism, while SEC18's unauthenticated Diffie-Hellman example explains why secrecy mechanisms alone are insufficient. The attacker may relay messages so both victims believe they communicate directly, making peer authentication and correct certificate/key checks essential.

Primary note proof

Study-note section SEC05

> Masquerade claims another identity. ARP spoofing poisons local IPv4-to-MAC associations; DNS spoofing/cache poisoning supplies false name resolutions; IP spoofing falsifies a source address. An intermediary attack intercepts and can alter exchanges. A replay reuses a valid old message; nonces, timestamps and sequence checks can reject it. Session hijacking steals or predicts a valid session token. Protect transport, regenerate session IDs after login, restrict cookies and check authorization server-side on every sensitive request.

Study-note section SEC18

> Diffie-Hellman agrees on a secret but unauthenticated DH permits intermediary substitution.

Study-note section SEC18

> Hybrid systems establish or encapsulate a symmetric secret with public-key mechanisms, then protect bulk data symmetrically.

Question sources

Computer Security review questions · Question 38

Question 159 | NS0455

What is the SET (Secure Electronic Transaction) protocol and who developed it?

Hint

Match the communication task to the protocol and trace key handling separately from signing.

Answer: SET means Secure Electronic Transaction. It was a Visa/Mastercard-led specification for protecting payment-card transactions with certificates and signatures. It is distinct from an ordinary HTTPS connection or a general payment-processing system.

SEC22 supplies the expansion, origin and protection role. Certificates/signatures support authenticated transaction relationships rather than defining the entire financial settlement infrastructure. Calling every TLS-protected checkout SET would conflate separate protocols with different scope and structure.

Primary note proof

Study-note section SEC22

> PGP/OpenPGP combines symmetric content protection with public-key key handling and signatures. S/MIME uses certificates for signed and/or enveloped MIME content. Signatures can be sent separately/clear-signed without confidentiality; enveloped data encrypts content and wraps content keys for recipients. SET, Secure Electronic Transaction, was a Visa/Mastercard-led specification for protecting card transactions using certificates and signatures; it is distinct from a payment-processing system or ordinary HTTPS.

Study-note section SEC21

> TLS succeeds obsolete SSL and supplies an authenticated protected channel.

Study-note section SEC21

> HTTPS is HTTP over TLS.

Question sources

Computer Security review questions · Question 39

Question 160 | NS0456

What is Session Hijacking?

Hint

Identify the trust claim or communication mapping being abused.

Answer: Session hijacking is taking over an existing authenticated session by stealing or predicting a valid session token. Defenses include protected transport, regenerating IDs after login, restrictive cookie handling and server-side authorization on sensitive requests.

SEC05 identifies token possession/prediction as the takeover path. Establishing a secure initial login does not alone protect the later bearer token, and checking authorization on every sensitive action remains necessary. The mechanism differs from replaying an old message, although stolen session material can enable reused requests.

Primary note proof

Study-note section SEC05

> Masquerade claims another identity. ARP spoofing poisons local IPv4-to-MAC associations; DNS spoofing/cache poisoning supplies false name resolutions; IP spoofing falsifies a source address. An intermediary attack intercepts and can alter exchanges. A replay reuses a valid old message; nonces, timestamps and sequence checks can reject it. Session hijacking steals or predicts a valid session token. Protect transport, regenerate session IDs after login, restrict cookies and check authorization server-side on every sensitive request.

Question sources

Computer Security review questions · Question 40

Question 161 | NS0457

What is a firewall and what are its three characteristics as a 'reference monitor'?

Hint

Separate security-policy enforcement and assurance from ordinary OS features.

Answer: A firewall enforces traffic policy on flows it mediates. As a reference-monitor design, enforcement must cover every relevant access, resist tampering and be small/simple enough to analyze. For a firewall this is its traffic boundary, not every host-memory operation.

SEC28 defines the three reference-monitor requirements and explicitly limits a firewall to traversing traffic. SEC23 describes policy enforcement and bypass limits. Thus complete mediation requires preventing alternate paths within the claimed boundary; deploying a firewall does not make it a universal host security kernel.

Primary note proof

Study-note section SEC28

> A reference monitor is an abstract access-checking mechanism: it must mediate every relevant access, resist tampering and be sufficiently small/simple to analyze. A security kernel implements core enforcement. A firewall can mediate its traversing traffic but cannot enforce every host-memory access. Assurance is justified confidence that controls implement the claims; functionality is what controls claim to do. A GUI or multitasking support alone does not establish trust.

Study-note section SEC23

> A firewall enforces traffic policy.

Study-note section SEC23

> Bypass paths, insiders, encrypted uninspected content and infected removable media limit firewall protection.

Question sources

Computer Security review questions · Question 41

Question 162 | NS0458

What is the key difference between a Packet-Filtering firewall and a Stateful Inspection firewall?

Hint

Identify which traffic is mediated and what information drives the device's decisions.

Answer: A stateless packet-filtering firewall matches each packet’s header fields such as addresses, protocol and ports. Stateful inspection also tracks permitted connection context, allowing decisions based on whether traffic belongs to an allowed exchange.

SEC23 distinguishes header matching from connection-aware inspection. Both can filter ports, so the difference is not port-filtering capability alone. State tracking does not imply unlimited application-content understanding or automatic encryption; those are additional, separate functions.

Primary note proof

Study-note section SEC23

> A firewall enforces traffic policy. Stateless packet filtering matches headers such as source/destination, protocol and ports. Stateful inspection tracks permitted connection context; application proxies terminate and relay application exchanges and can inspect their content. A circuit gateway relays connections, commonly SOCKS, without full application-content interpretation; textbooks associate it with session/transport functions. Such a gateway need not encrypt and is not automatically a VPN.

Question sources

Computer Security review questions · Question 42

Question 163 | NS0459

What is an Application-Level Gateway (proxy firewall)?

Hint

Identify which traffic is mediated and what information drives the device's decisions.

Answer: An application-level gateway/proxy terminates and relays application exchanges on behalf of clients/services and can inspect application content. It differs from a simple header packet filter or circuit relay that lacks full application-content interpretation.

SEC23 defines the proxy by its application mediation boundary. It can enforce application-specific policy because it participates in the exchanges rather than merely routing packets. That role does not inherently mean encryption or protection against traffic that bypasses the proxy.

Primary note proof

Study-note section SEC23

> A firewall enforces traffic policy. Stateless packet filtering matches headers such as source/destination, protocol and ports. Stateful inspection tracks permitted connection context; application proxies terminate and relay application exchanges and can inspect their content. A circuit gateway relays connections, commonly SOCKS, without full application-content interpretation; textbooks associate it with session/transport functions. Such a gateway need not encrypt and is not automatically a VPN.

Computer Security review questions · Question 43

Question 164 | NS0460

What is the difference between an IDS and an IPS?

Hint

Separate observation from blocking and sensor placement from detection method.

Answer: An IDS detects suspicious activity and alerts. An IPS can enforce prevention/blocking, usually on the traffic path. Both need contextual analysis because false positives and missed attacks remain possible.

SEC24 makes action the distinction, independently of host/network sensor location or signature/anomaly detection method. Observing a suspected attack does not itself prevent it. Inline blocking can affect legitimate service when an alert is false, so evidence and policy determine the appropriate response.

Primary note proof

Study-note section SEC24

> An IDS observes and alerts; an IPS can enforce blocking, usually inline. Host-based sensors examine host events, network-based sensors inspect traffic. Signature detection recognizes known patterns; anomaly detection compares with a baseline and may detect novel behavior. Neither guarantees every attack is detected; anomaly detection can raise many false positives, and signatures can sometimes match variants.

Study-note section SEC24

> A true positive is a real attack detected, false negative is a missed attack, false positive is innocent activity flagged, and true negative is innocent activity accepted.

Study-note section SEC24

> Obfuscation makes code harder to understand and can hamper analysis, but does not reliably protect embedded secrets or remove vulnerabilities.

Question sources

Computer Security review questions · Question 44

Question 165 | NS0461

What are the two main types of IDS detection methods?

Hint

Separate observation from blocking and sensor placement from detection method.

Answer: The two main detection methods are signature-based and anomaly-based. Signatures recognize known patterns; anomaly methods compare behavior with a baseline and may find novel deviations. Both can miss attacks or produce false positives.

SEC24 explicitly gives these methods and their limitations. A deviation is not automatically malicious, and a matching signature does not prove every attack variant is captured. Host-based versus network-based describes sensor placement, a different classification from how the detection decision is made.

Primary note proof

Study-note section SEC24

> An IDS observes and alerts; an IPS can enforce blocking, usually inline. Host-based sensors examine host events, network-based sensors inspect traffic. Signature detection recognizes known patterns; anomaly detection compares with a baseline and may detect novel behavior. Neither guarantees every attack is detected; anomaly detection can raise many false positives, and signatures can sometimes match variants.

Study-note section SEC24

> Detecting 90 of 100 spam messages with five innocent messages flagged gives recall90%, precision90/95≈94.7%.

Study-note section SEC24

> A true positive is a real attack detected, false negative is a missed attack, false positive is innocent activity flagged, and true negative is innocent activity accepted.

Question sources

Computer Security review questions · Question 45

Question 166 | NS0462

What limitation does a firewall have regarding data outside its perimeter?

Hint

Identify which traffic is mediated and what information drives the device's decisions.

Answer: A firewall cannot enforce policy on data or attack paths that bypass it. Insiders, removable media and uninspected encrypted content can evade its protection, so outside/perimeter-bypassing data needs endpoint, access and other controls.

SEC23 confines firewall protection to traffic actually mediated and inspectable under its design. A boundary rule does not sanitize every file after it arrives through another path. This is a scope limitation rather than proof that firewalls are useless or that all encrypted traffic is malicious.

Primary note proof

Study-note section SEC23

> Host firewalls protect individual machines; network firewalls segment networks and can create a DMZ for public-facing services. Rules should be explicit, ordered as implemented, least-privilege and logged appropriately. Stateful and next-generation devices can also filter ports; port filtering is not exclusive to one firewall category. Bypass paths, insiders, encrypted uninspected content and infected removable media limit firewall protection. Hardware firewall does not imply any fixed number of ports.

Question sources

Computer Security review questions · Question 46

Question 167 | NS0463

What is PGP (Pretty Good Privacy) and what security services does it provide?

Hint

Match the communication task to the protocol and trace key handling separately from signing.

Answer: PGP (Pretty Good Privacy)/OpenPGP combines symmetric encryption for content, public-key handling of content keys and digital signatures. It can provide confidentiality and integrity/origin-authentication evidence according to which operations are used and how keys are validated.

SEC22 gives the hybrid composition and SEC20 explains signature scope. A signature alone does not conceal content; encryption alone is not the same as a validated signature. Recipient/signer key authenticity and custody therefore matter to the protection actually obtained.

Primary note proof

Study-note section SEC22

> PGP/OpenPGP combines symmetric content protection with public-key key handling and signatures. S/MIME uses certificates for signed and/or enveloped MIME content. Signatures can be sent separately/clear-signed without confidentiality; enveloped data encrypts content and wraps content keys for recipients. SET, Secure Electronic Transaction, was a Visa/Mastercard-led specification for protecting card transactions using certificates and signatures; it is distinct from a payment-processing system or ordinary HTTPS.

Study-note section SEC-S03

> PGP expands to Pretty Good Privacy; its message-protection design combines conventional and public-key encryption with digital signatures.

Study-note section SEC20

> Verification checks origin/integrity under key-identity and key-custody assumptions; it does not conceal content.

Question sources

Computer Security review questions · Question 47

Question 168 | NS0464

What is S/MIME and how does 'Signed and Enveloped Data' work?

Hint

Match the communication task to the protocol and trace key handling separately from signing.

Answer: S/MIME protects MIME messages using certificates for signatures and/or enveloped encryption. In sign-then-encrypt, sign the MIME entity, package its content/signature, encrypt it with a fresh symmetric content key and protect that key for each recipient. The recipient recovers the key, decrypts, then verifies with the validated signer certificate.

SEC22 specifies this construction while allowing other nesting orders with different coverage. Signed data supplies origin/integrity evidence without inherently concealing content; enveloped data encrypts content and wraps keys. Signing is not generic private-key encryption of the whole message, and certificate/key validation is essential to interpreting verification.

Primary note proof

Study-note section SEC22

> PGP/OpenPGP combines symmetric content protection with public-key key handling and signatures. S/MIME uses certificates for signed and/or enveloped MIME content. Signatures can be sent separately/clear-signed without confidentiality; enveloped data encrypts content and wraps content keys for recipients. SET, Secure Electronic Transaction, was a Visa/Mastercard-led specification for protecting card transactions using certificates and signatures; it is distinct from a payment-processing system or ordinary HTTPS.

Study-note section SEC22

> A recipient recovers the key, decrypts the signed entity and verifies its signature using the validated signer certificate/public key.

Study-note section SEC22

> One signed-and-encrypted S/MIME construction first signs the MIME entity, packages its content and signature, then encrypts that signed entity with a fresh symmetric content key.

Related reading (context, not primary note proof)

Study-note section SEC20

Study-note section SEC21

Question sources

Computer Security review questions · Question 48

Question 169 | NS0465

What is a Circuit-Level Gateway and what OSI layer does it operate at?

Hint

Identify which traffic is mediated and what information drives the device's decisions.

Answer: A circuit-level gateway relays connections, commonly using SOCKS, without full application-content interpretation. Textbook OSI mappings associate it with session/transport functions rather than a universally fixed physical OSI device layer. It need not encrypt traffic or constitute a VPN.

A circuit gateway relays connections, while application proxies inspect content and packet filters match headers. The session/transport layer label is a teaching mapping; the relay function is the stable distinction. Unspecified circuit gateways must not be assumed to supply authenticated encrypted tunnels.

Primary note proof

Study-note section SEC23

> A firewall enforces traffic policy. Stateless packet filtering matches headers such as source/destination, protocol and ports. Stateful inspection tracks permitted connection context; application proxies terminate and relay application exchanges and can inspect their content. A circuit gateway relays connections, commonly SOCKS, without full application-content interpretation; textbooks associate it with session/transport functions. Such a gateway need not encrypt and is not automatically a VPN.

Question sources

Computer Security review questions · Question 49

Question 170 | NS0466

In the RSA example where p=3, q=13, and public key e=3, what is the ciphertext for plaintext m=5?

Hint

Check key-generation conditions as well as modular arithmetic.

Answer: The modular exponentiation gives c=5^3 mod(3×13)=125 mod39=8. However φ=(3−1)(13−1)=24 and gcd(3,24)=3, so e=3 has no modular inverse. This is an arithmetic result, not a valid RSA encryption/decryption key pair.

SEC19 explicitly identifies the defective source example. Showing ciphertext 8 must not endorse the key setup: RSA requires e coprime to φ so a private exponent can invert it. The calculation and the validity check answer different parts of the example, and both must be preserved.

Primary note proof

Study-note section SEC19

> For textbook RSA choose distinct primes p,q; n=pq and φ=(p-1)(q-1). Choose 1<e<φ with gcd(e,φ)=1, then compute d=e^-1 modφ. Public key is (n,e), private includes d. Encrypt 0≤m<n by c=m^e modn; decrypt by m=c^d modn. Use modular repeated squaring for large exponents. Real RSA requires appropriate standardized padding; raw arithmetic is not a secure deployment recipe.

Study-note section SEC19

> With p=3,q=13,e=3,m=5, 5^3 mod39=8 arithmetically, but gcd(3,24)=3, so e has no inverse and this is not a valid RSA key.

Study-note section SEC19

> Check key validity before treating arithmetic results as a working encryption/decryption pair.

Question sources

Computer Security review questions · Question 50

Question 171 | NS0467

What is the Hill Cipher and why is it considered strong?

Hint

Identify the cipher's unit, key structure and assumptions before judging its strength.

Answer: Hill is a polygraphic matrix substitution cipher, C=KP mod26. Its key must be invertible modulo 26, with determinant coprime to 26. It is not strong by modern standards: enough independent known plaintext/ciphertext blocks reveal the key through its linear structure.

SEC14 rejects the supplied claim of known-plaintext resistance. Combining letters into vectors does not remove linear algebraic relationships, and a large-looking matrix key is not proof of modern security. The correct answer explains the construction while correcting the question's implied blanket strength claim.

Primary note proof

Study-note section SEC14

> Hill uses C=KP mod26 for letter vectors. K needs an inverse modulo26, equivalently determinant coprime to26. It is linear: enough independent known plaintext/ciphertext blocks reveal K=CP^-1 mod26. Hill is vulnerable to known-plaintext attacks; polygraphic substitution alone is not modern strength.

Network and System Administration

Questions & Worked Answers

101 questions

Question 1 | Q00011

You administer a network and need to display active connections with their protocol, local address and port, foreign address and port, and connection state. Which command provides this connection table?

A. traceroute

B. ipconfig

C. netstat

D. nslookup

Hint

Match the requested observation to the tool’s actual output; distinguish configuration, name lookup, reachability and hop discovery.

Answer C: netstat.

NSA07 identifies netstat as the tool that displays connections, protocol names, local and foreign endpoints, and TCP connection states. That is the complete set of information requested, so option C is right. Numeric-output flags can keep addresses and ports numeric; the Windows form netstat -ano also includes process IDs.

Why each choice is right or wrong

A - Incorrect: Traceroute reports responding hops on a network path, not a connection table with local/foreign ports and TCP states.

B - Incorrect: Ipconfig reports adapter addressing and configuration, not active transport connections and their remote endpoints.

C - Correct: Netstat displays the requested protocol, endpoint and connection-state information.

D - Incorrect: Nslookup queries DNS records rather than listing active connections or TCP states.

Primary note proof

Study-note section NSA07

> netstat displays connections/endpoints/protocols and TCP states; netstat -ano displays numeric addresses/ports and PIDs. Use the exact command name netstat rather than netstart. ping probes IP reachability; traceroute/tracert reveals responding hops using TTL/hop-limit expiry. ICMP filtering can prevent replies without proving the service is down. nslookup inspects DNS.

Study-note section NSA07

Windows ipconfig shows addresses, mask and gateway; ipconfig /all adds complete adapter configuration including physical/MAC address, DHCP and DNS information. /renew requests renewal, /release releases a dynamic address and /flushdns clears the client DNS cache. Linux ip addr and ip route show interface addresses and routes; exact persistent configuration varies by distribution.

MOE Computer Science Exit Exam · 2016 · Question 11

Question 2 | Q00077

Which statements about ordinary dynamic DHCP allocation are incorrect? Select all that apply.

A. An IP leased by the DHCP for a host is permanent

B. DHCP assures connectivity ever users move from location to location

C. The IP address are chosen from a predetermined range of address

D. DHCP allows a host to acquire an IP address automatically

Hint

Identify the required operational function, then compare its scope, inputs and constraints with the cited note definitions.

Answer A, B: An IP leased by the DHCP for a host is permanent; DHCP assures connectivity ever users move from location to location

A dynamic DHCP lease lasts for a specified interval and must be renewed; it is not a permanent assignment. DHCP can automate address configuration after moving, but connectivity also depends on a reachable server or relay, a suitable scope and a working network. The server selects addresses from its configured pool. Thus the permanence and guaranteed-connectivity claims are false, while pool selection and automatic acquisition are true.

Why each choice is right or wrong

A - Correct: A leased dynamic address is time-limited and can become reusable after expiration; it is not permanent.

B - Correct: DHCP alone cannot assure connectivity after every location change; server, relay and network conditions matter.

C - Incorrect: A DHCP server manages an address scope/pool, supporting selection from a predetermined range.

D - Incorrect: Automatic acquisition of an address and options is a supported DHCP function.

Primary note proof

Study-note section NSA04

> DHCP supplies addresses and configuration options. Typical initial IPv4 allocation is Discover→Offer→Request→ACK. The server manages its scope/pool, allocated leases, exclusions and reservations; options may include mask, gateway and DNS servers. A dynamic lease lasts for a specified interval, not forever.

Study-note section NSA05

> Use a scope matching the subnet, exclude manually assigned server/router addresses, set correct options and provide a relay when client broadcasts must cross a router. Static assignments and DHCP can coexist; avoid address conflicts. DHCP lowers repetitive administration but availability/security depend on deployment and protection from rogue replies. It does not guarantee connectivity whenever a device changes location.

MOE Computer Science Exit Exam · 2016 · Question 77

Question 3 | Q00091

Which listed operation is not a DHCP server function?

A. It grants an IP address when receives a request from a client.

B. It maintains the information about client configuration parameters.

C. It maintains a database of available IP addresses.

D. Resolve hostnames to IP addresses using DNS records.

Hint

Identify the required operational function, then compare its scope, inputs and constraints with the cited note definitions.

Answer D: Resolve hostnames to IP addresses using DNS records.

A DHCP server manages address pools, lease allocations and configuration parameters supplied to clients. It may allocate an address in response to a client exchange and retain information about availability and options. Hostname-to-address resolution is a DNS function instead. Repairing the duplicated malformed option supplies a distinct nonfunction while preserving the original distinction between automatic configuration and other network services.

Why each choice is right or wrong

A - Incorrect: Allocating an address in response to client requests is a DHCP server function.

B - Incorrect: The server manages lease and configuration parameters, so this is not a nonfunction.

C - Incorrect: Maintaining scope/pool availability is explicitly part of DHCP server management.

D - Correct: Hostname-to-address resolution belongs to DNS rather than DHCP allocation.

Primary note proof

Study-note section NSA04

> DHCP supplies addresses and configuration options. Typical initial IPv4 allocation is Discover→Offer→Request→ACK. The server manages its scope/pool, allocated leases, exclusions and reservations; options may include mask, gateway and DNS servers. A dynamic lease lasts for a specified interval, not forever.

Study-note section NSA06

> Forward resolution obtains an address from a name, using A for IPv4 and AAAA for IPv6. Reverse lookup uses a PTR record in the reverse namespace to obtain a name from an address. CNAME aliases a name, MX identifies mail exchangers and NS identifies authoritative name servers. Forward and reverse records need not both exist or be perfect inverses.

MOE Computer Science Exit Exam · 2016 · Question 91

Question 4 | Q00185

Based on the predefined policy of Network management, controlling access to the network is the task of

A. Fault Management

B. Performance Management

C. Security Management

D. Configuration Management

E. None

Hint

Distinguish the security objective from the control that prevents, detects or recovers from the stated problem.

Answer C: Security Management

PDF p.30 places restricting access to authorized users under security procedures. The requested access-control responsibility therefore matches Security Management.

Why each choice is right or wrong

A - Incorrect: Fault management concerns failures rather than the access authorization described on p.30.

B - Incorrect: Capacity/performance is a different responsibility (p.29), not authorization.

C - Correct: Security procedures explicitly ensure only authorized users have network access (p.30).

D - Incorrect: Configuration management is not the named access-security responsibility.

E - Incorrect: The security alternative directly matches the stated responsibility.

Primary note proof

Study-note section NSA01

Use documentation, standardization, least privilege, automation and measured change. Record the current state, intended change, rollback and validation. Schedule maintenance according to service impact and urgency, not merely because a calendar date arrived. Fault management restores failures; performance management measures service behavior; configuration management tracks settings; security management controls access; accounting tracks usage.

Study-note section NSA26

A security policy states required behavior, scope, accountable roles and enforcement. Begin with assets/service objectives, assess threats and weaknesses, choose controls, define exceptions/incident procedures, approve/communicate, monitor and periodically review. CIA means confidentiality, integrity and availability; neither sensitive-data protection nor availability alone is the universal primary goal.

Module passages - related reading

• Putting security procedures in place to make certain that only authorized users have access to the network and ensuring that all security procedures are followed
• Making sure the network personnel can respond quickly and effectively in the event of a network operational or security failure.

Question sources

Addis Ababa University mock exam · Question 87

Question 5 | Q00186

A Unix utility which used for checking and repairing file system inconsistencies.

A. init

B. halt

C. inittab

D. fsck

Hint

Identify the required operational function, then compare its scope, inputs and constraints with the cited note definitions.

Answer D: fsck

NSA20 directly defines fsck as the filesystem-checking and optional repair utility. Repairs must follow the filesystem's supported safe or offline procedure. The alternatives refer to initialization/shutdown or an initialization configuration file, not the checking-and-repair role stated in the question.

Why each choice is right or wrong

A - Incorrect: Init concerns system initialization/service management rather than the filesystem-checking utility defined in NSA20.

B - Incorrect: Halt stops a system; it is not the utility for checking and repairing filesystem inconsistencies.

C - Incorrect: Inittab is an initialization configuration file, not the filesystem-checking command.

D - Correct: Fsck checks filesystems and can invoke filesystem-specific repair tools under supported safe conditions.

Primary note proof

Study-note section NSA20

> ext2 is a Linux filesystem; ext4 is a later filesystem; HPFS is historically associated with OS/2, while swap is backing space rather than an ordinary user-file filesystem. fsck checks and optionally repairs filesystems through filesystem-specific tools; it is not init, halt or an inittab file. Repairs require the filesystem's supported offline/safe procedure. Mount attaches a filesystem to a directory; partitioning, mounting, quotas and capacity belong to storage administration.

Study-note section NSA-S03

> In a traditional SysV-style system, init starts and supervises configured processes; /etc/inittab is its configuration file. The halt command stops the system through the supported shutdown procedure. Neither initialization, shutdown nor their configuration file is a filesystem-consistency check; fsck supplies that separate checking and optional repair role.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Data Communication and Computer Networking module | PDF page 61 | lines 26-36

> What is Unix/Linux?
> The Unix OS is a set of programs that act as a link between the computer and the user. The computer program that allocates the system resources and coordinates all the details of the computer‘s internals is called the operating system or the kernel. Users communicate with the kernel through a program known as the shell. The shell is a command line interpreter; it translates commands entered by the user and converts them into a language that is understood by the kernel.

Question sources

Addis Ababa University mock exam · Question 88

Question 6 | Q00188

A PC obtains its IP address from a DHCP server. If the PC is taken off the network for repair, what happens to the IP address configuration?

A. The address is returned to the pool for reuse when the lease expires

B. The address lease is automatically renewed until the PC is returned

C. The configuration is held by the server to be reissued when the PC is returned

D. The configuration is permanent and nothing changes

Hint

Identify the required operational function, then compare its scope, inputs and constraints with the cited note definitions.

Answer A: The address becomes reusable when its lease expires

Taking the PC offline does not make the dynamic assignment permanent or cause endless automatic renewal. NSA04 says a disconnected client's lease can expire and the address then becomes eligible for reuse. On return, the client must validate, renew or obtain new configuration rather than assume it still owns its former address.

Why each choice is right or wrong

A - Correct: After expiry the address becomes eligible for return to the available pool, subject to server policy.

B - Incorrect: A disconnected client does not automatically renew indefinitely while it remains off the network.

C - Incorrect: The server need not hold the old address for that client after lease expiry without a reservation.

D - Incorrect: A dynamic lease has a finite interval and is not an unchanging permanent assignment.

Primary note proof

Study-note section NSA04

A client renews before expiry; it later tries rebinding if renewal fails. A disconnected host does not automatically renew forever. On lease expiry the address becomes eligible for reuse, subject to server policy. Reconnection normally triggers validation/renewal/new allocation, so an expired lease alone does not prove persistent failure. A reservation gives a predictable address to a known client while retaining DHCP configuration.

Study-note section NSA04

DHCP supplies addresses and configuration options. Typical initial IPv4 allocation is Discover→Offer→Request→ACK. The server manages its scope/pool, allocated leases, exclusions and reservations; options may include mask, gateway and DNS servers. A dynamic lease lasts for a specified interval, not forever.

Question 7 | Q00189

Which command in Microsoft Windows allows you to verify your IP address, subnet mask, default gateway, and MAC address?

A. C:\>ipconfig/all

B. C:\>ping

C. C:\>ipconfig

D. C:\>ipstatus

Hint

Match the requested observation to the tool's actual output; distinguish configuration, name lookup, reachability and hop discovery.

Answer A: ipconfig /all

The distinguishing requirement is the MAC address as well as IP, mask and gateway. NSA07 assigns this complete adapter detail to ipconfig /all; basic ipconfig covers the ordinary addressing summary. A displays the command with its /all switch. Ping tests reachability and ipstatus is not the defined Windows diagnostic.

Why each choice is right or wrong

A - Correct: The /all switch supplies the detailed adapter information, including the physical/MAC address requested.

B - Incorrect: Ping probes reachability rather than reporting the adapter's complete IP and MAC configuration.

C - Incorrect: Basic ipconfig reports IP, mask and gateway but omits the requested detailed physical/MAC information.

D - Incorrect: Ipstatus is not the Windows adapter-configuration command established by the complete note.

Primary note proof

Study-note section NSA07

> Windows ipconfig shows addresses, mask and gateway; ipconfig /all adds complete adapter configuration including physical/MAC address, DHCP and DNS information. /renew requests renewal, /release releases a dynamic address and /flushdns clears the client DNS cache. Linux ip addr and ip route show interface addresses and routes; exact persistent configuration varies by distribution.

Study-note section NSA07

> netstat displays connections/endpoints/protocols and TCP states; netstat -ano displays numeric addresses/ports and PIDs. Use the exact command name netstat rather than netstart. ping probes IP reachability; traceroute/tracert reveals responding hops using TTL/hop-limit expiry. Question 8 | Q00191

You are the administrator of an active directory domain. A user complains to you that he is unable to change his password. No other users have this issue. What is the most likely cause of the problem?

A. Insufficient login credentials

B. He is a member of the Administrators group

C. He is not a member of the domain

D. The property "User cannot change password" has been enabled when it was created

Hint

Identify the required operational function, then compare its scope, inputs and constraints with the cited note definitions.

Answer D: The account’s User cannot change password property

A failure isolated to one domain user favors inspecting that user’s permissions and cannot-change-password setting. D is the specific account control matching the symptom, and NSA17 explicitly identifies it as a plausible exam cause. It remains a most-likely option among these choices, not proof of its actual state: password age/rules and other account conditions would require real diagnosis.

Why each choice is right or wrong

A - Incorrect: Generic insufficient credentials gives no specific cause for this domain user’s isolated password-change restriction.

B - Incorrect: Administrators membership does not inherently prohibit users from changing their own passwords.

C - Incorrect: The scenario concerns a domain user; lacking domain membership is not the specific account restriction supported here.

D - Correct: The cannot-change-password setting directly blocks the operation and matches the isolated account symptom.

Primary note proof

Study-note section NSA17

If only one domain user cannot change a password, inspect that account's cannot-change-password setting and relevant policy/permission before blaming all directory infrastructure. Other possibilities include minimum password age, password rules or account state; the setting is a plausible exam cause, not a conclusion from failure alone. Membership in Administrators does not inherently prohibit changing one's password. Privileged reset and user-initiated password change are different operations.

Data Communication and Computer Networking module | PDF page 42 | lines 36-49

All user accounts have specific capabilities, privileges, and rights. When you create a user account, you can grant the user specific capabilities by making the user a member of one or more groups. This gives the user the capabilities of these groups. You then assign additional capabilities by making a user a member of the appropriate groups or withdraw capabilities by removing a user from a group. An important part of an administrator‘s job is being able to determine and set permissions, privileges, and logon rights as necessary. Although you can‘t change a group‘s built-in capabilities, you can change a group‘s default privileges and logon rights. For example, you could revoke network access to a computer by removing agroup‘s right to access the computer from the network.

Addis Ababa University mock exam · Question 93

Question 9 | Q00353

Which is the most specific DNS term for obtaining an IP address from a hostname?

A. Forward resolution

B. Backward resolution

C. Binding

D. Resolving

Hint

Identify the required operational function, then compare its scope, inputs and constraints with the cited note definitions.

Answer A: Forward resolution

Forward resolution names the specific direction from a hostname to an address record. Resolving is a broader term that also includes this operation, so it is less specific than the requested answer. Reverse lookup goes from an address to a name, and binding is not the DNS operation defined here. Asking for the most specific term makes the overlapping general description a meaningful distractor.

Why each choice is right or wrong

A - Correct: Forward resolution is the precise name-to-address operation defined by NSA06.

B - Incorrect: Reverse lookup runs in the opposite direction, obtaining a name from an address.

C - Incorrect: Binding is not the note's term for the DNS name-to-address operation; LDAP bind authenticates a session.

D - Incorrect: Resolving includes forward lookup but is broader than the most specific term requested.

Primary note proof

Study-note section NSA06

> Forward resolution obtains an address from a name, using A for IPv4 and AAAA for IPv6. Reverse lookup uses a PTR record in the reverse namespace to obtain a name from an address. CNAME aliases a name, MX identifies mail exchangers and NS identifies authoritative name servers. Forward and reverse records need not both exist or be perfect inverses.

Study-note section NSA06

> Resolvers cache answers for their TTL. Query nslookup name or specify the DNS server explicitly; compare the configured resolver with the authoritative answer when appropriate. A successful ping by address but failed name lookup suggests naming/configuration trouble. Ping by name may display a resolved address, but nslookup is the direct DNS diagnostic. "Resolving" is a general term that includes forward resolution.

Study-note section NSA14

LDAP accesses directory entries/attributes identified by distinguished names. Bind authenticates a session; search retrieves matching entries; compare tests an attribute value; add/delete/modify change entries; modify-DN renames or moves; unbind ends the session. StartTLS upgrades a connection to TLS where supported; LDAPS uses TLS from connection setup. Protect credentials and verify server identity.

/etc/hosts
The /etc/hosts file always contains the localhost IP
address, 127.0.0.1, which is
usedfor interprocess communication.
Never remove this line! Sometimes contains
addresses of additional hosts, whichcan be contacted
without using an external naming service such as
DNS (the Domain Name Server).

Question sources

Computer Science model exam · Question 84

University of Gondar model exam · Question 83

Question 10 | Q00354

You know a server hostname and want to query its DNS address records directly, optionally choosing the DNS server. Which listed diagnostic tool is designed for that task?

A. Nslookup

B. Ping command

C. Traceroute

D. Netstat

Hint

Match the requested observation to the tool’s actual output; distinguish configuration, name lookup, reachability and hop discovery.

Answer A: Nslookup

Nslookup directly queries DNS for the address records associated with a name and can use a specified DNS server. Ping may display a resolved address, but its principal task is testing IP reachability. Traceroute examines responding path hops, while netstat exposes endpoints and connection state. The direct-DNS-query requirement identifies the intended diagnostic without relying on incidental address displays from other commands.

Why each choice is right or wrong

A - Correct: Nslookup directly queries DNS records for the known name and is the conventional diagnostic here.

B - Incorrect: Ping primarily tests reachability; displaying a resolved address is not the direct DNS-record query requested.

C - Incorrect: Traceroute inspects responding hops rather than directly querying DNS address records.

D - Incorrect: Netstat reports existing endpoints/connections and is not a direct lookup for an arbitrary server name.

Primary note proof

Study-note section NSA06

> Resolvers cache answers for their TTL. Query nslookup name or specify the DNS server explicitly; compare the configured resolver with the authoritative answer when appropriate. A successful ping by address but failed name lookup suggests naming/configuration trouble. Ping by name may display a resolved address, but nslookup is the direct DNS diagnostic. “Resolving” is a general term that includes forward resolution.

Study-note section NSA07

> netstat displays connections/endpoints/protocols and TCP states; netstat -ano displays numeric addresses/ports and PIDs. Use the exact command name netstat rather than netstart. ping probes IP reachability; traceroute/tracert reveals responding hops using TTL/hop-limit expiry. ICMP filtering can prevent replies without proving the service is down. nslookup inspects DNS.

University of Gondar model exam · Question 84

Question 11 | Q00355

LAN clients must reach public IPv4 destinations through a gateway with working routes. Which listed address situation commonly calls for source NAT at that gateway?

A. Default gateway of LAN isn't configured

B. Global IP address is used in the LAN

C. He/she don't know type of IP address used in the LAN

D. Private IP address is used in the LAN

Hint

Identify the required operational function, then compare its scope, inputs and constraints with the cited note definitions.

Answer D: Private IP address is used in the LAN

Private IPv4 addresses are not directly routed as public Internet destinations. A gateway can translate those source addresses, often using port bindings so several clients share a public address. This works together with valid routing and the external connection. A missing default gateway must be repaired separately, and public addressing or uncertainty about the current configuration is not by itself a reason to enable NAT.

Why each choice is right or wrong

A - Incorrect: A missing gateway requires routing configuration; address translation is not a replacement for it.

B - Incorrect: Public addressing in a LAN does not automatically require address translation.

C - Incorrect: Not knowing the address type calls for inspecting configuration, not blindly enabling NAT.

D - Correct: Private IPv4 clients commonly need source translation when reaching public destinations through this gateway.

Primary note proof

Study-note section NSA03

An IPv4 address is 32 bits; a CIDR prefix determines its network. Compute network=address AND mask; devices use a route/gateway for remote subnets. Private ranges are 10/8,172.16/12 and 192.168/16; private addresses are not directly Internet-routable. Neither IP alone nor a class label determines today's subnet.

Study-note section NSA11

Routing selects a next hop using a destination prefix; NAT rewrites addresses. Many-to-one address-and-port translation (PAT/NAPT) maps internal flows to one public address using distinct port bindings. For example, two private client sockets can appear as public-address ports 40001 and 40002, with replies translated back to the correct clients.

Study-note section NSA11

NAT is often used when private IPv4 clients access public networks; it does not itself replace a gateway, route, firewall or authentication. One-to-one NAT and destination translation are other forms, so NAT does not always mean many hosts share one address. Public addressing inside a LAN does not automatically require NAT. Unsolicited inbound service access may require explicit mapping and filtering.

These source passages provide context; the primary note proof is identified separately above.

Data Communication and Computer Networking module | PDF page 48 | lines 29-40

Network Address Translation (NAT)
NAT translates the IP addresses of computers in a local network to a single IP address. This address is often used by the router that connects the computers to the Internet. The router can be connected to a DSL modem, cable modem, T1 line, or even a dial-up modem. When other computers on the Internet attempt to access computers within the local network, they only see the IP address of the router. This adds an extra level of security, since the router can be configured as a firewall, only allowing authorized systems to access the computers within the network.

Computer Science model exam · Question 86

University of Gondar model exam · Question 85

Question 12 | Q00356

Which single option gives the complete set of scenarios where DHCP can meet the stated address-management goal, assuming a correctly deployed service?

A. A small network needing automatic host address configuration.

B. Fixed-purpose devices needing predictable addresses through DHCP reservations.

C. A large device population needing centrally managed address configuration.

D. All are correct

Hint

Identify the required operational function, then compare its scope, inputs and constraints with the cited note definitions.

Answer D: All are correct

DHCP can reduce repetitive configuration in small as well as large networks. Reservations allow a known device to receive a predictable address while retaining centrally supplied options. A complex population of clients may also benefit from centrally managed scopes and configuration. The scenarios state these goals rather than treating size or complexity alone as a mandate. Each individual option is valid but incomplete as the requested complete set.

Why each choice is right or wrong

A - Incorrect: DHCP can automate this small network, but A alone omits the other qualifying scenarios.

B - Incorrect: Reservations meet the predictable-address goal, but B alone is incomplete.

C - Incorrect: Centralized DHCP management can meet this goal, but C alone is incomplete.

D - Correct: All three stated goals can be met by an appropriately configured DHCP service.

Primary note proof

Study-note section NSA04

> A client renews before expiry; it later tries rebinding if renewal fails. A disconnected host does not automatically renew forever. On lease expiry the address becomes eligible for reuse, subject to server policy. Reconnection normally triggers validation/renewal/new allocation, so an expired lease alone does not prove persistent failure. A reservation gives a predictable address to a known client while retaining DHCP configuration.

Study-note section NSA05

> Use a scope matching the subnet, exclude manually assigned server/router addresses, set correct options and provide a relay when client broadcasts must cross a router. Static assignments and DHCP can coexist; avoid address conflicts. DHCP lowers repetitive administration but availability/security depend on deployment and protection from rogue replies. It does not guarantee connectivity whenever a device changes location.

Question sources

Computer Science model exam · Question 87

University of Gondar model exam · Question 86

Question 13 | Q00550

A disconnected client returns after its old DHCP lease expired. The correct scope has 20 assignable addresses, all now leased to other active clients; the server and relay are reachable. What best explains why the returning client cannot obtain an address?

A. the IP address lease has expired on the DHCP server.

B. the DHCP scope needs to be redefined.

C. the DHCP pool limit has been reached.

D. the DHCP server needs to be restarted.

Hint

Identify the required operational function, then compare its scope, inputs and constraints with the cited note definitions.

Answer C: the DHCP pool limit has been reached.

A reachable DHCP service still needs an available address in the correct pool. Here all twenty assignable addresses are already leased to other active clients, so the returning client cannot receive a free dynamic allocation. Its expired lease permits reuse but does not alone explain persistent failure after reconnection. The pool-capacity observation supplies the diagnosis; it does not establish a need to redefine the scope or restart the server.

Why each choice is right or wrong

A - Incorrect: The old lease expired, but normal reacquisition would succeed if pool capacity remained; expiry alone is insufficient.

B - Incorrect: The scope is correct; the evidence identifies exhausted capacity rather than an incorrect subnet definition.

C - Correct: All assignable pool addresses are leased, so the pool limit prevents a new allocation.

D - Incorrect: The server is reachable and processing requests; a restart does not create free pool capacity.

Primary note proof

Study-note section NSA04

A client renews before expiry; it later tries rebinding if renewal fails. A disconnected host does not automatically renew forever. On lease expiry the address becomes eligible for reuse, subject to server policy. Reconnection normally triggers validation/renewal/new allocation, so an expired lease alone does not prove persistent failure. A reservation gives a predictable address to a known client while retaining DHCP configuration.

Study-note section NSA05

For a returning client, inspect current lease/address, reachable server/relay, free pool capacity and logs. New devices can exhaust a pool, but absent observations this is only a hypothesis. Some clients self-configure IPv4 link-local addresses such as 169.254.2.33 after DHCP failure; these support same-link communication, not ordinary routed Internet access. 0.0.0.0 is unspecified and 255.255.255.255 is limited broadcast.

Question sources

Computer Science model exam · 2015 · Question 19

Question 14 | Q00563

After a NIC replacement, the adapter is recognized and enabled in firmware and Device Manager, but there is no link light. On the same switch port, replacing only the CAT5 cable with a known-good cable restores connectivity. Which listed fault is isolated?

A. the CAT5 cable is defective

B. the NIC is disabled in BIOS

C. The NIC is disabled in Device Manager

D. The RJ11 jack is defective

Hint

Identify the required operational function, then compare its scope, inputs and constraints with the cited note definitions.

Answer A: the CAT5 cable is defective

The test changes one relevant factor while keeping the adapter and switch port unchanged. Connectivity returns with a known-good cable, which isolates the original cable or its terminations as the failing component. The explicit enabled-state checks exclude the two disabling explanations. RJ11 is a telephone connector rather than the Ethernet connection being tested, so it does not describe the observed fault.

Why each choice is right or wrong

A - Correct: Replacing only the cable restores the link, isolating the original CAT5 cable or its terminations.

B - Incorrect: The adapter is explicitly enabled in firmware.

C - Incorrect: The adapter is explicitly enabled in Device Manager.

D - Incorrect: RJ11 is a telephone connector, not the expected Ethernet RJ45 connection in this NIC scenario.

Primary note proof

Study-note section NSA09

> Check power, cable/connector and link state, then NIC/driver state, VLAN membership, address/prefix, local gateway, route, DNS and finally application port/authentication. A recognized NIC makes a missing driver less likely, not proof of a working physical link. Ethernet commonly uses RJ45 connectors; an RJ11 telephone jack is not the expected Ethernet connection.

Study-note section NSA09

> If same-subnet traffic works but remote traffic fails, compare gateway/routes and filtering. If ping fails but the application connection works, ICMP filtering is plausible. If an application port is refused, the destination is reachable enough to reject it; inspect service/listener policy. A timeout can result from loss, filtering or a down host and needs more evidence.

Study-note section NSA08

Define the symptom, scope, time and recent changes; gather the configuration, baseline and logs. Form a testable hypothesis, test the least disruptive explanation, isolate the failing component, apply a targeted fix, verify the user service and document the result. Change one relevant factor at a time when possible. A reboot can hide evidence and is not a diagnosis by itself.

Question sources

Computer Science model exam · 2015 · Question 32

Question 15 | Q00586

Permissions of a file are represented by which of the following characters?

A. r,w,x

B. w,x

C. x,w,e

D. x,w

Hint

Identify the platform and permission model; for an rwx string, separate owner/group/other triplets and use the stated bit weights.

Answer A: r, w and x

NSA19 groups ordinary Unix permission bits into owner/group/other triplets, each containing read, write and execute. Their conventional letters are r, w and x, with numeric weights 4, 2 and 1 respectively. Only A contains the complete set; the alternatives omit read or substitute a nonpermission letter.

Why each choice is right or wrong

A - Correct: r, w and x denote the complete read, write and execute permission set.

B - Incorrect: This omits r, the read bit, and therefore is not the full ordinary permission-letter set.

C - Incorrect: The letter e is not an ordinary Unix rwx permission bit and read is missing.

D - Incorrect: This lists execute and write but omits the read permission represented by r.

Primary note proof

Study-note section NSA19

The nine ordinary permission bits are owner, group and other triplets. In each triplet read=4,write=2,execute=1; sum enabled bits to get an octal digit. A leading ls -l character denotes file type, not another permission bit. For directories, read lists names, execute permits traversal/search, and write changes entries subject to other checks. File deletion usually depends on parent directory permissions, with sticky-bit/ACL rules also possible.

Question sources

Computer Science model exam · 2015 · Question 55

Question 16 | Q00633

In a centralized client-server deployment, where must centralized file/directory service software be installed at minimum? Client networking support is a separate component.

A. Server

B. every system in the network

C. both server and every system in the network

D. None

Hint

Identify the required operational function, then compare its scope, inputs and constraints with the cited note definitions.

Answer A: Server

The question distinguishes server-side service software from the networking support required on every participant. A centralized service runs on a server that provides it; clients need their own networking support but do not all need the server component installed. Options requiring deployment on every system therefore exceed the minimum location asked for. This does not imply that client operating systems lack networking capabilities.

Why each choice is right or wrong

A - Correct: The server hosts the centralized server-side component.

B - Incorrect: Installing the server component on every system is not the minimum required deployment.

C - Incorrect: Requiring every client as well as the server exceeds the minimum server-side placement.

D - Incorrect: A centralized service does require a host, so none is false.

Primary note proof

Study-note section NSA02

> Clients request services; servers provide them. Peer-to-peer systems can do both. A server can also be a client of DNS or backups, so dedicated role does not mean it never makes requests. A network OS is not universally installed only on a dedicated server: clients also require networking support. Specify centralized service software versus the OS on all participants.

Question sources

Computer Science model exam · 2015 · Question 102

Question 17 | Q00635

Which listed item is a native Linux filesystem for ordinary user files, rather than a foreign-origin filesystem or paging area?

A. ext2

B. hpfs

C. swap

D. All

Hint

Identify the required operational function, then compare its scope, inputs and constraints with the cited note definitions.

Answer A: ext2

Ext2 is a Linux filesystem used for ordinary files. HPFS has its historical origin in OS/2, although Linux can access it when the appropriate driver is available. Swap supplies paging backing space rather than an ordinary user-file filesystem. The native-origin scope therefore identifies ext2 without incorrectly denying Linux support for foreign filesystems or treating swap as a conventional file-storage format.

Why each choice is right or wrong

A - Correct: Ext2 is the native Linux filesystem listed.

B - Incorrect: HPFS is historically associated with OS/2, so it is not the native Linux example requested.

C - Incorrect: Swap is paging backing space, not an ordinary filesystem for storing user files.

D - Incorrect: The all option includes swap as a filesystem, contrary to the note's explicit distinction.

Primary note proof

Study-note section NSA20

ext2 is a Linux filesystem; ext4 is a later filesystem; HPFS is historically associated with OS/2, while swap is backing space rather than an ordinary user-file filesystem. fsck checks and optionally repairs filesystems through filesystem-specific tools; it is not init, halt or an inittab file. Repairs require the filesystem's supported offline/safe procedure. Mount attaches a filesystem to a directory; partitioning, mounting, quotas and capacity belong to storage administration.

Study-note section NSA20

Linux can access some foreign-origin filesystems, including HPFS when its driver is available. Filesystem origin and Linux driver support are different questions. Swap is a paging area rather than an ordinary user-file filesystem. ext2 is a native Linux-filesystem example; broader Linux filesystem support can also include HPFS, so distinguish origin from driver support.

Question 18 | Q00650

The top-level directory on a Linux system is represented as _____

A. /

B. $

C. *

D. #

Hint

Identify the required operational function, then compare its scope, inputs and constraints with the cited note definitions.

Answer A: /

PDF p.63 states that the tree begins at a forward slash and calls that directory root. Thus the top-level directory is /.

Why each choice is right or wrong

A - Correct: The forward slash is explicitly the root directory (p.63).

B - Incorrect: The cited root symbol is /, not $.

C - Incorrect: The cited root symbol is /, not *.

D - Incorrect: The cited root symbol is /, not #.

Primary note proof

Study-note section NSA20

> / is the filesystem root; /root is the administrative user’s home. /etc stores configuration, /home ordinary user homes, /var variable data/logs, /dev device nodes, /proc kernel/process information, /boot boot material and /tmp temporary files. Cleanup/mount layouts vary; do not assume every partition has lost+found or every reboot erases every temporary directory.

Question sources

Computer Science model exam · 2015 · Question 119

Question 19 | Q00900

Which listed item is a traffic-prioritization mechanism that can operate across layers, rather than an application mediator or service installation/configuration activity?

A. Proxies and agents

B. Installing a new service

C. .
E-mail configuration

D. Quality of service

Hint

Identify the required operational function, then compare its scope, inputs and constraints with the cited note definitions.

Answer D: Quality of service

Quality of service classifies, queues and prioritizes traffic to meet performance objectives such as low delay or limited loss. It can span layers while supporting applications. Proxies and agents are mediating components, and installing a service or configuring email are administrative activities. The revised question uses those explicit functional categories, so it does not require an unsupported taxonomy that labels every item an application-layer service.

Why each choice is right or wrong

A - Incorrect: Proxies and agents mediate requests as components rather than naming the traffic-prioritization mechanism.

B - Incorrect: Installing a service is an administrative activity, not a traffic-prioritization mechanism.

C - Incorrect: Email configuration is an administrative activity rather than cross-layer traffic prioritization.

D - Correct: QoS classifies and prioritizes traffic and can operate across layers.

Primary note proof

Study-note section NSA12

> A proxy acts on behalf of a client or backend service and can cache, filter or mediate application requests. A default IP gateway is a next-hop router; an application gateway may translate protocols. It need not be a modem/router combination. These terms describe functions that can coexist on one machine.

Study-note section NSA12

> QoS classifies, queues and prioritizes traffic to meet performance objectives such as low delay or limited loss. It can operate across layers and support applications, so it is not exclusively an application-layer service. Installing a new service is an administrative action; email configuration is another action and proxies/agents are components. Distinguish service-management actions from components using a stated taxonomy.

Question 20 | Q00924

A data-center volume has exactly two equal disks and must retain service after either disk fails. One disk’s usable capacity is sufficient. Which listed RAID level meets these requirements?

A. RAID level 3

B. RAID level 1

C. .

RAID level 2

D. RAID level 0

Hint

Compare striping granularity, redundancy placement, usable capacity and required disk-failure tolerance.

Answer B: RAID level 1

With exactly two equal disks, RAID1 mirrors the data and leaves one disk's usable capacity while tolerating either disk failing. RAID0 provides no disk-failure tolerance. RAID2 and RAID3 rely on different striping and redundancy layouts rather than the two-disk mirrored arrangement that meets these requirements. The choice follows the stated disk count, capacity and failure goal rather than the institution's size or industry.

Why each choice is right or wrong

A - Incorrect: RAID3 uses byte striping with dedicated parity, not the required two-disk fault-tolerant layout.

B - Correct: A two-disk RAID1 mirror has one disk's capacity and survives either disk failing.

C - Incorrect: RAID2 uses bit striping with Hamming redundancy, rather than the two-disk solution meeting this requirement.

D - Incorrect: RAID0 has no disk-failure tolerance.

Primary note proof

Study-note section NSA25

> RAID0 stripes for capacity/throughput with no disk-failure tolerance. RAID1 mirrors; a two-disk mirror has one disk's usable capacity and survives one disk failure. RAID2 uses bit striping/Hamming-code redundancy, RAID3 byte striping with dedicated parity, RAID4 block striping with dedicated parity and RAID5 block striping with distributed parity. RAID6 distributes dual parity and tolerates two disk failures. RAID10 stripes mirrored pairs; survival depends on which disks fail.

Study-note section NSA25

> With N equal disks of capacity D, RAID0 usable=ND, paired RAID1/10≈ND/2, RAID5=(N−1)D and RAID6=(N−2)D. Hardware RAID may offload work to controller resources/cache but does not universally outperform software RAID. Rebuilds consume bandwidth; parity writes have overhead. A large university/bank alone does not select a level. Striping plus parity is not uniquely RAID5 unless distributed block parity is specified.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Data Communication and Computer Networking module | PDF page 59 | lines 14-24

> Data is distributed across the drives in one of several ways, referred to as RAID levels, depending on the required level of redundancy and performance. The different schemes, or data distribution layouts, are namedby the word —RAID‖ followed by a number, for example RAID 0 or RAID 1. Each scheme, or RAID level, provides a different balance among the key goals: reliability, availability, performance, and capacity. RAIDlevels greater than RAID 0 provide

protection against unrecoverable sector read errors,
as well as against failures of whole physical drives.

Data Communication and Computer Networking module | PDF page 59 | lines 46-52

RAID 1 consists of data mirroring, without parity or
striping . Data is written identically to two or more
drives,thereby producing a —mirrored set‖ of drives.
Thus, any read request can be serviced by any drive in
the set. If a request is broadcast to every drive in the set,
it can be serviced by the drive that accesses the data first
(depending on its seek time and rotational latency),

Data Communication and Computer Networking module | PDF page 60 | lines 12-26

RAID 2 consists of bit-level striping with dedicated
Hamming-code parity. All disk spindle rotation is
synchronized and data is striped such that each sequential
bit is on a different drive. Hamming-code parity is
calculated across corresponding bits and stored on at least
one parity drive. This level is of historical significance
only; as of 2014 it is not used by any commercially
available system.
RAID 3 consists of byte-level striping with dedicated
parity. All disk spindle rotation is synchronized and data
is striped such that each sequential byte is on a different
drive. Parity is calculated across corresponding bytes and
stored on a dedicated parity drive. Although
implementations exist, RAID 3 is not commonly used in
practice.

Data Communication and Computer Networking module | PDF page 59 | lines 33-45

RAID 0 consists of striping, but no mirroring or
parity. Compared to a spanned volume, the capacity
of a RAID 0 volume is the same; it is the sum of the
capacities of the drives in the set. But because
striping distributes the contents of each file among all
drives in the set, the failure of any drive causes the
entire RAID 0 volume and all files to be lost. In
comparison, a spanned volume preserves thefiles on
the unfailing drives. The benefits of RAID 0 is that
the throughput of read and write operations to any file
is multiplied by the number of drives because, unlike
spanned volumes, reads and writes are done
concurrently.

Computer Science Exit Exam · 2018 · Question 37

Question 21 | Q00937

Which listed RAID layout uses block-level striping with distributed parity and tolerates one disk failure?

A. RAID 2

B. RAID 1

C. RAID 5

D. RAID 0

Hint

Compare striping granularity, redundancy placement, usable capacity and required disk-failure tolerance.

Answer C: RAID 5

RAID5 distributes parity across disks while striping data at block level. That distinguishes it from RAID2's bit striping and Hamming-code redundancy. RAID1 mirrors copies instead of organizing the array as distributed-parity striping, while RAID0 adds no redundancy. The explicit granularity and parity placement identify the intended layout rather than treating every form of redundant striping as equivalent.

Why each choice is right or wrong

A - Incorrect: RAID2 uses bit striping with Hamming redundancy, not distributed block parity.

B - Incorrect: RAID1 mirrors data rather than using the specified striping-with-parity organization.

C - Correct: RAID5 uses block striping with distributed parity and one-disk failure tolerance.

D - Incorrect: RAID0 stripes without redundant parity and provides no disk-failure tolerance.

Primary note proof

Study-note section NSA25

> RAID0 stripes for capacity/throughput with no disk-failure tolerance. RAID1 mirrors; a two-disk mirror has one disk's usable capacity and survives one disk failure. RAID2 uses bit striping/Hamming-code redundancy, RAID3 byte striping with dedicated parity, RAID4 block striping with dedicated parity and RAID5 block striping with distributed parity. RAID6 distributes dual parity and tolerates two disk failures. RAID10 stripes mirrored pairs; survival depends on which disks fail.

Study-note section NSA25

> With N equal disks of capacity D, RAID0 usable=ND, paired RAID1/10≈ND/2, RAID5=(N−1)D and RAID6=(N−2)D. Hardware RAID may offload work to controller resources/cache but does not universally outperform software RAID. Rebuilds consume bandwidth; parity writes have overhead. A large university/bank alone does not select a level. Striping plus parity is not uniquely RAID5 unless distributed block parity is specified.

RAID 3 consists of byte-level striping with dedicated parity. All disk spindle rotation is synchronized and data is striped such that each sequential byte is on a different drive. Parity is calculated across corresponding bytes and stored on a dedicated parity drive. Although implementations exist, RAID 3 is not commonly used in practice.

Data Communication and Computer Networking module | PDF page 60 | lines 35-46

RAID 5 consists of block-level striping with distributed parity. Unlike RAID 4, parity information is distributed among the drives, requiring all drives but one to be present to operate. Upon failure of a single drive, subsequent reads can be calculated from the distributed parity such that no data is lost. RAID 5 requires at least three disks. Like all single-parity concepts, large RAID 5 implementations are susceptible to system failures because of trends regarding array rebuild time and the chance of drive failure during rebuild. Rebuilding an array requires reading all data from all disks, opening a chance for a second drive failure and the loss of the entire array.

Data Communication and Computer Networking module | PDF page 59 | lines 46-52

RAID 1 consists of data mirroring, without parity or striping . Data is written identically to two or more drives,thereby producing a —mirrored set‖ of drives. Thus, any read request can be serviced by any drive in the set. Question sources

Computer Science Exit Exam · 2018 · Question 50

Question 22 | Q00954

Which tool directly sends ICMP echo probes to test IP reachability?

A. Ipconfig

B. Ping

C. Encryption

D. Firewall

Hint

Match the requested observation to the tool’s actual output; distinguish configuration, name lookup, reachability and hop discovery.

Answer B: Ping

Ping sends ICMP echo requests and observes replies to test IP reachability. A reply confirms that the path and target support that exchange. A missing reply may reflect filtering or loss, so it does not alone prove disconnection. Interface configuration inspection, confidentiality protection and traffic-policy enforcement serve different purposes from sending this diagnostic probe.

Why each choice is right or wrong

A - Incorrect: Ipconfig displays local adapter configuration; it does not send the requested echo probes.

B - Correct: Ping sends ICMP echo requests and checks for replies.

C - Incorrect: Encryption protects confidentiality rather than generating an echo reachability test.

D - Incorrect: A firewall permits or blocks traffic according to policy rather than being the echo-probe utility.

Primary note proof

Study-note section NSA07

Windows ipconfig shows addresses, mask and gateway; ipconfig /all adds complete adapter configuration including physical/MAC address, DHCP and DNS information. /renew requests renewal, /release releases a dynamic address and /flushdns clears the client DNS cache. Linux ip addr and ip route show interface addresses and routes; exact persistent configuration varies by distribution.

Study-note section NSA-S04

Ping uses ICMP echo messages to test IP reachability. A reply shows that the addressed host and path support that exchange; no reply alone does not prove the host is disconnected, because filtering or loss can suppress responses. Traceroute instead discovers responding intermediate hops through packet-lifetime expiry; it is a path-discovery diagnostic, not the same question as an end-to-end echo test.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Data Communication and Computer Networking module | PDF page 27 | lines 26-28

Ping (Packet Internet Groper) uses ICMP echo
messages to check the physical and logical
connectivity of machineson a network.

Data Communication and Computer Networking module | PDF page 48 | lines 29-40

Network Address Translation (NAT)
NAT translates the IP addresses of computers in a local network to a single IP address. This address is often used by the router that connects the computers to the Internet. The router can be connected to a DSL modem, cable modem, T1 line, or even a dial-up modem. When other computers on the Internet attempt to access computers within the local network, they only see the IP address of the router. This adds an extra level of security, since the router can be configured as a firewall, only allowing authorized systems to access the computers within the network.

Question sources

Computer Science Exit Exam · 2018 · Question 67

Question 23 | Q01003

Suppose you are network administrator, you want to determine the path between two connections, often a connection to another device will have to go through multiple routers. Which command would you use?

A. ping

B. nslookup

C. traceroute

D. All of the above

Hint

Match the requested observation to the tool's actual output; distinguish configuration, name lookup, reachability and hop discovery.

Answer C: traceroute

Traceroute discovers responding intermediate hops by using packet-lifetime expiry. That provides evidence about the multi-router path toward a destination. Ping instead tests an end-to-end echo exchange, and nslookup asks DNS questions. Neither produces the requested hop sequence, so combining all the tools is not the correct description of the specific path-discovery command. Some routers may suppress responses, leaving gaps in the trace.

Why each choice is right or wrong

A - Incorrect: Ping probes end-to-end reachability, not the intermediate-hop sequence.

B - Incorrect: Nslookup inspects DNS name-resolution information, not router hops.

C - Correct: Traceroute discovers responding intermediate hops toward the destination.

D - Incorrect: Not all listed commands perform hop discovery.

Primary note proof

Study-note section NSA07

> netstat displays connections/endpoints/protocols and TCP states; netstat -ano displays numeric addresses/ports and PIDs. Use the exact command name netstat rather than netstart. ping probes IP reachability; traceroute/tracert reveals responding hops using TTL/hop-limit expiry. ICMP filtering can prevent replies without proving the service is down. nslookup inspects DNS.

Study-note section NSA06

> Resolvers cache answers for their TTL. Query nslookup name or specify the DNS server explicitly; compare the configured resolver with the authoritative answer when appropriate. A successful ping by address but failed name lookup suggests naming/configuration trouble. Ping by name may display a resolved address, but nslookup is the direct DNS diagnostic. "Resolving" is a general term that includes forward resolution.

Question sources

National Exit Exam practice questions · Question 17

Question 24 | Q01191

In a deployment with one unprotected DHCP server, which statements are not actual disadvantages of DHCP? Select all that apply.

A. Fault on the DHCP server can affect the whole network

B. It is not a secured way of assigning IP addresses

C. Static IP address assignment can't be used.

D. It minimizes the load of network admin

Hint

Identify the required operational function, then compare its scope, inputs and constraints with the cited note definitions.

Answer C, D: Static IP address assignment can't be used.; It minimizes the load of network admin

A single DHCP service can become an availability dependency for clients needing configuration, and rogue replies are a risk in an unprotected deployment. However, DHCP does not prohibit static assignments: administrators can exclude manually used addresses to avoid conflicts. Reducing repetitive administration is also an advantage. Therefore the false limitation about static addressing and the genuine administrative benefit are the requested exceptions.

Why each choice is right or wrong

A - Incorrect: Depending on deployment, DHCP-server failure can impair clients needing leases, so this can be a disadvantage.

B - Incorrect: Rogue replies and insecure deployment are genuine risks, although DHCP security depends on protections.

C - Correct: This alleged disadvantage is false: static assignments and DHCP can coexist safely with exclusions.

D - Correct: Reducing repetitive administrator work is an advantage rather than a disadvantage.

Primary note proof

Study-note section NSA05

> Use a scope matching the subnet, exclude manually assigned server/router addresses, set correct options and provide a relay when client broadcasts must cross a router. Static assignments and DHCP can coexist; avoid address conflicts. DHCP lowers repetitive administration but availability/security depend on deployment and protection from rogue replies. It does not guarantee connectivity whenever a device changes location.

Study-note section NSA04

> DHCP supplies addresses and configuration options. Typical initial IPv4 allocation is Discover→Offer→Request→ACK. The server manages its scope/pool, allocated leases, exclusions and reservations; options may include mask, gateway and DNS servers. A dynamic lease lasts for a specified interval, not forever.

Question sources

Computer Science model exam 2 · Question 12

Question 25 | Q01210

Which listed address is the conventional IPv4 loopback address normally chosen to test the local IP stack? Select one.

A. 127.0.0.1

B. 1.0.0.127

C. 127.0.0.0

D. 127.0.0.255

Hint

Identify the required operational function, then compare its scope, inputs and constraints with the cited note definitions.

Answer A: 127.0.0.1

The whole 127/8 range is reserved for loopback, but 127.0.0.1 is the conventional address normally used for this test. The other 127-prefixed choices belong to the broader reserved block without being the conventional address requested. The reversed-looking 1.0.0.127 is outside loopback space. A successful loopback probe tests local protocol processing and does not establish that cables or remote devices work.

Why each choice is right or wrong

A - Correct: 127.0.0.1 is the conventional IPv4 loopback address explicitly named in the note.

B - Incorrect: 1.0.0.127 is outside the reserved 127/8 loopback block.

C - Incorrect: This belongs to loopback-reserved 127/8, but is not the conventional address requested.

D - Incorrect: This also lies in 127/8, but is not the conventional loopback address requested.

Primary note proof

Study-note section NSA03

> 127.0.0.1 conventionally names the local IPv4 loopback interface; 127/8 is reserved for loopback. Loopback tests local protocol processing, not cable, switch or remote reachability. Programs can use it for local services. Several loopback descriptions or several 127/8 addresses may be valid; compare each with the stated role.

Question sources

Computer Science model exam 2 · Question 31

Question 26 | Q01216

Most of the time, it is recommended to apply a Hardware RAID into your system in terms of system performance. Why? Because Hardware RAID:

A. A physical storage device that is built into a system

B. Can appear as a single hard disk in the system

C. There is no difference between regular hardware and the RAID devices

D. Can use its own resources

Hint

Compare striping granularity, redundancy placement, usable capacity and required disk-failure tolerance.

Answer D: Hardware RAID can use its own controller resources

NSA25 supports controller resources/cache as a reason hardware RAID may offload work from the host. D directly states that relevant mechanism. Appearing as one disk is a presentation property rather than the performance explanation, and neither simply being physical nor denying differences explains offload. The note also rejects any universal claim that hardware RAID always performs better.

Why each choice is right or wrong

A - Incorrect: Being a physical device alone does not explain any RAID performance advantage or computation offload.

B - Incorrect: A single logical-disk presentation does not establish that host processing work is offloaded.

C - Incorrect: Denying differences provides no performance mechanism and ignores dedicated controller resources.

D - Correct: Dedicated controller resources/cache can perform RAID work rather than relying entirely on the host CPU.

Primary note proof

Study-note section NSA25

> With N equal disks of capacity D, RAID0 usable=ND, paired RAID1/10≈ND/2, RAID5=(N−1)D and RAID6=(N−2)D. Hardware RAID may offload work to controller resources/cache but does not universally outperform software RAID. Rebuilds consume bandwidth; parity writes have overhead. A large university/bank alone does not select a level. Striping plus parity is not uniquely RAID5 unless distributed block parity is specified.

Study-note section NSA25

RAID0 stripes for capacity/throughput with no disk-failure tolerance. RAID1 mirrors; a two-disk mirror has one disk's usable capacity and survives one disk failure. RAID2 uses bit striping/Hamming-code redundancy, RAID3 byte striping with dedicated parity, RAID4 block striping with dedicated parity and RAID5 block striping with distributed parity. RAID6 distributes dual parity and tolerates two disk failures. RAID10 stripes mirrored pairs; survival depends on which disks fail.

Data is distributed across the drives in one of several ways, referred to as RAID levels, depending on the required level of redundancy and performance. The different schemes, or data distribution layouts, are namedby the word —RAID‖ followed by a number, for example RAID 0 or RAID 1. Each scheme, or RAID level, provides a different balance among the key goals: reliability, availability, performance, and capacity. RAIDlevels greater than RAID 0 provide protection against unrecoverable sector read errors, as well as against failures of whole physical drives.

Question sources

Computer Science model exam 2 · Question 37

Question 27 | Q01271

All of the following are the roles of a system admin related to the file system and disk space management EXCEPT?

A. Assigning user ID and User name for system users

B. Determining desk usage and quota

C. Creating a Mounting point

D. Partition disk space

Hint

Identify the required operational function, then compare its scope, inputs and constraints with the cited note definitions.

Answer A: Assigning user ID and User name for system users

PDF p.42 assigns account permissions and capabilities to user administration, p.53 monitors free disk space, and p.64 identifies a mount point. Assigning a username/ID is the account task, while the other options concern storage organization or capacity.

Why each choice is right or wrong

A - Correct: This belongs to account administration (p.42), making it the requested exception.

B - Incorrect: Disk usage and quota concern the storage capacity being monitored on p.53.

C - Incorrect: A mounting point belongs to the filesystem organization illustrated by /mnt (p.64).

D - Incorrect: Partitioning concerns organizing disk space, within the storage subject rather than naming users.

Primary note proof

Study-note section NSA20

> ext2 is a Linux filesystem; ext4 is a later filesystem; HPFS is historically associated with OS/2, while swap is backing space rather than an ordinary user-file filesystem. fsck checks and optionally repairs filesystems through filesystem-specific tools; it is not init, halt or an inittab file. Repairs require the filesystem's supported offline/safe procedure. Mount attaches a filesystem to a directory; partitioning, mounting, quotas and capacity belong to storage administration.

Study-note section NSA17

> Create named accounts, assign only needed groups/rights, disable departed users and audit privileged activity. Authentication verifies the account; authorization permits operations. A user right such as remote logon differs from a permission on one file. Group-based administration is easier to review than many hidden individual grants.

> withdraw capabilities by removing a user from a group.
> An important part of an administrator‘s job is being able
> to determine and set permissions, privileges, and logon
> rights as necessary. Although you can‘t change a group‘s
> built-in capabilities, you can change a group‘s default
> privileges and logon rights. For example, you could
> revoke network access to a computer by removing agroup‘s
> right to access the computer from the network.

Data Communication and Computer Networking module | PDF page 53 | lines 2-20

> Monitoring storage normally takes place at two
> different levels:
> • Monitoring for sufficient disk space
> • Monitoring for storage-related

performanceproblems
The reason for this is that it is possible to have dire problems in one area and no problems whatsoever in the other. For example, it is possible to cause a disk drive to run out of disk space without once causing any kind of performance-related problems. Likewise, it is possible tohave a disk drive that has 99% free space, yet is being pushed past its limits in terms of performance.
In any case, the following statistics are useful for monitoring storage:
• Free Space
• File System-Related Statistics
• Transfers per Second
• Reads/Writes per Second

Data Communication and Computer Networking module | PDF page 64 | lines 8-12

/lost+found: Every partition has a lost+found for files that were saved during failures are here.

Question sources

Computer Science model exam 2 · Question 92

Question 28 | Q01307

In the ordinary Unix owner/group/other rwx permission-bit model, which operation has no separate file permission bit?

A. Read

B. Write

C. Execute

D. Delete

Hint

Identify the platform and permission model; for an rwx string, separate owner/group/other triplets and use the stated bit weights.

Answer D: Delete

Each ordinary Unix permission triplet contains read, write and execute bits. There is no fourth delete bit in that model. Deletion generally depends on permissions on the parent directory, with other mechanisms such as sticky bits or ACLs able to add restrictions. Windows can have an explicit delete permission, so naming the Unix rwx model is essential to make the exception accurate.

Why each choice is right or wrong

A - Incorrect: Read is a recognized permission in both Windows and ordinary Unix permission models.

B - Incorrect: Write is a recognized access permission, not the requested generic exception.

C - Incorrect: Execute/read-execute permissions exist in the models described in the note.

D - Correct: Unix rwx has no separate delete bit; deletion usually depends on the parent directory.

Primary note proof

Study-note section NSA19

> The nine ordinary permission bits are owner, group and other triplets. In each triplet read=4,write=2,execute=1; sum enabled bits to get an octal digit. A leading ls -l character denotes file type, not another permission bit. For directories, read lists names, execute permits traversal/search, and write changes entries subject to other checks. File deletion usually depends on parent directory permissions, with sticky-bit/ACL rules also possible.

Study-note section NSA18

> Deleting can be an explicit permission in Windows; specify the operating system before comparing permission names. Modify and full control are not identical: full control includes changing permission/ownership capabilities. Separate data access from logon rights. A user allowed to read a file is not necessarily allowed to write it or administer its parent folder.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Data Communication and Computer Networking module | PDF page 43 | lines 19-35

> In Windows, a user account or a user group can receive one of the following permissions to any file or folder:
> Read: allows the viewing and listing of a file or folder. When viewing a folder, you can view all its files and subfolders.
> Write: allows writing to a file or adding files and subfolders to a folder.
> List folder contents: this permission can be assigned only to folders. It permits the viewing and listing of files and subfolders, as well as executing files that are found inthat folder.

> Read & execute: permits the reading and accessing of a file‘s contents as well as its execution. When dealing withfolders, it allows the viewing and listing of files and subfolders, as well as the execution of files.

Data Communication and Computer Networking module | PDF page 43 | lines 36-44

> Modify: when dealing with files, it allows their reading, writing and deletion. When dealing with folders, it allowsthe reading and writing of files and subfolders, plus the deletion of the folder.
> Full control: it allows reading, writing, changing and deleting of any file and subfolder. Generally, files inheritthe permissions of the folder where they are placed, but users can also define specific permissions that are assigned only to a specific file.

Question sources

Operating Systems practice questions · Question 25

Question 29 | Q01495

After DHCP fails at startup, a client self-configures an IPv4 link-local interface address for same-link communication. Which address could it assign?

A. 255.255.255.255

B. 127.0.0.1

C. 169.254.2.33

D. 0.0.0.0

Hint

Identify the required operational function, then compare its scope, inputs and constraints with the cited note definitions.

Answer C: 169.254.2.33 as an IPv4 link-local fallback

An IPv4 link-local fallback uses the 169.254 range; 169.254.2.33 is a usable example. This can permit communication with peers on the same link, but does not provide ordinary routed Internet connectivity. The other values serve special broadcast, loopback or unspecified-address roles. In particular, 0.0.0.0 may appear before configuration but is not the assigned link-local address requested here.

Why each choice is right or wrong

A - Incorrect: This is the limited-broadcast destination, not an assigned host address.

B - Incorrect: Loopback addresses the local host, not its link-local interface.

C - Correct: 169.254.2.33 is an IPv4 link-local fallback address.

D - Incorrect: The unspecified address is not a configured link-local host address.

Primary note proof

Study-note section NSA05

> For a returning client, inspect current lease/address, reachable server/relay, free pool capacity and logs. New devices can exhaust a pool, but absent observations this is only a hypothesis. Some clients self-configure IPv4 link-local addresses such as 169.254.2.33 after DHCP failure; these support same-link communication, not ordinary routed Internet access. 0.0.0.0 is unspecified and 255.255.255.255 is limited broadcast.

Study-note section NSA03

> 127.0.0.1 conventionally names the local IPv4 loopback interface; 127/8 is reserved for loopback. Loopback tests local protocol processing, not cable, switch or remote reachability. Programs can use it for local services. Several loopback descriptions or several 127/8 addresses may be valid; compare each with the stated role.

Module passages - related reading

Question sources

Mock exam 1 · Question 11

Question 30 | Q01592

Which action is not sound OS hardening when required services must remain available?

A. Remove unnecessary applications and services

B. Install patches

C. Configure users and permissions

D. Block every port, including ports required by legitimate services.

Hint

Identify the required operational function, then compare its scope, inputs and constraints with the cited note definitions.

Answer D: Block every port, including ports required by legitimate services.

Hardening reduces unnecessary exposure while preserving the services the system must provide. Removing unused software, deploying supported patches and restricting accounts or permissions all support that goal. Filtering unused ports can help too, but indiscriminately blocking ports required by legitimate services destroys availability. The port option states that harmful action explicitly rather than treating every form of port filtering as inappropriate.

Why each choice is right or wrong

A - Incorrect: Removing unnecessary applications/services reduces attack surface and is an explicit hardening action.

B - Incorrect: Supported patches repair known weaknesses and are part of hardening.

C - Incorrect: Restricting users and permissions is an explicit hardening measure.

D - Correct: Blocking ports required by legitimate services defeats availability rather than sound hardening.

Primary note proof

Study-note section NSA27

> Hardening reduces exposure through unnecessary-service removal, supported patches, restricted accounts/permissions and appropriate port filtering. Blocking an unused known port can be hardening; blocking every useful port merely destroys availability. Weak passwords and unpatched exploitable software are vulnerabilities; attacks exploit weaknesses, and risk combines likelihood with impact.

Study-note section NSA01

> Use documentation, standardization, least privilege, automation and measured change. Record the current state, intended change, rollback and validation. Schedule maintenance according to service impact and urgency, not merely because a calendar date arrived. Fault management restores failures; performance management measures service behavior; configuration management tracks settings; security management controls access; accounting tracks usage.

Although the specifics of being a system administrator may change from platform to platform, there are underlying themes that do not. These themes make up the philosophy of system administration. The themes are:
• Automate everything
• Document everything
• Communicate as much as possible
• Know your resources
• Know your users
• Know your business
• Security cannot be an afterthought
• Plan ahead
• Expect the unexpected
• Backup and disaster recovery planning
• Patching

Data Communication and Computer Networking module | PDF page 58 | lines 33-40

Disadvantages of Remote Administration
Remote administration has many disadvantages too apart from its advantages. The first and foremost disadvantage is the security. Generally, certain ports to be open at Server level to do remote administration. Due to open ports, the hackers/attackers takes advantage to compromise the system. It is advised that remote administration to be used only in emergency or essential

Data Communication and Computer Networking module | PDF page 42 | lines 36-49

All user accounts have specific capabilities, privileges, and rights. When you create a user account, you can grant the user specific capabilities by making the user a member of one or more groups. This gives the user the capabilities of these groups. You then assign additional capabilities by making a user a member of the appropriate groups or withdraw capabilities by removing a user from a group. An important part of an administrator‘s job is being able to determine and set permissions, privileges, and logon rights as necessary. Although you can‘t change a group‘s built-in capabilities, you can change a group‘s default privileges and logon rights. For example, you could revoke network access to a computer by removing agroup‘s right to access the computer from the network.

Data Communication and Computer Networking module | PDF page 59 | lines 2-4

situations only to do administration remotely. In normal situations, it is ideal to block the ports to avoid remote administration.

Question sources

Mock exam 3 · Question 24

Question 31 | SM0028

You know the upstairs computer's IP address and want a basic end-to-end ICMP echo reachability test, rather than a router-hop trace. Which command should you use?

A. nslookup

B. ping

C. DHCP discover

D. traceroute

Hint

Match the requested observation to the tool's actual output; distinguish configuration, name lookup, reachability and hop discovery.

Answer B: ping

Ping directly tests whether the addressed computer and path support an ICMP echo exchange. A reply is useful reachability evidence; absence of a reply may result from filtering or loss. Nslookup tests DNS, DHCP discovery seeks configuration service, and traceroute identifies responding intermediate hops. These answer different operational questions from the basic echo test requested.

Why each choice is right or wrong

A - Incorrect: Nslookup queries DNS, which is unnecessary for the specified known-IP echo test.

B - Correct: Ping performs the requested end-to-end ICMP echo test.

C - Incorrect: DHCP discovery locates configuration service rather than testing this remote host.

D - Incorrect: Traceroute probes the hop path rather than performing the requested basic echo test.

Primary note proof

Study-note section NSA-S04

Ping uses ICMP echo messages to test IP reachability. A reply shows that the addressed host and path support that exchange; no reply alone does not prove the host is disconnected, because filtering or loss can suppress responses. Traceroute instead discovers responding intermediate hops through packet-lifetime expiry; it is a path-discovery diagnostic, not the same question as an end-to-end echo test.

Study-note section NSA07

netstat displays connections/endpoints/protocols and TCP states; netstat -ano displays numeric addresses/ports and PIDs. Use the exact command name netstat rather than netstart. ping probes IP reachability; traceroute/tracert reveals responding hops using TTL/hop-limit expiry. ICMP filtering can prevent replies without proving the service is down. nslookup inspects DNS.

Question 32 | SM0084

Which one of the following is correct about human role in system administration?

A. Ethics is not a requirement to manage computers

B. It requires patience, understanding and knowledge

C. It doesn't need organizational skills

D. System administrator is not expected to have skills and confidence

Hint

Identify the required operational function, then compare its scope, inputs and constraints with the cited note definitions.

Answer B: Patience, understanding and knowledge

NSA01 includes human abilities and responsible conduct in administration: patience, communication, ethics, technical understanding and organization. B agrees with that account. The other statements deny ethics, organization or expected competence, directly contradicting the note's description of the role rather than identifying a valid human requirement.

Why each choice is right or wrong

A - Incorrect: NSA01 explicitly includes ethics among the qualities required for responsible administration.

B - Correct: Patience and technical understanding/knowledge agree directly with the human qualities listed in NSA01.

C - Incorrect: Organization is explicitly important, so denying organizational skills contradicts the note.

D - Incorrect: The role requires technical understanding and competent administration rather than an absence of skills.

Primary note proof

Study-note section NSA01

> System administrators maintain hosts, accounts, storage, software and availability; network administrators maintain connectivity, addressing, routes, network devices and performance. Security administrators coordinate controls and policy. These duties overlap, so account management, testing patches and training users are not exclusive to one job title. Patience, communication, ethics, technical understanding and organization matter alongside command knowledge.

Question 33 | SM0270

A planned hardware upgrade requires the system to be powered off, and an acceptable maintenance window and rollback are arranged. Which listed circumstance justifies the planned shutdown?

A. Using regular schedules

B. For maintenance and upgrade

C. To check for security alerts

D. When there is a failure

Hint

Identify the required operational function, then compare its scope, inputs and constraints with the cited note definitions.

Answer B: For maintenance and upgrade

A shutdown is justified when the required procedure needs it and its service impact has been planned. Here the hardware upgrade explicitly requires power-off and an acceptable window has been arranged. A calendar schedule alone is insufficient, checking alerts ordinarily requires no shutdown, and no failure is described. The decision therefore follows the actual maintenance requirement rather than a universal rule that systems should stop periodically.

Why each choice is right or wrong

A - Incorrect: A regular calendar schedule alone does not justify shutting down a service without considering impact and necessity.

B - Correct: The stated maintenance/upgrade procedure requires a planned power-off.

C - Incorrect: Checking alerts does not ordinarily require stopping the system and supplies no shutdown justification here.

D - Incorrect: No failure is described; the shutdown is required for the planned upgrade.

Primary note proof

Study-note section NSA01

> Use documentation, standardization, least privilege, automation and measured change. Record the current state, intended change, rollback and validation. Schedule maintenance according to service impact and urgency, not merely because a calendar date arrived. Fault management restores failures; performance management measures service behavior; configuration management tracks settings; security management controls access; accounting tracks usage.

Study-note section NSA08

> Define the symptom, scope, time and recent changes; gather the configuration, baseline and logs. Form a testable hypothesis, test the least disruptive explanation, isolate the failing component, apply a targeted fix, verify the user service and document the result. Change one relevant factor at a time when possible. A reboot can hide evidence and is not a diagnosis by itself.

Question 34 | SM0287

Which one of the following is NOT a reason for the need of backups?

A. Security incidents

B. Upgrades and migrations

C. Hardware failures

D. Authorization

Hint

Identify the required operational function, then compare its scope, inputs and constraints with the cited note definitions.

Answer D: Authorization

Backups preserve recoverable earlier data after hardware loss, compromise, corruption or failed upgrades and migrations. These events can destroy or damage the live copy, so independent protected copies and tested restores address their consequences. Authorization instead decides who may access current resources. It is essential security policy, but is a separate function from preserving copies for recovery.

Why each choice is right or wrong

A - Incorrect: Compromise can damage or delete data, creating a restoration need.

B - Incorrect: Failed upgrades or migrations can require restoring the previous valid data.

C - Incorrect: Hardware failure can destroy the live copy and require recovery.

D - Correct: Authorization governs current access rights; it is not a data-loss recovery reason.

Primary note proof

Study-note section NSA24

> Backups recover previous data after deletion, compromise, corruption, failed upgrades/migrations or hardware loss. Authorization controls current access, a different function. A mirror/replica also copies deletions or corruption and does not replace versioned independent backups. Keep protected copies in separate failure domains, define retention and test restores.

Study-note section NSA17

> Create named accounts, assign only needed groups/rights, disable departed users and audit privileged activity. Authentication verifies the account; authorization permits operations. A user right such as remote logon differs from a permission on one file. Group-based administration is easier to review than many hidden individual grants.

Computer Science Exit Exam · Sene 2016 · Question 28-3

Computer Science Exit Exam practice collection · Question 190

Question 35 | SS099

The ordinary file permission string -rwxr--r-- is represented by which octal mode?

A. 744

B. 700

C. 755

D. 766

Hint

Identify the platform and permission model; for an rwx string, separate owner/group/other triplets and use the stated bit weights.

Answer A: 744.

The leading hyphen identifies an ordinary file and is not a permission bit. Split the remaining characters as rwx | r-- | r--. The owner has 4+2+1=7, the group has read only (4), and others have read only (4). Writing those three octal digits in order gives 744, so A is correct.

Why each choice is right or wrong

A - Correct: 744 exactly represents owner rwx, group r-- and others r--.

B - Incorrect: 700 would deny both group and others all permissions, unlike the two read permissions shown.

C - Incorrect: 755 would give group and others execute permission as well as read permission; those execute bits are absent.

D - Incorrect: 766 would give group and others write permission; neither triplet contains w.

Primary note proof

Study-note section NSA19

The nine ordinary permission bits are owner, group and other triplets. In each triplet read=4,write=2,execute=1; sum enabled bits to get an octal digit. A leading ls -l character denotes file type, not another permission bit. For directories, read lists names, execute permits traversal/search, and write changes entries subject to other checks. File deletion usually depends on parent directory permissions, with sticky-bit/ACL rules also possible.

Computer Science model exam collection · Question 6

Question 36 | AM0564

What is the primary role of a system administrator?

A. Designing computer networks

B. Developing software applications

C. Managing and maintaining computer systems

D. Providing technical support to end-users

Hint

Identify the required operational function, then compare its scope, inputs and constraints with the cited note definitions.

Answer C: Managing and maintaining computer systems

PDF p.28 describes getting computer systems running and keeping them running; p.29 calls system administration the management of computers. C captures that broad primary role rather than one subtask.

Why each choice is right or wrong

A - Incorrect: Network design is one challenge (p.30), narrower than maintaining computer systems.

B - Incorrect: The definition is operational management, not developing applications (p.28).

C - Correct: Managing and maintaining systems directly matches pp.28-29.

D - Incorrect: User support is included (p.29), but is only part of the broader role.

Primary note proof

Study-note section NSA01

> System administrators maintain hosts, accounts, storage, software and availability; network administrators maintain connectivity, addressing, routes, network devices and performance. Security administrators coordinate controls and policy. These duties overlap, so account management, testing patches and training users are not exclusive to one job title. Patience, communication, ethics, technical understanding and organization matter alongside command knowledge.

Study-note section NSA01

> Use documentation, standardization, least privilege, automation and measured change. Record the current state, intended change, rollback and validation. Schedule maintenance according to service impact and urgency, not merely because a calendar date arrived. > Philosophy of System Administration
> Network and system administration is a branch of engineering that concerns the operational management of human-computer systems. It is about putting together a network of computers (workstations, PCs and supercomputers), getting them running and then keeping them running in spite of the activities of users who tend to cause the systems to fail.

Data Communication and Computer Networking module | PDF page 29 | lines 25-36

> System administration is the term used traditionally by mainframe and Unix engineers to describe the management of computers whether they are coupled by a network or not. To this community, network administration means the management of network infrastructure devices (routers and switches). The world of personal computers (PCs) has no tradition of managingindividual computers and their subsystems, and thus doesnot speak of system administration, per se. To this community, network administration is the management ofPCs in a network. In this material, we shall take the first view, since this is more precise.

Question sources

Computer Science MCQ practice collection · Question 564

Question 37 | AM0565

Under the note’s primary division of administrative responsibilities, which listed task directly concerns ongoing network connectivity, performance and protection?

A. Installing and configuring operating systems

B. Monitoring network performance and security

C. Developing software applications

D. Providing end-user training

Hint

Identify the required operational function, then compare its scope, inputs and constraints with the cited note definitions.

Answer B: Monitoring network performance and security

Network administrators primarily maintain connectivity, addressing, routes, devices and performance. Monitoring network performance and security directly matches that operational scope. Operating-system installation and user training may be shared administrative duties, but they do not directly describe the ongoing network-monitoring task asked for. Developing software applications has a different primary purpose. The scope selects the core network responsibility without claiming exclusive job boundaries.

Why each choice is right or wrong

A - Incorrect: OS installation can overlap with administrative work, but is not the ongoing network-monitoring task requested.

B - Correct: Monitoring network performance and security directly matches network-administration responsibilities.

C - Incorrect: Developing application software is not a network-administration responsibility established by this note.

D - Incorrect: User training may be shared, but does not directly name monitoring network operation.

Primary note proof

Study-note section NSA01

> System administrators maintain hosts, accounts, storage, software and availability; network administrators maintain connectivity, addressing, routes, network devices and performance. Security administrators coordinate controls and policy. These duties overlap, so account management, testing patches and training users are not exclusive to one job title. Patience, communication, ethics, technical understanding and organization matter alongside command knowledge.

Study-note section NSA22

> Measure a baseline, sample over an interval, compare with workload and correlate symptoms before changing hardware. CPU utilization/run queues identify processing pressure; low free memory alone is weak evidence because cache may be reclaimable. Persistent paging with high latency indicates memory pressure. Storage capacity and I/O latency are separate: a disk can be nearly empty but saturated, or nearly full while lightly loaded.

Data Communication and Computer Networking module | PDF page 29 | lines 44-56

> Scope of Network administration
> The management of a network, usually called
> network administration, consists of procedures and
> services that keep the network running properly. An
> important part of network management entails
> making sure that the network is available (or up and

running as IT professionals say) when employees and managers need it.Other admin activities are:
• Monitoring the network capacity to ensure that alltransmission requirements can be met.
• Adding capacity to the network by increasing band width interconnecting additional modes, or creating and interconnecting additional networks.

Data Communication and Computer Networking module | PDF page 30 | lines 9-15

• Putting security procedures in place to make certain that only authorized users have access to the network and ensuring that all security procedures are followed
• Making sure the network personnel can respond quickly and effectively in the event of a network operational or security failure.

Data Communication and Computer Networking module | PDF page 30 | lines 41-51

The challenges of system administration
System administration is not just about installing operating systems. It is about planning and designing an efficient community of computers so that real users will be able to get their jobs done. That means:
• Designing a network which is logical and efficient.
• Deploying large numbers of machines which can be easily upgraded later.
• Deciding what services are needed.
• Planning and implementing adequate security.
• Providing a comfortable environment for users.

Data Communication and Computer Networking module | PDF page 30 | lines 2-5

• Training people to use the network effectively
• Assisting IT professionals in organizational applications that will make good use of the network‘s capabilities.

Question sources

Computer Science MCQ practice collection · Question 565

Question 38 | AM0566

What is the purpose of system administration?

A. Managing software development projects

B. Ensuring the availability and reliability of computer systems

C. Managing user accounts and permissions

D. Designing computer networks

Hint

Identify the required operational function, then compare its scope, inputs and constraints with the cited note definitions.

Answer B: Ensuring the availability and reliability of computer systems

Keeping systems running (PDF p.28) and seeking predictability as the basis of reliability (p.31) support availability and reliability as the purpose. User permissions are a means of administration (p.42), not its full goal.

Why each choice is right or wrong

A - Incorrect: Software-project management is not the system-operation goal defined on p.28.

B - Correct: Availability follows from keeping systems running; reliability is explicitly tied to predictability (pp.28,31).

C - Incorrect: Account and permission management is a narrower activity (p.42).

D - Incorrect: Design is one planning task, narrower than the operational goal (pp.28,30).

Primary note proof

Study-note section NSA01

> System administrators maintain hosts, accounts, storage, software and availability; network administrators maintain connectivity, addressing, routes, network devices and performance. Security administrators coordinate controls and policy. These duties overlap, so account management, testing patches and training users are not exclusive to one job title. Philosophy of System Administration
Network and system administration is a branch of engineering that concerns the operational management of human-computer systems. It is about putting together a network of computers (workstations, PCs and supercomputers), getting them running and then keeping them running in spite of the activities of users who tend to cause the systems to fail.

Data Communication and Computer Networking module | PDF page 31 | lines 30-35

Principle 2 (Predictability)
The highest level aim in system administration is to work towards a predictable system. Predictability has limits. It is the basis of reliability, hence trust and therefore security.

Data Communication and Computer Networking module | PDF page 42 | lines 36-49

All user accounts have specific capabilities, privileges, and rights. When you create a user account, you can grant the user specific capabilities by making the user a member of one or more groups. This gives the user the capabilities of these groups. You then assign additional capabilities by making a user a member of the appropriate groups or withdraw capabilities by removing a user from a group. An important part of an administrator‘s job is being able to determine and set permissions, privileges, and logon rights as necessary. Although you can‘t change a group‘s built-in capabilities, you can change a group‘s default privileges and logon rights. For example, you could revoke network access to a computer by removing agroup‘s right to access the computer from the network.

Question sources

Computer Science MCQ practice collection · Question 566

Question 39 | AM0567

What is a key principle of system administration?

A. Least privilege

B. Agile development

C. Object-oriented programming

D. Cloud computing

Hint

Identify the required operational function, then compare its scope, inputs and constraints with the cited note definitions.

Answer A: Least privilege

NSA01 explicitly identifies least privilege among administration principles: give accounts and processes only the access required for their work. Agile development and object-oriented programming are development approaches; cloud computing is a computing/deployment model. They may occur in administered systems but are not the administration access principle asked for.

Why each choice is right or wrong

A - Correct: Least privilege is explicitly named as a system-administration principle in NSA01.

B - Incorrect: Agile development organizes software work rather than specifying the administration access principle in the note.

C - Incorrect: Object-oriented programming structures software; it is not the stated system-administration principle.

D - Incorrect: Cloud computing is a delivery/deployment model, not the access-control principle listed in NSA01.

Primary note proof

Study-note section NSA17

> Create named accounts, assign only needed groups/rights, disable departed users and audit privileged activity. Authentication verifies the account; authorization permits operations. A user right such as remote logon differs from a permission on one file. Group-based administration is easier to review than many hidden individual grants.

Study-note section NSA-S01

> Least privilege limits an account or process to the rights its task needs. Agile development instead organizes frequent delivery and adaptation of software. Object-oriented programming organizes software around objects with state and behavior. Cloud computing supplies on-demand access to a shared pool of configurable computing resources. A development approach or hosting model does not itself define an access-rights principle.

Assigning User Rights
The most efficient way to assign user rights is to make the
user a member of a group that already has the right. In
some cases, however, you might want a user to have a
particular right but not have all the other rights of the
group. One way to resolve this problem is to give the user

Question sources

Computer Science MCQ practice collection · Question 567

Question 40 | AM0568

Using the note’s primary role division, which role is responsible for host-local accounts together with host storage, software and availability?

A. Network administrator

B. Database administrator

C. Security administrator

D. System administrator

Hint

Identify the required operational function, then compare its scope, inputs and constraints with the cited note definitions.

Answer D: System administrator

System administrators maintain hosts, accounts, storage, software and availability. Network administrators focus on connectivity and routes, while security administrators coordinate controls and policy. Database administration concerns a different resource scope. Responsibilities can overlap, but the stated question asks for the primary host-level role associated with the complete stated set of duties rather than implying that no other administrator ever manages accounts.

Why each choice is right or wrong

A - Incorrect: The primary network role concerns connectivity, addressing and routing rather than this host-level bundle.

B - Incorrect: Database-account administration is a narrower resource scope than the host-level duties listed.

C - Incorrect: Security administration coordinates controls and policy rather than the complete host-maintenance bundle.

D - Correct: System administration is assigned hosts, accounts, storage, software and availability.

Primary note proof

Study-note section NSA01

> System administrators maintain hosts, accounts, storage, software and availability; network administrators maintain connectivity, addressing, routes, network devices and performance. Security administrators coordinate controls and policy. These duties overlap, so account management, testing patches and training users are not exclusive to one job title. Patience, communication, ethics, technical understanding and organization matter alongside command knowledge.

Study-note section NSA17

> Create named accounts, assign only needed groups/rights, disable departed users and audit privileged activity. Authentication verifies the account; authorization permits operations. A user right such as remote logon differs from a permission on one file. Group-based administration is easier to review than many hidden individual grants.

Data Communication and Computer Networking module | PDF page 42 | lines 36-49

> All user accounts have specific capabilities, privileges,
> and rights. When you create a user account, you can grant
> the user specific capabilities by making the user a member
> of one or more groups. This gives the user the capabilities
> of these groups. You then assign additional capabilities by
> making a user a member of the appropriate groups or
> withdraw capabilities by removing a user from a group.
> An important part of an administrator‘s job is being able

to determine and set permissions, privileges, and logon rights as necessary. Although you can‘t change a group‘s built-in capabilities, you can change a group‘s default privileges and logon rights. For example, you could revoke network access to a computer by removing agroup‘s right to access the computer from the network.

Data Communication and Computer Networking module | PDF page 30 | lines 9-15

• Putting security procedures in place to make certain that only authorized users have access to the network and ensuring that all security procedures are followed
• Making sure the network personnel can respond quickly and effectively in the event of a network operational or security failure.

Question sources

Computer Science MCQ practice collection · Question 568

Question 41 | AM0569

What is the purpose of network administration?

A. Managing computer hardware

B. Managing computer software

C. Managing network infrastructure

D. Managing user accounts

Hint

Identify the required operational function, then compare its scope, inputs and constraints with the cited note definitions.

Answer C: Managing network infrastructure

PDF p.29 distinguishes the management of computers from management of network infrastructure devices, explicitly adopting the latter meaning for network administration. C is the direct match.

Why each choice is right or wrong

A - Incorrect: General hardware management is broader than the infrastructure-device definition on p.29.

B - Incorrect: General software management is not the adopted network-administration definition.

C - Correct: The module defines network administration as managing routers, switches and network infrastructure (p.29).

D - Incorrect: Account management is an administration subtask but not the adopted infrastructure-focused definition.

Primary note proof

Study-note section NSA01

System administrators maintain hosts, accounts, storage, software and availability; network administrators maintain connectivity, addressing, routes, network devices and performance. Security administrators coordinate controls and policy. These duties overlap, so account management, testing patches and training users are not exclusive to one job title. Patience, communication, ethics, technical understanding and organization matter alongside command knowledge.

Study-note section NSA02

Switching normally forwards frames using MAC addresses within a LAN; routing forwards IP packets between networks. TCP supplies an ordered reliable byte stream, while UDP preserves datagrams without that guarantee. Ports distinguish application endpoints, not physical connectors. Draw switches, links, subnets, gateways, service hosts and dependencies in a network diagram. A topology's shape alone does not guarantee security.

Data Communication and Computer Networking module | PDF page 29 | lines 25-36

System administration is the term used traditionally by mainframe and Unix engineers to describe the management of computers whether they are coupled by a network or not. To this community, network administration means the management of network infrastructure devices (routers and switches). The world of personal computers (PCs) has no tradition of managingindividual computers and their subsystems, and thus doesnot speak of system administration, per se. To this community, network administration is the management ofPCs in a network. In this material, we shall take the first view, since this is more precise.

Computer Science MCQ practice collection · Question 569

Question 42 | AM0570

What is the role of a security administrator in system administration?

A. Monitoring network performance

B. Managing user accounts and permissions

C. Enforcing security policies and procedures

D. Configuring network devices

Hint

Distinguish the security objective from the control that prevents, detects or recovers from the stated problem.

Answer C: Enforcing security policies and procedures

PDF p.30 requires putting security procedures in place and ensuring they are followed; p.34 says domain controllers enforce security policy. Enforcing policies and procedures is therefore the best statement of the security role, without assuming exclusive staffing boundaries.

Why each choice is right or wrong

A - Incorrect: Performance monitoring is separately discussed as capacity management (p.29).

B - Incorrect: Account permissions contribute to access security but are narrower than enforcing security procedures.

C - Correct: The duty to ensure security procedures are followed is explicit on p.30.

D - Incorrect: Configuring devices is not by itself the policy-enforcement purpose described on p.30.

Primary note proof

Study-note section NSA26

> A security policy states required behavior, scope, accountable roles and enforcement. Begin with assets/service objectives, assess threats and weaknesses, choose controls, define exceptions/incident procedures, approve/communicate, monitor and periodically review. CIA means confidentiality, integrity and availability; neither sensitive-data protection nor availability alone is the universal primary goal.

Study-note section NSA01

> System administrators maintain hosts, accounts, storage, software and availability; network administrators maintain connectivity, addressing, routes, network devices and performance. Security administrators coordinate controls and policy. These duties overlap, so account management, testing patches and training users are not exclusive to one job title. Patience, communication, ethics, technical understanding and organization matter alongside command knowledge.

> • Putting security procedures in place to make certain that only authorized users have access to the network and ensuring that all security procedures are followed
> • Making sure the network personnel can respond quickly and effectively in the event of a network operational or security failure.

Data Communication and Computer Networking module | PDF page 34 | lines 7-14

> Domain Controllers
> A domain controller (DC) is a server computer that responds to security authentication requests within a computer network domain. It is a network server that is responsible for allowing end devices to access shared domain resources. It authenticates users, stores user account information and enforces security policy for a domain. It is most commonly implemented in Microsoft

Question sources

Computer Science MCQ practice collection · Question 570

Question 43 | AM0571

Which concept in system administration emphasizes the importance of regularly backing up data?

A. Redundancy

B. Fault tolerance

C. Disaster recovery

D. Load balancing

Hint

Identify the required operational function, then compare its scope, inputs and constraints with the cited note definitions.

Answer C: Disaster recovery

PDF p.30 explicitly pairs “Backup and disaster recovery planning.” Its backup duty protects against network/component failure. Disaster recovery is therefore the choice directly connected to regular data backup in the module.

Why each choice is right or wrong

A - Incorrect: Redundancy can protect operation but is not the theme explicitly paired with backups on p.30.

B - Incorrect: Fault tolerance is not the module's named backup-planning concept here.

C - Correct: Backup and disaster recovery planning are explicitly paired (p.30).

D - Incorrect: Load balancing is not connected to backup planning in this passage.

Primary note proof

Study-note section NSA-S02

> Disaster recovery planning prepares for restoring systems and data after disruptive loss. Regular protected backups and tested restoration are part of that plan. Continuing operation despite a component failure is a fault-tolerance objective; possessing extra components alone does not establish that older valid data can be recovered.

Study-note section NSA24

> Backups recover previous data after deletion, compromise, corruption, failed upgrades/migrations or hardware loss. Authorization controls current access, a different function. A mirror/replica also copies deletions or corruption and does not replace versioned independent backups. Keep protected copies in separate failure domains, define retention and test restores.

Question sources

Computer Science MCQ practice collection · Question 571

Question 44 | AM0572

Which skill describes the general process of diagnosing faults and selecting fixes across system-administration tasks, rather than a specialized design, database or cabling task?

A. Graphic design

B. Database query optimization

C. Troubleshooting and problem-solving

D. Network cable installation

Hint

Identify the required operational function, then compare its scope, inputs and constraints with the cited note definitions.

Answer C: Troubleshooting and problem-solving

Troubleshooting and problem-solving cover defining symptoms, gathering evidence, forming testable hypotheses, isolating causes, applying targeted fixes and verifying service. This process applies across many administration duties. Graphic design, query optimization and cable installation may be useful specialized activities, but none names the broad diagnostic process requested. The scope does not imply that administrators never perform those other tasks.

Why each choice is right or wrong

A - Incorrect: Graphic design concerns visual communication rather than the general diagnostic process.

B - Incorrect: Query optimization improves database query behavior, a specialized task.

C - Correct: Troubleshooting and problem-solving name the requested cross-task diagnostic skill.

D - Incorrect: Cable installation is a physical infrastructure task rather than the general reasoning process.

Primary note proof

Study-note section NSA08

> Define the symptom, scope, time and recent changes; gather the configuration, baseline and logs. Form a testable hypothesis, test the least disruptive explanation, isolate the failing component, apply a targeted fix, verify the user service and document the result. Change one relevant factor at a time when possible. A reboot can hide evidence and is not a diagnosis by itself.

Study-note section NSA09

> Check power, cable/connector and link state, then NIC/driver state, VLAN membership, address/prefix, local gateway, route, DNS and finally application port/authentication. A recognized NIC makes a missing driver less likely, not proof of a working physical link. Ethernet commonly uses RJ45 connectors; an RJ11 telephone jack is not the expected Ethernet connection.

> It‘s about hardware, software, user support, diagnosis, repair and prevention. System administrators need to know a bit of everything: the skills are technical, administrative and socio-psychological.

Data Communication and Computer Networking module | PDF page 30 | lines 16-18

> • Diagnosing and troubleshooting problems on the network and determining the best course of action to take to solve them.

Data Communication and Computer Networking module | PDF page 31 | lines 7-14

> Some system administrators are responsible for both the hardware of the network and the computers which it connects, i.e. the cables as well as the computers. Some are only responsible for the computers. Either way, an understanding of how data flow from machine to machineis essential as well as an understanding of how each machine affects every other.

Question sources

Computer Science MCQ practice collection · Question 572

Question 45 | AM0573

Which tasks belong to administrator-side software update and patch management, rather than authoring the software patch? Select all that apply.

A. Developing software patches

B. Testing software updates

C. Installing and deploying software updates

D. Analyzing software vulnerabilities

Hint

Identify the required operational function, then compare its scope, inputs and constraints with the cited note definitions.

Answer B, C, D: Testing software updates; Installing and deploying software updates; Analyzing software vulnerabilities

Patch administration includes assessing relevant weaknesses, testing or staging an update, preparing rollback, deploying it and verifying the result. These steps help choose and safely apply the appropriate repair. Writing the vendor's software patch is a development activity rather than the operational workflow being classified. The multiple-selection instruction retains the complementary assessment, testing and deployment responsibilities instead of forcing an installation-only answer.

Why each choice is right or wrong

A - Incorrect: Writing the software patch is a development responsibility, not the patch-administration workflow stated here.

B - Correct: Testing/staging updates before deployment is an explicit administrator duty.

C - Correct: Deploying and verifying software updates is also an explicit administrator duty.

D - Correct: Assessing known weaknesses helps prioritize relevant patches and is part of the stated vulnerability-management workflow.

Primary note proof

Study-note section NSA27

> Hardening reduces exposure through unnecessary-service removal, supported patches, restricted accounts/permissions and appropriate port filtering. Blocking an unused known port can be hardening; blocking every useful port merely destroys availability. Weak passwords and unpatched exploitable software are vulnerabilities; attacks exploit weaknesses, and risk combines likelihood with impact.

Study-note section NSA27

> Preventive controls restrict harmful actions, detective controls expose them and recovery controls restore service. Account lifecycle, backup procedures, device configuration and traffic analysis can all be security controls under a stated objective. A vulnerability scan checks known weakness patterns, not bandwidth. Test/stage patches, prepare rollback, deploy and verify; testing and installation are both legitimate administrator duties.

System Monitoring Software Essentials
In order to keep your system fit for purpose, your monitoring activities need to cover the following priorities:
• Acceptable delivery speeds
• Constant availability
• Preventative maintenance
• Software version monitoring and patching
• Intrusion detection
• Data integrity
• Security monitoring
• Attack mitigation
• Virus prevention and detection

Question sources

Computer Science MCQ practice collection · Question 573

Question 46 | AM0574

Which listed protocol sends or relays email messages between mail systems?

A. FTP

B. HTTP

C. SMTP

D. DHCP

Hint

Identify the required operational function, then compare its scope, inputs and constraints with the cited note definitions.

Answer C: SMTP

SMTP is the mail sending and relay protocol. HTTP serves web resources, so a webmail interface can use HTTP without making it the mail-transfer protocol requested here. FTP transfers files as its named service, and DHCP supplies host configuration. Distinguishing the mail transport role from a user-facing web interface removes the broad interpretation of providing email services.

Why each choice is right or wrong

A - Incorrect: FTP is a file-transfer protocol, not the listed mail relay protocol.

B - Incorrect: HTTP serves web resources; webmail access is distinct from mail-system relay.

C - Correct: SMTP sends and relays email messages.

D - Incorrect: DHCP supplies host configuration rather than transferring email.

Primary note proof

Study-note section NSA10

> DNS resolves names; DHCP supplies host configuration. SMTP sends/relays mail, while IMAP/POP retrieve it. FTP is a named file-transfer protocol; HTTP also transfers files, so “transfers files” is not an exclusive FTP description. HTTP/HTTPS serve web resources. SSH provides encrypted remote login; SFTP transfers files over SSH and differs from FTP or FTPS.

Question sources

Computer Science MCQ practice collection · Question 574

Question 47 | AM0575

Which service translates domain names into IP addresses?

A. DNS

B. DHCP

C. FTP

D. HTTP

Hint

Identify the required operational function, then compare its scope, inputs and constraints with the cited note definitions.

Answer A: DNS

Name-to-address translation is forward DNS resolution. NSA06 specifies A records for IPv4 and AAAA for IPv6. DHCP instead provides host configuration, while FTP and HTTP provide application data-transfer services. Those functions are distinct from resolving a domain name into its address records.

Why each choice is right or wrong

A - Correct: DNS forward resolution maps names to address records, using A or AAAA as appropriate.

B - Incorrect: DHCP supplies client addresses and options rather than translating arbitrary domain names.

C - Incorrect: FTP transfers files and does not provide the domain-name resolution service.

D - Incorrect: HTTP exchanges web resources rather than serving as the name-to-address directory service.

Primary note proof

Study-note section NSA06

> Forward resolution obtains an address from a name, using A for IPv4 and AAAA for IPv6. Reverse lookup uses a PTR record in the reverse namespace to obtain a name from an address. CNAME aliases a name, MX identifies mail exchangers and NS identifies authoritative name servers. Forward and reverse records need not both exist or be perfect inverses.

Study-note section NSA10

> DNS resolves names; DHCP supplies host configuration. SMTP sends/relays mail, while IMAP/POP retrieve it. FTP is a named file-transfer protocol; HTTP also transfers files, so “transfers files” is not an exclusive FTP description. HTTP/HTTPS serve web resources. SSH provides encrypted remote login; SFTP transfers files over SSH and differs from FTP or FTPS.

• Simple Network Management Protocol (SNMP)
• Domain Name Service (DNS)
• Dynamic Host Configuration Protocol (DHCP)

Question sources

Computer Science MCQ practice collection · Question 575

Question 48 | AM0576

Which listed protocols transfer file content from a server to a client as part of their ordinary service? Select all that apply.

A. SMTP

B. DNS

C. FTP

D. HTTP

Hint

Identify the required operational function, then compare its scope, inputs and constraints with the cited note definitions.

Answer C, D: FTP; HTTP

FTP is specifically a file-transfer protocol, while HTTP also transfers file resources through web request and response exchanges. Their service semantics differ, but the broad content-transfer capability applies to both. SMTP is classified here as mail submission and relay, and DNS as name resolution. The revised selection instruction recognizes the two qualifying services without pretending that file transfer is exclusive to one protocol.

Why each choice is right or wrong

A - Incorrect: SMTP is identified with mail submission/relay rather than the file-transfer service in this comparison.

B - Incorrect: DNS resolves names and is not the offered file-content transfer service.

C - Correct: FTP is explicitly a named protocol for client/server file transfer.

D - Correct: HTTP also transfers file resources, so the general function is not exclusive to FTP.

Primary note proof

Study-note section NSA10

> DNS resolves names; DHCP supplies host configuration. SMTP sends/relays mail, while IMAP/POP retrieve it. FTP is a named file-transfer protocol; HTTP also transfers files, so “transfers files” is not an exclusive FTP description. HTTP/HTTPS serve web resources. SSH provides encrypted remote login; SFTP transfers files over SSH and differs from FTP or FTPS.

Study-note section NSA06

> Forward resolution obtains an address from a name, using A for IPv4 and AAAA for IPv6. Reverse lookup uses a PTR record in the reverse namespace to obtain a name from an address. CNAME aliases a name, MX identifies mail exchangers and NS identifies authoritative name servers. Forward and reverse records need not both exist or be perfect inverses.

Question sources

Computer Science MCQ practice collection · Question 576

Question 49 | AM0577

Which service is responsible for assigning IP addresses to devices on a network?

A. DNS

B. DHCP

C. FTP

D. HTTP

Hint

Identify the required operational function, then compare its scope, inputs and constraints with the cited note definitions.

Answer B: DHCP

NSA04 assigns host-address configuration to DHCP, including a server-managed scope and time-limited leases. DNS resolves names, while FTP and HTTP transfer application content. Therefore DHCP is the network service responsible for automatically supplying a device's IP configuration among these options.

Why each choice is right or wrong

A - Incorrect: DNS resolves names into records; it does not lease the device's own network address.

B - Correct: DHCP supplies addresses and configuration options to clients from a managed scope.

C - Incorrect: FTP transfers files rather than assigning network addresses to devices.

D - Incorrect: HTTP provides web request/response services and not host-address allocation.

Primary note proof

Study-note section NSA04

DHCP supplies addresses and configuration options. Typical initial IPv4 allocation is Discover→Offer→Request→ACK. The server manages its scope/pool, allocated leases, exclusions and reservations; options may include mask, gateway and DNS servers. A dynamic lease lasts for a specified interval, not forever.

Study-note section NSA10

DNS resolves names; DHCP supplies host configuration. SMTP sends/relays mail, while IMAP/POP retrieve it. FTP is a named file-transfer protocol; HTTP also transfers files, so “transfers files” is not an exclusive FTP description. HTTP/HTTPS serve web resources. SSH provides encrypted remote login; SFTP transfers files over SSH and differs from FTP or FTPS.

• Simple Network Management Protocol (SNMP)
• Domain Name Service (DNS)
• Dynamic Host Configuration Protocol (DHCP)

Question sources

Computer Science MCQ practice collection · Question 577

Question 50 | AM0578

Which protocol is used for secure remote login and file transfer?

A. SSH

B. DNS

C. FTP

D. HTTP

Hint

Identify the required operational function, then compare its scope, inputs and constraints with the cited note definitions.

Answer A: SSH, with SFTP for file transfer over SSH

NSA10 assigns protected remote login to SSH and file transfer over that protected connection to SFTP. Thus SSH is the underlying secure protocol family among these options. DNS provides naming; ordinary FTP and HTTP do not by themselves provide the protected remote-login capability in the stem.

Why each choice is right or wrong

A - Correct: SSH protects remote login and supports the SFTP file-transfer service over SSH.

B - Incorrect: DNS resolves names and supplies neither remote terminal login nor a secure file-transfer session.

C - Incorrect: Ordinary FTP transfers files but is distinct from SFTP and does not supply encrypted remote login.

D - Incorrect: Ordinary HTTP supplies web exchange semantics, not the SSH remote-login and SFTP functions.

Primary note proof

Study-note section NSA10

DNS resolves names; DHCP supplies host configuration. SMTP sends/relays mail, while IMAP/POP retrieve it. FTP is a named file-transfer protocol; HTTP also transfers files, so “transfers files” is not an exclusive FTP description. HTTP/HTTPS serve web resources. SSH provides encrypted remote login; SFTP transfers files over SSH and differs from FTP or FTPS.

Study-note section NSA30

Use authenticated protected remote administration such as SSH or properly secured management services, with restricted source access and auditing. VPNs provide protected connectivity under their defined security model; they are not packet analyzers. Firewall filtering permits/blocks traffic according to policy; it is not inherently encryption. Losing remote connectivity while changing a management route/firewall is an operational risk to plan for.

Question sources

Computer Science MCQ practice collection · Question 578

Question 51 | AM0579

Which service is used for translating private IP addresses to public IP addresses?

A. NAT

B. DNS

C. FTP

D. HTTP

Hint

Identify the required operational function, then compare its scope, inputs and constraints with the cited note definitions.

Answer A: NAT

NAT rewrites network addresses, commonly translating private internal IPv4 addresses for access to a public network. Routing still selects the path and NAT does not replace firewall or authentication policy. DNS resolves names, FTP transfers files, and HTTP serves web resources. Those application services may run through a translating router, but they do not perform the address-rewriting function themselves.

Why each choice is right or wrong

A - Correct: NAT performs the requested address translation.

B - Incorrect: DNS maps names and related records rather than rewriting packet addresses.

C - Incorrect: FTP transfers files rather than translating network addresses.

D - Incorrect: HTTP serves web resources rather than rewriting IP addresses.

Primary note proof

Study-note section NSA11

> Routing selects a next hop using a destination prefix; NAT rewrites addresses. Many-to-one address-and-port translation (PAT/NAPT) maps internal flows to one public address using distinct port bindings. For example, two private client sockets can appear as public-address ports 40001 and 40002, with replies translated back to the correct clients.

Study-note section NSA11

> NAT is often used when private IPv4 clients access public networks; it does not itself replace a gateway, route, firewall or authentication. One-to-one NAT and destination translation are other forms, so NAT does not always mean many hosts share one address. Public addressing inside a LAN does not automatically require NAT. Unsolicited inbound service access may require explicit mapping and filtering.

Study-note section NSA06

Forward resolution obtains an address from a name, using A for IPv4 and AAAA for IPv6. Reverse lookup uses a PTR record in the reverse namespace to obtain a name from an address. CNAME aliases a name, MX identifies mail exchangers and NS identifies authoritative name servers. Forward and reverse records need not both exist or be perfect inverses.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Data Communication and Computer Networking module | PDF page 48 | lines 29-40

Network Address Translation (NAT)
NAT translates the IP addresses of computers in a local network to a single IP address. This address is often used by the router that connects the computers to the Internet. The router can be connected to a DSL modem, cable modem, T1 line, or even a dial-up modem. When other computers on the Internet attempt to access computers within the local network, they only see the IP address of the router. This adds an extra level of security, since the router can be configured as a firewall, only allowing authorized systems to access the computers within the network.

Question 52 | AM0580

Which protocol is used for web browsing?

A. SMTP

B. DNS

C. FTP

D. HTTP

Hint

Identify the required operational function, then compare its scope, inputs and constraints with the cited note definitions.

Answer D: HTTP

Web browsing obtains resources through web request/response exchanges. NSA10 identifies HTTP/HTTPS for these resources, making HTTP the offered protocol. SMTP handles mail submission/relay, DNS handles name resolution and FTP handles its own file-transfer service; they may assist applications but do not define the web exchange asked for.

Why each choice is right or wrong

A - Incorrect: SMTP submits and relays email rather than serving browser web resources.

B - Incorrect: DNS resolves server names and is a supporting service rather than the web resource-transfer protocol.

C - Incorrect: FTP is a separate file-transfer protocol, not the normal web-browsing exchange named in the note.

D - Correct: HTTP supplies web-resource request/response exchanges and is explicitly named for web services.

Primary note proof

Study-note section NSA10

> DNS resolves names; DHCP supplies host configuration. SMTP sends/relays mail, while IMAP/POP retrieve it. FTP is a named file-transfer protocol; HTTP also transfers files, so “transfers files” is not an exclusive FTP description. HTTP/HTTPS serve web resources. SSH provides encrypted remote login; SFTP transfers files over SSH and differs from FTP or FTPS.

Question sources

Computer Science MCQ practice collection · Question 580

Question 53 | AM0581

Which service provides remote access to a network from a different location?

A. VPN

B. DNS

C. FTP

D. HTTP

Hint

Identify the required operational function, then compare its scope, inputs and constraints with the cited note definitions.

Answer A: VPN

A remote user can extend private-network connectivity through a VPN over another network, matching the service in the stem. DNS performs lookup, FTP transfers files and HTTP serves web resources. Those can be reachable remotely but do not by themselves extend private network access as the VPN service does.

Why each choice is right or wrong

A - Correct: A VPN extends private connectivity across another network to support remote access.

B - Incorrect: DNS supplies name resolution rather than a remote private-network connection.

C - Incorrect: FTP supplies access to a file-transfer service rather than general remote network connectivity.

D - Incorrect: HTTP supplies web-resource access rather than the private-network extension described.

Primary note proof

Study-note section NSA10

> A VPN extends private connectivity over another network; secure tunneling commonly encrypts/authenticates traffic but depends on protocol/configuration. RTP carries real-time media timing/sequence information, often over UDP; it does not guarantee timely delivery. Network printers expose services shared by clients. Provide accounts, permissions, configuration, monitoring and recovery for each service, not just its protocol name.

Study-note section NSA30

> Use authenticated protected remote administration such as SSH or properly secured management services, with restricted source access and auditing. VPNs provide protected connectivity under their defined security model; they are not packet analyzers. Firewall filtering permits/blocks traffic according to policy; it is not inherently encryption. Losing remote connectivity while changing a management route/firewall is an operational risk to plan for.

Question sources

Computer Science MCQ practice collection · Question 581

Question 54 | AM0582

Which protocol is used for real-time communication, such as video conferencing?

A. SMTP

B. DNS

C. FTP

D. RTP

Hint

Identify the required operational function, then compare its scope, inputs and constraints with the cited note definitions.

Answer D: RTP

NSA10 identifies RTP as carrying real-time media timing and sequence information, commonly over UDP. That is the relevant protocol for conference media among the options. The answer does not imply guaranteed deadlines: actual delivery depends on the network and application. SMTP, DNS and FTP have unrelated mail, naming and file-transfer roles.

Why each choice is right or wrong

A - Incorrect: SMTP handles mail submission/relay, not real-time conference media timing and sequencing.

B - Incorrect: DNS resolves names and is not the media transport protocol described.

C - Incorrect: FTP transfers files rather than carrying the real-time media timing/sequence service.

D - Correct: RTP carries real-time media timing and sequence information, including uses such as video conferencing.

Primary note proof

Study-note section NSA10

> A VPN extends private connectivity over another network; secure tunneling commonly encrypts/authenticates traffic but depends on protocol/configuration. RTP carries real-time media timing/sequence information, often over UDP; it does not guarantee timely delivery. Network printers expose services shared by clients. Provide accounts, permissions, configuration, monitoring and recovery for each service, not just its protocol name.

Study-note section NSA10

> DNS resolves names; DHCP supplies host configuration. SMTP sends/relays mail, while IMAP/POP retrieve it. FTP is a named file-transfer protocol; HTTP also transfers files, so “transfers files” is not an exclusive FTP description. HTTP/HTTPS serve web resources. SSH provides encrypted remote login; SFTP transfers files over SSH and differs from FTP or FTPS.

Question sources

Computer Science MCQ practice collection · Question 582

Question 55 | AM0583

Which service, using its many-to-one address-and-port translation form, lets several private IPv4 devices share one public IPv4 address?

A. NAT

B. DNS

C. FTP

D. HTTP

Hint

Identify the required operational function, then compare its scope, inputs and constraints with the cited note definitions.

Answer A: NAT

Many-to-one NAT with port translation maintains separate bindings for internal flows. Multiple clients can therefore appear under one public address while distinct translated ports allow replies to return to the right client. This is a particular form of NAT, not a property of every NAT configuration. DNS, FTP and HTTP supply naming, file-transfer and web services rather than the address-sharing mechanism.

Why each choice is right or wrong

A - Correct: NAT in its PAT/NAPT form maps multiple internal flows to one public address.

B - Incorrect: DNS resolves names rather than maintaining address-and-port translation bindings.

C - Incorrect: FTP transfers files; it is not the address-sharing mechanism.

D - Incorrect: HTTP serves web resources; it does not provide the translation bindings.

Primary note proof

Study-note section NSA11

> Routing selects a next hop using a destination prefix; NAT rewrites addresses. Many-to-one address-and-port translation (PAT/NAPT) maps internal flows to one public address using distinct port bindings. For example, two private client sockets can appear as public-address ports 40001 and 40002, with replies translated back to the correct clients.

Study-note section NSA11

> NAT is often used when private IPv4 clients access public networks; it does not itself replace a gateway, route, firewall or authentication. One-to-one NAT and destination translation are other forms, so NAT does not always mean many hosts share one address. Public addressing inside a LAN does not automatically require NAT. Unsolicited inbound service access may require explicit mapping and filtering.

Network Address Translation (NAT)
NAT translates the IP addresses of computers in a local network to a single IP address. This address is often used by the router that connects the computers to the Internet. The router can be connected to a DSL modem, cable modem, T1 line, or even a dial-up modem. When other computers on the Internet attempt to access computers within the local network, they only see the IP address of the router. This adds an extra level of security, since the router can be configured as a firewall, only allowing authorized systems to access the computers within the network.

Question sources

Computer Science MCQ practice collection · Question 583

Question 56 | AM0584

Which policy conflicts with restricting access to a protected internal network to authorized users, assuming the wireless service directly admits users to that network?

A. Password complexity requirements

B. Firewall configuration

C. Regular data backups

D. Open wireless network access

Hint

Distinguish the security objective from the control that prevents, detects or recovers from the stated problem.

Answer D: Open wireless network access

A protected internal network requires controlled admission. Password requirements, appropriately configured firewall rules and protected regular backups can implement security and recovery policy. Unrestricted open wireless admission to the same protected network bypasses that admission requirement. An intentionally isolated guest service would be a different case; it is excluded by the stated direct-access condition.

Why each choice is right or wrong

A - Incorrect: Password requirements support authentication and controlled access.

B - Incorrect: Firewall policy can restrict access to authorized systems.

C - Incorrect: Regular backups support recovery and availability.

D - Correct: Unrestricted open wireless admission bypasses authorization for the protected network.

Primary note proof

Study-note section NSA26

A security policy states required behavior, scope, accountable roles and enforcement. Begin with assets/service objectives, assess threats and weaknesses, choose controls, define exceptions/incident procedures, approve/communicate, monitor and periodically review. CIA means confidentiality, integrity and availability; neither sensitive-data protection nor availability alone is the universal primary goal.

Study-note section NSA26

A policy can require password controls, approved encryption, restricted administrative access, backups and patch deadlines; firewall rules implement part of it. Open unrestricted wireless access conflicts with controlled internal access unless intentionally isolated as a guest service. “Use the system passively” is not a purpose of security policy. Policies coordinate action and reduce risk; they do not guarantee every attack will fail.

The router can be connected to a DSL modem, cable modem, T1 line, or even a dial-up modem. When other computers on the Internet attempt to access computers within the local network, they only see the IP address of the router. This adds an extra level of security, since the router can be configured as a firewall, only allowing authorized systems to access the computers within the network.

Question sources

Computer Science MCQ practice collection · Question 584

Question 57 | AM0585

Which purpose is directly served when a firewall applies permit/deny rules to incoming network traffic?

A. To prevent unauthorized access to the network

B. To encrypt network traffic

C. To manage network bandwidth

D. To monitor network performance

Hint

Distinguish the security objective from the control that prevents, detects or recovers from the stated problem.

Answer A: To prevent unauthorized access to the network

A firewall applies policy to allow permitted traffic and reject disallowed access. This directly supports preventing unauthorized network access. Encryption protects confidentiality, bandwidth management allocates or shapes traffic capacity, and performance monitoring measures service behavior. A device may combine these features, but the stated permit/deny operation is access enforcement rather than those separate functions.

Why each choice is right or wrong

A - Correct: Permit/deny filtering directly prevents disallowed network access.

B - Incorrect: Encryption protects confidentiality and is not inherent in traffic filtering.

C - Incorrect: Bandwidth management controls traffic capacity rather than authorization.

D - Incorrect: Performance monitoring measures behavior rather than enforcing permit/deny policy.

Primary note proof

Study-note section NSA30

> Use authenticated protected remote administration such as SSH or properly secured management services, with restricted source access and auditing. VPNs provide protected connectivity under their defined security model; they are not packet analyzers. Firewall filtering permits/blocks traffic according to policy; it is not inherently encryption. Losing remote connectivity while changing a management route/firewall is an operational risk to plan for.

Study-note section NSA28

> Encryption provides confidentiality with correct key/nonce use; authenticated encryption adds integrity/authenticity. Unspecified encryption alone does not guarantee both properties. A password hash supports verification without recovering the original password; it is not a

reversible credential store. Encryption can protect a recoverable credential only if its key is separately protected.

Study-note section NSA12

QoS classifies, queues and prioritizes traffic to meet performance objectives such as low delay or limited loss. It can operate across layers and support applications, so it is not exclusively an application-layer service. Installing a new service is an administrative action; email configuration is another action and proxies/agents are components. Distinguish service-management actions from components using a stated taxonomy.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Question sources

Computer Science MCQ practice collection · Question 585

Question 58 | AM0586

Which of the following is an example of a network security vulnerability?

A. Weak password policies

B. Regular software updates

C. Use of strong encryption algorithms

D. Implementing access control lists

Hint

Distinguish the security objective from the control that prevents, detects or recovers from the stated problem.

Answer A: Weak password policies

NSA27 identifies weak passwords as exploitable weaknesses. A policy permitting them creates the corresponding vulnerability. Regular updates, appropriate encryption and access-control lists are protective measures when correctly deployed, rather than examples of the weakness requested. They are not guarantees of security, but their stated role here is defensive.

Why each choice is right or wrong

A - Correct: Weak password policy permits easily compromised credentials and creates an exploitable access weakness.

B - Incorrect: Regular updates address known software weaknesses rather than constituting the vulnerability example requested.

C - Incorrect: Strong appropriately used encryption is a protective measure rather than an example of weak authentication policy.

D - Incorrect: Access-control lists restrict permitted actions/traffic and are a defensive control when properly configured.

Primary note proof

Study-note section NSA27

> Hardening reduces exposure through unnecessary-service removal, supported patches, restricted accounts/permissions and appropriate port filtering. Blocking an unused known port can be hardening; blocking every useful port merely destroys availability. Weak passwords and unpatched exploitable software are vulnerabilities; attacks exploit weaknesses, and risk combines likelihood with impact.

Study-note section NSA28

> Encryption provides confidentiality with correct key/nonce use; authenticated encryption adds integrity/authenticity. Unspecified encryption alone does not guarantee both properties. A password hash supports verification without recovering the original password; it is not a reversible credential store. Encryption can protect a recoverable credential only if its key is separately protected.

Study-note section NSA30

> Segmentation separates groups of systems and enforces allowed flows with routing/filtering policies; VLAN membership alone does not establish complete security. NAC assesses device/user admission and can reject or quarantine unauthorized/noncompliant devices. Authentication proves an identity, while access rules decide which resources it may use.

System Monitoring Software Essentials
In order to keep your system fit for purpose, your monitoring activities need to cover the following priorities:
• Acceptable delivery speeds
• Constant availability
• Preventative maintenance
• Software version monitoring and patching
• Intrusion detection
• Data integrity
• Security monitoring
• Attack mitigation
• Virus prevention and detection

Question sources

Computer Science MCQ practice collection · Question 586

Question 59 | AM0587

What is the purpose of intrusion detection systems (IDS)?

A. To prevent network attacks

B. To monitor network traffic for suspicious activities

C. To encrypt network communications

D. To block malicious software

Hint

Identify the required operational function, then compare its scope, inputs and constraints with the cited note definitions.

Answer B: Monitor for suspicious activity and alert

NSA23 distinguishes detection from prevention. An IDS monitors for suspicious activity and generates detection/alerts; blocking inline is an IPS capability. Encryption is a separate data-protection mechanism. Although IDS findings can support a broader prevention program, direct prevention or malware blocking is not the defining IDS role stated here.

Why each choice is right or wrong

A - Incorrect: Direct blocking/prevention is the IPS distinction; an IDS primarily detects and alerts.

B - Correct: Monitoring traffic for suspicious behavior matches the IDS detection/alert role.

C - Incorrect: Encrypting communications is a confidentiality mechanism, not intrusion detection.

D - Incorrect: Blocking malicious software is a preventive action, not the defining monitoring/alert purpose of an IDS.

Primary note proof

Study-note section NSA23

> An IDS detects/alerts; an IPS can block inline. Scanning identifies potential weaknesses rather than proving successful exploitation. A captured packet, open port or alert needs context. Monitoring network usage is not the same as configuring access control or encrypting communications.

Study-note section NSA28

> Encryption provides confidentiality with correct key/nonce use; authenticated encryption adds integrity/authenticity. Unspecified encryption alone does not guarantee both properties. A password hash supports verification without recovering the original password; it is not a reversible credential store. Encryption can protect a recoverable credential only if its key is separately protected.

Bandwidth monitoring tools and NetFlow and sFlow based traffic analyzers help you stay aware of the activity, capacity, and health of your network. They allow you to watch traffic as it flows through routers and switches, or arrive at and leaves hosts.

Question sources

Computer Science MCQ practice collection · Question 587

Question 60 | AM0588

During troubleshooting, which action tests IP reachability with ICMP echo messages without changing the system or network configuration?

A. Configuring a firewall rule

B. Conducting a security audit

C. Installing antivirus software

D. Ping testing network connectivity

Hint

Identify the required operational function, then compare its scope, inputs and constraints with the cited note definitions.

Answer D: Ping testing network connectivity

A ping test gathers reachability evidence by exchanging ICMP echo messages. It is a diagnostic observation rather than a configuration change. Firewall rule changes can be legitimate fixes for a diagnosed filtering fault, while audits and antivirus installation serve other security purposes. None of those alternatives performs the specific echo test requested. A failed test must still be interpreted alongside filtering and loss.

Why each choice is right or wrong

A - Incorrect: Changing a firewall rule changes policy rather than performing the specified observation.

B - Incorrect: A security audit assesses controls; it is not an ICMP echo test.

C - Incorrect: Installing antivirus changes host protection rather than sending echo probes.

D - Correct: Ping performs the specified reachability test without changing network policy.

Primary note proof

Study-note section NSA08

> Define the symptom, scope, time and recent changes; gather the configuration, baseline and logs. Form a testable hypothesis, test the least disruptive explanation, isolate the failing component, apply a targeted fix, verify the user service and document the result. Change one relevant factor at a time when possible. A reboot can hide evidence and is not a diagnosis by itself.

Study-note section NSA-S04

> Ping uses ICMP echo messages to test IP reachability. A reply shows that the addressed host and path support that exchange; no reply alone does not prove the host is disconnected, because filtering or loss can suppress responses. Traceroute instead discovers responding intermediate hops through packet-lifetime expiry; it is a path-discovery diagnostic, not the same question as an end-to-end echo test.

Question sources

Computer Science MCQ practice collection · Question 588

Question 61 | AM0589

Under the note’s primary tool-role classification, which is the conventional general-purpose packet capture and dissection analyzer?

A. Wireshark

B. Nmap

C. Snort

D. Nessus

Hint

Match the requested observation to the tool’s actual output; distinguish configuration, name lookup, reachability and hop discovery.

Answer A: Wireshark

Wireshark is identified as the conventional analyzer for capturing and dissecting packets. Snort also has sniffing and logging capabilities, but its primary role in this comparison is suspicious-traffic detection and alerting. Nmap discovers hosts, ports and services, while Nessus assesses vulnerabilities and configuration. The primary-role scope distinguishes the intended analyzer without incorrectly denying overlapping packet capabilities in other tools.

Why each choice is right or wrong

A - Correct: Wireshark captures and dissects packets and is a conventional general packet analyzer.

B - Incorrect: Nmap performs host, port and service discovery rather than general packet capture/dissection.

C - Incorrect: Snort can sniff and log, but is classified primarily here by suspicious-traffic detection rather than as the conventional general analyzer.

D - Incorrect: Nessus is identified with vulnerability/configuration assessment rather than the packet-analyzer role.

Primary note proof

Study-note section NSA23

> Task Manager shows running processes/resource use; Resource Monitor/Performance Monitor give more detailed counters. Wireshark captures and dissects packets. Nmap discovers hosts/ports/services. Nessus assesses vulnerabilities/configuration. Snort can detect suspicious traffic and alert, and can prevent traffic in suitable inline deployments; it also has sniffing/logging roles. Thus packet-capture capability is not exclusive to one product, although Wireshark is the conventional analyzer choice.

Study-note section NSA23

> An IDS detects/alerts; an IPS can block inline. Scanning identifies potential weaknesses rather than proving successful exploitation. A captured packet, open port or alert needs context. Monitoring network usage is not the same as configuring access control or encrypting communications.

Module passages - related reading

Question sources

Computer Science MCQ practice collection · Question 589

Question 62 | AM0590

Which of the following is an example of a denial-of-service (DoS) attack?

A. Man-in-the-middle attack

B. Phishing attack

C. Distributed denial-of-service (DDoS) attack

D. Brute-force attack

Hint

Identify the required operational function, then compare its scope, inputs and constraints with the cited note definitions.

Answer C: Distributed denial-of-service (DDoS)

DDoS is denial of service performed from distributed sources, so it is directly a type of DoS. Interception, phishing and brute force describe different attack mechanisms; each might have secondary effects, but those names alone do not identify the service-availability attack requested. NSA29 supplies the explicit DoS/DDoS relationship.

Why each choice is right or wrong

A - Incorrect: An interception attack reads or alters communications; its name does not identify denial of service.

B - Incorrect: Phishing deceives users rather than specifically exhausting or denying a service.

C - Correct: DDoS is a denial-of-service attack using distributed sources.

D - Incorrect: Brute force tries credentials; that mechanism is distinct from the denial-of-service category asked about.

Primary note proof

Study-note section NSA29

> DoS harms service availability; DDoS uses distributed sources. Phishing deceives users, brute force tries credentials and an interception attack reads/alters communications. Correlate logs using time and identity/context. Preserve relevant evidence before resetting systems. A suspicious event is not automatically confirmed compromise; record facts and uncertainty.

Module passages - related reading

Question sources

Computer Science MCQ practice collection · Question 590

Question 63 | AM0591

For a secure VPN tunnel already providing private connectivity, which option identifies the mechanism that keeps intercepted tunnel payloads confidential?

A. To encrypt network traffic

B. To block unauthorized access

C. To manage network bandwidth

D. To analyze network performance

Hint

Identify the required operational function, then compare its scope, inputs and constraints with the cited note definitions.

Answer A: To encrypt network traffic

A secure VPN commonly encrypts and authenticates its tunnel traffic. Encryption protects the content against disclosure to an observer who intercepts packets, assuming appropriate configuration and keys. Admission rules can restrict who connects, but that is a different question from protecting intercepted payloads. Bandwidth management and performance analysis also serve different purposes. The secure-tunnel scope avoids claiming that every unqualified VPN automatically encrypts.

Why each choice is right or wrong

A - Correct: Encryption hides tunnel payload contents from an interceptor without the required keys.

B - Incorrect: Blocking unauthorized admission is distinct from protecting the content of already intercepted packets.

C - Incorrect: Bandwidth management is QoS/traffic management, not the defining private-connectivity purpose of a VPN.

D - Incorrect: Performance analysis is monitoring; VPN connectivity does not make it a packet or performance analyzer.

Primary note proof

Study-note section NSA10

A VPN extends private connectivity over another network; secure tunneling commonly encrypts/authenticates traffic but depends on protocol/configuration. RTP carries real-time media timing/sequence information, often over UDP; it does not guarantee timely delivery. Network printers expose services shared by clients. Provide accounts, permissions, configuration, monitoring and recovery for each service, not just its protocol name.

Study-note section NSA28

Encryption provides confidentiality with correct key/nonce use; authenticated encryption adds integrity/authenticity. Unspecified encryption alone does not guarantee both properties. A password hash supports verification without recovering the original password; it is not a reversible credential store. Encryption can protect a recoverable credential only if its key is separately protected.

Study-note section NSA12

QoS classifies, queues and prioritizes traffic to meet performance objectives such as low delay or limited loss. It can operate across layers and support applications, so it is not exclusively an application-layer service. Installing a new service is an administrative action; email configuration is another action and proxies/agents are components. Question 64 | AM0592

Which of the following is an example of a security incident response action?

A. Regular software updates

B. Password policy enforcement

C. Incident investigation and analysis

D. Network configuration backup

Hint

Distinguish the security objective from the control that prevents, detects or recovers from the stated problem.

Answer C: Incident investigation and analysis

PDF p.30 requires personnel to respond quickly and effectively to security failures and to diagnose and troubleshoot problems. Investigation and analysis is the option that reacts to an incident rather than routine prevention or preservation.

Why each choice is right or wrong

A - Incorrect: Regular updating is a routine patching activity (p.30), rather than investigating an incident.

B - Incorrect: Password-policy enforcement is an ongoing access-security measure, not the incident investigation requested.

C - Correct: Investigation/analysis implements diagnosis and effective response after security failure (p.30).

D - Incorrect: Configuration backup preserves data and is not the investigative response action.

Primary note proof

Study-note section NSA29

Incident response prepares, detects/analyzes, contains, removes the cause, restores service and learns from the event. Investigation is reactive response; routine patching and backup are normally preventive/preparatory operations. Document timestamps, affected systems, evidence, impact, actions, responsible people and recovery results. An incident report may record policy violations, but its scope is broader than that alone.

Study-note section NSA27

Preventive controls restrict harmful actions, detective controls expose them and recovery controls restore service. Account lifecycle, backup procedures, device configuration and traffic analysis can all be security controls under a stated objective. A vulnerability scan checks known weakness patterns, not bandwidth. Test/stage patches, prepare rollback, deploy and verify; testing and installation are both legitimate administrator duties.

Question sources

Computer Science MCQ practice collection · Question 592

Question 65 | AM0593

Which tool is commonly used for network scanning and host discovery?

A. Wireshark

B. Nmap

C. Snort

D. Nessus

Hint

Match the requested observation to the tool’s actual output; distinguish configuration, name lookup, reachability and hop discovery.

Answer B: Nmap

The requested scanning and discovery role directly matches Nmap in NSA23. Wireshark captures/dissects packets, Snort detects suspicious traffic and Nessus assesses vulnerabilities/configurations. These capabilities can complement discovery, but Nmap is the tool explicitly named for the requested host/port/service scan rather than those other primary purposes.

Why each choice is right or wrong

A - Incorrect: Wireshark's identified role is packet capture/dissection rather than active host and port discovery.

B - Correct: Nmap is explicitly described as discovering hosts, ports and services.

C - Incorrect: Snort's identified role is traffic inspection/detection, not the host-discovery scanning tool requested.

D - Incorrect: Nessus assesses vulnerabilities/configuration; Nmap is the note's explicit general host/port discovery tool.

Primary note proof

Study-note section NSA23

> Task Manager shows running processes/resource use; Resource Monitor/Performance Monitor give more detailed counters. Wireshark captures and dissects packets. Nmap discovers hosts/ports/services. Nessus assesses vulnerabilities/configuration. Snort can detect suspicious traffic and alert, and can prevent traffic in suitable inline deployments; it also has sniffing/logging roles. Thus packet-capture capability is not exclusive to one product, although Wireshark is the conventional analyzer choice.

• Automatically alerting you of problems, such as servers or network devices that are overloaded or down, or worrisome trends. Customized alerts that can use multiple methods to contact you - email, SMS text messages, pager, etc.
• Triggering actions in response to alerts, to handle certain classes of problems automatically.

Question sources

Computer Science MCQ practice collection · Question 593

Question 66 | AM0594

A policy is being developed specifically to prevent disclosure of confidential records to unauthorized people. Which listed goal directly matches that objective?

A. Ensuring system availability

B. Protecting sensitive data

C. Increasing network speed

D. Enhancing user experience

Hint

Distinguish the security objective from the control that prevents, detects or recovers from the stated problem.

Answer B: Protecting sensitive data

Security policies can support confidentiality, integrity and availability, with priorities set by organizational objectives. This scenario explicitly prioritizes preventing unauthorized disclosure of confidential records, which is sensitive-data protection. Availability remains a legitimate security goal but addresses continued service rather than disclosure. Network speed and user experience have different primary objectives. The explicit policy objective determines the selection without imposing one universal priority on all policies.

Why each choice is right or wrong

A - Incorrect: Availability concerns continued service rather than the specified disclosure objective.

B - Correct: Protecting sensitive data directly addresses the stated confidentiality goal.

C - Incorrect: Network speed is a performance objective, not the security-policy priority defined in the note.

D - Incorrect: User experience can affect usability but is not the stated universal security-policy goal.

Primary note proof

Study-note section NSA26

A security policy states required behavior, scope, accountable roles and enforcement. Begin with assets/service objectives, assess threats and weaknesses, choose controls, define exceptions/incident procedures, approve/communicate, monitor and periodically review. CIA means confidentiality, integrity and availability; neither sensitive-data protection nor availability alone is the universal primary goal.

Study-note section NSA28

Encryption provides confidentiality with correct key/nonce use; authenticated encryption adds integrity/authenticity. Unspecified encryption alone does not guarantee both properties. A password hash supports verification without recovering the original password; it is not a reversible credential store. Encryption can protect a recoverable credential only if its key is separately protected.

Data Communication and Computer Networking module | PDF page 30 | lines 9-15

• Putting security procedures in place to make certain that only authorized users have access to the network and ensuring that all security procedures are followed
• Making sure the network personnel can respond quickly and effectively in the event of a network operational or security failure.

Data Communication and Computer Networking module | PDF page 54 | lines 18-30

System Monitoring Software Essentials
In order to keep your system fit for purpose, your monitoring activities need to cover the following priorities:
• Acceptable delivery speeds
• Constant availability
• Preventative maintenance
• Software version monitoring and patching
• Intrusion detection
• Data integrity
• Security monitoring
• Attack mitigation
• Virus prevention and detection

Data Communication and Computer Networking module | PDF page 31 | lines 30-35

Principle 2 (Predictability)
The highest level aim in system administration is to work towards a

predictable system. Predictability has limits. It is the basis of reliability, hence trust and therefore security.

Question sources

Computer Science MCQ practice collection · Question 594

Question 67 | AM0595

Which of the following is an example of a security policy?

A. Setting strong password requirements

B. Monitoring network bandwidth

C. Updating software patches

D. Configuring firewall rules

Hint

Distinguish the security objective from the control that prevents, detects or recovers from the stated problem.

Answer A: Strong password requirements

A states a required behavior: passwords must satisfy specified strength requirements. That matches policy rather than an observation or operational change. Patching and firewall configuration implement controls and can be required by policy, but the options describe those actions without stating the governing requirement. Monitoring bandwidth is measurement rather than a policy statement.

Why each choice is right or wrong

A - Correct: Requiring strong passwords states mandatory behavior and is an explicit security-policy example.

B - Incorrect: Monitoring bandwidth is an operational measurement, not a stated security requirement.

C - Incorrect: Applying patches implements protection; a policy would state the required deadline/scope rather than merely the action.

D - Incorrect: Configuring rules implements policy, whereas the option does not itself state required behavior or governance.

Primary note proof

Study-note section NSA26

A security policy states required behavior, scope, accountable roles and enforcement. Begin with assets/service objectives, assess threats and weaknesses, choose controls, define exceptions/incident procedures, approve/communicate, monitor and periodically review. CIA

means confidentiality, integrity and availability; neither sensitive-data protection nor availability alone is the universal primary goal.

Study-note section NSA26

A policy can require password controls, approved encryption, restricted administrative access, backups and patch deadlines; firewall rules implement part of it. Open unrestricted wireless access conflicts with controlled internal access unless intentionally isolated as a guest service. “Use the system passively” is not a purpose of security policy. Policies coordinate action and reduce risk; they do not guarantee every attack will fail.

Data Communication and Computer Networking module | PDF page 30 | lines 9-15

• Putting security procedures in place to make
certain that only authorized users have access to
the network and ensuring that all security
procedures are followed
• Making sure the network personnel can respond
quickly and effectively in the event of a network
operational or security failure.

Data Communication and Computer Networking module | PDF page 31 | lines 17-29

Principle 1 (Policy is the foundation)
System administration begins with a
policy - adecision about what we want
and what should be, in relation to what we
can afford.
Policy speaks of what we wish to
accomplish with the system, and what we
are willing to tolerate of behavior within it.
It must refer to both the component parts and
to the environmentwith which the system
interacts. If we cannot secure predictability,
then we cannot expect
long-term conformance with a policy.

Data Communication and Computer Networking module | PDF page 48 | lines 29-40

Network Address Translation (NAT)
NAT translates the IP addresses of computers in a local
network to a single IP address. This address is often used
by the router that connects the computers to the Internet.
The router can be connected to a DSL modem, cable
modem, T1 line, or even a dial-up modem. When other
computers on the Internet attempt to access computers
within the local network, they only see the IP address of
the router. This adds an extra level of security, since the

router can be configured as a firewall, only allowing authorized systems to access the computers within the network.

Question sources

Computer Science MCQ practice collection · Question 595

Question 68 | AM0596

Which option states the most general purpose of access control, covering user permissions on logical resources as well as physical restrictions?

A. Limiting physical access to servers

B. Controlling user access to resources

C. Monitoring network traffic

D. Performing system backups

Hint

Distinguish the security objective from the control that prevents, detects or recovers from the stated problem.

Answer B: Controlling user access to resources

Access control decides which users or other subjects may use protected resources and which actions they may perform. Limiting physical entry to a server is one particular control, but does not express the broader account-and-resource permission function. Traffic monitoring observes activity, and backups preserve recoverable data. The general resource-access description therefore best covers the stated scope.

Why each choice is right or wrong

A - Incorrect: Physical server access restriction is a valid but narrower example.

B - Correct: Controlling user access to resources expresses the general purpose.

C - Incorrect: Monitoring observes activity rather than deciding resource permissions.

D - Incorrect: Backups preserve copies for recovery rather than granting access rights.

Primary note proof

Study-note section NSA17

Create named accounts, assign only needed groups/rights, disable departed users and audit privileged activity. Authentication verifies the account; authorization permits operations. A user right such as remote logon differs from a permission on one file. Group-based administration is easier to review than many hidden individual grants.

Study-note section NSA18

Windows file/folder permissions include read, write, read/execute, modify and full control, plus more granular rights such as delete. Inherited and explicit entries, group membership, deny entries and object scope affect effective access; use the effective-access view for a real account rather than adding labels informally. Network access can be constrained by both share and filesystem permissions.

Study-note section NSA30

Segmentation separates groups of systems and enforces allowed flows with routing/filtering policies; VLAN membership alone does not establish complete security. NAC assesses device/user admission and can reject or quarantine unauthorized/noncompliant devices. Authentication proves an identity, while access rules decide which resources it may use.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Data Communication and Computer Networking module | PDF page 43 | lines 2-10

What is File & Folder Permissions?
Permissions are a method for assigning access rights to specific user accounts and user groups. Through the use of permissions, Windows defines which user accounts and user groups can access which files and folders, and what they can do with them. To put it simply, permissions are the operating system‘s way of telling you what you can or cannot do with a file or folder.

Data Communication and Computer Networking module | PDF page 42 | lines 36-49

All user accounts have specific capabilities, privileges, and rights. When you create a user account, you can grant the user specific capabilities by making the user a member of one or more groups. This gives the user the capabilities of these groups. You then assign additional capabilities by making a user a member of the appropriate groups or withdraw capabilities by removing a user from a group. An important part of an administrator‘s job is being able to determine and set permissions, privileges, and logon rights as necessary. Although you can‘t change a group‘s built-in capabilities, you can change a group‘s default privileges and logon rights. For example, you could revoke network access to a computer by removing agroup‘s right to access the computer from the network.

Question sources

Computer Science MCQ practice collection · Question 596

Question 69 | AM0597

Which option describes a firewall's direct traffic-enforcement role, rather than observation, auditing or confidentiality protection?

A. Monitoring network traffic for security threats

B. Encrypting network communications

C. Blocking unauthorized access to the network

D. Auditing network activity

Hint

Distinguish the security objective from the control that prevents, detects or recovers from the stated problem.

Answer C: Blocking unauthorized access to the network

A firewall enforces traffic policy by permitting authorized flows and blocking disallowed ones. Monitoring and audit records can accompany this enforcement, but observing or recording activity does not itself express the requested permit-or-block action. Encryption protects communication confidentiality and is a separate function, even when a product combines it with firewall features.

Why each choice is right or wrong

A - Incorrect: Monitoring may accompany filtering, but observation is not the requested enforcement action.

B - Incorrect: Encryption protects confidentiality rather than deciding whether a flow is permitted.

C - Correct: Blocking unauthorized access directly enforces the traffic policy.

D - Incorrect: Auditing records or reviews activity rather than directly enforcing a traffic decision.

Primary note proof

Study-note section NSA30

> Use authenticated protected remote administration such as SSH or properly secured management services, with restricted source access and auditing. VPNs provide protected connectivity under their defined security model; they are not packet analyzers. Firewall filtering permits/blocks traffic according to policy; it is not inherently encryption. Losing remote connectivity while changing a management route/firewall is an operational risk to plan for.

Study-note section NSA23

> An IDS detects/alerts; an IPS can block inline. Scanning identifies potential weaknesses rather than proving successful exploitation. A captured packet, open port or alert needs context. Monitoring network usage is not the same as configuring access control or encrypting communications.

> Network Address Translation (NAT)
> NAT translates the IP addresses of computers in a local network to a single IP address. This address is often used by the router that connects the computers to the Internet. The router can be connected to a DSL modem, cable modem, T1 line, or even a dial-up modem. When other computers on the Internet attempt to access computers within the local network, they only see the IP address of the router. This adds an extra level of security, since the router can be configured as a firewall, only allowing authorized systems to access the computers within the network.

Question sources

Computer Science MCQ practice collection · Question 597

Question 70 | AM0598

What is the purpose of vulnerability scanning in network and system administration?

A. Identifying security weaknesses and vulnerabilities

B. Encrypting sensitive data during transmission

C. Monitoring network bandwidth usage

D. Managing system logs

Hint

Distinguish the security objective from the control that prevents, detects or recovers from the stated problem.

Answer A: Identify potential security weaknesses

Vulnerability scanning assesses potential weaknesses and configuration problems, as NSA23 explains. It does not itself prove successful exploitation. Encryption, bandwidth measurement and log management are separate administration functions. Therefore A identifies the scan's purpose while retaining the note's caution that scan findings require contextual verification.

Why each choice is right or wrong

A - Correct: Finding potential security weaknesses and configuration vulnerabilities is the purpose assigned to vulnerability assessment.

B - Incorrect: Encryption protects data confidentiality and is not the act of checking for weaknesses.

C - Incorrect: Bandwidth monitoring measures traffic use rather than testing known vulnerability patterns.

D - Incorrect: Log management stores/organizes records and is distinct from scanning systems for weaknesses.

Primary note proof

Study-note section NSA23

Task Manager shows running processes/resource use; Resource Monitor/Performance Monitor give more detailed counters. Wireshark captures and dissects packets. Nmap discovers hosts/ports/services. Nessus assesses vulnerabilities/configuration. Snort can detect suspicious traffic and alert, and can prevent traffic in suitable inline deployments; it also has sniffing/logging roles. Thus packet-capture capability is not exclusive to one product, although Wireshark is the conventional analyzer choice.

Study-note section NSA23

An IDS detects/alerts; an IPS can block inline. Scanning identifies potential weaknesses rather than proving successful exploitation. A captured packet, open port or alert needs context. Monitoring network usage is not the same as configuring access control or encrypting communications.

Study-note section NSA27

Preventive controls restrict harmful actions, detective controls expose them and recovery controls restore service. Account lifecycle, backup procedures, device configuration and traffic analysis can all be security controls under a stated objective. A vulnerability scan checks known weakness patterns, not bandwidth. Test/stage patches, prepare rollback, deploy and verify; testing and installation are both legitimate administrator duties.

System Monitoring Software Essentials
In order to keep your system fit for purpose, your monitoring activities need to cover the following priorities:
• Acceptable delivery speeds
• Constant availability
• Preventative maintenance
• Software version monitoring and patching
• Intrusion detection
• Data integrity
• Security monitoring
• Attack mitigation
• Virus prevention and detection

Data Communication and Computer Networking module | PDF page 53 | lines 29-43

In networking, it is typical to think of a system as a layered stack. User software sits at the top of the stack and system applications and services on the next layer down. Beneath the services and applications, you will encounter operating systems and firmware. Theperformance of software elements needs to be monitoredas an application stack. Users will notice performance problems with the software that they use, but those problems rarely arise within that software. All layers of the application stack need to be examined to find the root cause of performance issues. You need to head off problems with real-time statusmonitoring before they occur. Monitoring tools help you spot errors and service failures before they start to impactusers.

Question sources

Computer Science MCQ practice collection · Question 598

Question 71 | AM0599

Which of the following is a common vulnerability in computer systems?

A. Strong password policies

B. Regular software updates

C. Unpatched software vulnerabilities

D. Secure network segmentation

Hint

Distinguish the security objective from the control that prevents, detects or recovers from the stated problem.

Answer C: Unpatched exploitable software

NSA27 explicitly gives unpatched exploitable software as a vulnerability. Strong password policy, software updates and secure segmentation are defensive practices intended to reduce exposure. They can be imperfectly implemented, but as stated they are not the example of an exploitable weakness requested by the question.

Why each choice is right or wrong

A - Incorrect: Strong password policy is intended to reduce credential weaknesses rather than exemplify one.

B - Incorrect: Regular updates address known flaws and are a hardening practice.

C - Correct: Unpatched exploitable software contains a known weakness that an attack can exploit.

D - Incorrect: Secure segmentation restricts exposure and permitted flows rather than constituting the vulnerability example.

Primary note proof

Study-note section NSA27

> Hardening reduces exposure through unnecessary-service removal, supported patches, restricted accounts/permissions and appropriate port filtering. Blocking an unused known port can be hardening; blocking every useful port merely destroys availability. Weak passwords and unpatched exploitable software are vulnerabilities; attacks exploit weaknesses, and risk combines likelihood with impact.

Study-note section NSA30

> Segmentation separates groups of systems and enforces allowed flows with routing/filtering policies; VLAN membership alone does not establish complete security. NAC assesses device/user admission and can reject or quarantine unauthorized/noncompliant devices. Authentication proves an identity, while access rules decide which resources it may use.

Question sources

Computer Science MCQ practice collection · Question 599

Question 72 | AM0600

What is the purpose of security incident response in network and system administration?

A. Preventing security incidents from occurring

B. Recovering data after a security breach

C. Analyzing network performance

D. Detecting and responding to security incidents

Hint

Distinguish the security objective from the control that prevents, detects or recovers from the stated problem.

Answer D: Detecting and responding to security incidents

PDF p.30 requires responding quickly and effectively to security failure, while p.54 includes intrusion detection and security monitoring. Detection and response therefore cover the requested process more fully than prevention alone or post-breach data recovery alone.

Why each choice is right or wrong

A - Incorrect: Prevention alone omits the explicit response to failures that occur (p.30).

B - Incorrect: Recovery is a narrower possible consequence; the response duty is broader (p.30).

C - Incorrect: Performance analysis addresses operational resources rather than the security-failure response.

D - Correct: Security detection/monitoring (p.54) plus responding to failures (p.30) jointly supports this.

Primary note proof

Study-note section NSA29

Incident response prepares, detects/analyzes, contains, removes the cause, restores service and learns from the event. Investigation is reactive response; routine patching and backup are normally preventive/preparatory operations. Document timestamps, affected systems, evidence, impact, actions, responsible people and recovery results. An incident report may record policy violations, but its scope is broader than that alone.

Study-note section NSA29

DoS harms service availability; DDoS uses distributed sources. Phishing deceives users, brute force tries credentials and an interception attack reads/alters communications. Correlate logs using time and identity/context. Preserve relevant evidence before resetting systems. A suspicious event is not automatically confirmed compromise; record facts and uncertainty.

Module passages - related reading

System Monitoring Software Essentials
In order to keep your system fit for purpose, your monitoring activities need to cover the following priorities:
• Acceptable delivery speeds
• Constant availability
• Preventative maintenance
• Software version monitoring and patching
• Intrusion detection
• Data integrity
• Security monitoring
• Attack mitigation
• Virus prevention and detection

Question sources

Computer Science MCQ practice collection · Question 600

Question 73 | AM0601

What protection does correctly implemented authenticated encryption provide for network data?

A. Preventing unauthorized access to the network

B. Monitoring network traffic for anomalies

C. Protecting data confidentiality and integrity

D. Performing system backups

Hint

Distinguish the security objective from the control that prevents, detects or recovers from the stated problem.

Answer C: Protecting data confidentiality and integrity

Encryption supplies confidentiality when keys and nonces are used correctly. Authenticated encryption also detects unauthorized alteration through integrity and authenticity protection. This explicit construction therefore supports both properties named together in the selected option. Network admission, traffic-anomaly monitoring and backup recovery are separate controls; none is performed merely by encrypting and authenticating a data payload.

Why each choice is right or wrong

A - Incorrect: Network admission/access control is distinct from encrypting content for confidentiality.

B - Incorrect: Anomaly detection is a monitoring function and does not describe the role of encryption.

C - Correct: Authenticated encryption combines confidentiality with integrity/authenticity protection.

D - Incorrect: Backups recover previous data and are not performed by encryption itself.

Primary note proof

Study-note section NSA28

> Encryption provides confidentiality with correct key/nonce use; authenticated encryption adds integrity/authenticity. Unspecified encryption alone does not guarantee both properties. A password hash supports verification without recovering the original password; it is not a reversible credential store. Encryption can protect a recoverable credential only if its key is separately protected.

Study-note section NSA30

> Segmentation separates groups of systems and enforces allowed flows with routing/filtering policies; VLAN membership alone does not establish complete security. NAC assesses device/user admission and can reject or quarantine unauthorized/noncompliant devices. Authentication proves an identity, while access rules decide which resources it may use.

Study-note section NSA24

> Backups recover previous data after deletion, compromise, corruption, failed upgrades/migrations or hardware loss. Authorization controls current access, a different function. A mirror/replica also copies deletions or corruption and does not replace versioned independent backups. Keep protected copies in separate failure domains, define retention and test restores.

Presentation Layer
• The communicating devices may be having different platforms. The presentation layer performs translation, encryption and compression of data.
• The presentation layer receives the data from the application layer adds header which contains information related to encryption and compression and sends it to the session layer.
• So, the main responsibility of the Presentation layer is translation, compression and encryption.

Question sources

Computer Science MCQ practice collection · Question 601

Question 74 | AM0602

Which listed activities can be security controls when implemented for the stated purpose: A recovery, B least-privilege account provisioning, C secure device configuration, D suspicious-traffic detection? Select all that apply.

A. Data backup and recovery procedures

B. User account creation

C. Network device configuration

D. Network traffic analysis

Hint

Distinguish the security objective from the control that prevents, detects or recovers from the stated problem.

Answer A, B, C, D: Data backup and recovery procedures; User account creation; Network device configuration; Network traffic analysis

Security controls include prevention, detection and recovery rather than only one technical mechanism. Backups support recovery, controlled account creation restricts access, secure device configuration reduces exposure, and traffic analysis can detect suspicious behavior. Each listed activity therefore qualifies under its explicit purpose. Simply performing an activity without an objective would not prove effectiveness, but the question supplies the security objective needed to classify it.

Why each choice is right or wrong

A - Correct: Backups and recovery procedures restore service/data after harmful events.

B - Correct: Controlled account creation implements identity lifecycle and access restriction.

C - Correct: Secure device configuration can reduce exposure and enforce permitted network behavior.

D - Correct: Traffic analysis is a detective control when used to identify suspicious behavior.

Primary note proof

Study-note section NSA27

> Preventive controls restrict harmful actions, detective controls expose them and recovery controls restore service. Account lifecycle, backup procedures, device configuration and traffic analysis can all be security controls under a stated objective. A vulnerability scan checks known weakness patterns, not bandwidth. Test/stage patches, prepare rollback, deploy and verify; testing and installation are both legitimate administrator duties.

Bandwidth monitoring tools and NetFlow and sFlow based traffic analyzers help you stay aware of the activity, capacity, and health of your network. They allow you to watch traffic as it flows through routers and switches, or arrive at and leaves hosts.

Question sources

Computer Science MCQ practice collection · Question 602

Question 75 | AM0603

What is the purpose of a security incident report in network and system administration?

A. Documenting security policy violations

B. Sharing threat intelligence with other organizations

C. Investigating network performance issues

D. Identifying system vulnerabilities

Hint

Distinguish the security objective from the control that prevents, detects or recovers from the stated problem.

Answer A: Document security incidents, including policy violations

NSA29 assigns reports the documentation of affected systems, evidence, impact, actions and recovery results, and explicitly includes policy violations within that scope. A therefore states a legitimate report purpose among the choices, although it is not exhaustive. Threat sharing, performance investigation and weakness identification are separate activities that incident findings may later support.

Why each choice is right or wrong

A - Correct: Documenting policy violations is a valid part of incident reporting, although reports also cover impact and response.

B - Incorrect: External threat-intelligence sharing is a separate activity, not the documentation purpose established for this report.

C - Incorrect: Performance investigation is broader troubleshooting and does not specifically define a security incident report.

D - Incorrect: Finding vulnerabilities is assessment; incident reporting documents observed events, evidence and response.

Primary note proof

Study-note section NSA29

> Incident response prepares, detects/analyzes, contains, removes the cause, restores service and learns from the event. Investigation is reactive response; routine patching and backup are normally preventive/preparatory operations. Document timestamps, affected systems, evidence, impact, actions, responsible people and recovery results. An incident report may record policy violations, but its scope is broader than that alone.

Question sources

Computer Science MCQ practice collection · Question 603

Question 76 | AM0604

Which actions can be valid troubleshooting steps when supported by a tested fault hypothesis and an appropriate recovery plan? Select all that apply.

A. Rebooting the system

B. Performing a software update

C. Resetting network configurations

D. Conducting a network scan

Hint

Identify the required operational function, then compare its scope, inputs and constraints with the cited note definitions.

Answer A, B, C, D: Rebooting the system; Performing a software update; Resetting network configurations; Conducting a network scan

Rebooting, updating software, resetting configuration and scanning can each help with an appropriate diagnosed problem. Their value depends on the hypothesis and operational context: an update may address a known bug, a reset may correct damaged settings, and a scan may gather service evidence. None should be performed blindly. The question asks which actions can belong to troubleshooting, not which one should always be tried first.

Why each choice is right or wrong

A - Correct: Rebooting can be a justified troubleshooting action, although it can hide evidence and is not itself diagnosis.

B - Correct: An update can address a diagnosed software defect affecting network behavior.

C - Correct: Resetting incorrect network settings can resolve a configuration fault after preserving needed evidence.

D - Correct: A targeted network scan can gather reachability/service evidence for diagnosis.

Primary note proof

Study-note section NSA08

Define the symptom, scope, time and recent changes; gather the configuration, baseline and logs. Form a testable hypothesis, test the least disruptive explanation, isolate the failing component, apply a targeted fix, verify the user service and document the result. Change one relevant factor at a time when possible. A reboot can hide evidence and is not a diagnosis by itself.

Study-note section NSA08

Use bottom-up checks from physical link, top-down checks from application errors, or divide-and-conquer by testing a middle layer. Divide-and-conquer narrows the working/failing boundary; it is not random trial-and-error. Rebooting, updates, resetting settings and scanning can all be troubleshooting actions in suitable circumstances; use fault evidence to choose among them.

• Diagnosing and troubleshooting problems on the network and determining the best course of action to take to solve them.

Data Communication and Computer Networking module | PDF page 53 | lines 29-43

In networking, it is typical to think of a system as a layered stack. User software sits at the top of the stack and system applications and services on the next layer down. Beneath the services and applications, you will encounter operating systems and firmware. Theperformance of software elements needs to be monitoredas an application stack. Users will notice performance problems with the software that they use, but those problems rarely arise within that software. All layers of the application stack need to be examined to find the root cause of performance issues. You need to head off problems with real-time statusmonitoring before they occur. Monitoring tools help you spot errors and service failures before they start to impactusers.

Data Communication and Computer Networking module | PDF page 30 | lines 19-33

Although the specifics of being a system administrator may change from platform to platform, there are underlying themes that do not. These themes make up the philosophy of system administration. The themes are:
• Automate everything
• Document everything

- Communicate as much as possible
- Know your resources
- Know your users
- Know your business
- Security cannot be an afterthought
- Plan ahead
- Expect the unexpected
- Backup and disaster recovery planning
- Patching

Question sources

Computer Science MCQ practice collection · Question 604

Question 77 | AM0605

Which purposes can analysis of existing system and network logs serve? Select all that apply.

A. Identifying potential security breaches

B. Monitoring network performance

C. Configuring firewall rules

D. Encrypting network communications

Hint

Identify the required operational function, then compare its scope, inputs and constraints with the cited note definitions.

Answer A, B: Identifying potential security breaches; Monitoring network performance

Logs can reveal suspicious activity that suggests a security breach and can also expose timing, error or workload patterns related to performance. These are complementary uses of recorded observations. Changing firewall rules may follow the analysis, but it is a separate configuration action. Encryption protects communications in transit or storage rather than emerging from analysis of past records. Both analytical purposes therefore qualify.

Why each choice is right or wrong

A - Correct: Security events in logs can reveal potential breaches and support incident investigation.

B - Correct: Log timing/errors can reveal performance faults and complement measured counters.

C - Incorrect: Rule configuration may follow findings, but is not the act or direct purpose of log analysis.

D - Incorrect: Encryption protects communications; parsing historical records does not itself encrypt traffic.

Primary note proof

Study-note section NSA35

Count the event actually requested, use timestamps/hosts to correlate, and separate absence of matches from failure to read the log. Logs support security and performance analysis, so neither purpose is universally exclusive.

Study-note section NSA22

Measure a baseline, sample over an interval, compare with workload and correlate symptoms before changing hardware. CPU utilization/run queues identify processing pressure; low free memory alone is weak evidence because cache may be reclaimable. Persistent paging with high latency indicates memory pressure. Storage capacity and I/O latency are separate: a disk can be nearly empty but saturated, or nearly full while lightly loaded.

System Monitoring Software Essentials
In order to keep your system fit for purpose, your monitoring activities need to cover the following priorities:
• Acceptable delivery speeds
• Constant availability
• Preventative maintenance
• Software version monitoring and patching
• Intrusion detection
• Data integrity
• Security monitoring
• Attack mitigation
• Virus prevention and detection

Data Communication and Computer Networking module | PDF page 54 | lines 49-63

• Monitoring a range of server metrics: availability, CPU usage, memory usage, disk space, response time, and upload/download rates. Monitoring CPU temperature and power supply voltages.
• Monitoring applications. Using deep knowledge of common applications and services to monitor key server processes, including web servers, database servers, and application stacks.
• Automatically alerting you of problems, such as servers or network devices that are overloaded or down, or worrisome trends. Customized alerts that can use multiple methods to contact you - email, SMS text messages, pager, etc.

• Triggering actions in response to alerts, to handle certain classes of problems automatically.

Question sources

Computer Science MCQ practice collection · Question 605

Question 78 | AM0606

A client has valid IP configuration. Which listed utility can send ICMP echo requests to a gateway as the next reachability diagnostic?

A. Ping

B. VPN

C. FTP

D. DNS

Hint

Match the requested observation to the tool’s actual output; distinguish configuration, name lookup, reachability and hop discovery.

Answer A: Ping

Ping sends ICMP echo requests and checks the returned replies. Testing the gateway can help isolate whether the client can exchange IP traffic with that next-hop device. A VPN provides extended protected connectivity, FTP transfers files and DNS resolves names; none is the requested echo-probe utility. Missing replies need further investigation because filtering or loss can suppress otherwise reachable devices.

Why each choice is right or wrong

A - Correct: Ping generates the requested ICMP echo probes.

B - Incorrect: A VPN provides protected connectivity rather than being an echo-test utility.

C - Incorrect: FTP transfers files rather than issuing the specified reachability probe.

D - Incorrect: DNS resolves names rather than sending ICMP echo requests.

Primary note proof

Study-note section NSA-S04

Ping uses ICMP echo messages to test IP reachability. A reply shows that the addressed host and path support that exchange; no reply alone does not prove the host is disconnected, because filtering or loss can suppress responses. Traceroute instead discovers responding intermediate hops through packet-lifetime expiry; it is a path-discovery diagnostic, not the same question as an end-to-end echo test.

Study-note section NSA10

DNS resolves names; DHCP supplies host configuration. SMTP sends/relays mail, while IMAP/POP retrieve it. FTP is a named file-transfer protocol; HTTP also transfers files, so “transfers files” is not an exclusive FTP description. HTTP/HTTPS serve web resources. SSH provides encrypted remote login; SFTP transfers files over SSH and differs from FTP or FTPS.

• POP3 is used to receive mail.
• Simple Network Management Protocol (SNMP)
• Domain Name Service (DNS)
• Dynamic Host Configuration Protocol (DHCP)

Question sources

Computer Science MCQ practice collection · Question 606

Question 79 | AM0607

An administrator is monitoring network capacity and utilization, rather than conducting a vulnerability assessment. Which activity directly measures that objective?

A. Identifying security vulnerabilities

B. Tracking network bandwidth usage

C. Configuring user access controls

D. Performing system backups

Hint

Identify the required operational function, then compare its scope, inputs and constraints with the cited note definitions.

Answer B: Tracking network bandwidth usage

Capacity monitoring compares observed traffic with the available link rate and follows usage over time. Tracking bandwidth usage therefore measures the specified performance objective. Vulnerability assessment searches for weaknesses, access-control configuration changes permissions, and backups preserve data for recovery. All can be administration activities, but they do not measure the traffic utilization asked for here.

Why each choice is right or wrong

A - Incorrect: Vulnerability identification assesses weaknesses rather than measuring capacity utilization.

B - Correct: Bandwidth-usage tracking measures traffic utilization against available capacity.

C - Incorrect: Configuring access controls changes authorization rather than measuring traffic load.

D - Incorrect: Backups preserve recovery copies rather than observing utilization.

Primary note proof

Study-note section NSA22

> Measure interface bytes/second, errors, drops, packet delay/loss and utilization against link rate. Distinguish capacity (maximum available rate) from observed throughput. Logs can reveal both security incidents and performance faults. Performance counters expose measured events; system calls/APIs and log parsers are ways scripts can collect them.

Study-note section NSA23

> An IDS detects/alerts; an IPS can block inline. Scanning identifies potential weaknesses rather than proving successful exploitation. A captured packet, open port or alert needs context. Monitoring network usage is not the same as configuring access control or encrypting communications.

Data Communication and Computer Networking module | PDF page 29 | lines 44-56

> Scope of Network administration
> The management of a network, usually called network administration, consists of procedures and services that keep the network running properly. An important part of network management entails making sure that the network is available (or up and running as IT professionals say) when employees and managers need it.Other admin activities are:
> • Monitoring the network capacity to ensure that alltransmission requirements can be met.
> • Adding capacity to the network by increasing band

width interconnecting additional modes, or
creating and interconnecting additional networks.

Data Communication and Computer Networking module | PDF page 54 | lines 13-17

Bandwidth monitoring tools and NetFlow and sFlow
based traffic analyzers help you stay aware of the activity,
capacity, and health of your network. They allow you to
watch traffic as it flows through routers and switches, or
arrive at and leaves hosts.

Question sources

Computer Science MCQ practice collection · Question 607

Question 80 | AM0608

Which troubleshooting approach tests a middle layer, then narrows the working/failing boundary upward or downward?

A. Divide and conquer

B. Trial and error

C. Random testing

D. Full system restore

Hint

Identify the required operational function, then compare its scope, inputs and constraints with the cited note definitions.

Answer A: Divide and conquer

Divide-and-conquer starts with a test at a middle layer and uses the result to decide which side of the boundary needs further investigation. It therefore narrows the scope systematically. Trial-and-error is a broader description of making attempts and does not specifically name this layer-boundary method. Random testing lacks the defined decision process, and a full restore is a recovery action rather than the approach described.

Why each choice is right or wrong

A - Correct: Divide-and-conquer is explicitly supported and isolates a working/failing boundary by testing a middle layer.

B - Incorrect: Trial-and-error does not specifically identify the middle-layer boundary-isolation approach described.

C - Incorrect: Random testing lacks the testable hypothesis and controlled isolation recommended by NSA08.

D - Incorrect: A full restore is a potentially disruptive recovery action, not the routine diagnostic approach identified in NSA08.

Primary note proof

Study-note section NSA08

> Use bottom-up checks from physical link, top-down checks from application errors, or divide-and-conquer by testing a middle layer. Divide-and-conquer narrows the working/failing boundary; it is not random trial-and-error. Rebooting, updates, resetting settings and scanning can all be troubleshooting actions in suitable circumstances; use fault evidence to choose among them.

Study-note section NSA08

> Define the symptom, scope, time and recent changes; gather the configuration, baseline and logs. Form a testable hypothesis, test the least disruptive explanation, isolate the failing component, apply a targeted fix, verify the user service and document the result. Change one relevant factor at a time when possible. A reboot can hide evidence and is not a diagnosis by itself.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

> monitoring is normally done as the first and last steps of a three-step process:
> Monitoring to identify the nature and scope of the resource shortages that are causing the performance problems.
> The data produced from monitoring is analyzed and a course of action (normally performance tuning

and/or the procurement of additional hardware) is taken to resolve the problem

Question sources

Computer Science MCQ practice collection · Question 608

Question 81 | AM0609

A static network diagram records devices, links and their arrangement for later troubleshooting. What direct purpose does creating this diagram serve?

A. Documenting network configurations

B. Identifying security vulnerabilities

C. Monitoring network performance

D. Configuring network devices

Hint

Identify the required operational function, then compare its scope, inputs and constraints with the cited note definitions.

Answer A: Documenting network configurations

A network diagram documents the arrangement of devices and links and may record configuration relationships. That record helps a troubleshooter reason about expected connectivity. An analyst might subsequently infer weaknesses from it, but creating a static diagram does not itself establish vulnerabilities, sample live performance or apply device settings. The question asks for the direct documentation purpose.

Why each choice is right or wrong

A - Correct: Documenting the network arrangement and configuration is the direct purpose.

B - Incorrect: A diagram can inform security analysis, but creating it does not itself establish vulnerabilities.

C - Incorrect: A static diagram does not measure live performance counters or traffic.

D - Incorrect: Drawing the topology does not apply settings to devices.

Primary note proof

Study-note section NSA02

Switching normally forwards frames using MAC addresses within a LAN; routing forwards IP packets between networks. TCP supplies an ordered reliable byte stream, while UDP preserves datagrams without that guarantee. Ports distinguish application endpoints, not physical connectors. Draw switches, links, subnets, gateways, service hosts and dependencies in a network diagram. A topology's shape alone does not guarantee security.

Study-note section NSA01

Use documentation, standardization, least privilege, automation and measured change. Record the current state, intended change, rollback and validation. Schedule maintenance according to service impact and urgency, not merely because a calendar date arrived. Fault management restores failures; performance management measures service behavior; configuration management tracks settings; security management controls access; accounting tracks usage.

Inter-connectivity: components of a network, including end devices and interconnecting devices, can be connected to each other differently in some fashion. By connectedness we mean either logically, physically or both ways. Network topology refers to the shape of a network, or the network‘s layout. It is the geometric representation of the relationship of all the links and linking devices to one another. There are

Question sources

Computer Science MCQ practice collection · Question 609

Question 82 | AM0610

Which measures can provide a network security control under their ordinary stated purposes? Select all that apply.

A. Intrusion Detection System (IDS)

B. User authentication

C. Data encryption

D. Network traffic analysis

Hint

Distinguish the security objective from the control that prevents, detects or recovers from the stated problem.

Answer A, B, C, D: Intrusion Detection System (IDS); User authentication; Data encryption; Network traffic analysis

An IDS detects suspicious activity and alerts, while traffic analysis can provide additional detective evidence. User authentication establishes identity for subsequent access decisions. Correctly implemented encryption protects data against unauthorized disclosure. These mechanisms address different security needs, so all are examples of controls under the broad question. Their inclusion does not imply that any single mechanism provides complete security by itself.

Why each choice is right or wrong

A - Correct: An IDS supplies detective monitoring and alerts about suspicious activity.

B - Correct: Authentication establishes an identity before access decisions and supports controlled admission.

C - Correct: Appropriate encryption protects transmitted content against unauthorized disclosure.

D - Correct: Traffic analysis can detect suspicious behavior and is explicitly included among security controls.

Primary note proof

Study-note section NSA23

> An IDS detects/alerts; an IPS can block inline. Scanning identifies potential weaknesses rather than proving successful exploitation. A captured packet, open port or alert needs context. Monitoring network usage is not the same as configuring access control or encrypting communications.

Study-note section NSA28

> Encryption provides confidentiality with correct key/nonce use; authenticated encryption adds integrity/authenticity. Unspecified encryption alone does not guarantee both properties. A password hash supports verification without recovering the original password; it is not a reversible credential store. Encryption can protect a recoverable credential only if its key is separately protected.

Study-note section NSA30

Segmentation separates groups of systems and enforces allowed flows with routing/filtering policies; VLAN membership alone does not establish complete security. NAC assesses device/user admission and can reject or quarantine unauthorized/noncompliant devices. Authentication proves an identity, while access rules decide which resources it may use.

Presentation Layer
• The communicating devices may be having different platforms. The presentation layer performs translation, encryption and compression of data.
• The presentation layer receives the data from the

application layer adds header which contains information related to encryption and compression and sends it to the session layer.
• So, the main responsibility of the Presentation layer is translation, compression and encryption.

Question sources

Computer Science MCQ practice collection · Question 610

Question 83 | AM0611

What is the direct network-structural purpose of segmentation with enforced intersegment policies? Select the most specific description.

A. Controlling user access to resources

B. Encrypting network communications

C. Isolating network segments for security purposes

D. Monitoring network traffic

Hint

Identify whether the task requires input/output, control flow, code organization, process execution or collection of a specific measurement.

Answer C: Isolating network segments for security purposes

Segmentation separates groups of systems and enforces permitted flows between them. This structural isolation can support access restrictions, but controlling user access is a broader result also achieved through other mechanisms. The most specific description is therefore isolating network segments for security. Encryption and monitoring are distinct controls and do not automatically follow from dividing the network into segments.

Why each choice is right or wrong

A - Incorrect: Access control may be an outcome, but this broad description does not name segmentation’s direct structural purpose.

B - Incorrect: Segmentation restricts connectivity but does not inherently encrypt the communications it permits.

C - Correct: Segmentation isolates system groups into network segments and enforces intersegment flows.

D - Incorrect: Traffic monitoring observes activity; it is distinct from establishing and enforcing segment boundaries.

Primary note proof

Study-note section NSA30

Segmentation separates groups of systems and enforces allowed flows with routing/filtering policies; VLAN membership alone does not establish complete security. NAC assesses device/user admission and can reject or quarantine unauthorized/noncompliant devices. Authentication proves an identity, while access rules decide which resources it may use.

Study-note section NSA30

Use authenticated protected remote administration such as SSH or properly secured management services, with restricted source access and auditing. VPNs provide protected connectivity under their defined security model; they are not packet analyzers. Firewall filtering permits/blocks traffic according to policy; it is not inherently encryption. Losing remote connectivity while changing a management route/firewall is an operational risk to plan for.

Question sources

Computer Science MCQ practice collection · Question 611

Question 84 | AM0612

What is the role of a Network Access Control (NAC) system in network security?

A. Managing user account credentials

B. Monitoring network bandwidth

C. Detecting and blocking unauthorized devices

D. Auditing network activity

Hint

Distinguish the security objective from the control that prevents, detects or recovers from the stated problem.

Answer C: Assess admission and reject unauthorized devices

NSA30 defines Network Access Control as assessing device/user admission and rejecting or quarantining unauthorized or noncompliant devices. C matches that admission function. Credential management, bandwidth monitoring and general activity auditing can support network operations, but they do not state the specific NAC enforcement role.

Why each choice is right or wrong

A - Incorrect: Managing account credentials is identity administration, not the complete device-admission role defined for NAC.

B - Incorrect: Bandwidth monitoring measures network use rather than deciding whether a device may join.

C - Correct: NAC can detect unauthorized/noncompliant devices during admission and reject or quarantine them.

D - Incorrect: Auditing records activity; NAC's distinguishing role is admission assessment and enforcement.

Primary note proof

Study-note section NSA30

> Segmentation separates groups of systems and enforces allowed flows with routing/filtering policies; VLAN membership alone does not establish complete security. NAC assesses device/user admission and can reject or quarantine unauthorized/noncompliant devices. Authentication proves an identity, while access rules decide which resources it may use.

Study-note section NSA22

> Measure interface bytes/second, errors, drops, packet delay/loss and utilization against link rate. Distinguish capacity (maximum available rate) from observed throughput. Logs can reveal both security incidents and performance faults. Performance counters expose measured events; system calls/APIs and log parsers are ways scripts can collect them.

> A domain controller (DC) is a server computer that responds to security authentication requests within a computer network domain. It is a network server that is responsible for allowing end devices to access shared domain resources. It authenticates users, stores user account information and enforces security policy for a domain. It is most commonly implemented in Microsoft

Question sources

Computer Science MCQ practice collection · Question 612

Question 85 | AM0613

In the note’s bottom-up connectivity procedure, which listed action belongs to the initial physical-link check?

A. Checking physical cable connections

B. Updating antivirus software

C. Configuring firewall rules

D. Performing system backups

Hint

Identify the required operational function, then compare its scope, inputs and constraints with the cited note definitions.

Answer A: Checking physical cable connections

A bottom-up procedure begins with power, cable or connector condition and link state before examining interfaces, addressing, routes or application policy. Checking physical cable connections directly fits that initial stage. Firewall configuration may become relevant later when evidence identifies filtering. Antivirus updates and backups serve maintenance or recovery purposes rather than the first physical-link inspection specified in this question.

Why each choice is right or wrong

A - Correct: Cable/connector and link-state checks directly diagnose physical connectivity problems.

B - Incorrect: Updating antivirus is maintenance rather than a direct connectivity-isolation technique supported by this stem.

C - Incorrect: Firewall rules may require later inspection, but are not the initial physical-link check.

D - Incorrect: Backups support recovery but do not directly test or correct the network-connectivity path.

Primary note proof

Study-note section NSA09

Check power, cable/connector and link state, then NIC/driver state, VLAN membership, address/prefix, local gateway, route, DNS and finally application port/authentication. A recognized NIC makes a missing driver less likely, not proof of a working physical link. Ethernet commonly uses RJ45 connectors; an RJ11 telephone jack is not the expected Ethernet connection.

Study-note section NSA08

Use bottom-up checks from physical link, top-down checks from application errors, or divide-and-conquer by testing a middle layer. Divide-and-conquer narrows the working/failing boundary; it is not random trial-and-error. Rebooting, updates, resetting settings and scanning can all be troubleshooting actions in suitable circumstances; use fault evidence to choose among them.

Network Address Translation (NAT)
NAT translates the IP addresses of computers in a local network to a single IP address. This address is often used by the router that connects the computers to the Internet. The router can be connected to a DSL modem, cable modem, T1 line, or even a dial-up modem. When other computers on the Internet attempt to access computers within the local network, they only see the IP address of the router. This adds an extra level of security, since the router can be configured as a firewall, only allowing authorized systems to access the computers within the network.

Data Communication and Computer Networking module | PDF page 22 | lines 45-52

Inter-connectivity: components of a network, including end devices and interconnecting devices, can be connected to each other differently in some fashion. Question sources

Computer Science MCQ practice collection · Question 613

Question 86 | AM0614

Which of the following scripting languages is commonly used for system administration tasks?

A. Java

B. C++

C. Python

D. HTML

Hint

Identify whether the task requires input/output, control flow, code organization, process execution or collection of a specific measurement.

Answer C: Python

NSA31 explicitly names Python among common system-administration scripting choices, along with shells and PowerShell. HTML is markup. Java and C++ are programming languages but are not the common scripting choice identified among these options. The answer concerns ordinary administration automation, not whether those languages could ever perform administrative work.

Why each choice is right or wrong

A - Incorrect: Java can implement programs, but it is not the common administration scripting choice identified in NSA31.

B - Incorrect: C++ is a compiled programming language rather than the listed common administration scripting choice.

C - Correct: Python is explicitly identified as a common language for administrative scripts.

D - Incorrect: HTML is markup and does not provide the administrative scripting control flow requested.

Primary note proof

Study-note section NSA31

> Scripts automate repeatable administration; they are not inherently faster than compiled programs or automatically secure. Python, shells and PowerShell are common choices; HTML is markup. Define inputs and outputs, use variables for state, if/elif/else for decisions, loops for repeated work and functions for reusable operations. Python indentation defines blocks; == compares while = assigns.

Study-note section NSA-S01

Least privilege limits an account or process to the rights its task needs. Agile development instead organizes frequent delivery and adaptation of software. Object-oriented programming organizes software around objects with state and behavior. Cloud computing supplies on-demand access to a shared pool of configurable computing resources. A development approach or hosting model does not itself define an access-rights principle.

Module passages - related reading

What is Unix/Linux?
The Unix OS is a set of programs that act as a link between the computer and the user. The computer program that allocates the system resources and coordinates all the details of the computer‘s internals is called the operating system or the kernel. Users communicate with the kernel through a program known as the shell. The shell is a command line interpreter; it translates commands entered by the user and converts them into a language that is understood by the kernel.

Question sources

Computer Science MCQ practice collection · Question 614

Question 87 | AM0615

What is the primary advantage of using scripts for system administration tasks?

A. Faster execution compared to compiled programs

B. Ability to automate repetitive tasks

C. Greater control over system resources

D. Enhanced security and encryption features

Hint

Identify whether the task requires input/output, control flow, code organization, process execution or collection of a specific measurement.

Answer B: Automate repetitive work

NSA31 identifies repeatable automation as the reason to use administration scripts. Their value is consistent execution of recurring tasks, not guaranteed speed relative to compiled code, stronger encryption or inherently greater resource control. Those properties depend on implementation and environment rather than following from the use of a script.

Why each choice is right or wrong

A - Incorrect: Scripts are not inherently faster than compiled programs; the note explicitly rejects that universal claim.

B - Correct: Automation of repetitive administrative work is the primary script benefit given in NSA31.

C - Incorrect: Greater resource control is not an inherent consequence of scripting rather than another implementation method.

D - Incorrect: Scripts are not automatically secure and do not inherently add encryption features.

Primary note proof

Study-note section NSA31

> Scripts automate repeatable administration; they are not inherently faster than compiled programs or automatically secure. Python, shells and PowerShell are common choices; HTML is markup. Define inputs and outputs, use variables for state, if/elif/else for decisions, loops for repeated work and functions for reusable operations. Python indentation defines blocks; == compares while = assigns.

Study-note section NSA31

> Make reruns predictable: compute the desired state, compare with current state and change only what differs. Validate a small dry run before mutation. Avoid requiring privilege for read-only reporting. A good script reports failures and has a meaningful exit status rather than printing success unconditionally.

What is Unix/Linux?
The Unix OS is a set of programs that act as a link between the computer and the user. The computer program that allocates the system resources and coordinates all the details of the computer‘s internals is called the operating system or the kernel. Users communicate with the kernel through a program known as the shell. The shell is a command line interpreter; it translates commands entered by the user and converts them into a language that is understood by the kernel.

Question sources

Computer Science MCQ practice collection · Question 615

Question 88 | AM0616

In Python, which listed module provides an API for launching child programs and collecting their results?

A. echo

B. ifconfig

C. grep

D. subprocess

Hint

Identify the required operational function, then compare its scope, inputs and constraints with the cited note definitions.

Answer D: subprocess

Python’s subprocess module launches child programs and provides interfaces for collecting output, checking status and limiting runtime. It is a language module rather than a universal shell command. Echo prints values, ifconfig handles interface configuration, and grep searches text. Naming the language and asking for the module makes the intended process-execution abstraction precise without confusing it with one particular program a script might launch.

Why each choice is right or wrong

A - Incorrect: Echo prints values and is not a general child-process execution abstraction.

B - Incorrect: Ifconfig reports/configures network interfaces rather than generally launching arbitrary programs.

C - Incorrect: Grep searches text and is not the general program-execution mechanism requested.

D - Correct: The Python subprocess module launches child programs and returns their results.

Primary note proof

Study-note section NSA32

Python subprocess is a module, not a universal shell command. run launches a child program and returns its result; capture_output collects stdout/stderr, text=True decodes text, timeout bounds waiting and check=True raises for nonzero exit. Pass an argument list to avoid accidental shell interpretation; quote handling differs from composing a shell string.

Study-note section NSA32

Echo prints, grep searches text and ipconfig/ifconfig reports/configures networking; none is the general Python child-process abstraction. Specify the scripting language before selecting subprocess for process execution.

Network configuration commands
The ip Command
The distribution-specific scripts and graphical tools are front-ends to ip (or ifconfig and route on older systems) to display and configure the kernel‘s networking configuration. The ip command is used for assigning IP addresses to interfaces, for setting up routes to the Internet and to other networks, for displaying TCP/IP

Question sources

Computer Science MCQ practice collection · Question 616

Question 89 | AM0617

Which scripting feature is useful for handling errors and exceptions in system administration scripts?

A. Looping constructs

B. Conditional statements

C. Exception handling

D. Function definitions

Hint

Identify whether the task requires input/output, control flow, code organization, process execution or collection of a specific measurement.

Answer C: Exception handling

The NSA34 example uses try with specific exception handlers to report expected read failures while exposing unexpected programming errors. Exception handling is therefore the language feature directly intended for handling errors and exceptions. Loops repeat work, conditions choose branches and functions package reusable operations; none alone supplies exception interception.

Why each choice is right or wrong

A - Incorrect: Loops repeat operations and do not themselves intercept raised exceptions.

B - Incorrect: Conditionals choose branches from ordinary conditions but do not replace exception handlers.

C - Correct: Exception handling catches specified failures and controls reporting or recovery when exceptions occur.

D - Incorrect: Functions organize reusable work; they still require appropriate error/exception handling inside or around calls.

Primary note proof

Study-note section NSA-S05

> Exception handling transfers control from a failing operation to a matching handler. A try block contains the attempted work; an except clause handles specified raised exceptions. A loop repeats operations, a conditional chooses an ordinary branch, and a function packages reusable work; these constructs do not by themselves intercept exceptions.

Study-note section NSA31

> Scripts automate repeatable administration; they are not inherently faster than compiled programs or automatically secure. Python, shells and PowerShell are common choices; HTML is markup. Define inputs and outputs, use variables for state, if/elif/else for decisions, loops for repeated work and functions for reusable operations. Python indentation defines blocks; == compares while = assigns.

Question sources

Computer Science MCQ practice collection · Question 617

Question 90 | AM0618

Which concept directly reads configuration bytes from a file or writes updated content back to it, rather than interpreting or holding values?

A. File input/output

B. Regular expressions

C. String manipulation

D. Variable assignment

Hint

Identify whether the task requires input/output, control flow, code organization, process execution or collection of a specific measurement.

Answer A: File input/output

File input/output obtains configuration content from storage and persists revised content. Regular expressions and string operations can interpret or construct that content after it has been read, while variables hold values during processing. All can assist a configuration script, but only file I/O directly crosses the file-storage boundary asked about. Structured formats should still be parsed with their appropriate parsers.

Why each choice is right or wrong

A - Correct: File I/O obtains and persists the configuration content being manipulated.

B - Incorrect: Regex interprets patterns in content rather than directly reading or writing file storage.

C - Incorrect: String manipulation processes text rather than directly transferring it to or from a file.

D - Incorrect: Variable assignment holds values in program state rather than performing file I/O.

Primary note proof

Study-note section NSA33

> File I/O obtains/persists configuration; string operations parse values; regex can recognize patterns. File I/O, string operations and regex can all help manipulate configuration; choose according to the task. Use the format's parser for structured JSON/INI rather than blindly replacing every matching substring. Open text with an explicit encoding and use with so files close even when processing fails.

Study-note section NSA31

> Scripts automate repeatable administration; they are not inherently faster than compiled programs or automatically secure. Python, shells and PowerShell are common choices; HTML is markup. Define inputs and outputs, use variables for state, if/elif/else for decisions, loops for repeated work and functions for reusable operations. Python indentation defines blocks; == compares while = assigns.

> CD before burning it.

Question sources

Computer Science MCQ practice collection · Question 618

Question 91 | AM0619

Which scripting technique recognizes textual patterns and extracts matching fields or events from individual system-log lines?

A. Database integration

B. File compression

C. Log rotation

D. Regular expression matching

Hint

Identify whether the task requires input/output, control flow, code organization, process execution or collection of a specific measurement.

Answer D: Regular expression matching

Regular expressions describe text patterns and can capture fields from matching log lines. A script can then count events, correlate entries or report anomalies. Database integration supplies storage or query infrastructure, compression reduces data size, and rotation manages log segments and retention. Those may support an overall monitoring system, but they do not themselves perform the specific textual matching operation requested.

Why each choice is right or wrong

A - Incorrect: Database integration stores or queries information rather than specifying the requested text pattern.

B - Incorrect: Compression reduces data size rather than extracting matching fields.

C - Incorrect: Rotation manages file size and historical segments, not textual matching.

D - Correct: Regular expressions match patterns and capture requested fields or events.

Primary note proof

Study-note section NSA35

> Regex recognizes textual patterns; it does not encrypt, compress or rotate logs. search finds a match anywhere, while fullmatch requires the entire string to fit. Use raw Python strings for backslash-heavy patterns, capture only the needed fields and treat unmatched/malformed lines explicitly. Log rotation bounds file size and preserves historical segments; it is complementary to parsing.

Study-note section NSA35

> Count the event actually requested, use timestamps/hosts to correlate, and separate absence of matches from failure to read the log. Logs support security and performance analysis, so neither purpose is universally exclusive.

Module passages - related reading

Question sources

Computer Science MCQ practice collection · Question 619

Question 92 | AM0620

Which scripting language feature allows passing command-line arguments to a script?

A. Functions

B. Modules

C. Classes

D. Command-line parsing

Hint

Match the requested observation to the tool’s actual output; distinguish configuration, name lookup, reachability and hop discovery.

Answer D: Command-line parsing

NSA34 identifies command-line parsing as the mechanism for interpreting invocation arguments as named, typed inputs and options. The example uses argparse. Functions, modules and classes can organize a parser's implementation, but they do not by themselves define argument interpretation or validation; D states the requested feature directly.

Why each choice is right or wrong

A - Incorrect: Functions organize callable work but do not inherently parse invocation arguments.

B - Incorrect: Modules organize code; a parser module still needs command-line parsing behavior to interpret inputs.

C - Incorrect: Classes organize state/behavior and do not themselves define command-line argument processing.

D - Correct: Command-line parsing interprets the arguments and options supplied when invoking a script.

Primary note proof

Study-note section NSA34

> Command-line parsing converts user inputs into named, typed values and displays usage. In Python argparse, positional arguments supply required inputs and flags enable options. Validate ranges and paths before work; do not let unchecked input become executable shell text.

Study-note section NSA-S05

> A module groups definitions and statements that can be imported. A class bundles data with functionality for its objects. These organize a program, while command-line parsing interprets the arguments and flags supplied at invocation. Their implementation can use functions or classes, but organization alone does not parse arguments.

Question sources

Computer Science MCQ practice collection · Question 620

Question 93 | AM0621

Which scripting technique is commonly used for automating system backup and restore tasks?

A. File compression

B. Version control

C. Scheduling

D. Event logging

Hint

Identify whether the task requires input/output, control flow, code organization, process execution or collection of a specific measurement.

Answer C: Scheduling

Automating recurring backup/restore work requires choosing when the operation runs. NSA37 assigns this to schedulers such as cron/systemd timers or Windows Task Scheduler. Compression packages data, version control tracks script changes and logging records outcomes. Those can support a backup process but do not themselves trigger the scheduled task.

Why each choice is right or wrong

A - Incorrect: Compression packages data but does not determine when a backup or restore operation executes.

B - Incorrect: Version control tracks changes in scripts and does not replace scheduling or data backups.

C - Correct: Scheduling triggers recurring work at configured times through the platform's scheduler.

D - Incorrect: Event logging records execution/results rather than initiating the recurring operation.

Primary note proof

Study-note section NSA37

> Schedule recurring work using cron/systemd timers on suitable Unix systems or Task Scheduler on Windows. A user crontab uses minute,hour,day-of-month,month,day-of-week then command. Use absolute paths, known environment, protected inputs, logs, bounded runtime and a lock when overlap is unsafe. Do not assume an interactive PATH, current directory or stored credentials exist in a scheduled job.

Study-note section NSA37

Compression packages data; scheduling chooses when the operation runs. Test exit status and the archive contents, then restore a sample into an isolated destination. A successful command alone does not prove a usable backup. Version control of scripts helps review but does not replace data backup.

Although the specifics of being a system administrator
may change from platform to platform, there are
underlying themes that do not. These themes make up the
philosophy of system administration. The themes are:
• Automate everything
• Document everything
• Communicate as much as possible
• Know your resources
• Know your users
• Know your business
• Security cannot be an afterthought
• Plan ahead
• Expect the unexpected
• Backup and disaster recovery planning
• Patching

Question sources

Computer Science MCQ practice collection · Question 621

Question 94 | AM0622

A script must recover a stored service credential to authenticate later. With the decryption key protected separately, which listed mechanism cryptographically protects that recoverable credential at rest?

A. Environment variables

B. Encryption algorithms

C. Hashing functions

D. Configuration files

Hint

Identify whether the task requires input/output, control flow, code organization, process execution or collection of a specific measurement.

Answer B: Encryption algorithms

The script needs the actual credential for later authentication, so a one-way password hash cannot meet the recoverability requirement. Encryption can protect the stored credential while allowing authorized decryption, provided the key is separately protected. Environment variables and configuration files describe storage or delivery choices and are not automatically encrypted. The explicit use case therefore identifies encryption without treating it as sufficient when its key is exposed.

Why each choice is right or wrong

A - Incorrect: Environment variables deliver or hold values but do not by themselves encrypt stored credentials.

B - Correct: Encryption protects a recoverable credential when its key is separately protected.

C - Incorrect: A one-way hash supports verification but cannot recover the service credential.

D - Incorrect: A configuration file is a storage choice and is not automatically cryptographically protected.

Primary note proof

Study-note section NSA28

> Encryption provides confidentiality with correct key/nonce use; authenticated encryption adds integrity/authenticity. Unspecified encryption alone does not guarantee both properties. A password hash supports verification without recovering the original password; it is not a reversible credential store. Encryption can protect a recoverable credential only if its key is separately protected.

Study-note section NSA28

> Keep reusable secrets out of source code and routine logs; obtain them from an appropriately protected credential service or restricted runtime source. Environment variables and configuration files are transport/storage choices, not automatic encryption. A script that must authenticate to another service often needs the actual credential/token, so replacing it with a one-way hash will not work. State whether the question is about password verification or recoverable service credentials.

Question sources

Computer Science MCQ practice collection · Question 622

Question 95 | AM0623

Which techniques can collect CPU or memory measurements when the relevant logs or OS interfaces expose those metrics? Select all that apply.

A. Log parsing

B. System calls

C. Signal handling

D. Performance counters

Hint

Identify the required operational function, then compare its scope, inputs and constraints with the cited note definitions.

Answer A, B, D: Log parsing; System calls; Performance counters

Resource measurements can be recorded in logs, exposed through operating-system APIs or published as performance counters. Scripts may use any of those interfaces when the requested metrics are available. Signal handling instead reacts to process notifications and is not itself a CPU or memory measurement interface. The multiple-selection instruction preserves the complementary collection techniques without claiming one universal platform-independent API.

Why each choice is right or wrong

A - Correct: Parsing logs can collect recorded resource metrics when suitable measurements are present.

B - Correct: OS system calls/APIs can expose resource measurements used by monitoring scripts.

C - Incorrect: Signal handling manages process notifications; it is not the measurement interface for CPU/memory utilization.

D - Correct: Performance counters directly expose measured resource events and utilization-related values.

Primary note proof

Study-note section NSA36

/proc/meminfo exposes MemAvailable, an estimate of memory available without swapping; MemFree alone excludes reclaimable memory. Windows Performance Counters and OS APIs expose analogous measurements through different interfaces. System calls, counters and log

parsing can all contribute; selecting one as the only monitoring technique is unjustified without a platform/API.

Study-note section NSA-S05

A signal handler responds when a process receives a specified asynchronous event notification. Handling such a notification is distinct from reading CPU or memory measurements through an OS interface, a performance counter or a log that actually records the metric.

Question sources

Computer Science MCQ practice collection · Question 623

Question 96 | CS0188

Suppose you are a network administrator and want to determine the path between two connections, which often goes through multiple routers. Which command would you use?

A. ping

B. nslookup

C. traceroute

D. All of the above

Hint

Match the requested observation to the tool's actual output; distinguish configuration, name lookup, reachability and hop discovery.

Answer C: traceroute

Traceroute discovers responding hops toward a destination by causing packet-lifetime expiry at successive distances. It is therefore the appropriate command for investigating a multi-router path. Ping checks an end-to-end echo exchange and nslookup inspects DNS resolution, which do not supply the requested hop sequence. Some intermediate devices may not reply, so the displayed trace is evidence from responding hops rather than a guarantee that every router is visible.

Why each choice is right or wrong

A - Incorrect: Ping checks end-to-end reachability, not the requested hop sequence.

B - Incorrect: Nslookup queries DNS information, not intermediate router hops.

C - Correct: Traceroute discovers responding intermediate hops along the path.

D - Incorrect: The other commands do not all perform route-hop discovery.

Primary note proof

Study-note section NSA-S04

> Ping uses ICMP echo messages to test IP reachability. A reply shows that the addressed host and path support that exchange; no reply alone does not prove the host is disconnected, because filtering or loss can suppress responses. Traceroute instead discovers responding intermediate hops through packet-lifetime expiry; it is a path-discovery diagnostic, not the same question as an end-to-end echo test.

Study-note section NSA07

> netstat displays connections/endpoints/protocols and TCP states; netstat -ano displays numeric addresses/ports and PIDs. Use the exact command name netstat rather than netstart. ping probes IP reachability; traceroute/tracert reveals responding hops using TTL/hop-limit expiry. ICMP filtering can prevent replies without proving the service is down. nslookup inspects DNS.

Question sources

Computer Science Exit Exam practice collection · Question 188

Question 97 | CS0189

Which statements correctly describe IPv4 loopback? In D, 127.0.0.1 means the conventional example rather than the entire reserved range. Select all that apply.

A. It helps to refer to the host itself

B. It allows programs to access network protocols for local services

C. It is an external pseudo address

D. It is denoted by the IP address: 127.0.0.1

Hint

Identify the required operational function, then compare its scope, inputs and constraints with the cited note definitions.

Answer A, B, D: It helps to refer to the host itself; It allows programs to access network protocols for local services; It is denoted by the IP address: 127.0.0.1

Loopback lets a host address its own protocol stack and reach local services without an external link. The conventional IPv4 address is 127.0.0.1, within the broader reserved 127/8 block. It is therefore local self-reference rather than an external address. The example wording permits all three true descriptions without incorrectly restricting the entire loopback range to a single address.

Why each choice is right or wrong

A - Correct: Loopback refers to the host itself rather than a remote device.

B - Correct: Programs can reach local services through network protocols using loopback.

C - Incorrect: Loopback is local and does not require an external network link.

D - Correct: 127.0.0.1 is the conventional IPv4 loopback address, although the reserved block is broader.

Primary note proof

Study-note section NSA03

127.0.0.1 conventionally names the local IPv4 loopback interface; 127/8 is reserved for loopback. Loopback tests local protocol processing, not cable, switch or remote reachability. Programs can use it for local services. Several loopback descriptions or several 127/8 addresses may be valid; compare each with the stated role.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

/etc/hosts
The /etc/hosts file always contains the localhost IP
address, 127.0.0.1, which is
usedfor interprocess communication.
Never remove this line! Sometimes contains
addresses of additional hosts, whichcan be contacted
without using an external naming service such as
DNS (the Domain Name Server).

Question sources

Computer Science Exit Exam practice collection · Question 189

Question 98 | NS0296

Which listed item is a traffic-prioritization mechanism that can operate across layers, rather than an application mediator or service installation/configuration activity?

A. Proxies and agents

B. Installing a new service

C. E-mail configuration

D. Quality of service

Hint

Identify the required operational function, then compare its scope, inputs and constraints with the cited note definitions.

Answer D: Quality of service

Quality of service classifies, queues and prioritizes traffic to meet performance objectives such as low delay or limited loss. It can span layers while supporting applications. Proxies and agents are mediating components, and installing a service or configuring email are administrative activities. The revised question uses those explicit functional categories, so it does not require an unsupported taxonomy that labels every item an application-layer service.

Why each choice is right or wrong

A - Incorrect: Proxies and agents mediate requests rather than naming the traffic-prioritization mechanism.

B - Incorrect: Installing a service is an administrative activity.

C - Incorrect: Email configuration is an administrative activity.

D - Correct: QoS classifies and prioritizes traffic and can operate across layers.

Primary note proof

Study-note section NSA12

> A proxy acts on behalf of a client or backend service and can cache, filter or mediate application requests. A default IP gateway is a next-hop router; an application gateway may translate protocols. It need not be a modem/router combination. These terms describe functions that can coexist on one machine.

Study-note section NSA12

> QoS classifies, queues and prioritizes traffic to meet performance objectives such as low delay or limited loss. It can operate across layers and support applications, so it is not exclusively an application-layer service. Installing a new service is an administrative action; email configuration is another action and proxies/agents are components. Distinguish service-management actions from components using a stated taxonomy.

Question sources

Computer Science Exit Exam · 2018 · Question 13

Question 99 | NS0313

A data-center volume has exactly two equal disks and must retain service after either disk fails. One disk’s usable capacity is sufficient. Which listed RAID level meets these requirements?

A. RAID level 3

B. RAID level1

C. RAID level 2

D. RAID level 0

Hint

Compare striping granularity, redundancy placement, usable capacity and required disk-failure tolerance.

Answer B: RAID level1

With exactly two equal disks, RAID1 mirrors the data and leaves one disk's usable capacity while tolerating either disk failing. RAID0 provides no disk-failure tolerance. RAID2 and RAID3 rely on different striping and redundancy layouts rather than the two-disk mirrored arrangement that meets these requirements. The choice follows the stated disk count, capacity and failure goal rather than the institution's size or industry.

Why each choice is right or wrong

A - Incorrect: RAID3 uses byte striping with dedicated parity, not the required two-disk fault-tolerant layout.

B - Correct: A two-disk RAID1 mirror provides one disk's capacity and survives either disk failing.

C - Incorrect: RAID2 uses bit striping and Hamming redundancy rather than the required two-disk solution.

D - Incorrect: RAID0 cannot tolerate a disk failure.

Primary note proof

Study-note section NSA25

> RAID0 stripes for capacity/throughput with no disk-failure tolerance. RAID1 mirrors; a two-disk mirror has one disk's usable capacity and survives one disk failure. RAID2 uses bit striping/Hamming-code redundancy, RAID3 byte striping with dedicated parity, RAID4 block striping with dedicated parity and RAID5 block striping with distributed parity. RAID6 distributes dual parity and tolerates two disk failures. RAID10 stripes mirrored pairs; survival depends on which disks fail.

Study-note section NSA25

> With N equal disks of capacity D, RAID0 usable=ND, paired RAID1/10≈ND/2, RAID5=(N−1)D and RAID6=(N−2)D. Hardware RAID may offload work to controller resources/cache but does not universally outperform software RAID. Rebuilds consume bandwidth; parity writes have overhead. A large university/bank alone does not select a level. Striping plus parity is not uniquely RAID5 unless distributed block parity is specified.

Question sources

Computer Science Exit Exam · 2018 · Question 37

Question 100 | NS0324

A storage administrator configures four equal 2 TB disks. Each stripe stores data blocks on three disks and a parity block on the fourth; the disk holding parity changes between stripes. Ignoring metadata, which listed RAID layout provides 6 TB of usable capacity and tolerates one disk failure?

A. RAID 2

B. RAID 1

C. RAID 5

D. RAID 0

Hint

Compare striping granularity, redundancy placement, usable capacity and required disk-failure tolerance.

Answer C: RAID 5

The changing parity disk means parity is distributed across the array while data are striped in blocks, identifying RAID5. Its usable capacity is (N−1)D, so four 2 TB disks provide 6 TB and retain one disk's worth of redundancy. RAID2 uses bit striping with Hamming-code redundancy, RAID1 mirrors data, and RAID0 provides no disk-failure tolerance.

Why each choice is right or wrong

A - Incorrect: RAID2 uses bit striping with Hamming-code redundancy, not the described block stripes with rotating parity.

B - Incorrect: RAID1 mirrors data; it does not place one rotating parity block in each stripe.

C - Correct: RAID5 distributes parity across block stripes and gives (4−1)×2 = 6 TB usable capacity.

D - Incorrect: RAID0 would provide 8 TB without parity, so it fails the one-disk-failure requirement.

Primary note proof

Study-note section NSA25

> RAID0 stripes for capacity/throughput with no disk-failure tolerance. RAID1 mirrors; a two-disk mirror has one disk's usable capacity and survives one disk failure. RAID2 uses bit striping/Hamming-code redundancy, RAID3 byte striping with dedicated parity, RAID4 block striping with dedicated parity and RAID5 block striping with distributed parity. RAID6 distributes dual parity and tolerates two disk failures. RAID10 stripes mirrored pairs; survival depends on which disks fail.

Study-note section NSA25

> With N equal disks of capacity D, RAID0 usable=ND, paired RAID1/10≈ND/2, RAID5=(N−1)D and RAID6=(N−2)D. Hardware RAID may offload work to controller resources/cache but does not universally outperform software RAID. Rebuilds consume bandwidth; parity writes have

overhead. A large university/bank alone does not select a level. Striping plus parity is not uniquely RAID5 unless distributed block parity is specified.

Question 101 | NS0350

Which one of the following is WRONGLY stated about an importance of security policy?

A. To help minimize risk.

B. To ensure the confidentiality, integrity and availability of data.

C. To coordinate and enforce a security program across an organization.

D. To use the system in a passive way

Hint

Distinguish the security objective from the control that prevents, detects or recovers from the stated problem.

Answer D: Passive system use is not a security-policy purpose

NSA26 assigns policies risk reduction, coordinated required behavior and CIA goals. D's passive-use statement does not describe those governance/protection purposes and is explicitly rejected here. B expresses the desired CIA objective, not a guarantee that policy alone prevents every incident. The remaining statements fit legitimate policy aims.

Why each choice is right or wrong

A - Incorrect: Reducing risk is a stated security-policy aim, so this is not wrongly stated.

B - Incorrect: CIA protection is a legitimate policy objective, with actual success depending on implemented controls.

C - Incorrect: Coordinating required behavior and enforcement across the organization is a legitimate policy purpose.

D - Correct: Passive use is not the defined purpose of security policy and does not express its governance/protection objectives.

Primary note proof

Study-note section NSA26

A security policy states required behavior, scope, accountable roles and enforcement. Begin with assets/service objectives, assess threats and weaknesses, choose controls, define exceptions/incident procedures, approve/communicate, monitor and periodically review. CIA means confidentiality, integrity and availability; neither sensitive-data protection nor availability alone is the universal primary goal.

Study-note section NSA26

A policy can require password controls, approved encryption, restricted administrative access, backups and patch deadlines; firewall rules implement part of it. Open unrestricted wireless access conflicts with controlled internal access unless intentionally isolated as a guest service. “Use the system passively” is not a purpose of security policy. Policies coordinate action and reduce risk; they do not guarantee every attack will fail.

Automata and Complexity Theory

Questions & Worked Answers

156 questions

Question 1 | Q00015

Which of the following term refers to the number of symbols composing a string?

A. Length

B. Symbols

C. Alphabet

D. Word

Hint

Distinguish symbols, finite strings, their lengths and sets of strings. Apply the operation to its stated operands, including empty cases.

Answer A: Length

Count symbols rather than distinct symbols: that count is the string's length, $|w|$. Alphabet is the set from which symbols are drawn, not the count in a particular string.

Why each choice is right or wrong

A - Correct: This is precisely the defined count $|w|$.

B - Incorrect: Symbols are the individual objects being counted.

C - Incorrect: An alphabet is a finite set of symbols.

D - Incorrect: A word/string is the sequence whose length is measured.

Primary note proof

Study-note section AUT01

> An alphabet Σ is a finite set of symbols. A word/string is a finite ordered sequence of symbols from Σ; a language is a set of words, $L \subseteq \Sigma^*$. An empty word ε, also written λ, has length zero. The empty language $\varnothing$ contains no words; $\{\varepsilon\}$ contains one.

Study-note section AUT01

> Length counts occurrences, not distinct symbols: $|caddba|=6$, so $|caddba|^2=36$.

MOE Computer Science Exit Exam · 2016 · Question 15

Question 2 | Q00024

Let L_1={c,d} and L_2={e,fgh}. Which lowercase word is NOT an element of L_2L_1?

A. fghc

B. ed

C. fghe

D. ec

Hint

Distinguish symbols, finite strings, their lengths and sets of strings. Apply the operation to its stated operands, including empty cases.

Answer C: fghe

Language concatenation preserves order: each word of L_2 is followed by a word of L_1. The four products are ec, ed, fghc and fghd. Thus fghe is the unique nonmember: its ending e is not one of the words available from L_1. The lowercase transcription repair makes the symbols consistent with the declared languages.

Why each choice is right or wrong

A - Incorrect: fghc is fgh followed by c, so it belongs to the product.

B - Incorrect: ed is e followed by d, so it belongs to the product.

C - Correct: fghe cannot be formed because e is not in L_1.

D - Incorrect: ec is e followed by c, so it belongs to the product.

Primary note proof

Study-note section AUT02

> Concatenation xy writes x followed by y: cddc·ababb=cddcababb; order generally matters. εx=xε=x. Define x^0=ε and x^n as n copies for n≥1. Reverse x^R reads symbols backward: caddba reverses to abddac; $(xy)^R=y^Rx^R$ and $(x^R)^R=x$.

Study-note section AUT02

For languages, LM={xy:x∈L,y∈M}, L^0={ε}, and L^{n+1}=L^nL. Thus {e,fgh}{c,d}={ec,ed,fghc,fghd}; fghe is absent.

Question 3 | Q00032

Which theory provides mechanisms for classifying combinatorial problems and measuring the computational resources necessary to solve them?

A. Computability theory

B. Set theory

C. Complexity theory

D. Automata theory

Hint

Check whether the required procedure must halt on every input, and distinguish solving a task from recognizing its yes-instances.

Answer C: Complexity theory

The requested quantity is the resources needed to solve a problem. Computational complexity estimates time and space requirements. Computability instead asks whether a membership algorithm exists at all.

Why each choice is right or wrong

A - Incorrect: Computability concerns existence of algorithms, rather than their resource costs.

B - Incorrect: Set theory does not name the study of time and space requirements.

C - Correct: Matches the resource-estimation definition directly.

D - Incorrect: Automata studies abstract machines; the specific resource classification asked here is complexity.

Primary note proof

Study-note section AUT-S01

> Computability theory asks whether an effective algorithm can solve a problem at all. For a decision problem, a decision procedure must terminate with the correct yes-or-no result on every input.

Study-note section AUT-S01

> Computational complexity theory studies the time and memory resources required to solve problems as functions of encoded input size. Automata theory studies abstract machine models and the languages they recognize; these subjects overlap but ask different questions.

Question sources

MOE Computer Science Exit Exam · 2016 · Question 32

Question 4 | Q00192

Which language over {0,1} is denoted by (0+1)*0(0+1)*0(0+1)*? Here + means union.

A. Strings with substring 00

B. Strings with at least two 0's

C. Strings with at most two 0's

D. Strings with postfix 1.

Hint

Track mandatory symbols and factors that may repeat or disappear. Use short test words to check both directions of each proposed language description.

Answer B: Strings with at least two 0's

Each starred factor denotes any binary string, including the empty string. The two unstarred zeros therefore require at least two zero occurrences, while permitting arbitrary symbols before, between and after them. Conversely, any word with at least two zeros can be split at two selected zero positions to fit the expression. For example, 010 fits without containing adjacent zeros, and 000 fits although it has more than two zeros. No final 1 is required.

Why each choice is right or wrong

A - Incorrect: 010 is generated but does not contain the adjacent substring 00.

B - Correct: Two explicit zeros are required; the starred factors allow additional zeros and ones.

C - Incorrect: 000 is generated, so there is no upper bound of two zeros.

D - Incorrect: 00 is generated and ends in 0.

Primary note proof

Study-note section AUT13

> To require at least one a anywhere over {a,b}, use (a|b)*a(a|b)*. b*ab* requires exactly one a. At least two zeros uses (0|1)*0(0|1)*0(0|1)*; the zeros need not be adjacent. Testing 010 distinguishes it from a requirement for substring 00. For S→aS|ε, any number of a's is generated, giving a*.

> A language is said to be a Regular language if and only if some finite state machine recognizes it

Question sources

Addis Ababa University mock exam · Question 94

Question 5 | Q00193

The transition function in a finite-state automaton maps which pair?

A. Q and Σ to Σ

B. Q and Q to Σ

C. Σ and Σ to Q

D. Q and Σ to Q

Hint

Read the transition domain and acceptance condition carefully. Track which inputs are consumed and evaluate the whole word under the stated model.

Answer D: Q and Σ to Q

For a deterministic finite automaton, finite control receives the current state and input symbol and chooses the next state. Thus $\delta:Q\times\Sigma\to Q$. A general NFA instead has a set of possible next states, so the stem tacitly uses the deterministic convention.

Why each choice is right or wrong

A - Incorrect: Outputs an input symbol, not a state.

B - Incorrect: The second input must be a symbol, not another state.

C - Incorrect: Omits the current state and uses two input symbols.

D - Correct: Correct deterministic domain and codomain.

Primary note proof

Study-note section AUT06

> A deterministic finite automaton (DFA) is $M=(Q,\Sigma,\delta,q_0,F)$, with finite nonempty Q, start $q_0\in Q$, accepting set $F\subseteq Q$ and total $\delta:Q\times\Sigma\to Q$. Exactly one next state is specified per state/symbol pair; this does not mean the whole machine has one transition. F may be empty, recognizing $\varnothing$.

Study-note section AUT06

> Start at q_0 and consume the entire input. Accept iff the ending state is in F; visiting an accepting state earlier is insufficient. ε is accepted exactly when $q_0\in F$. A nonaccepting sink loops on every symbol and cannot reach acceptance; it still finishes after finite input. Finite automata have finite memory encoded by states, not no state or no ability to remember any history.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Automata and Complexity Theory module | PDF page 5 | lines 3-5

> DFA refers to deterministic finite automata. Deterministic refers to the uniqueness of the computation. In the DFA, the machine goes to one state only for a particular input character. DFA does not accept the null move.

Question sources

Addis Ababa University mock exam · Question 95

Question 6 | Q00194

With start variable A and productions A→aB|bA|bBa and B→bB|cA|b, which offered string is generated?

A. abbcabbcbbbcbbaca

B. bcbbbcabbcbaa

C. acbcbbbbcabaa

D. bbbbcbbbbcab

Hint

Apply the stated transition, closure or equivalence rule step by step; distinguish a guaranteed bound from a value for one particular machine.

Answer C: acbcbbbbcabaa

With A as the start variable, the candidate follows the production sequence A⇒aB⇒acA⇒acbBa⇒acbcAa⇒acbcbAa⇒acbcbbAa⇒acbcbbbAa⇒acbcbbbbBaa⇒acbcbbbbcAaa⇒acbcbbbbcaBaa⇒acbcbbbbcabaa. Each rewrite uses one of the displayed rules, including a final B→b that removes the remaining variable. The other three offered words fail the complete shrinking-residual membership test.

Why each choice is right or wrong

A - Incorrect: Every permitted prefix or wrapper decomposition eventually leaves a residual that neither required variable generates.

B - Incorrect: The required A/B prefix and wrapper decompositions do not reach the terminating B→b production.

C - Correct: The displayed derivation produces acbcbbbbcabaa from start A.

D - Incorrect: Following the required variable after each prefix does not produce this word.

Primary note proof

Study-note section AUT40

> For A→aB|bA|bBa and B→bB|cA|b, specify a start variable first. With A assumed, a terminating membership test recursively removes the required a/b prefix or b…a wrapper; B either matches b or removes b before B/c before A. Every recursive residual is shorter. Apply the membership test to every candidate word; none qualifies in this four-word example under the assumed start A. Use the membership test to justify whether a candidate word belongs to the language.

Study-note section AUT16

> In a context-free grammar (CFG) each production has one variable on the left, A→α with α∈(V∪Σ)*.

Question sources

Addis Ababa University mock exam · Question 96

Question 7 | Q00195

When can we say two grammars are equivalent?

A. When the language derived from one grammar is a subset of the other

B. When the alphabets of the two grammars are the same

C. When the languages represented by both grammars are the same

D. When a single string is a member of both languages

Hint

Distinguish symbols, finite strings, their lengths and sets of strings. Apply the operation to its stated operands, including empty cases.

Answer C: When the languages represented by both grammars are the same

A grammar specifies its generated sentences. Equality of the generated sets, not equality of alphabets or overlap, is the criterion for semantic equivalence. For example {a} and {a,aa} have the same alphabet and a common string but different languages.

Why each choice is right or wrong

A - Incorrect: One-way inclusion allows extra strings in the other language.

B - Incorrect: Same terminal alphabet permits different sets of sentences.

C - Correct: Equality of the full generated languages establishes equivalence.

D - Incorrect: A single shared string establishes overlap only.

Primary note proof

Study-note section AUT04

> Write $G=(V,\Sigma,P,S)$: finite variables V, terminals Σ disjoint from V, productions P and start variable $S \in V$. A production replaces its left side by its right side. The language is $L(G)=\{w \in \Sigma^* : S \Rightarrow^* w\}$. A recognizer processes a word and accepts exactly the language members. Grammars generate languages; automata recognize languages, not grammars.

Study-note section AUT04

> Two grammars are equivalent when their generated languages are equal, regardless of rule counts or variable names. One common word, equal alphabets or one-way inclusion is insufficient.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Question 8 | Q00196

If L1 and L2 are two regular languages, which one of the following is true

A. LiU L2 is a regular language only if empty string is not a member

B. Li* is the same with L2* and are both regular languages

C. LiL is also a regular language

D. L:* is a regular language and is equivalent to L;

Hint

Track mandatory symbols and factors that may repeat or disappear. Use short test words to check both directions of each proposed language description.

Answer C: The concatenation L1L2 is regular.

Regular languages are closed under concatenation, so any two regular languages have a regular concatenation. Reversal preserves regularity but need not preserve the original language. Union needs no exclusion of the empty word, and arbitrary closures need not coincide.

Why each choice is right or wrong

A - Incorrect: Union is regular even if it contains the empty word; the only-if restriction is false.

B - Incorrect: Both stars are regular, but arbitrary regular languages need not have equal Kleene closures.

C - Correct: The image reads L1L2; regular languages are closed under this concatenation operation.

D - Incorrect: The image reads reversal: it remains regular but need not equal L1, for example {ab} reverses to {ba}.

Primary note proof

Study-note section AUT14

> Right-linear rules have form A→aB, A→a or permitted ε rules; left-linear rules put the single variable at the opposite end, A→Ba. Both consistent orientations generate REG; arbitrarily mixing them can generate nonregular languages, for example S→aA|ε, A→Sb generates a^nb^n. A CFG rule A→aBA is legal but not regular-grammar form.

Study-note section AUT14

> Regular languages are closed under union, concatenation, star, reversal, intersection, difference and complement.

Module passages - related reading

Automata and Complexity Theory module | PDF page 7 | lines 16-16

> A language is said to be a Regular language if and only if some finite state machine recognizes it

Automata and Complexity Theory module | PDF page 6 | lines 4-4

> Kleen closure: If L is a regular language then its Kleen closure L1* will also be a regular language.

Question sources

Addis Ababa University mock exam · Question 98

Question 9 | Q00197

Let G = {N, T, P, S} be a grammar where:
N={S, A}, T={ 0, 1}, S={S} and P= {S-11S|0A]|1A,A>0]|1] 0S}.
Which one of the following is a sentential form?

A. 111011110S

B. 11111101

C. 0000111001AS

D. OOO011L1I0A

Hint

Apply the stated transition, closure or equivalence rule step by step; distinguish a guaranteed bound from a value for one particular machine.

Answer B: 11111101

The grammar is S→11S|0A|1A, A→0|1|0S, and option D is 00001110A. Terminal sentences are also sentential forms. B has the derivation S⇒11S⇒1111S⇒111111S⇒1111110A⇒11111101. Every reachable form contains at most one nonterminal, at the right end. Before final termination, a return to S appends either 11, 00, or 10. A cannot be segmented into these pairs (its last prefix pair is 01); C has two variables; D has prefix ending at A which cannot be obtained by those pairs followed by 0 or 1.

Why each choice is right or wrong

A - Incorrect: Before S the terminal prefix must be a sequence of pairs 11,00,10; 111011110 contains a forbidden pair 01 and has odd length.

B - Correct: The explicit derivation ends at this terminal sentence, which is also a sentential form.

C - Incorrect: Two variables AS cannot arise from rules that never introduce two variables.

D - Incorrect: The form 00001110A would require an odd-length prefix before A (pairs followed by one symbol); its eight-symbol prefix has even length.

Primary note proof

Study-note section AUT40

> For S→11S|0A|1A and A→0|1|0S, every reachable form has at most one variable, at the right end. A complete terminal word is still a sentential form. For example S⇒11S⇒1111S⇒111111S⇒1111110A⇒11111101. Returning to S appends a pair 11,00 or 10; use that invariant to rule out impossible prefixes rather than guessing from string length.

Study-note section AUT16

> A sentential form is any string derived from S, including terminal-only sentences and S itself.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Automata and Complexity Theory module | PDF page 9 | lines 2-2

> A sentential form is any string derivable from the start symbol.

> R is a set of production rules where each production rule maps a variable to a string $s \in (V \cup \Sigma)*$;

Question sources

Addis Ababa University mock exam · Question 99

Question 10 | Q00198

In a derivation graph whose root is S, whose vertices are sentential forms, and whose directed edges are single production applications, which property records the steps generating a terminal string?

A. Root of the graph

B. Degree of the vertex

C. Path of a vertex from the root

D. Parent vertex

Hint

Apply the stated transition, closure or equivalence rule step by step; distinguish a guaranteed bound from a value for one particular machine.

Answer C: Path of a vertex from the root

A derivation is a sequence of production applications beginning at S and ending at a terminal word. Under the specified graph model, each application is one directed edge, so the root-to-terminal-vertex path records the complete sequence. A root alone gives only the start; degree and an immediate parent give local information. This graph is not being treated as a parse tree.

Why each choice is right or wrong

A - Incorrect: The root identifies S but contains no sequence of applications.

B - Incorrect: Degree counts incident edges rather than their ordered traversal.

C - Correct: A root-to-vertex path lists the successive production applications.

D - Incorrect: A parent identifies one predecessor rather than the entire derivation.

Primary note proof

Study-note section AUT16

> In a context-free grammar (CFG) each production has one variable on the left, $A \to \alpha$ with $\alpha \in (V \cup \Sigma)^*$. The left side therefore also belongs to $V \cup \Sigma$ and its string closure; alternatives stating these weaker memberships can all be true. A sentential form is any string derived from S, including terminal-only sentences and S itself.

Study-note section AUT16

> A leftmost derivation always replaces the leftmost variable; a rightmost one replaces the rightmost variable. This is not scanning the completed input in opposite directions. A complete parse tree has root S, internal variable nodes expanded by productions and terminal leaves, with ε leaves when that convention is used. Read the leaves left-to-right for the yielded word. The whole tree represents derivation structure; a path in a derivation graph is a different object.

Module passages - related reading

Automata and Complexity Theory module | PDF page 9 | lines 5-6

> The derivation tree is a graphical representation of the given production rules of context-free grammar (CFG).

Question sources

Addis Ababa University mock exam · Question 100

Question 11 | Q00329

A context free Grammar is called ambiguous if there exists a string that can have?

A. only one parse tree

B. no parse tree

C. Partial parse tree

D. more than one parse tree

Hint

Compare production restrictions, memory access and language-family containments. Distinguish an exact characterization from an included subclass.

Answer D: more than one parse tree

Ambiguity is witnessed by one terminal string having two distinct parse trees. It does not require every string to be ambiguous, and a string with no parse tree is simply not generated.

Why each choice is right or wrong

A - Incorrect: A unique tree is consistent with unambiguity.

B - Incorrect: No tree means failure to derive the string, not competing derivations.

C - Incorrect: A partial tree is unfinished and does not witness two full derivations.

D - Correct: Two or more full trees for the same string meet the definition.

Primary note proof

Study-note section AUT18

> A CFG is ambiguous when some word has two distinct parse trees, equivalently two different leftmost derivations. Different expansion orders that give the same tree do not prove ambiguity.

Study-note section AUT18

> Separate precedence levels: E→E+T|T, T→T*F|F, F→id|(E). Multiplication binds inside T before addition at E, and left recursion encodes left association. Uniqueness follows by the top-level last

operator split and induction. S→SS|ε is already ambiguous for ε. S→A|B is ambiguous if A→ab and B→abB|ε both produce ab. Ambiguous grammar and inherently ambiguous language differ: another grammar may remove ambiguity.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Automata and Complexity Theory module | PDF page 8 | lines 33-34

Grammar can be implemented with multiple parse
trees to get the same resulting string, this is said to be ambiguous.

Computer Science model exam · Question 60

University of Gondar model exam · Question 60

Question 12 | Q00330

A context free grammar with production rules: S->aS / ¢ is equivalent to the regular expression

A. a*

B. (atb)*

C. a(at+b)*

D. a+

Hint

Track mandatory symbols and factors that may repeat or disappear. Use short test words to check both directions of each proposed language description.

Answer A: a*

The grammar is S→aS|ε. Applying the recursive rule n times followed by ε produces a^n for each n≥0, and no production creates any other terminal. This is exactly a*, including ε. Positive closure a+ omits ε.

Why each choice is right or wrong

A - Correct: Contains exactly all finite repetitions of a, including zero.

B - Incorrect: The expression (a+b)* also contains b.

C - Incorrect: The expression a(a+b)* contains ab and omits ε.

D - Incorrect: Requires at least one a, although S⇒ε is permitted.

Primary note proof

Study-note section AUT13

To require at least one a anywhere over {a,b}, use (a|b)*a(a|b)*. b*ab* requires exactly one a. At least two zeros uses (0|1)*0(0|1)*0(0|1)*; the zeros need not be adjacent. Testing 010 distinguishes it from a requirement for substring 00. For S→aS|ε, any number of a's is generated, giving a*.

Module passages - related reading

Question 13 | Q00331

A push down automaton employs data structure.

A. Linked List

B. Stack

C. Hash Table

D. Queue

Hint

Compare production restrictions, memory access and language-family containments. Distinguish an exact characterization from an included subclass.

Answer B: Stack

A PDA augments finite control with a stack. Push and pop operations supply its unbounded LIFO memory.

Why each choice is right or wrong

A - Incorrect: A linked list is an implementation possibility, not the abstract PDA storage discipline.

B - Correct: A PDA uses stack memory.

C - Incorrect: Hash lookup is not the PDA memory mechanism.

D - Incorrect: A queue is FIFO, unlike the required pushdown stack.

Primary note proof

Study-note section AUT21

> A nondeterministic pushdown automaton (PDA) adds a stack to finite control: $(Q,\Sigma,\Gamma,\delta,q_0,Z_0,F)$. Its transition relation maps (state,input symbol or ε,stack top) to possible (new state,replacement stack string) pairs.

Study-note section AUT-S02

> A stack is last-in, first-out: push adds an item at the top and pop removes the top item, so the most recently pushed item is removed first. A PDA accesses this top rather than an arbitrary interior position.

Study-note section AUT-S02

> A queue is first-in, first-out: insertion at the rear and removal at the front returns the oldest waiting item. A linked list can implement a storage discipline, but the implementation container is different from the abstract push/pop or enqueue/dequeue access rule.

Question 14 | Q00332

Which of the following Machine is Equivalent for Regular grammar?

A. Push down automata

B. Linear bounded automata

C. Finite state automata

D. Turing Machine

Hint

Compare production restrictions, memory access and language-family containments. Distinguish an exact characterization from an included subclass.

Answer C: Finite state automata

Regular grammars generate exactly the regular languages, which finite-state automata recognize. The visual hierarchy pairs the innermost regular class with finite-state automata. More powerful models can accept those languages too but are not equivalent in class-wide expressive power.

Why each choice is right or wrong

A - Incorrect: PDA languages include nonregular CFLs, so the whole model is more powerful.

B - Incorrect: The diagram pairs LBAs with the larger context-sensitive class.

C - Correct: Matches exactly the class generated by regular grammars.

D - Incorrect: The outer Turing machine class is larger.

Primary note proof

Study-note section AUT05

> Type 3 regular grammars correspond to finite automata; type 2 CFGs to nondeterministic PDAs; type 1 context-sensitive/noncontracting grammars to nondeterministic LBAs; type 0 unrestricted grammars to Turing recognizers.

Study-note section AUT05

> Use REG ⊊ CFL ⊊ CSL ⊊ DECIDABLE ⊊ RE, under the usual convention allowing S→ε with S absent from right sides when needed.

Question sources

Computer Science model exam · Question 63

University of Gondar model exam · Question 63

Question 15 | Q00333

For a CFG G=(V,Σ,P,S), consider a production α→β. Treat a symbol also as its length-one string. Which statements hold? Select all that apply.

A. α∈(V∪Σ)

B. α∈V

C. α∈(V∪Σ)*

D. β∈(V∪Σ)*

Hint

Apply the stated transition, closure or equivalence rule step by step; distinguish a guaranteed bound from a value for one particular machine.

Answer A, B, C, D: α∈(V∪Σ); α∈V; α∈(V∪Σ)*; β∈(V∪Σ)*

A context-free production has exactly one variable on its left and a finite string of variables and terminals on its right. Therefore α∈V. Since V⊆V∪Σ, that same α belongs to the union and, as a one-symbol string, to its Kleene closure. The right-hand side β belongs to (V∪Σ)*, including the possibility of ε. All four memberships hold.

Why each choice is right or wrong

A - Correct: A variable is also an element of V∪Σ.

B - Correct: The left side of a CFG rule is one variable.

C - Correct: That variable is a length-one string in (V∪Σ)*.

D - Correct: The right side is a finite string over variables and terminals.

Primary note proof

Study-note section AUT16

> In a context-free grammar (CFG) each production has one variable on the left, A→α with α∈(V∪Σ)*. The left side therefore also belongs to V∪Σ and its string closure; alternatives stating these weaker memberships can all be true. A sentential form is any string derived from S, including terminal-only sentences and S itself.

Study-note section AUT16

> A leftmost derivation always replaces the leftmost variable; a rightmost one replaces the rightmost variable. This is not scanning the completed input in opposite directions. A complete parse tree has root S, internal variable nodes expanded by productions and terminal leaves, with ε leaves when that convention is used. Read the leaves left-to-right for the yielded word. The whole tree represents derivation structure; a path in a derivation graph is a different object.

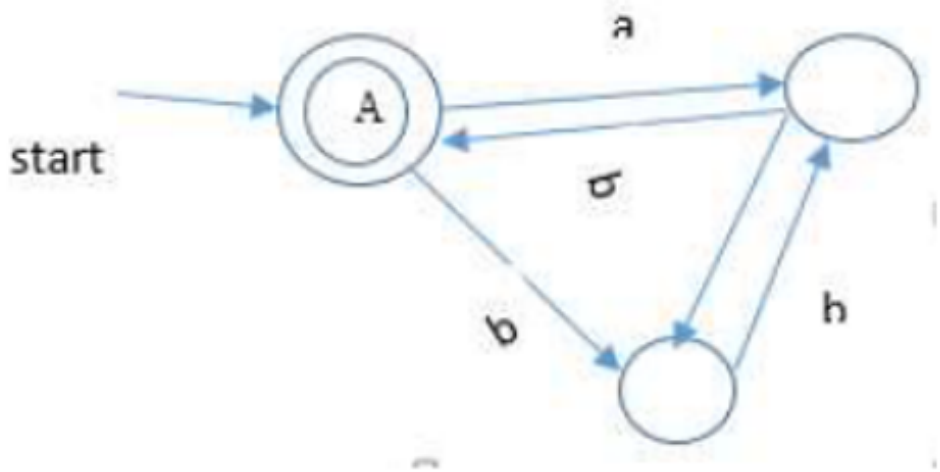
Context-free grammars have a start symbol and set of terminals, non-terminals, and production rule components.



Question sources

Computer Science model exam · Question 64

University of Gondar model exam · Question 64

Question 16 | Q00334

For the diagram, name the top-right state B and bottom state C. Use A as start and sole accepting state; transitions are A-a→B, A-b→C, B-a→C, B-b→A, C-b→B. Unshown transitions reject. Which regular expression denotes its language? Here + means union.

A. a*(a+b)ab(ab+bb+aa*(a+b)ab)*

B. ((a+bb)(ab)*b)*

C. (a+b)ab(ab+bb+aa*(a+b)ab)*

D. a*ab(ab+bb+aa*(a+b)ab)*

Hint

Apply the stated transition, closure or equivalence rule step by step; distinguish a guaranteed bound from a value for one particular machine.

Answer B: ((a+bb)(ab)*b)*

A return to A first reaches B either directly by a or via C by bb. While at B, the machine may make any number of ab detours through C. It returns to A by b. Thus one return has form (a+bb)(ab)*b, and any number of returns gives ((a+bb)(ab)*b)*. This also accepts ε and ab, as the accepting start and shortest return require.

Why each choice is right or wrong

A - Incorrect: Its mandatory prefix excludes ε, which must be accepted.

B - Correct: Its starred blocks describe exactly all excursions from A back to A.

C - Incorrect: Its mandatory prefix excludes the empty word.

D - Incorrect: Its mandatory ab suffix excludes ε.

Primary note proof

Study-note section AUT12

> Classical expressions use ∅, ε, symbols, union, concatenation and star. A union B is written A|B or A+B; postfix r^+ means one-or-more r repetitions and is a different use of +.

Study-note section AUT13

> For automaton→RE, eliminate a state k while updating edge i→j as $r_{ij} \mid r_{ik}(r_{kk})^*r_{kj}$; include new start/final nodes where required.

Study-note section AUT06

> Start at q_0 and consume the entire input. Accept iff the ending state is in F; visiting an accepting state earlier is insufficient. ε is accepted exactly when $q_0 \in F$.

Computer Science model exam · Question 65

University of Gondar model exam · Question 65

Question 17 | Q00634

Which one of the following regular expressions gives zero or one?

A. r + =rr*

B. r* = r+ | ε

C. r? =r|ε

D. All

Hint

Apply the stated transition, closure or equivalence rule step by step; distinguish a guaranteed bound from a value for one particular machine.

Answer C: The optional expression r? = r|ε.

AUT12 defines r? as r|ε: one occurrence of a word matching r or no occurrence. Positive closure requires one or more occurrences; star permits arbitrarily many including zero. Their identities may be valid, but only the optional expression denotes the requested zero-or-one repetition count, so the aggregate is false.

Why each choice is right or wrong

A - Incorrect: Positive closure rr* requires at least one repetition and also allows more than one.

B - Incorrect: Star allows zero or arbitrarily many repetitions, not just zero or one.

C - Correct: The union with ε makes r optional: either one r match or none.

D - Incorrect: The positive and Kleene closures do not impose the zero-or-one bound.

Primary note proof

Study-note section AUT12

> Classical expressions use ∅, ε, symbols, union, concatenation and star. A union B is written A|B or A+B; postfix r^+ means one-or-more r repetitions and is a different use of +. Parenthesize when conventions might clash. Star binds tightest, concatenation next, union last. r? means r|ε; r^+=rr*.

Study-note section AUT12

> (a|b)*a denotes words ending a; 0*10* denotes exactly one 1; a*(b|c) gives zero-or-more a's then exactly one b or c, so aab belongs but aaa and aaabc do not.

Question sources

Computer Science model exam · 2015 · Question 103

Question 18 | Q00751

If a grammar produces more than one leftmost derivation for a sentence, it is called as:

A. Ambiguous grammar

B. Perfect grammar

C. Associative grammar

D. Precedence

Hint

Compare production restrictions, memory access and language-family containments. Distinguish an exact characterization from an included subclass.

Answer A: Ambiguous grammar

Each parse tree determines a unique leftmost sequence of expansions. Two distinct leftmost derivations of the same sentence therefore encode distinct parse trees and witness ambiguity under this definition.

Why each choice is right or wrong

A - Correct: Two leftmost derivations of one sentence witness two parse trees.

B - Incorrect: Perfect is not the relevant defined grammar property.

C - Incorrect: Associativity is an operator grouping convention, not this definition.

D - Incorrect: Precedence concerns ordering of operators; it does not name multiple leftmost derivations.

Primary note proof

Study-note section AUT18

> A CFG is ambiguous when some word has two distinct parse trees, equivalently two different leftmost derivations. Different expansion orders that give the same tree do not prove ambiguity.

Study-note section AUT18

> Separate precedence levels: E→E+T|T, T→T*F|F, F→id|(E). Multiplication binds inside T before addition at E, and left recursion encodes left association. Uniqueness follows by the top-level last operator split and induction. S→SS|ε is already ambiguous for ε. S→A|B is ambiguous if A→ab and B→abB|ε both produce ab. Ambiguous grammar and inherently ambiguous language differ: another grammar may remove ambiguity.

Question sources

Computer Science model exam 2 · Question 92

Question 19 | Q00752

The intersection of a context-free language and a regular language is _____

A. context-free

B. neither context-free nor regular.

C. regular but not context-free

D. both regular and context-free.

Hint

Compare production restrictions, memory access and language-family containments. Distinguish an exact characterization from an included subclass.

Answer A: Always context-free, but not necessarily regular.

AUT23 constructs the intersection by combining PDA control with DFA control and retaining the original stack. It therefore guarantees a CFL. Regularity does not follow: intersecting $\{a^n b^n\}$ with a*b* gives the same nonregular CFL. Some individual intersections can be regular, but the question's general result cannot assert that extra property.

Why each choice is right or wrong

A - Correct: Closure under intersection with a regular language guarantees that the result is context-free.

B - Incorrect: The stated closure theorem directly rules out a result outside the context-free family.

C - Incorrect: Every regular language is context-free, so regular but not context-free is impossible.

D - Incorrect: Some intersections are regular, but the counterexample in AUT23 shows regularity is not guaranteed.

Primary note proof

Study-note section AUT23

CFLs are closed under union, concatenation, star, reversal and intersection with a regular language. For CFL∩REG combine PDA control with DFA control, using the original stack; each consumed symbol updates both states, while an ε move leaves the DFA state unchanged. The result is guaranteed context-free, not necessarily regular: intersect a^nb^n with a*b* to get a^nb^n.

A language is said to be a Regular language if and only if some finite state machine recognizes it

Question sources

Computer Science model exam 2 · Question 93

Question 20 | Q00753

Which one of the following is not part of Turing machine?

A. Finite control

B. Input

C. Tape

D. Head

Hint

Compare production restrictions, memory access and language-family containments. Distinguish an exact characterization from an included subclass.

Answer B: Input is data, not a separate hardware component.

AUT27 lists finite control, a read/write head and an unbounded tape as the standard TM architecture. Input is initial tape content rather than a separate hardware organ. Thus input is the distinction requested by not part, under that structural reading; the other three options are actual machine components, not merely values processed by them.

Why each choice is right or wrong

A - Incorrect: Finite control is explicitly part of the standard machine's architecture.

B - Correct: Input is initial tape content rather than a separate machine hardware component.

C - Incorrect: The unbounded tape is the standard TM's storage component.

D - Incorrect: The read/write head is an explicit machine component used for tape access.

Primary note proof

Study-note section AUT27

> For a Turing machine (TM), use $M=(Q,\Sigma,\Gamma,\delta,q_0,q\text{accept},q\text{reject})$, with finite state/tape alphabets, $\Sigma\subseteq\Gamma$ and blank $\square\in\Gamma-\Sigma$. The blank symbol belongs to the tape alphabet Γ, not the input alphabet Σ. The standard machine has finite control, a read/write head and an unbounded tape. Input is initial tape content, not a separate hardware organ; no separate stack is required.

Question sources

Computer Science model exam 2 · Question 94

Question 21 | Q00891

Which automaton is powerful enough to recognize the language $L = \{a^n b^n c^n \mid n > 1\}$, where n is an integer?

A. DFA

B. Linear Bounded Automaton (LBA)

C. NFA

D. Pushdown Automaton (PDA)

Hint

Respect the quantifier order and length constraints. A valid nonmembership argument must address every allowed decomposition, not one convenient split.

Answer B: Linear Bounded Automaton (LBA).

The language contains equal numbers of a, b and c in that order. This family is context-sensitive but not context-free. Restricting n to integers greater than 1 does not remove the unbounded equal-count requirement. An LBA checks the order and repeatedly marks one a, one b and one c, using only the input-sized tape region. B therefore recognizes the stated language; DFA, NFA and single-stack PDA cannot.

Why each choice is right or wrong

A - Incorrect: A DFA recognizes regular languages; this three-equal-count language is not even context-free.

B - Correct: An LBA can mark matching a, b and c symbols while staying within space proportional to the input length.

C - Incorrect: An NFA recognizes exactly the regular languages, so nondeterminism does not give it the memory needed here.

D - Incorrect: A standard single-stack PDA recognizes context-free languages; the stated three-equal-count language is not context-free.

Primary note proof

Study-note section AUT25

> A context-sensitive rule $\alpha A\beta \to \alpha\gamma\beta$ replaces A in context, with γ nonempty. Equivalently, noncontracting grammar presentations preserve/increase total length, with the isolated ε exception. The condition is on the complete sides, not an unrelated comparison $|\beta| \geq |\alpha|$.

Study-note section AUT25

> A linear bounded automaton (LBA) is a TM with O(n) tape cells on length-n input; the standard CSL characterization uses nondeterministic LBAs. For $a^n b^n c^n$ first verify a*b*c* order, repeatedly mark one unmarked a, b and c, and reject missing/excess symbols.

Study-note section AUT25

> Thus every CSL is decidable.

Study-note section AUT24

> If L is context-free, some p ensures each sufficiently long $s \in L$ has $s=uvxyz$ with $|vxy| \leq p$, $|vy| \geq 1$ and $uv^i xy^i z \in L$ for every $i \geq 0$. The two pieces v and y are pumped together; either may be empty, not both. A non-CFL proof must defeat every allowed decomposition.

Study-note section AUT24

> For $s=a^p b^p c^p$, the window vxy cannot contain both an a and a c. Pumping affects at most two blocks and at least one count. Use i=0 or 2: the unaffected third block retains p while another count changes, or symbol order breaks. Hence $a^n b^n c^n$ is not CFL.

Question sources

Computer Science Exit Exam · 2018 · Question 4

Question 22 | Q00917

A recognizer reads input once from left to right and stores all its working memory in a fixed finite set of states. Which universal statement correctly explains why its language can also be described by a context-free grammar?

A. Every regular language is context-free.

B. Every context-free language is regular.

C. Every context-sensitive language is regular.

D. Every recursively enumerable language is recursive

Hint

Check whether the required procedure must halt on every input, and distinguish solving a task from recognizing its yes-instances.

Answer A: Every regular language is context-free.

A recognizer whose memory is a fixed finite state has regular-language power. Every regular language is context-free, so a context-free grammar can also describe its language. The reverse inclusion fails: equal-count matching such as {0^n1^n} is context-free but not regular. Context-sensitive languages need not be regular either. Finally, the halting language separates recognizable from decidable languages, so not every recursively enumerable language is recursive.

Why each choice is right or wrong

A - Correct: Every regular language has an equivalent context-free grammar.

B - Incorrect: {0^n1^n : n≥0} is context-free but not regular.

C - Incorrect: The context-sensitive family includes nonregular languages, including equal-count matching languages.

D - Incorrect: The halting language is recursively enumerable but undecidable, disproving this converse.

Primary note proof

Study-note section AUT05

> Type 3 regular grammars correspond to finite automata; type 2 CFGs to nondeterministic PDAs; type 1 context-sensitive/noncontracting grammars to nondeterministic LBAs; type 0 unrestricted grammars to Turing recognizers.

Study-note section AUT05

> Use REG ⊊ CFL ⊊ CSL ⊊ DECIDABLE ⊊ RE, under the usual convention allowing S→ε with S absent from right sides when needed.

Study-note section AUT29

A decider halts on every input and accepts exactly its language; these languages are recursive/decidable. A recognizer must halt and accept every member, but on a nonmember may halt-reject or loop. Its languages are recursively enumerable (RE), Turing-recognizable or semidecidable. Looping is nonacceptance, not a rejecting halt. An undecidable language may still have a recognizer.

Study-note section AUT29

Every decidable language is RE, and the containment is strict.

Study-note section AUT06

Finite automata have finite memory encoded by states, not no state or no ability to remember any history.

Computer Science Exit Exam · 2018 · Question 30

Question 23 | Q00934

In the CNF-first route for converting a CFG into Greibach normal form, which initial normalization is performed before the later ordering, substitution and left-recursion work?

A. Convert the grammar into CNF

B. If any production rule in the grammar is not in GNF form, convert it.

C. .
Convert the grammar into GNF

D. If the grammar exists left recursion, eliminate it.

Hint

Compare production restrictions, memory access and language-family containments. Distinguish an exact characterization from an included subclass.

Answer A: Convert the grammar into CNF

The specified route begins by putting the grammar into Chomsky normal form. Later ordering and substitution arrange terminal-leading productions and eliminate left recursion as required for Greibach form. CNF is an intermediate normalization in this particular route, not a universal prerequisite for every GNF construction. The other conversion choices state the goal broadly rather than identify this route's initial normalization.

Why each choice is right or wrong

A - Correct: CNF conversion is the initial normalization in the selected route.

B - Incorrect: Converting arbitrary offending rules does not identify the route's initial normalization.

C - Incorrect: GNF conversion is the overall goal, not this preliminary operation.

D - Incorrect: Left recursion must be handled later in this chosen route.

Primary note proof

Study-note section AUT20

> Some algorithms first convert to CNF; this is a method choice, not a universally mandatory first step.

Question 24 | Q00953

Among the listed grammar families in the Chomsky hierarchy, which has the greatest expressive power?

A. Context-free

B. Context-sensitive

C. Unrestricted (Type 0)

D. Regular

Hint

Compare production restrictions, memory access and language-family containments. Distinguish an exact characterization from an included subclass.

Answer C: Unrestricted (Type 0)

Unrestricted, Type 0 grammars generate the recursively enumerable languages, the family recognized by Turing machines. Context-sensitive, context-free and regular grammars generate successively smaller families. Asking for the most expressive listed family makes this an exact hierarchy comparison. It does not claim that every conceivable set of strings is recursively enumerable or that weaker grammars cannot generate complete languages of their own.

Why each choice is right or wrong

A - Incorrect: Context-free grammars generate a smaller family than RE.

B - Incorrect: Context-sensitive grammars generate a smaller family than RE.

C - Correct: Unrestricted grammars generate exactly RE.

D - Incorrect: Regular grammars generate the least expressive listed family.

Primary note proof

Study-note section AUT05

> Type 3 regular grammars correspond to finite automata; type 2 CFGs to nondeterministic PDAs; type 1 context-sensitive/noncontracting grammars to nondeterministic LBAs; type 0 unrestricted grammars to Turing recognizers.

Question 25 | Q00977

ou have given that Grammar G1 -({S, A, B}, {a, b}, S, {S - AB, A- a, B-> b}).
Which one is terminal symbol in the give?

A. b

B. S

C. .
S- AB,A--a,B-b

D. S,A,B

Hint

Distinguish symbols, finite strings, their lengths and sets of strings. Apply the operation to its stated operands, including empty cases.

Answer A: b

The given terminal alphabet is {a,b}, so b is a terminal. S, A and B are variables, and the arrow expressions are productions. These categories match the four-component CFG definition.

Why each choice is right or wrong

A - Correct: b belongs to the given terminal alphabet.

B - Incorrect: S belongs to the variables and is the start symbol.

C - Incorrect: This is a set/list of productions, not one terminal symbol.

D - Incorrect: These are the variables, not the terminals.

Primary note proof

Study-note section AUT04

> Write G=(V,Σ,P,S): finite variables V, terminals Σ disjoint from V, productions P and start variable S∈V. A production replaces its left side by its right side. The language is L(G)={w∈Σ*:S⇒*w}. A recognizer processes a word and accepts exactly the language members. Grammars generate languages; automata recognize languages, not grammars.

Study-note section AUT04

> Two grammars are equivalent when their generated languages are equal, regardless of rule counts or variable names. One common word, equal alphabets or one-way inclusion is insufficient.

Computer Science Exit Exam · 2018 · Question 90

Question 26 | Q00981

Over $\Sigma=\{a,b\}$, classify $L=\{ww^R \mid w \in \Sigma^*\}$, the unmarked even-length palindrome language, by the most specific listed description.

A. Regular

B. Non-deterministic CFL but not deterministic

C. Deterministic context-free

D. Context-sensitive but not context-free

Hint

Compare production restrictions, memory access and language-family containments. Distinguish an exact characterization from an included subclass.

Answer B: Non-deterministic CFL but not deterministic

An NPDA can push a guessed first half, choose its midpoint nondeterministically, and pop matching symbols while reading the reverse half. This binary unmarked palindrome language is not deterministic context-free. It is context-free and nonregular. With exponent R denoting reversal, ww^R is the stated palindrome language; the forward-copy language ww would instead fall outside CFL.

Why each choice is right or wrong

A - Incorrect: Binary unmarked even palindromes are nonregular.

B - Correct: An NPDA recognizes them, but a DPDA cannot recognize this unmarked binary language.

C - Incorrect: The missing center marker prevents deterministic context-free recognition.

D - Incorrect: The language has a CFG, so the claim that it is not context-free is false.

Primary note proof

Study-note section AUT22

> For even palindromes ww^R over {a,b}, push the first half, nondeterministically guess its midpoint, then pop matching symbols. No center marker makes that language context-free but not deterministic context-free. With a marker wcw^R the switch point is visible and a DPDA suffices. Unary even palindromes are merely even-length words and regular. A PDA cannot compare two arbitrary halves in the same forward order: {ww:w∈{a,b}*} is the copy language, not the palindrome language.

Module passages - related reading

Computer Science Exit Exam · 2018 · Question 94

Question 27 | Q01185

Which of the following statements is false about classes of language in automaton theory?

A. Context-free language is the subset of context-sensitive language

B. Regular language is the subset of context-sensitive language

C. Recursively enumerable language is the superset of regular language

D. Context-sensitive language is a subset of context-free language

Hint

Compare production restrictions, memory access and language-family containments. Distinguish an exact characterization from an included subclass.

Answer D: Context-sensitive language is a subset of context-free language

The inspected diagram nests regular inside context-free inside context-sensitive inside recursively enumerable. Thus A, B and C follow the depicted inclusions, while D reverses the middle inclusion. This uses the traditional hierarchy convention, which suppresses technical empty-word qualifications.

Why each choice is right or wrong

A - Incorrect: Context-free is drawn inside context-sensitive.

B - Incorrect: Regular is inside context-free and hence inside context-sensitive.

C - Incorrect: RE is the outer class surrounding regular.

D - Correct: Reverses the diagram: context-sensitive is not contained in the smaller CFL class.

Primary note proof

Study-note section AUT05

> Type 3 regular grammars correspond to finite automata; type 2 CFGs to nondeterministic PDAs; type 1 context-sensitive/noncontracting grammars to nondeterministic LBAs; type 0 unrestricted grammars to Turing recognizers.

Suppose you are asked to construct a DFA for the strings ending with an 'n'
length substring. How many minimal states may the DFA require?

A. n

B. n+1

C. n+2

D. n*2

Hint

Read the transition domain and acceptance condition carefully. Track which inputs are consumed and evaluate the whole word under the stated model.

Answer B: n+1 states for a fixed valid suffix word.

AUT08 gives n+1 states for a valid fixed suffix of length n: states remember the longest suffix of the consumed input that is a prefix of the target. Distinguishable prefixes establish the lower bound. The answer presumes the target word uses the declared alphabet; no extra rejecting sink is needed for a suffix matcher.

Why each choice is right or wrong

A - Incorrect: n states omit one of the n+1 necessary prefix-match stages.

B - Correct: The note gives one state for each matched-prefix length from zero through n.

C - Incorrect: An extra rejecting sink is unnecessary because later input may always form the required suffix.

D - Incorrect: Doubling n is not the general suffix-matching state bound; accidental numeric equality does not define it.

Primary note proof

Study-note section AUT08

> For a fixed valid word w of length n, a DFA for strings ending in w needs n+1 states representing the longest consumed suffix that is a prefix of w. Overlapping prefixes determine fallback transitions. Distinct prefixes are distinguishable by suitable continuations, proving the lower bound; do not add an unnecessary rejecting sink.

Study-note section AUT08

> For strings starting with w, a complete DFA ordinarily has n matched-prefix stages, an accepting continuation state and a rejecting sink: n+2 when n≥1 and the alphabet allows mismatches.

Question sources

Computer Science model exam 2 · Question 27

Question 29 | Q01223

Under the standard total-DFA model, which statements about finite automata are NOT correct? Select all that apply.

A. Finite automaton accept a string or word by final state

B. Finite Automaton has at least one final state

C. Finite Automaton has at least one initial state

D. Deterministic Finite Automaton has a single transition.

Hint

Read the transition domain and acceptance condition carefully. Track which inputs are consumed and evaluate the whole word under the stated model.

Answer B, D: Finite Automaton has at least one final state; Deterministic Finite Automaton has a single transition.

A DFA requires a designated start state and accepts when the state after the complete input is accepting. Its accepting set may nevertheless be empty, producing the empty language, so B is false. Determinism requires one successor for each state/symbol pair, not one transition in the entire automaton, making D false as well. The two remaining statements describe standard acceptance and initialization.

Why each choice is right or wrong

A - Incorrect: Final-state acceptance after all input is consumed is correct, so A is not selected.

B - Correct: The accepting set can be empty, making the asserted minimum of one false.

C - Incorrect: A designated initial state is required, so C is not selected.

D - Correct: One successor per state/symbol pair does not mean one transition in the entire machine.

Primary note proof

Study-note section AUT06

> A deterministic finite automaton (DFA) is $M=(Q,\Sigma,\delta,q_0,F)$, with finite nonempty Q, start $q_0 \in Q$, accepting set $F \subseteq Q$ and total $\delta: Q \times \Sigma \to Q$. Exactly one next state is specified per state/symbol pair; this does not mean the whole machine has one transition. F may be empty, recognizing $\varnothing$.

Study-note section AUT06

> Start at q_0 and consume the entire input. Accept iff the ending state is in F; visiting an accepting state earlier is insufficient. ε is accepted exactly when $q_0 \in F$. A nonaccepting sink loops on every symbol and cannot reach acceptance; it still finishes after finite input. Finite automata have finite memory encoded by states, not no state or no ability to remember any history.

Computer Science model exam 2 · Question 44

Question 30 | Q01253

Finite automaton recognizes:

A. Any class of language.

B. Context-free language.

C. Context-sensitive languages.

D. Regular languages.

Hint

Read the transition domain and acceptance condition carefully. Track which inputs are consumed and evaluate the whole word under the stated model.

Answer D: Regular languages.

Regular languages are exactly those recognized by finite-state automata. This is an exact language-family question: some CFLs and context-sensitive languages happen to be regular, but the whole larger families are beyond finite automata.

Why each choice is right or wrong

A - Incorrect: The hierarchy shows larger families outside finite-state power.

B - Incorrect: All CFLs is too broad, though regular examples are CFLs.

C - Incorrect: All context-sensitive languages is too broad.

D - Correct: Exactly matches the finite-state/regular equivalence.

Primary note proof

Study-note section AUT06

A deterministic finite automaton (DFA) is $M=(Q,\Sigma,\delta,q_0,F)$, with finite nonempty Q, start $q_0 \in Q$, accepting set $F \subseteq Q$ and total $\delta: Q \times \Sigma \to Q$. Exactly one next state is specified per state/symbol pair; this does not mean the whole machine has one transition. F may be empty, recognizing ∅.

Study-note section AUT06

Question sources

Computer Science model exam 2 · Question 74

Question 31 | Q01273

Which one of the following grammars is unambiguous?

A. E → I; E → E + E; E → E * E; E → (E); I → ε | 0 | 1 | 2 | ... | 9

B. S → aSb | SS; S → ε

C. E → E + T / T; T → T x F / F; F → id

D. S → A / B; A → aAb / ab; B → abB / ∈

Hint

Compare production restrictions, memory access and language-family containments. Distinguish an exact characterization from an included subclass.

Answer C: E → E + T / T; T → T x F / F; F → id

In C, F generates id, T is a nonempty sequence of Fs separated by ×, and E a nonempty sequence of Ts separated by +. The last + uniquely determines the top E→E+T split; each T is uniquely split at its last ×. Induction on operator count gives a unique parse. A allows different groupings of id-like operands through E+E and E*E. B already has two trees for ε: S→ε and S→SS→εε. D is also ambiguous: ab is generated by S→A→ab and S→B→abB→ab.

Why each choice is right or wrong

A - Incorrect: For 1+1*1, E→E+E permits a top + parse while E→E*E permits a top * parse; I→1 supplies the operands. These are different trees for the same string (PDF page 8).

B - Incorrect: ε has both a direct leaf expansion and an SS expansion with two empty children.

C - Correct: Operator levels fix the unique split at each stage, giving a unique tree.

D - Incorrect: ab is obtained via either A or B, yielding distinct root expansions.

Primary note proof

Study-note section AUT18

> A CFG is ambiguous when some word has two distinct parse trees, equivalently two different leftmost derivations. Different expansion orders that give the same tree do not prove ambiguity.

Study-note section AUT18

> Separate precedence levels: E→E+T|T, T→T*F|F, F→id|(E). Multiplication binds inside T before addition at E, and left recursion encodes left association. Uniqueness follows by the top-level last operator split and induction. S→SS|ε is already ambiguous for ε. S→A|B is ambiguous if A→ab and B→abB|ε both produce ab. Ambiguous grammar and inherently ambiguous language differ: another grammar may remove ambiguity.

Question sources

Computer Science model exam 2 · Question 94

Question 32 | Q01418

Which language family is recognized exactly by nondeterministic pushdown automata?

A. Type 0 language

B. Type 1 language

C. Type 2 language

D. Type 3 language

Hint

Compare production restrictions, memory access and language-family containments. Distinguish an exact characterization from an included subclass.

Answer C: Type 2 language

Nondeterministic pushdown automata recognize exactly the context-free languages, corresponding to Type 2 grammars. Regular languages are included in that family, but Type 3 is too narrow to describe all PDA languages. Context-sensitive and unrestricted languages include non-context-free languages that an ordinary single-stack PDA cannot recognize. The exact-family wording therefore makes Type 2 the unique classification.

Why each choice is right or wrong

A - Incorrect: Type 0 includes languages beyond PDA recognition.

B - Incorrect: Type 1 includes non-context-free languages beyond PDA recognition.

C - Correct: Type 2 is exactly the context-free family characterized by NPDAs.

D - Incorrect: Type 3 covers only the regular subfamily of PDA languages.

Primary note proof

Study-note section AUT05

> Type 3 regular grammars correspond to finite automata; type 2 CFGs to nondeterministic PDAs; type 1 context-sensitive/noncontracting grammars to nondeterministic LBAs; type 0 unrestricted grammars to Turing recognizers.

Study-note section AUT05

Question sources

Compiler Design review questions · Question 26

Question 33 | Q01419

Among context-sensitive, context-free and regular grammar families, which is most expressive under the usual isolated-start ε convention?

A. Context-sensitive grammar

B. Context-free grammar

C. Regular grammar

D. All of these

Hint

Compare production restrictions, memory access and language-family containments. Distinguish an exact characterization from an included subclass.

Answer A: Context-sensitive grammar

The hierarchy places regular languages strictly inside context-free languages and context-free languages strictly inside context-sensitive languages. Context-sensitive grammars are therefore the most expressive of the three named families. Unrestricted grammars would be stronger if included, but the question explicitly limits the comparison. The three named classes are not tied for maximum expressive power, so the aggregate alternative does not apply.

Why each choice is right or wrong

A - Correct: Context-sensitive is the largest of the three compared families.

B - Incorrect: Context-free is strictly below context-sensitive.

C - Incorrect: Regular is strictly below both other named families.

D - Incorrect: The three families are not equally most expressive.

Primary note proof

Study-note section AUT05

> Type 3 regular grammars correspond to finite automata; type 2 CFGs to nondeterministic PDAs; type 1 context-sensitive/noncontracting grammars to nondeterministic LBAs; type 0 unrestricted grammars to Turing recognizers.

Study-note section AUT05

Question sources

Compiler Design review questions · Question 27

Question 34 | Q01426

In which derivation the right-most non-terminal symbol is replaced at each step?

A. Right look ahead

B. Right claim

C. Rightmost

D. Right non-terminal

Hint

Apply the stated transition, closure or equivalence rule step by step; distinguish a guaranteed bound from a value for one particular machine.

Answer C: Rightmost

At every derivation step choose the rightmost remaining variable and replace it by a production right side. That is a rightmost derivation.

Why each choice is right or wrong

A - Incorrect: Lookahead is not the name of the expansion order.

B - Incorrect: Right claim does not name a derivation method.

C - Correct: Names the specified rightmost expansion rule.

D - Incorrect: Names a symbol position but not the derivation method.

Primary note proof

Study-note section AUT16

In a context-free grammar (CFG) each production has one variable on the left, $A \to \alpha$ with $\alpha \in (V \cup \Sigma)^*$. The left side therefore also belongs to $V \cup \Sigma$ and its string closure; alternatives stating these weaker memberships can all be true. A sentential form is any string derived from S, including terminal-only sentences and S itself.

Study-note section AUT16

A leftmost derivation always replaces the leftmost variable; a rightmost one replaces the rightmost variable. This is not scanning the completed input in opposite directions. A complete parse tree has root S, internal variable nodes expanded by productions and terminal leaves, with ε leaves when that convention is used. Read the leaves left-to-right for the yielded word. The whole tree represents derivation structure; a path in a derivation graph is a different object.

Module passages - related reading

Question sources

Compiler Design review questions · Question 34

Question 35 | Q01427

In which derivation the leftmost non-terminal symbol is replaced at each step?

A. Left recursion

B. Left non-terminal

C. Left pushdown

D. Leftmost

Hint

Apply the stated transition, closure or equivalence rule step by step; distinguish a guaranteed bound from a value for one particular machine.

Answer D: Leftmost

Choose the leftmost variable at each step, rather than arbitrarily choosing any remaining variable. This is precisely leftmost derivation.

Why each choice is right or wrong

A - Incorrect: Left recursion is a form of production, not the choice of variable at each derivation step.

B - Incorrect: A left nonterminal is a location, not the derivation name.

C - Incorrect: Left pushdown is not the defined method.

D - Correct: Matches left-to-right variable expansion.

Primary note proof

Study-note section AUT16

> In a context-free grammar (CFG) each production has one variable on the left, A→α with α∈(V∪Σ)*. The left side therefore also belongs to V∪Σ and its string closure; alternatives stating these weaker memberships can all be true. A sentential form is any string derived from S, including terminal-only sentences and S itself.

Study-note section AUT16

A leftmost derivation always replaces the leftmost variable; a rightmost one replaces the rightmost variable. This is not scanning the completed input in opposite directions. A complete parse tree has root S, internal variable nodes expanded by productions and terminal leaves, with ε leaves when that convention is used. Read the leaves left-to-right for the yielded word. Question sources

Compiler Design review questions · Question 35

Question 36 | Q01429

Which symbol is not related to context-free grammar?

A. End symbol

B. Start symbol

C. Non-terminal symbol

D. Terminal symbol

Hint

Distinguish symbols, finite strings, their lengths and sets of strings. Apply the operation to its stated operands, including empty cases.

Answer A: End symbol

A CFG consists of a start symbol, terminals, nonterminals and productions. A dedicated end symbol is not one of the four CFG components, even though a parser may add an input end marker for a separate purpose.

Why each choice is right or wrong

A - Correct: Not a required CFG component in the four-element definition.

B - Incorrect: The distinguished S is required.

C - Incorrect: Variables/nonterminals form V.

D - Incorrect: The alphabet Σ supplies terminals.

Primary note proof

Study-note section AUT04

Write G=(V,Σ,P,S): finite variables V, terminals Σ disjoint from V, productions P and start variable S∈V. A production replaces its left side by its right side. The language is L(G)={w∈Σ*:S⇒*w}. A recognizer processes a word and accepts exactly the language members. Grammars generate languages; automata recognize languages, not grammars.

Study-note section AUT04

Two grammars are equivalent when their generated languages are equal, regardless of rule counts or variable names. One common word, equal alphabets or one-way inclusion is insufficient.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Automata and Complexity Theory module | PDF page 8 | lines 22-23

Context-free grammars have a start symbol and set of terminals, non-terminals, and production rule components.

Compiler Design review questions · Question 37

Question 37 | Q01432

Which of the following tree is the pictorial identification of the derivation?

A. The oct tree

B. The parse tree

C. The binary tree

D. None of the above

Hint

Apply the stated transition, closure or equivalence rule step by step; distinguish a guaranteed bound from a value for one particular machine.

Answer B: The parse tree

A parse/derivation tree labels nodes with grammar symbols and uses edges to show applications of productions. That is the pictorial representation asked for; it need not be a binary tree because productions may have arbitrary finite right sides.

Why each choice is right or wrong

A - Incorrect: An octree is not the grammar representation defined here.

B - Correct: A parse tree is this graphical representation.

C - Incorrect: Production right sides need not have two children, so binary tree is not the general answer.

D - Incorrect: The parse-tree option already supplies the defined representation.

Primary note proof

Study-note section AUT16

> In a context-free grammar (CFG) each production has one variable on the left, A→α with α∈(V∪Σ)*. The left side therefore also belongs to V∪Σ and its string closure; alternatives stating these weaker memberships can all be true. Question sources

Compiler Design review questions · Question 40

Question 38 | Q01435

Which grammar forms are guaranteed to have an equivalent DFA? Select all that apply. Use consistently linear orientations throughout each grammar.

A. Generic grammar (arbitrary unrestricted grammar)

B. Left Linear Grammar

C. Right-linear grammar

D. All of the above

Hint

Track mandatory symbols and factors that may repeat or disappear. Use short test words to check both directions of each proposed language description.

Answer B, C: Left Linear Grammar; Right-linear grammar

Consistently left-linear and consistently right-linear grammars both generate regular languages. Every regular language has an equivalent DFA; a right-linear grammar can first be converted to an NFA and then determinized. Arbitrary unrestricted grammars can generate nonregular languages and have no such guarantee. The all-of-the-above alternative fails because that generic case is not constrained to regular languages.

Why each choice is right or wrong

A - Incorrect: An arbitrary unrestricted grammar need not generate a regular language.

B - Correct: A consistently left-linear grammar generates a regular language.

C - Correct: A consistently right-linear grammar generates a regular language.

D - Incorrect: The generic-grammar case prevents all of the above from being true.

Primary note proof

Study-note section AUT14

> Right-linear rules have form A→aB, A→a or permitted ε rules; left-linear rules put the single variable at the opposite end, A→Ba. Both consistent orientations generate REG; arbitrarily mixing them can generate nonregular languages, for example S→aA|ε, A→Sb generates $a^n b^n$. A CFG rule A→aBA is legal but not regular-grammar form.

Study-note section AUT14

> Regular languages are closed under union, concatenation, star, reversal, intersection, difference and complement.

Question sources

Compiler Design review questions · Question 43

Question 39 | Q01437

Classify FORTRAN's computational power under an idealized model with ordinary loops and unbounded indexed read/write storage. Which description is intended, rather than a classification of its token patterns or source syntax?

A. Turing-complete language

B. Context-sensitive language

C. Context-free language

D. Regular language

Hint

Compare production restrictions, memory access and language-family containments. Distinguish an exact characterization from an included subclass.

Answer A: Turing-complete language

Under the stated idealization, indexed writable storage can represent a Turing tape, with an index recording the head position and variables recording the finite control. A loop implements successive read, write, move and state-update steps. This gives the intended Turing-complete computational classification. The other choices classify word-language families rather than naming this general simulation capability; the conclusion depends on the explicit storage model.

Why each choice is right or wrong

A - Correct: Turing-complete describes the specified general computation capability.

B - Incorrect: Context-sensitive classifies formal word languages rather than this simulation capability.

C - Incorrect: Context-free syntax does not itself characterize general computation power.

D - Incorrect: Regular token structure does not describe Turing-machine simulation power.

Primary note proof

Study-note section AUT28

> An off-line TM has a read-only input tape and separate read/write work tape. Multitape, multihead, two-way-infinite-tape and nondeterministic TMs have the same language-recognition power as standard TMs, though simulation costs differ. Two unbounded stacks can simulate a tape. Turing completeness means ability to simulate general TM computation, not polynomial speed or literally using infinitely many cells in a finite run. The Church-Turing thesis connects effective procedures to this formal model; it is not a proved runtime theorem.

Compiler Design review questions · Question 45

Question 40 | Q01451

DFA is an abbreviation of.

A. Non Deterministic Finite set Automata

B. Deterministic Finite Automata

C. Non Deterministic Finite Automata

D. Deterministic Finite set Automata

Hint

Read the transition domain and acceptance condition carefully. Track which inputs are consumed and evaluate the whole word under the stated model.

Answer B: Deterministic Finite Automata

DFA stands for deterministic finite automaton; deterministic specifies a unique next state for a given current state and input.

Why each choice is right or wrong

A - Incorrect: Adds nondeterministic and set, neither in the abbreviation.

B - Correct: This is the exact expansion of the abbreviation.

C - Incorrect: This is NFA, not DFA.

D - Incorrect: Inserts set, which is absent from the expansion.

Primary note proof

Study-note section AUT06

> A deterministic finite automaton (DFA) is $M=(Q,\Sigma,\delta,q_0,F)$, with finite nonempty Q, start $q_0 \in Q$, accepting set $F \subseteq Q$ and total $\delta: Q \times \Sigma \to Q$. Exactly one next state is specified per state/symbol pair; this does not mean the whole machine has one transition. F may be empty, recognizing $\varnothing$.

Study-note section AUT06

> Start at q_0 and consume the entire input. Accept iff the ending state is in F; visiting an accepting state earlier is insufficient. ε is accepted exactly when $q_0 \in F$. A nonaccepting sink loops on every symbol and cannot reach acceptance; it still finishes after finite input. Finite automata have finite memory encoded by states, not no state or no ability to remember any history.

Automata and Complexity Theory module | PDF page 5 | lines 3-5

> DFA refers to deterministic finite automata. Deterministic refers to the uniqueness of the computation. In the DFA, the machine goes to one state only for a particular input character. DFA does not accept the null move.

Question sources

Compiler Design review questions · Question 59

Question 41 | Q01452

NFA is an abbreviation of.

A. Non Deterministic Finite set Automata

B. Deterministic Finite Automata

C. Non Deterministic Finite Automata

D. Deterministic Finite set Automata

Hint

Read the transition domain and acceptance condition carefully. Track which inputs are consumed and evaluate the whole word under the stated model.

Answer C: Non Deterministic Finite Automata

NFA stands for nondeterministic finite automaton; it permits multiple possible next states and null moves.

Why each choice is right or wrong

A - Incorrect: Inserts set, which is absent from the abbreviation.

B - Incorrect: This expands DFA instead.

C - Correct: This is the exact expansion of the abbreviation.

D - Incorrect: This describes a deterministic model and inserts set.

Primary note proof

Study-note section AUT09

> A nondeterministic finite automaton (NFA) permits zero, one or many successors: $\delta:Q\times\Sigma\to P(Q)$. An ε-NFA additionally permits moves without consuming input, using domain $Q\times(\Sigma\cup\{\varepsilon\})$. Some books include ε moves in the term NFA; state the convention. An NFA accepts iff at least one finite path consumes the complete word and finishes in F, including permitted ε moves before/after symbols.

Study-note section AUT09

An NFA is not more expressive than a DFA: both recognize exactly REG. Nondeterminism can make a description smaller. A DFA is a special NFA after interpreting its unique successor as a singleton set.

Module passages - related reading

NFA stands for non-deterministic finite automata.

Question sources

Compiler Design review questions · Question 60

Question 42 | SM0018

Which branch of study deals with whether a problem can be solved at all or not, regardless of the resources required?

A. Computability theory

B. Automata theory

C. Set theory

D. Complexity theory

Hint

Check whether the required procedure must halt on every input, and distinguish solving a task from recognizing its yes-instances.

Answer A: Computability theory

The resource-independent question is whether an algorithm can decide the problem at all. Computability concerns membership algorithms and the limits of what Turing machines compute; computational complexity concerns resource estimates.

Why each choice is right or wrong

A - Correct: Matches existence of an algorithm regardless of cost.

B - Incorrect: Automata concerns abstract machines; computability specifically asks the solvability question.

C - Incorrect: Computability, rather than set theory, studies algorithmic solvability.

D - Incorrect: Complexity concerns time and space resources once solving a problem is considered.

Primary note proof

Study-note section AUT-S01

Computability theory asks whether an effective algorithm can solve a problem at all. For a decision problem, a decision procedure must terminate with the correct yes-or-no result on every input.

Study-note section AUT-S01

Computational complexity theory studies the time and memory resources required to solve problems as functions of encoded input size. Automata theory studies abstract machine models and the languages they recognize; these subjects overlap but ask different questions.

Let a Grammar G = ({S}, {a, b}, S, P), where {S} is set of variables, {a, b} is set of terminal symbols, S is start variable and P is set of productions. Then which one of the following is not an element of the language (L) (L) which is generated from G. Given:
P:S-- aSb,
S-A

A. aabb

B. ab

C. X

D. a

Hint

Apply the stated transition, closure or equivalence rule step by step; distinguish a guaranteed bound from a value for one particular machine.

Answer D: a is not generated.

The image restores S→aSb|λ and option C as λ, not the extracted X. AUT17 derives exactly $a^n b^n$ for n≥0. Two recursions generate aabb, one generates ab, and the base rule gives λ. A lone a has unequal counts and cannot arise. The readable source resolves the OCR damage rather than changing the grammar by assumption.

Why each choice is right or wrong

A - Incorrect: Two recursive pair additions followed by the empty rule derive aabb.

B - Incorrect: One application of S→aSb followed by S→λ derives ab.

C - Incorrect: The image reads lambda here, and the empty base production derives it directly.

D - Correct: A lone a has no matching b and is outside the generated equal-count language.

Primary note proof

Study-note section AUT17

> Use a recursive rule to enforce matched structure and a base rule to stop. S→aSb|ε generates exactly $a^n b^n$ for n≥0: n recursive steps add n a's on the left and n b's on the right. Derive aabb by S⇒aSb⇒aaSbb⇒aabb. For n≥1 replace ε by base ab.

Question 44 | SM0056

Which type of Turing machine has two tapes: one tape read-only and the other read-write?

A. Multi-head Turing machine

B. Off-line Turing machine

C. Non-deterministic Turing machine

D. Multi-dimensional Turing machine

Hint

Compare production restrictions, memory access and language-family containments. Distinguish an exact characterization from an included subclass.

Answer B: An off-line Turing machine.

AUT28 directly defines an off-line TM as having a read-only input tape and a separate read/write work tape. The question gives that architecture. Multiple heads, nondeterministic transition choices and multidimensional tape geometry are independent variants; none defines this input/work separation. The number of tape roles alone does not imply those other variants.

Why each choice is right or wrong

A - Incorrect: Multi-head describes head multiplicity rather than this read-only input and writable work-tape separation.

B - Correct: The off-line model explicitly separates a read-only input tape from a read/write work tape.

C - Incorrect: Nondeterministic describes transition choices, not which tape permits writes.

D - Incorrect: Multidimensional describes tape geometry rather than the two tape roles specified here.

Primary note proof

Study-note section AUT28

> An off-line TM has a read-only input tape and separate read/write work tape. Multitape, multihead, two-way-infinite-tape and nondeterministic TMs have the same language-recognition power as standard TMs, though simulation costs differ. Two unbounded stacks can simulate a tape. Turing completeness means ability to simulate general TM computation, not polynomial speed or literally using infinitely many cells in a finite run. The Church-Turing thesis connects effective procedures to this formal model; it is not a proved runtime theorem.

Question 45 | SM0094

Given input alphabet Σ = {a, b, c, d} and empty string λ, which one of the following is true about Σ*?

A. $\Sigma^* = \Sigma^1 \cup \Sigma^2 \cup \Sigma^3 \cup \Sigma^4$

B. $\Sigma^* = \Sigma^+$

C. $\Sigma^* = \Sigma^+ \cup \{\lambda\}$

D. $\Sigma^* = \{\lambda\}$

Hint

Distinguish symbols, finite strings, their lengths and sets of strings. Apply the operation to its stated operands, including empty cases.

Answer C: $\Sigma^* = \Sigma^+ \cup \{\lambda\}$

Σ* consists of all finite symbol sequences including zero occurrences; Σ+ supplies the positive-length sequences. Since the alphabet has no empty symbol, exactly λ separates the two sets. Thus Σ*=Σ+∪{λ}.

Why each choice is right or wrong

A - Incorrect: Only lengths 1-4 are included; both λ and words of length 5 are missing.

B - Incorrect: Positive closure omits λ, unlike star.

C - Correct: Adds exactly the missing zero-length word.

D - Incorrect: Star also contains a and every other nonempty finite word over the alphabet.

Primary note proof

Study-note section AUT03

Σ^n contains words of exactly n symbols; for $|\Sigma|=k$, $|\Sigma^n|=k^n$, including $\Sigma^0=\{\varepsilon\}$. $\Sigma^*=\bigcup n\geq 0\Sigma^n$ and $\Sigma^+=\bigcup n\geq 1\Sigma^n$. Over a nonempty alphabet, Σ^+ excludes ε and $\Sigma^*=\Sigma^+\cup\{\varepsilon\}$. Σ^2 over {a,b} is {aa,ab,ba,bb}.

Study-note section AUT03

> For an arbitrary language L, $L^*=\cup n\geq 0 L^n$ and $L^+=LL^*$. Unlike alphabet positive closure, L^+ can contain ε when $\varepsilon \in L$. $\varnothing^*=\{\varepsilon\}$, $\varnothing^+=\varnothing$, and $\{\varepsilon\}^*=\{\varepsilon\}$. Union means membership in either set; intersection requires the same word in both, not concatenation. Complement is Σ^*-L and needs a fixed alphabet.

Question 46 | SM0095

Given input alphabet Σ = {a, b, c, d} and empty string λ, which one of the following is equivalent to Σ^0?

A. Σ^+

B. Σ^*

C. Σ

D. $\{\lambda\}$

Hint

Distinguish symbols, finite strings, their lengths and sets of strings. Apply the operation to its stated operands, including empty cases.

Answer D: The singleton set {λ}.

AUT03 defines Σ^n as all words of length n, including $\Sigma^0=\{\varepsilon\}$; AUT01 identifies λ with ε. There is exactly one length-zero word, so its set is {λ}. Σ, positive closure and Kleene closure contain nonempty words for the given nonempty alphabet and therefore are not equal to the zero power.

Why each choice is right or wrong

A - Incorrect: Σ^+ contains positive-length words over the alphabet and excludes the empty word.

B - Incorrect: Σ^* contains every finite-length word, not just the single empty word.

C - Incorrect: Σ contains four alphabet symbols, each forming a length-one word rather than a length-zero word.

D - Correct: λ denotes the empty word, and its singleton set is exactly the alphabet's zero power.

Primary note proof

Study-note section AUT03

> Σ^n contains words of exactly n symbols; for $|\Sigma|=k$, $|\Sigma^n|=k^n$, including $\Sigma^0=\{\varepsilon\}$. $\Sigma^*=\bigcup n\geq 0\Sigma^n$ and $\Sigma^+=\bigcup n\geq 1\Sigma^n$. Over a nonempty alphabet, Σ^+ excludes ε and $\Sigma^*=\Sigma^+\cup\{\varepsilon\}$. Σ^2 over {a,b} is {aa,ab,ba,bb}.

Study-note section AUT03

> For an arbitrary language L, $L^*=\bigcup n\geq 0L^n$ and $L^+=LL^*$. Unlike alphabet positive closure, L^+ can contain ε when $\varepsilon\in L$. $\varnothing^*=\{\varepsilon\}$, $\varnothing^+=\varnothing$, and $\{\varepsilon\}^*=\{\varepsilon\}$. Union means membership in either set; intersection requires the same word in both, not concatenation. Complement is Σ^*-L and needs a fixed alphabet.

Study-note section AUT01

> An alphabet Σ is a finite set of symbols. A word/string is a finite ordered sequence of symbols from Σ; a language is a set of words, $L\subseteq\Sigma^*$. An empty word ε, also written λ, has length zero. The empty language $\varnothing$ contains no words; $\{\varepsilon\}$ contains one.

Question 47 | SM0206

a - b, L state transition in a Turing Machine means,

A. read a, write b and move left

B. delete a, read b and move left

C. write a, read b and move left

D. replace 6 by a and move left

Hint

Compare production restrictions, memory access and language-family containments. Distinguish an exact characterization from an included subclass.

Answer A: read a, write b and move left

In an edge label (a,b,L), the first symbol is the scanned symbol, the second is written in its cell, and L moves the head left. The finite control also moves to the destination state of the arrow.

Why each choice is right or wrong

A - Correct: Exactly follows read, write, move-left order.

B - Incorrect: The scanned symbol is a, and b is written, not read.

C - Incorrect: Reverses reading and writing.

D - Incorrect: Reverses the direction of replacement; the cell changes a to b.

Primary note proof

Study-note section AUT27

> δ(q,a)=(p,b,L) means read a in q, write b, move one cell left and enter p. Accept/reject halting states have no further moves under this convention.

Module passages - related reading

Computer Science Exit Exam · Sene 2016 · Question 2-2

Question 48 | SM0234

Which of the following IS NOT a component of a Turing machine?

A. Read-write head

B. Control Unit

C. Stack

D. Tape

Hint

Compare production restrictions, memory access and language-family containments. Distinguish an exact characterization from an included subclass.

Answer C: Stack

The standard Turing machine uses an unbounded tape, a read/write head, and finite state control. Stack is the distinctive added memory of a PDA and is not a separate structural component required by this standard TM model.

Why each choice is right or wrong

A - Incorrect: Explicitly named as the reading/writing/moving device.

B - Incorrect: Finite states and transition rules provide control.

C - Correct: The standard TM model has tape storage, whereas the PDA description explicitly adds a stack.

D - Incorrect: The tape provides the TM's memory.

Primary note proof

Study-note section AUT27

> For a Turing machine (TM), use $M=(Q,\Sigma,\Gamma,\delta,q_0,q_{accept},q_{reject})$, with finite state/tape alphabets, $\Sigma\subseteq\Gamma$ and blank $\square\in\Gamma-\Sigma$. The blank symbol belongs to the tape alphabet Γ, not the input alphabet Σ. The standard machine has finite control, a read/write head and an unbounded tape. Input is initial tape content, not a separate hardware organ; no separate stack is required.

Question 49 | SM0246

In a grammar, if the production S -> lambda (where S is a non-terminal) exists, such a production is called:

A. Null production

B. Unit production

C. Secondary production

D. Sigma production

Hint

Distinguish symbols, finite strings, their lengths and sets of strings. Apply the operation to its stated operands, including empty cases.

Answer A: A null (epsilon) production.

AUT19 defines a null production as A→ε, while AUT01 identifies λ as another notation for the empty word. Substituting S for A gives the displayed S→λ rule. A unit production instead has one nonterminal on the right; secondary and sigma production are not the defined names for an empty right-hand side.

Why each choice is right or wrong

A - Correct: The right-hand side is the empty word, exactly the definition of a null production.

B - Incorrect: A unit production has one nonterminal on the right, not the empty word.

C - Incorrect: Secondary production is not the defined term for a rule deriving the empty word.

D - Incorrect: Sigma denotes an alphabet conventionally, not the null-production category described here.

Primary note proof

Study-note section AUT19

A null production is A→ε; a unit production is A→B with one variable.

Study-note section AUT01

An alphabet Σ is a finite set of symbols. A word/string is a finite ordered sequence of symbols from Σ; a language is a set of words, L⊆Σ*. An empty word ε, also written λ, has length zero. The empty language ∅ contains no words; {ε} contains one.

Study-note section AUT01

Length counts occurrences, not distinct symbols: |caddba|=6, so $|caddba|^2=36$.

Question 50 | SM0256

Which string from the following is a member of the language represented by the regular expression a*(b+c)?

A. aab

B. bc

C. aaa

D. aaabc

Hint

Apply the stated transition, closure or equivalence rule step by step; distinguish a guaranteed bound from a value for one particular machine.

Answer A: aab

a* permits any number of initial a symbols; (b+c) then contributes exactly one b or c. aab factors as aa followed by b. No further suffix is allowed after that final symbol.

Why each choice is right or wrong

A - Correct: aa is in a*, followed by the permitted b.

B - Incorrect: Contains two symbols from the final alternative; the a* prefix cannot consume b.

C - Incorrect: Lacks the compulsory final b or c.

D - Incorrect: After aa a and b there is an extra c; the expression allows only one final alternative.

Primary note proof

Study-note section AUT12

> Classical expressions use ∅, ε, symbols, union, concatenation and star. A union B is written A|B or A+B; postfix r^+ means one-or-more r repetitions and is a different use of +. Parenthesize when conventions might clash. Star binds tightest, concatenation next, union last. r? means r|ε; r^+=rr*.

Study-note section AUT12

> (a|b)*a denotes words ending a; 0*10* denotes exactly one 1; a*(b|c) gives zero-or-more a's then exactly one b or c, so aab belongs but aaa and aaabc do not.

Question 51 | SM0303

Which class of languages is most suited to be represented by pushdown automata?

A. Context-free language

B. Regular language

C. Recursively enumerable language

D. Unrestricted language

Hint

Compare production restrictions, memory access and language-family containments. Distinguish an exact characterization from an included subclass.

Answer A: Context-free language

PDAs and CFGs characterize the same family of context-free languages. Regular languages are included, but the question most suited asks for the full family rather than a subclass.

Why each choice is right or wrong

A - Correct: Exactly the class characterized by PDAs.

B - Incorrect: A smaller included family, already recognizable by finite automata.

C - Incorrect: The hierarchy places RE at the larger Turing machine level.

D - Incorrect: Unrestricted languages are not the PDA/CFG class.

Primary note proof

Study-note section AUT21

> A nondeterministic pushdown automaton (PDA) adds a stack to finite control: $(Q,\Sigma,\Gamma,\delta,q_0,Z_0,F)$. Its transition relation maps (state,input symbol or ε,stack top) to possible (new state,replacement stack string) pairs. Fix which end denotes the top before tracing. Replacing X by X leaves the stack unchanged; ε input means consume no symbol, while replacing X by ε pops it. These are different uses of ε.

Study-note section AUT05

> Type 3 regular grammars correspond to finite automata; type 2 CFGs to nondeterministic PDAs; type 1 context-sensitive/noncontracting grammars to nondeterministic LBAs; type 0 unrestricted grammars to Turing recognizers.

Study-note section AUT05

> Use $REG \subsetneq CFL \subsetneq CSL \subsetneq DECIDABLE \subsetneq RE$, under the usual convention allowing $S \to \varepsilon$ with S absent from right sides when needed.

Question 52 | AM0744

Which statement correctly describes the generation and recognition roles of formal grammars and automata?

A. Formal grammars generate formal languages, and automata recognize those languages.

B. Formal languages recognize automata, which are generated by formal grammars.

C. Formal grammars generate automata, which recognize formal languages.

D. Formal grammars recognize formal languages, which generate automata.

Hint

Distinguish symbols, finite strings, their lengths and sets of strings. Apply the operation to its stated operands, including empty cases.

Answer A: Formal grammars generate formal languages, and automata recognize those languages.

A formal grammar generates terminal words, collectively its language. An automaton processes words and accepts exactly those in the language it recognizes. Thus languages are generated by grammars and recognized by automata. The relationship concerns the same set of strings, not a claim that automata recognize grammar descriptions or that languages themselves perform machine operations. Option A states those roles explicitly.

Why each choice is right or wrong

A - Correct: It correctly assigns language generation to grammars and recognition to automata.

B - Incorrect: Languages do not perform recognition or generate machines.

C - Incorrect: Grammars generate word languages rather than automata in this relationship.

D - Incorrect: Grammars generate languages; languages do not generate automata.

Primary note proof

Study-note section AUT04

> Write G=(V,Σ,P,S): finite variables V, terminals Σ disjoint from V, productions P and start variable S∈V. A production replaces its left side by its right side. The language is L(G)={w∈Σ*:S⇒*w}. A recognizer processes a word and accepts exactly the language members. Grammars generate languages; automata recognize languages, not grammars.

Study-note section AUT04

> Two grammars are equivalent when their generated languages are equal, regardless of rule counts or variable names. One common word, equal alphabets or one-way inclusion is insufficient.

Question sources

Computer Science MCQ practice collection · Question 744

Question 53 | AM0745

Which offered item is a precisely specified formal language, rather than a natural-language name?

A. English

B. Spanish

C. L={w∈{a,b}* | w ends in a}, denoted by (a|b)*a

D. French

Hint

Apply the stated transition, closure or equivalence rule step by step; distinguish a guaranteed bound from a value for one particular machine.

Answer C: L={w∈{a,b}* | w ends in a}, denoted by (a|b)*a

A formal language is a set of strings with precisely defined membership. Option C gives the language of all words over {a,b} that end in a, denoted by (a|b)*a. English, Spanish and French are natural-language names in this comparison. A regular expression alone names a specification notation; explicitly naming its denoted word set provides the actual language example.

Why each choice is right or wrong

A - Incorrect: English is a natural-language name.

B - Incorrect: Spanish is a natural-language name.

C - Correct: This specifies a set of words over a fixed alphabet with an exact ending condition.

D - Incorrect: French is a natural-language name.

Primary note proof

Study-note section AUT04

Write G=(V,Σ,P,S): finite variables V, terminals Σ disjoint from V, productions P and start variable S∈V. A production replaces its left side by its right side. The language is L(G)={w∈Σ*:S⇒*w}. A

recognizer processes a word and accepts exactly the language members. Grammars generate languages; automata recognize languages, not grammars.

Study-note section AUT04

Two grammars are equivalent when their generated languages are equal, regardless of rule counts or variable names. One common word, equal alphabets or one-way inclusion is insufficient.

Study-note section AUT12

Classical expressions use ∅, ε, symbols, union, concatenation and star. A union B is written A|B or A+B; postfix r^+ means one-or-more r repetitions and is a different use of +. Parenthesize when conventions might clash. Star binds tightest, concatenation next, union last. r? means r|ε; r^+=rr*.

Study-note section AUT12

(a|b)*a denotes words ending a; 0*10* denotes exactly one 1; a*(b|c) gives zero-or-more a's then exactly one b or c, so aab belongs but aaa and aaabc do not.

Question sources

Computer Science MCQ practice collection · Question 745

Question 54 | AM0746

Which is the least expressive listed machine family that recognizes every regular language?

A. Turing machine

B. Pushdown automaton

C. Finite automaton

D. Nondeterministic Turing machine

Hint

Compare production restrictions, memory access and language-family containments. Distinguish an exact characterization from an included subclass.

Answer C: Finite automaton

Finite automata recognize exactly the regular languages. Pushdown automata and Turing machines can also recognize regular languages, but their families recognize strictly more languages and are not the least sufficient choice. The nondeterministic Turing-machine alternative is likewise stronger than finite automata. This compares expressive power across machine families, rather than implementation size or execution speed.

Why each choice is right or wrong

A - Incorrect: Turing machines recognize a strictly larger family than REG.

B - Incorrect: Pushdown automata recognize all CFLs, exceeding REG.

C - Correct: Finite automata characterize REG exactly and are least sufficient here.

D - Incorrect: Nondeterministic Turing machines exceed finite-automaton recognition power.

Primary note proof

Study-note section AUT05

> Type 3 regular grammars correspond to finite automata; type 2 CFGs to nondeterministic PDAs; type 1 context-sensitive/noncontracting grammars to nondeterministic LBAs; type 0 unrestricted grammars to Turing recognizers.

Question sources

Computer Science MCQ practice collection · Question 746

Question 55 | AM0747

Which statements follow from the Chomsky hierarchy and decidability? Select all that apply.

A. Context-free languages are a subset of regular languages.

B. Context-sensitive languages are a subset of recursive languages.

C. Regular languages are a subset of recursive languages.

D. Context-free languages are a subset of recursive languages.

Hint

Compare production restrictions, memory access and language-family containments. Distinguish an exact characterization from an included subclass.

Answer B, C, D: Context-sensitive languages are a subset of recursive languages.; Regular languages are a subset of recursive languages.; Context-free languages are a subset of recursive languages.

The hierarchy is REG⊊CFL⊊CSL⊊DECIDABLE⊊RE under the stated ε convention. Recursive means decidable, so context-sensitive languages are recursive, and transitivity gives the same conclusion for regular and context-free languages. A reverses the first strict inclusion: every regular language is context-free, but not every context-free language is regular. Therefore the three recursive-containment statements are all true.

Why each choice is right or wrong

A - Incorrect: The REG/CFL inclusion is reversed.

B - Correct: CSL is contained in the decidable or recursive family.

C - Correct: REG is contained in CSL and therefore in the recursive family.

D - Correct: CFL is contained in CSL and therefore in the recursive family.

Primary note proof

Study-note section AUT05

> Type 3 regular grammars correspond to finite automata; type 2 CFGs to nondeterministic PDAs; type 1 context-sensitive/noncontracting grammars to nondeterministic LBAs; type 0 unrestricted grammars to Turing recognizers.

Question sources

Computer Science MCQ practice collection · Question 747

Question 56 | AM0748

Which statement is true of ordinary DFAs? In D, the claim concerns every context-free language.

A. DFAs can recognize all regular languages.

B. DFAs have multiple possible transitions for each input symbol.

C. DFAs can have empty transitions.

D. DFAs can recognize every context-free language.

Hint

Respect the quantifier order and length constraints. A valid nonmembership argument must address every allowed decomposition, not one convenient split.

Answer A: DFAs can recognize all regular languages.

Ordinary DFAs recognize exactly the regular languages. Each state/input pair has one next state, and transitions consume an input symbol rather than ε. Some context-free languages are regular, but others, such as $a^n b^n$, are not and cannot be recognized by a DFA. Making D explicitly universal removes its weaker existential reading and leaves A as the unique true statement.

Why each choice is right or wrong

A - Correct: Every regular language has a DFA.

B - Incorrect: A DFA has a unique successor for each state/symbol pair.

C - Incorrect: Ordinary DFAs do not have ε moves.

D - Incorrect: Nonregular CFLs such as $a^n b^n$ cannot be recognized by DFAs.

Primary note proof

Study-note section AUT06

A deterministic finite automaton (DFA) is $M=(Q,\Sigma,\delta,q_0,F)$, with finite nonempty Q, start $q_0 \in Q$, accepting set $F \subseteq Q$ and total $\delta: Q \times \Sigma \to Q$. Exactly one next state is specified per state/symbol pair; this does not mean the whole machine has one transition.

Study-note section AUT09

An NFA is not more expressive than a DFA: both recognize exactly REG.

Study-note section AUT15

For $L=\{a^n b^n : n \geq 0\}$, choose $a^p b^p$. Every allowed $y=a^k$ with $k \geq 1$; pumping $i=0$ leaves fewer a's than b's. The contradiction excludes every DFA.

Question sources

Computer Science MCQ practice collection · Question 748

Question 57 | AM0749

Which listed automaton family has recognition power strictly between finite automata and Turing machines and uses one unbounded stack as its auxiliary memory?

A. Pushdown automaton

B. Non-deterministic finite automaton

C. Turing machine

D. Nondeterministic linear bounded automaton

Hint

Compare production restrictions, memory access and language-family containments. Distinguish an exact characterization from an included subclass.

Answer A: Pushdown automaton

A nondeterministic PDA adds one stack to finite control and recognizes the context-free languages. This family strictly contains REG and lies strictly below Turing-recognizable languages. NFAs have the same power as DFAs, while Turing machines are the upper endpoint. A nondeterministic LBA also lies between those endpoints, but uses bounded tape rather than the specified single-stack model.

Why each choice is right or wrong

A - Correct: A PDA has one unbounded stack and the required intermediate expressive power.

B - Incorrect: An NFA has no stack and recognizes only REG.

C - Incorrect: A TM is the upper endpoint, not strictly below it.

D - Incorrect: An LBA uses linearly bounded tape rather than the specified single stack.

Primary note proof

Study-note section AUT05

> Type 3 regular grammars correspond to finite automata; type 2 CFGs to nondeterministic PDAs; type 1 context-sensitive/noncontracting grammars to nondeterministic LBAs; type 0 unrestricted grammars to Turing recognizers.

Question sources

Computer Science MCQ practice collection · Question 749

Question 58 | AM0751

Which statements about NP-complete decision problems are true? Select all that apply. In C, exponential time is an upper bound.

A. NP-complete problems are only solvable by nondeterministic algorithms.

B. NP-complete problems are a subset of NP problems.

C. NP-complete problems can be solved in exponential time.

D. NP-complete problems have no practical applications.

Hint

Separate resource bounds, certificate verification and reduction requirements. Use proved containments without assuming unresolved class separations.

Answer B, C: NP-complete problems are a subset of NP problems.; NP-complete problems can be solved in exponential time.

NP-completeness includes membership in NP and hardness for every NP language under polynomial reductions. Polynomial-size certificates permit finite deterministic exhaustive search, giving a 2^poly(n) upper bound. Thus B and C are true together. This does not show that exponential time is necessary. SAT, coloring and tour-decision formulations illustrate meaningful problems, so the blanket denial of applications is also false.

Why each choice is right or wrong

A - Incorrect: Deterministic exhaustive certificate search also decides these problems.

B - Correct: Membership in NP is part of the definition.

C - Correct: Enumerating polynomial-size certificates gives a deterministic exponential-time upper bound.

D - Incorrect: The note gives substantive SAT, coloring and tour-decision examples.

Primary note proof

Study-note section AUT36

> X is NP-hard if every A∈NP satisfies A≤pX. It need not belong to NP and can even be undecidable. X is NP-complete if X∈NP and X is NP-hard. NP-complete languages lie inside NP and can be decided by finite exhaustive certificate search in exponential time. They are not known to require exponential time.

Question 59 | AM0752

Which of the following complexity classes represents the hardest problems in NP?

A. P

B. NP-complete

C. NP-hard

D. PSPACE

Hint

Separate resource bounds, certificate verification and reduction requirements. Use proved containments without assuming unresolved class separations.

Answer B: NP-complete: the problems both in NP and NP-hard.

AUT36 defines NP-complete as NP membership together with hardness for every NP problem under polynomial reductions. That is the precise class described by hardest problems in NP. NP-hard alone can extend beyond NP, even to undecidable problems; PSPACE is a larger resource class, and P does not impose the required hardness.

Why each choice is right or wrong

A - Incorrect: P means deterministic polynomial time and does not define hardness for every NP language.

B - Correct: NP-completeness combines being in NP with being at least as hard as every NP problem.

C - Incorrect: NP-hardness alone does not ensure membership in NP, so it is broader than the class requested.

D - Incorrect: PSPACE is defined by polynomial space and can contain languages outside the specified NP-complete class.

Primary note proof

Study-note section AUT36

X is NP-hard if every A∈NP satisfies A≤pX. It need not belong to NP and can even be undecidable. X is NP-complete if X∈NP and X is NP-hard. NP-complete languages lie inside NP and can be decided by finite exhaustive certificate search in exponential time. They are not known to require exponential time.

Question sources

Computer Science MCQ practice collection · Question 752

Question 60 | AM0753

Which of the following is true regarding the halting problem?

A. The halting problem can be solved by a Turing machine.

B. The halting problem is decidable for all programs.

C. The halting problem is an undecidable problem.

D. The halting problem is only relevant to regular languages.

Hint

Check whether the required procedure must halt on every input, and distinguish solving a task from recognizing its yes-instances.

Answer C: The general halting problem is undecidable.

AUT30 constructs a machine that contradicts a hypothetical universal halting decider when run on its own description. Hence no decider answers halting correctly for all machine/input pairs. HALT is recognizable by simulation, but that process need not terminate on nonhalting instances; recognizing some yes-instances is not solving the general decision problem.

Why each choice is right or wrong

A - Incorrect: Simulation recognizes halting yes-instances but no TM decides the general halting problem on every input.

B - Incorrect: The diagonal argument rules out a decider correct for all programs and inputs.

C - Correct: Undecidability is the exact result proved by the halting diagonalization argument in AUT30.

D - Incorrect: HALT concerns arbitrary computations and is not confined to regular languages or finite automata.

Primary note proof

Study-note section AUT30

> HALT={⟨M,w⟩:M halts on w} is recognizable: simulate and accept upon any halt. Suppose a decider H determines halting. Construct D(x) that loops if H(x,x) says halt, otherwise halts. Running D on its own description contradicts H in both cases. Thus HALT is undecidable and witnesses RE beyond DECIDABLE. Its complement is not RE, or both recognizers would yield a decider.

Question sources

Computer Science MCQ practice collection · Question 753

Question 61 | AM0754

Which of the following is a regular language?

A. {anbn | n ≥ 0}

B. {anbncn | n ≥ 0}

C. {an | n is a prime number}

D. {anb | n ≥ 0}

Hint

Compare production restrictions, memory access and language-family containments. Distinguish an exact characterization from an included subclass.

Answer D: {anb | n ≥ 0}

Reading the powers as a^n b^n, a^n b^n c^n, a^n for prime n, and a^n b. D is a*b, a regular expression. A and B fail the pumping lemma's condition: choose a^p b^p (or a^p b^p c^p); any nonempty pumped block in the first p positions consists only of a, so pumping changes only its count. For C choose a prime q at least p. If the pumped block has k≥1 a symbols, pumping with i=q+1 gives length q+qk=q(k+1), composite. Thus no pumping decomposition works. The argument uses the arithmetic fact that arbitrarily large primes exist.

Why each choice is right or wrong

A - Incorrect: Pumping only a symbols destroys equality with the b count.

B - Incorrect: Pumping only a symbols destroys equality with both later blocks.

C - Incorrect: Pumping the unary block q+1 times makes a composite length q(k+1).

D - Correct: a*b produces any number of a symbols followed by exactly one b.

Primary note proof

Study-note section AUT26

> a*b* and {$a^n b$:n≥0} are regular. $a^n b^n$ is CFL but not regular. Over a two-symbol alphabet, ww^R is CFL, ww is not CFL; both are decidable. $a^n b^n c^n$ is CSL but not CFL, and therefore decidable. Every finite language is regular. A stronger grammar or TM can still recognize any of these lower-family languages.

Study-note section AUT26

> Unary prime length {a^p:p prime} is nonregular: choose prime q above pumping length p; if pump piece has length k≥1, using exponent q+1 gives length q(k+1), composite. Every unary CFL is regular, so this language is not CFL either. It is nevertheless context-sensitive: count the input in bounded workspace and test divisors. The balanced-three-count, prime-length, palindrome and $a^n b$ examples above are all recursive languages.

Computer Science MCQ practice collection · Question 754

Question 62 | AM0755

Which is the least expressive listed grammar family capable of generating every context-free language?

A. Regular grammar

B. Context-free grammar

C. Context-sensitive grammar

D. Unrestricted grammar

Hint

Compare production restrictions, memory access and language-family containments. Distinguish an exact characterization from an included subclass.

Answer B: Context-free grammar

Context-free grammars generate exactly the context-free languages. Regular grammars are insufficient because CFL contains nonregular languages such as a^nb^n. Context-sensitive and unrestricted grammars can also generate CFLs under the stated ε convention, but their expressive power is greater than required. The least-family qualifier distinguishes the exact defining family from stronger families that merely have the same capability as a subset.

Why each choice is right or wrong

A - Incorrect: Regular grammars fail for nonregular CFLs such as a^nb^n.

B - Correct: Context-free grammars cover exactly the required family.

C - Incorrect: Context-sensitive grammars suffice but are stronger than required.

D - Incorrect: Unrestricted grammars suffice but are stronger than required.

Primary note proof

Study-note section AUT05

> Type 3 regular grammars correspond to finite automata; type 2 CFGs to nondeterministic PDAs; type 1 context-sensitive/noncontracting grammars to nondeterministic LBAs; type 0 unrestricted grammars to Turing recognizers.

Question sources

Computer Science MCQ practice collection · Question 755

Question 63 | AM0756

Under the usual isolated-start ε convention, which statements about CFLs and CSLs are true? Select all that apply.

A. Every context-sensitive language is also a context-free language.

B. Every context-free language is also a context-sensitive language.

C. Context-free languages are a strict subset of context-sensitive languages.

D. Context-free languages are unrelated to context-sensitive languages.

Hint

Compare production restrictions, memory access and language-family containments. Distinguish an exact characterization from an included subclass.

Answer B, C: Every context-free language is also a context-sensitive language.; Context-free languages are a strict subset of context-sensitive languages.

Every context-free language is context-sensitive under the stated ε convention. The containment is strict: $a^n b^n c^n$ is context-sensitive but not context-free. Hence both the inclusive statement B and the stronger proper-subset statement C are true. A reverses the containment, and D denies an established relationship. Selecting the stronger statement alone would incorrectly discard a weaker statement that it logically entails.

Why each choice is right or wrong

A - Incorrect: The three-equal-count language is a CSL outside CFL.

B - Correct: Every CFL belongs to CSL.

C - Correct: CSL contains additional languages, making the inclusion strict.

D - Incorrect: The two families are related by strict containment.

Primary note proof

Study-note section AUT05

Type 3 regular grammars correspond to finite automata; type 2 CFGs to nondeterministic PDAs; type 1 context-sensitive/noncontracting grammars to nondeterministic LBAs; type 0 unrestricted grammars to Turing recognizers.

Question sources

Computer Science MCQ practice collection · Question 756

Question 64 | AM0757

Which listed machine family can recognize every context-sensitive language? Interpret D as a nondeterministic finite automaton.

A. Finite automaton

B. Pushdown automaton

C. Turing machine

D. Nondeterministic finite automaton

Hint

Compare production restrictions, memory access and language-family containments. Distinguish an exact characterization from an included subclass.

Answer C: Turing machine

Context-sensitive languages are recognized by nondeterministic linear bounded automata. An unrestricted Turing machine can simulate their bounded-tape computations, so it can recognize every CSL. Finite automata and NFAs recognize only regular languages, and ordinary PDAs recognize only context-free languages. Those weaker families cannot cover the three-equal-count CSL, so they fail the universal capability requirement.

Why each choice is right or wrong

A - Incorrect: Finite automata cannot recognize nonregular CSLs.

B - Incorrect: PDAs cannot recognize CSLs outside CFL.

C - Correct: A TM can simulate the LBA model for every CSL.

D - Incorrect: NFAs recognize only REG, not every CSL.

Primary note proof

Study-note section AUT05

> Type 3 regular grammars correspond to finite automata; type 2 CFGs to nondeterministic PDAs; type 1 context-sensitive/noncontracting grammars to nondeterministic LBAs; type 0 unrestricted grammars to Turing recognizers.

Study-note section AUT05

> Use REG ⊊ CFL ⊊ CSL ⊊ DECIDABLE ⊊ RE, under the usual convention allowing S→ε with S absent from right sides when needed.

Study-note section AUT25

> A context-sensitive rule αAβ→αγβ replaces A in context, with γ nonempty. Equivalently, noncontracting grammar presentations preserve/increase total length, with the isolated ε exception. The condition is on the complete sides, not an unrelated comparison |β|≥|α|.

Study-note section AUT25

> A linear bounded automaton (LBA) is a TM with O(n) tape cells on length-n input; the standard CSL characterization uses nondeterministic LBAs. For $a^nb^nc^n$ first verify a*b*c* order, repeatedly mark one unmarked a, b and c, and reject missing/excess symbols.

Study-note section AUT25

Question sources

Computer Science MCQ practice collection · Question 757

Question 65 | AM0758

Which listed term names exactly the recursively enumerable language family, rather than a proper subfamily?

A. Regular language

B. Context-free language

C. Context-sensitive language

D. Turing-recognizable language

Hint

Check whether the required procedure must halt on every input, and distinguish solving a task from recognizing its yes-instances.

Answer D: Turing-recognizable language

Recursively enumerable, Turing-recognizable and semidecidable are names for the same language family. Regular, context-free and context-sensitive languages are all contained in RE, but each is a proper subfamily. The exact-family wording therefore singles out Turing-recognizable. Recognizers must halt and accept members; on a nonmember they may either reject or loop, unlike deciders which halt on every input.

Why each choice is right or wrong

A - Incorrect: REG is a proper subfamily of RE.

B - Incorrect: CFL is a proper subfamily of RE.

C - Incorrect: CSL is a proper subfamily of RE.

D - Correct: Turing-recognizable is an exact synonym for RE.

Primary note proof

Study-note section AUT29

> A decider halts on every input and accepts exactly its language; these languages are recursive/decidable. A recognizer must halt and accept every member, but on a nonmember may halt-reject or loop. Its languages are recursively enumerable (RE), Turing-recognizable or semidecidable. Looping is nonacceptance, not a rejecting halt. An undecidable language may still have a recognizer.

Study-note section AUT29

> Every decidable language is RE, and the containment is strict.

Study-note section AUT05

> Type 3 regular grammars correspond to finite automata; type 2 CFGs to nondeterministic PDAs; type 1 context-sensitive/noncontracting grammars to nondeterministic LBAs; type 0 unrestricted grammars to Turing recognizers.

All recursive set is recursively enumerable.

Question sources

Computer Science MCQ practice collection · Question 758

Question 66 | AM0759

Which class of languages is the most powerful in terms of generative power?

A. Regular languages

B. Context-free languages

C. Context-sensitive languages

D. Recursively enumerable languages

Hint

Compare production restrictions, memory access and language-family containments. Distinguish an exact characterization from an included subclass.

Answer D: Recursively enumerable languages

Reading most powerful as largest generative family in the traditional hierarchy, the outermost region is recursively enumerable. It properly surrounds context-sensitive, context-free and regular classes.

Why each choice is right or wrong

A - Incorrect: Innermost family, hence smallest listed.

B - Incorrect: Contains regular but is inside context-sensitive.

C - Incorrect: Larger than CFL but still inside RE.

D - Correct: Outermost family in the diagram.

Primary note proof

Study-note section AUT05

> Type 3 regular grammars correspond to finite automata; type 2 CFGs to nondeterministic PDAs; type 1 context-sensitive/noncontracting grammars to nondeterministic LBAs; type 0 unrestricted grammars to Turing recognizers.

Question sources

Computer Science MCQ practice collection · Question 759

Question 67 | AM0760

Which statements about recursive and recursively enumerable languages are true? Select all that apply.

A. Every recursive language is also a recursively enumerable language.

B. Every recursively enumerable language is also a recursive language.

C. Recursive languages are a strict subset of recursively enumerable languages.

D. Recursive languages are unrelated to recursively enumerable languages.

Hint

Check whether the required procedure must halt on every input, and distinguish solving a task from recognizing its yes-instances.

Answer A, C: Every recursive language is also a recursively enumerable language.; Recursive languages are a strict subset of recursively enumerable languages.

Every decider is also a recognizer, so each recursive language is recursively enumerable. The containment is proper: the halting language can be recognized by simulation but cannot be decided on every input. Thus both the inclusion statement and the strict-subset statement are true. The converse would turn every recognizer into a total decider, contradicting the halting example; describing the two families as unrelated also contradicts their inclusion.

Why each choice is right or wrong

A - Correct: A decider recognizes its language and halts on every input, establishing inclusion.

B - Incorrect: The recognizable but undecidable halting language is a counterexample.

C - Correct: The halting language belongs to RE but not to the recursive family, making inclusion strict.

D - Incorrect: The families are related by proper containment.

Primary note proof

Study-note section AUT29

> A decider halts on every input and accepts exactly its language; these languages are recursive/decidable. A recognizer must halt and accept every member, but on a nonmember may halt-reject or loop. Its languages are recursively enumerable (RE), Turing-recognizable or semidecidable. Looping is nonacceptance, not a rejecting halt. An undecidable language may still have a recognizer.

Study-note section AUT29

> Every decidable language is RE, and the containment is strict.

Study-note section AUT30

> HALT={⟨M,w⟩:M halts on w} is recognizable: simulate and accept upon any halt. Suppose a decider H determines halting. Construct D(x) that loops if H(x,x) says halt, otherwise halts. Running D on its own description contradicts H in both cases. Thus HALT is undecidable and

> witnesses RE beyond DECIDABLE. Its complement is not RE, or both recognizers would yield a decider.

> X or not.

Question sources

Computer Science MCQ practice collection · Question 760

Question 68 | AM0761

Which of the following is an example of an undecidable problem?

A. Checking if a given number is prime

B. Sorting a list of numbers in ascending order

C. Solving a system of linear equations

D. Determining if a Turing machine halts on a given input

Hint

Check whether the required procedure must halt on every input, and distinguish solving a task from recognizing its yes-instances.

Answer D: Determining whether an arbitrary TM halts on its given input.

AUT30 proves HALT undecidable, directly matching D. The other choices describe ordinary finite mathematical computation: primality can test finitely many candidate divisors, a finite list can be sorted, and an exact finite linear system can be processed by elimination. Their cost can vary, but no general undecidability follows from those ordinary formulations.

Why each choice is right or wrong

A - Incorrect: For an integer, testing finitely many candidate divisors decides primality; AUT26 uses bounded divisor testing.

B - Incorrect: A finite numeric list can be sorted by a terminating comparison procedure.

C - Incorrect: An ordinarily encoded finite linear system can be decided and solved by finite elimination steps.

D - Correct: This is the general halting decision problem proved undecidable in AUT30.

Primary note proof

Study-note section AUT30

Thus HALT is undecidable and witnesses RE beyond DECIDABLE.

Study-note section AUT26

It is nevertheless context-sensitive: count the input in bounded workspace and test divisors.

Study-note section AUT-S04

Sorting a finite numeric list is a terminating computation. Quicksort, for example, chooses a pivot, partitions the other entries and recursively sorts the smaller sublists. Each recursive subproblem has fewer entries. A large running time does not make the task undecidable.

Study-note section AUT-S04

A finite linear system with exactly represented rational coefficients can be processed by Gaussian elimination and back substitution. Row exchanges handle unsuitable pivots; row reduction detects inconsistency or leaves free variables describing multiple solutions. These finite algebraic procedures differ from a general halting decider, which does not exist.

X or not.

Question sources

Computer Science MCQ practice collection · Question 761

Question 69 | AM0762

Which offered language is nonrecursive (undecidable)? Use finite standard encodings and a fixed finite alphabet for mirror words.

A. HALT={⟨M,w⟩ | M halts on w}

B. {an | n is a prime number}

C. {wwR | w is any string}

D. {anb | n ≥ 0}

Hint

Check whether the required procedure must halt on every input, and distinguish solving a task from recognizing its yes-instances.

Answer A: HALT={⟨M,w⟩ | M halts on w}

The halting language HALT contains encoded machine/input pairs for which the machine eventually halts. The diagonal argument in the note proves that no algorithm decides HALT on every input. The remaining examples are decidable: unary primality uses finite divisor testing, mirror words can be compared finitely, and a^nb is regular. Thus nonregularity or an expensive test alone does not imply nonrecursiveness.

Why each choice is right or wrong

A - Correct: HALT is recognizable but undecidable by the diagonal argument.

B - Incorrect: Finite counting and divisor testing decide unary prime length.

C - Incorrect: A finite mirror comparison decides palindrome membership.

D - Incorrect: The language a^nb is regular and hence decidable.

Primary note proof

Study-note section AUT30

> HALT={⟨M,w⟩:M halts on w} is recognizable: simulate and accept upon any halt. Suppose a decider H determines halting. Construct D(x) that loops if H(x,x) says halt, otherwise halts. Running D on its own description contradicts H in both cases. Thus HALT is undecidable and witnesses RE beyond DECIDABLE. Its complement is not RE, or both recognizers would yield a decider.

Study-note section AUT26

> a*b* and $\{a^nb:n\geq 0\}$ are regular. a^nb^n is CFL but not regular. Over a two-symbol alphabet, ww^R is CFL, ww is not CFL; both are decidable. $a^nb^nc^n$ is CSL but not CFL, and therefore decidable. Every finite language is regular. A stronger grammar or TM can still recognize any of these lower-family languages.

At the level of generated language families, what criterion orders the Chomsky hierarchy?

A. It categorizes formal languages based on their computational complexity.

B. It categorizes formal languages based on their expressive power.

C. It categorizes formal languages based on their alphabet size.

D. It categorizes languages by the surface structure of individual input strings.

Hint

Compare production restrictions, memory access and language-family containments. Distinguish an exact characterization from an included subclass.

Answer B: It categorizes formal languages based on their expressive power.

The hierarchy orders families by expressive power: regular languages form a proper subfamily of CFLs, then CSLs, then the stronger computable families. Grammar production restrictions define the corresponding types, but the resulting language-family comparison concerns generative capability. It is not a ranking of algorithm runtimes, alphabet sizes, or surface appearance of particular strings. That scope makes B the unique criterion.

Why each choice is right or wrong

A - Incorrect: The hierarchy is not a runtime or workspace ranking.

B - Correct: It compares the language families that the models can describe.

C - Incorrect: Alphabet size does not determine the family.

D - Incorrect: Surface structure of individual strings is not the language-family ordering criterion.

Primary note proof

A grammar defines a set of rules, and with the use of these rules, valid sentences in a language are
generated.

Question sources

Computer Science MCQ practice collection · Question 763

Question 71 | AM0764

What is the least expressive listed grammar family that generates $L=\{a^nb^n \mid n\geq 0\}$? Use the usual isolated-start ε convention.

A. Regular grammar

B. Context-free grammar

C. Context-sensitive grammar

D. Unrestricted grammar

Hint

Respect the quantifier order and length constraints. A valid nonmembership argument must address every allowed decomposition, not one convenient split.

Answer B: Context-free grammar

The CFG $S\to aSb|\varepsilon$ generates exactly equal blocks of a and b: every recursive step adds one of each and the base supplies n=0. The pumping argument rules out regularity. Context-sensitive and unrestricted grammars can also generate this language, but are stronger than necessary under the ε convention. The least expressive sufficient family is therefore context-free.

Why each choice is right or wrong

A - Incorrect: Regular grammars cannot enforce these unbounded equal counts.

B - Correct: The displayed matched recursive CFG generates the language.

C - Incorrect: Context-sensitive grammars are stronger than necessary.

D - Incorrect: Unrestricted grammars are stronger than necessary.

Primary note proof

Study-note section AUT17

Use a recursive rule to enforce matched structure and a base rule to stop. $S\to aSb|\varepsilon$ generates exactly a^nb^n for $n\geq 0$: n recursive steps add n a's on the left and n b's on the right. Derive aabb by $S\Rightarrow aSb\Rightarrow aaSbb\Rightarrow aabb$. For $n\geq 1$ replace ε by base ab.

Study-note section AUT15

If L is regular, some $p\geq 1$ satisfies: every $s\in L$ with $|s|\geq p$ has a split $s=xyz$, $|xy|\leq p$, $|y|\geq 1$, and $xy^iz\in L$ for every $i\geq 0$.

Study-note section AUT15

For L={$a^n b^n$:n≥0}, choose $a^p b^p$. Every allowed y=a^k with k≥1; pumping i=0 leaves fewer a's than b's. The contradiction excludes every DFA.

Study-note section AUT05

Type 3 regular grammars correspond to finite automata; type 2 CFGs to nondeterministic PDAs; type 1 context-sensitive/noncontracting grammars to nondeterministic LBAs; type 0 unrestricted grammars to Turing recognizers.

Study-note section AUT05

Use REG ⊊ CFL ⊊ CSL ⊊ DECIDABLE ⊊ RE, under the usual convention allowing S→ε with S absent from right sides when needed.

Question sources

Computer Science MCQ practice collection · Question 764

Question 72 | AM0765

Which listed language is context-sensitive but NOT context-free? Interpret the notation as powers and use the usual ε convention.

A. {$a^n b^n$ | n≥0}

B. {$a^n b^m$ | n,m≥0}

C. {a^n | n is prime}

D. {$a^n b$ | n≥0}

Hint

Compare production restrictions, memory access and language-family containments. Distinguish an exact characterization from an included subclass.

Answer C: {a^n | n is prime}

Unary prime length is context-sensitive because bounded-workspace counting and divisor testing decide it. It is not regular by the prime-length pumping argument, and every unary CFL is regular; consequently it is not context-free. In contrast, a^nb^n is context-free, while independently chosen a/b counts and any number of a followed by one b are regular. These weaker examples are excluded by the explicit non-CFL condition.

Why each choice is right or wrong

A - Incorrect: Equal two-block counts form a CFL.

B - Incorrect: Independent counts give the regular language a*b*.

C - Correct: Unary prime length is CSL but not CFL.

D - Incorrect: Any number of a followed by one b is regular.

Primary note proof

Study-note section AUT26

> a*b* and {a^nb:n≥0} are regular. a^nb^n is CFL but not regular. Over a two-symbol alphabet, ww^R is CFL, ww is not CFL; both are decidable. $a^nb^nc^n$ is CSL but not CFL, and therefore decidable. Every finite language is regular. A stronger grammar or TM can still recognize any of these lower-family languages.

Study-note section AUT26

> Unary prime length {a^p:p prime} is nonregular: choose prime q above pumping length p; if pump piece has length k≥1, using exponent q+1 gives length q(k+1), composite. Every unary CFL is regular, so this language is not CFL either. It is nevertheless context-sensitive: count the input in bounded workspace and test divisors. The balanced-three-count, prime-length, palindrome and a^nb examples above are all recursive languages.

Question sources

Computer Science MCQ practice collection · Question 765

Question 73 | AM0766

What is the least expressive listed machine family that recognizes $L=\{a^nb^n \mid n\geq 0\}$? Interpret D as a nondeterministic finite automaton.

A. Finite automaton

B. Pushdown automaton

C. Turing machine

D. Nondeterministic finite automaton

Hint

Respect the quantifier order and length constraints. A valid nonmembership argument must address every allowed decomposition, not one convenient split.

Answer B: Pushdown automaton

A PDA pushes one stack symbol for each a, then pops one for each b, accepting exactly when the blocks finish together. The language is nonregular, so neither deterministic nor nondeterministic finite automata suffice. A TM can simulate the matching procedure, but has greater expressive power than required. The least sufficient listed family is the pushdown automaton.

Why each choice is right or wrong

A - Incorrect: Finite automata cannot recognize the nonregular matched-count language.

B - Correct: A PDA stack matches each a with one later b.

C - Incorrect: A TM works but is stronger than necessary.

D - Incorrect: An NFA recognizes only regular languages.

Primary note proof

Study-note section AUT22

> For a^nb^n, push one X per a, switch to a b-reading phase, pop one X per b, and accept when input ends at the bottom marker. Reject a after entering the b phase and b when no X remains. Handle ε explicitly if n=0 is permitted. A stack counts without storing the full input as random-access memory.

Study-note section AUT15

> If L is regular, some $p\geq 1$ satisfies: every $s\in L$ with $|s|\geq p$ has a split $s=xyz$, $|xy|\leq p$, $|y|\geq 1$, and $xy^iz\in L$ for every $i\geq 0$.

Study-note section AUT15

> For $L=\{a^nb^n : n\geq 0\}$, choose a^pb^p. Every allowed $y=a^k$ with $k\geq 1$; pumping $i=0$ leaves fewer a's than b's. The contradiction excludes every DFA.

Question sources

Computer Science MCQ practice collection · Question 766

Question 74 | AM0767

Over $\Sigma=\{a,b\}$, what is the least expressive listed grammar family generating $L=\{ww^R \mid w \in \Sigma^*\}$? Use the usual isolated-start ε convention.

A. Regular grammar

B. Context-free grammar

C. Context-sensitive grammar

D. Unrestricted grammar

Hint

Compare production restrictions, memory access and language-family containments. Distinguish an exact characterization from an included subclass.

Answer B: Context-free grammar

The grammar $S \to aSa \mid bSb \mid \varepsilon$ generates precisely binary even-length palindromes: matching symbols wrap a shorter mirror word until the empty center is reached. This language is context-free and nonregular over the stated two-symbol alphabet. Context-sensitive and unrestricted grammars also suffice but exceed the minimum expressive power required. Fixing the alphabet excludes the unary even-length case, which would be regular.

Why each choice is right or wrong

A - Incorrect: Binary unmarked even palindromes are nonregular.

B - Correct: The wrapping CFG generates exactly this mirror language.

C - Incorrect: Context-sensitive grammars are stronger than necessary.

D - Incorrect: Unrestricted grammars are stronger than necessary.

Primary note proof

Study-note section AUT22

For even palindromes ww^R over {a,b}, push the first half, nondeterministically guess its midpoint, then pop matching symbols. No center marker makes that language context-free but not deterministic context-free. With a marker wcw^R the switch point is visible and a DPDA suffices. Unary even palindromes are merely even-length words and regular. A PDA cannot compare two arbitrary halves in the same forward order: {ww:w∈{a,b}*} is the copy language, not the palindrome language.

Question sources

Computer Science MCQ practice collection · Question 767

Question 75 | AM0768

Over Σ={a,b}, what is the least expressive listed machine family recognizing $L=\{ww^R \mid w \in \Sigma^*\}$? There is no center marker; D means NFA.

A. Finite automaton

B. Nondeterministic pushdown automaton

C. Turing machine

D. Nondeterministic finite automaton

Hint

Compare production restrictions, memory access and language-family containments. Distinguish an exact characterization from an included subclass.

Answer B: Nondeterministic pushdown automaton

An NPDA pushes the first half, guesses the midpoint and matches the remaining symbols against the stack in reverse order. That recognizes the binary even-palindrome language, which is nonregular. Finite automata and NFAs therefore fail, whereas a TM can recognize it but is stronger than necessary. The unmarked midpoint requires nondeterminism in the PDA family, as distinguished in the note.

Why each choice is right or wrong

A - Incorrect: A finite automaton cannot recognize binary unmarked even palindromes.

B - Correct: A nondeterministic PDA guesses the midpoint and matches using its stack.

C - Incorrect: A TM is sufficient but stronger than necessary.

D - Incorrect: An NFA still recognizes only regular languages.

Primary note proof

Study-note section AUT22

> For even palindromes ww^R over {a,b}, push the first half, nondeterministically guess its midpoint, then pop matching symbols. Question 76 | AM0769

What is the least expressive listed grammar family generating $L=\{0^n1^n2^n \mid n\geq 0\}$? Use the usual isolated-start ε convention.

A. Regular grammar

B. Context-free grammar

C. Context-sensitive grammar

D. Unrestricted grammar

Hint

Respect the quantifier order and length constraints. A valid nonmembership argument must address every allowed decomposition, not one convenient split.

Answer C: Context-sensitive grammar

Renaming the symbols in $a^nb^nc^n$ gives $0^n1^n2^n$ without changing its classification. The three matched blocks form a context-sensitive language but not a context-free one. The isolated-start ε convention covers n=0. Regular grammars are weaker still, and unrestricted grammars can generate it but exceed what is needed. Thus the least sufficient listed grammar family is context-sensitive.

Why each choice is right or wrong

A - Incorrect: Regular grammars cannot generate this nonregular language.

B - Incorrect: The language lies outside the context-free family.

C - Correct: The context-sensitive family suffices and is the least listed family that does.

D - Incorrect: Unrestricted grammars suffice but exceed the required expressive power.

Primary note proof

Study-note section AUT25

> A context-sensitive rule $\alpha A\beta\rightarrow\alpha\gamma\beta$ replaces A in context, with γ nonempty. Equivalently, noncontracting grammar presentations preserve/increase total length, with the isolated ε exception. The condition is on the complete sides, not an unrelated comparison $|\beta|\geq|\alpha|$.

Study-note section AUT25

> A linear bounded automaton (LBA) is a TM with O(n) tape cells on length-n input; the standard CSL characterization uses nondeterministic LBAs. For $a^nb^nc^n$ first verify a*b*c* order, repeatedly mark one unmarked a, b and c, and reject missing/excess symbols.

Study-note section AUT25

> Thus every CSL is decidable.

Study-note section AUT24

If L is context-free, some p ensures each sufficiently long $s \in L$ has $s=uvxyz$ with $|vxy| \le p$, $|vy| \ge 1$ and $uv^ixy^iz \in L$ for every $i \ge 0$. The two pieces v and y are pumped together; either may be empty, not both. A non-CFL proof must defeat every allowed decomposition.

Study-note section AUT24

For $s=a^pb^pc^p$, the window vxy cannot contain both an a and a c. Pumping affects at most two blocks and at least one count. Use i=0 or 2: the unaffected third block retains p while another count changes, or symbol order breaks. Hence $a^nb^nc^n$ is not CFL.

Question 77 | AM0770

Which listed machine family can recognize $L=\{0^n1^n2^n \mid n \ge 0\}$? Interpret D as a nondeterministic finite automaton.

A. Finite automaton

B. Pushdown automaton

C. Turing machine

D. Nondeterministic finite automaton

Hint

Respect the quantifier order and length constraints. A valid nonmembership argument must address every allowed decomposition, not one convenient split.

Answer C: Turing machine

A Turing machine verifies the 0*1*2* order, repeatedly marks one symbol from each block, and checks that none remains unmatched. Each round marks additional symbols, so the procedure halts. This is the three-equal-count language with renamed symbols, which is not context-free. Consequently neither a finite automaton, an NFA nor a single-stack PDA recognizes it, leaving the TM as the sufficient listed model.

Why each choice is right or wrong

A - Incorrect: Finite automata cannot recognize this nonregular language.

B - Incorrect: A single-stack PDA cannot recognize this non-CFL language.

C - Correct: A TM implements the terminating membership test described in the note.

D - Incorrect: An NFA recognizes only REG and cannot recognize this language.

Primary note proof

Study-note section AUT25

A context-sensitive rule $\alpha A\beta \to \alpha\gamma\beta$ replaces A in context, with γ nonempty. Equivalently, noncontracting grammar presentations preserve/increase total length, with the isolated ε exception. The condition is on the complete sides, not an unrelated comparison $|\beta| \geq |\alpha|$.

Study-note section AUT25

A linear bounded automaton (LBA) is a TM with O(n) tape cells on length-n input; the standard CSL characterization uses nondeterministic LBAs. For $a^n b^n c^n$ first verify a*b*c* order, repeatedly mark one unmarked a, b and c, and reject missing/excess symbols.

Study-note section AUT25

Thus every CSL is decidable.

Study-note section AUT24

If L is context-free, some p ensures each sufficiently long $s \in L$ has $s=uvxyz$ with $|vxy| \leq p$, $|vy| \geq 1$ and $uv^i xy^i z \in L$ for every $i \geq 0$. The two pieces v and y are pumped together; either may be empty, not both. A non-CFL proof must defeat every allowed decomposition.

Study-note section AUT24

For $s=a^p b^p c^p$, the window vxy cannot contain both an a and a c. Pumping affects at most two blocks and at least one count. Use i=0 or 2: the unaffected third block retains p while another count changes, or symbol order breaks. Hence $a^n b^n c^n$ is not CFL.

Computer Science MCQ practice collection · Question 770

Question 78 | AM0771

What is the least expressive listed grammar family generating $L=\{a^n \mid n \text{ is prime}\}$? Use the usual isolated-start ε convention.

A. Regular grammar

B. Context-free grammar

C. Context-sensitive grammar

D. Unrestricted grammar

Hint

Compare production restrictions, memory access and language-family containments. Distinguish an exact characterization from an included subclass.

Answer C: Context-sensitive grammar

Unary prime length is nonregular by the pumping argument. Since every unary context-free language is regular, it is not context-free either. Bounded-workspace counting and divisor testing establish context sensitivity. Unrestricted grammars also suffice but are more expressive than necessary. The least sufficient listed family is therefore context-sensitive, rather than one of the two weaker grammar families.

Why each choice is right or wrong

A - Incorrect: Regular grammars cannot generate this nonregular language.

B - Incorrect: The language lies outside the context-free family.

C - Correct: The context-sensitive family suffices and is the least listed family that does.

D - Incorrect: Unrestricted grammars suffice but exceed the required expressive power.

Primary note proof

Study-note section AUT26

> a^*b^* and $\{a^nb : n \geq 0\}$ are regular. a^nb^n is CFL but not regular. Question 79 | AM0772

Which listed machine family can recognize $L=\{a^n \mid n \text{ is prime}\}$? Interpret D as a nondeterministic finite automaton.

A. Finite automaton

B. Pushdown automaton

C. Turing machine

D. Nondeterministic finite automaton

Hint

Compare production restrictions, memory access and language-family containments. Distinguish an exact characterization from an included subclass.

Answer C: Turing machine

A Turing machine can count the input and test finitely many divisors to determine whether its length is prime. This procedure halts on every input. The language is nonregular, and every unary CFL is regular, so it is also outside CFL. Finite automata, NFAs and single-stack PDAs therefore fail, while the TM provides the required recognition procedure.

Why each choice is right or wrong

A - Incorrect: Finite automata cannot recognize this nonregular language.

B - Incorrect: A single-stack PDA cannot recognize this non-CFL language.

C - Correct: A TM implements the terminating membership test described in the note.

D - Incorrect: An NFA recognizes only REG and cannot recognize this language.

Primary note proof

Study-note section AUT26

a*b* and {$a^n b$:n≥0} are regular. $a^n b^n$ is CFL but not regular. Over a two-symbol alphabet, ww^R is CFL, ww is not CFL; both are decidable. $a^n b^n c^n$ is CSL but not CFL, and therefore decidable. Every finite language is regular. A stronger grammar or TM can still recognize any of these lower-family languages.

Study-note section AUT26

Unary prime length {a^p:p prime} is nonregular: choose prime q above pumping length p; if pump piece has length k≥1, using exponent q+1 gives length q(k+1), composite. Every unary CFL is regular, so this language is not CFL either. It is nevertheless context-sensitive: count the input in bounded workspace and test divisors. Computer Science MCQ practice collection · Question 772

Question 80 | AM0773

What is the least expressive listed grammar family generating L={$a^n b$ | n≥0}?

A. Regular grammar

B. Context-free grammar

C. Context-sensitive grammar

D. Unrestricted grammar

Hint

Track mandatory symbols and factors that may repeat or disappear. Use short test words to check both directions of each proposed language description.

Answer A: Regular grammar

A right-linear grammar S→aS|b generates any number of a symbols followed by exactly one b, including the word b for n=0. The language is therefore regular. Context-free, context-sensitive and unrestricted grammars can all generate regular languages too, but are more expressive than necessary. The least-family question uniquely selects regular grammar without denying the capabilities of the stronger classes.

Why each choice is right or wrong

A - Correct: The right-linear rule S→aS|b suffices.

B - Incorrect: CFGs work but are stronger than necessary.

C - Incorrect: Context-sensitive grammars work but are stronger than necessary.

D - Incorrect: Unrestricted grammars work but are stronger than necessary.

Primary note proof

Study-note section AUT14

> Right-linear rules have form A→aB, A→a or permitted ε rules; left-linear rules put the single variable at the opposite end, A→Ba. Both consistent orientations generate REG; arbitrarily mixing them can generate nonregular languages, for example S→aA|ε, A→Sb generates $a^n b^n$. A CFG rule A→aBA is legal but not regular-grammar form.

Study-note section AUT14

> Regular languages are closed under union, concatenation, star, reversal, intersection, difference and complement.

Question sources

Computer Science MCQ practice collection · Question 773

Question 81 | AM0774

Which class is defined as the decision languages decidable by a deterministic algorithm in polynomial time?

A. P

B. NP

C. PSPACE

D. EXPTIME

Hint

Separate resource bounds, certificate verification and reduction requirements. Use proved containments without assuming unresolved class separations.

Answer A: P

P is defined by deterministic polynomial-time decidability. NP, PSPACE and EXPTIME all contain P, so broad containment would not distinguish the choices. They have different defining bounds: nondeterministic polynomial time, deterministic polynomial workspace and deterministic exponential time, respectively. The explicit deterministic-time definition uniquely identifies P without assuming any unresolved separation among neighboring classes.

Why each choice is right or wrong

A - Correct: P is defined by deterministic polynomial-time decisions.

B - Incorrect: NP is defined by nondeterministic polynomial time or polynomial verification.

C - Incorrect: PSPACE is defined by polynomial workspace.

D - Incorrect: EXPTIME is defined by exponential-time bounds rather than precisely the stated polynomial-time bound.

Primary note proof

Study-note section AUT34

> Complexity classes here contain decision languages. P consists of deterministic polynomial-time decidable languages; NP consists of nondeterministic polynomial-time decidable languages, equivalently polynomially verifiable yes-instances with polynomial-size certificates. A verifier must accept some certificate exactly for yes-inputs; no certificate may falsely establish a no-instance. NP means nondeterministic polynomial, not non-polynomial.

Study-note section AUT34

> P⊆NP because a verifier can ignore its certificate and run the P algorithm. P=NP remains open; NP does not mean definitely hard or definitely outside P.

Study-note section AUT39

> Use L⊆NL⊆P⊆NP⊆PSPACE⊆EXPTIME⊆EXPSPACE. Here L/NL use logarithmic workspace; EXPTIME is ⋃kTIME(2^(n^k)), an upper-bound class that also contains P, not a statement that every member requires exponential time.

Study-note section AUT39

> P versus NP, NP versus PSPACE and PSPACE versus EXPTIME remain unresolved. coNP contains complements of NP languages; P⊆NP∩coNP, and NP=coNP is open.

Question sources

Computer Science MCQ practice collection · Question 774

Question 82 | AM0775

Which class consists of decision problems whose yes-instances have polynomial-size certificates checkable by a deterministic polynomial-time verifier?

A. P

B. NP

C. PSPACE

D. EXPTIME

Hint

Separate resource bounds, certificate verification and reduction requirements. Use proved containments without assuming unresolved class separations.

Answer B: NP

NP is defined by polynomially bounded certificates and deterministic polynomial-time verification, equivalently nondeterministic polynomial-time decision. P instead names deterministic polynomial-time decision; its members also admit efficient verification, but P is not the name for the full verifier-defined class. PSPACE bounds deterministic working space by a polynomial, and EXPTIME bounds deterministic time exponentially. These are different resource-based definitions; their inclusion relationships do not make them alternative names for NP.

Why each choice is right or wrong

A - Incorrect: P is defined by deterministic polynomial-time decision, not by the full certificate-verification characterization.

B - Correct: The certificate-and-verifier definition is precisely NP.

C - Incorrect: PSPACE is defined by a polynomial bound on deterministic space.

D - Incorrect: EXPTIME is defined by exponential deterministic time bounds.

Primary note proof

Study-note section AUT34

> Complexity classes here contain decision languages. P consists of deterministic polynomial-time decidable languages; NP consists of nondeterministic polynomial-time decidable languages, equivalently polynomially verifiable yes-instances with polynomial-size certificates. A verifier must accept some certificate exactly for yes-inputs; no certificate may falsely establish a no-instance. NP means nondeterministic polynomial, not non-polynomial.

Study-note section AUT34

> P⊆NP because a verifier can ignore its certificate and run the P algorithm. P=NP remains open; NP does not mean definitely hard or definitely outside P.

Study-note section AUT38

> PSPACE is $\bigcup_k \mathrm{SPACE}(n^k)$, using deterministic polynomial workspace. NP⊆PSPACE because candidate polynomial witnesses can be enumerated and checked one at a time, reusing memory; exponentially many candidates do not require retaining them all.

Study-note section AUT39

> Use L⊆NL⊆P⊆NP⊆PSPACE⊆EXPTIME⊆EXPSPACE. Here L/NL use logarithmic workspace; EXPTIME is $\bigcup_k \mathrm{TIME}(2^{(n^k)})$, an upper-bound class that also contains P, not a statement that every member requires exponential time.

Study-note section AUT39

> P versus NP, NP versus PSPACE and PSPACE versus EXPTIME remain unresolved. coNP contains complements of NP languages; P⊆NP∩coNP, and NP=coNP is open.

Question sources

Computer Science MCQ practice collection · Question 775

Question 83 | AM0776

Which class is defined as the decision languages decidable using deterministic polynomial workspace?

A. P

B. NP

C. PSPACE

D. EXPTIME

Hint

Separate resource bounds, certificate verification and reduction requirements. Use proved containments without assuming unresolved class separations.

Answer C: PSPACE

PSPACE consists of decision languages decidable with deterministic workspace bounded by a polynomial in input length. P and NP use polynomial-time definitions, whereas EXPTIME uses an exponential-time definition and contains PSPACE. Those containments do not change which class the workspace condition defines. Nor is it necessary to assume unresolved strict separations among the classes to identify the definition.

Why each choice is right or wrong

A - Incorrect: P has a deterministic polynomial-time definition.

B - Incorrect: NP has a nondeterministic polynomial-time or certificate-verification definition.

C - Correct: PSPACE has exactly the stated deterministic polynomial-workspace definition.

D - Incorrect: EXPTIME contains PSPACE but is defined by a time bound.

Primary note proof

Study-note section AUT38

PSPACE is $\bigcup_k \mathrm{SPACE}(n^k)$, using deterministic polynomial workspace. NP$\subseteq$PSPACE because candidate polynomial witnesses can be enumerated and checked one at a time, reusing memory; exponentially many candidates do not require retaining them all.

Study-note section AUT34

Complexity classes here contain decision languages. P consists of deterministic polynomial-time decidable languages; NP consists of nondeterministic polynomial-time decidable languages, equivalently polynomially verifiable yes-instances with polynomial-size certificates. A verifier must accept some certificate exactly for yes-inputs; no certificate may falsely establish a no-instance. NP means nondeterministic polynomial, not non-polynomial.

Study-note section AUT34

P⊆NP because a verifier can ignore its certificate and run the P algorithm. P=NP remains open; NP does not mean definitely hard or definitely outside P.

Study-note section AUT39

Use L⊆NL⊆P⊆NP⊆PSPACE⊆EXPTIME⊆EXPSPACE. Here L/NL use logarithmic workspace; EXPTIME is ⋃kTIME(2^(n^k)), an upper-bound class that also contains P, not a statement that every member requires exponential time.

Study-note section AUT39

P versus NP, NP versus PSPACE and PSPACE versus EXPTIME remain unresolved. coNP contains complements of NP languages; P⊆NP∩coNP, and NP=coNP is open.

Question sources

Computer Science MCQ practice collection · Question 776

Question 84 | AM0777

Which concept is used to show that one problem can be reduced to another problem in order to prove hardness or completeness?

A. Reductions

B. Hierarchy

C. Completeness

D. Complexity classes

Hint

Separate resource bounds, certificate verification and reduction requirements. Use proved containments without assuming unresolved class separations.

Answer A: Reductions.

AUT35 defines a polynomial reduction as a computable transformation preserving yes/no membership and explains how reducing a known hard problem to a new target proves target hardness. AUT32 supplies the computable version for undecidability. Thus reductions name the proof concept itself, while hierarchy, completeness and classes describe relationships or resulting properties rather than the transformation method.

Why each choice is right or wrong

A - Correct: A reduction transforms instances while preserving membership, enabling hardness or completeness arguments with the stated resource bound.

B - Incorrect: A hierarchy organizes classes; it does not itself supply the instance transformation used in a hardness proof.

C - Incorrect: Completeness is the property proved using membership and hardness, not the reduction method itself.

D - Incorrect: Complexity classes group problems by resources; reductions establish the required relationships between individual problems.

Primary note proof

Study-note section AUT35

> $A \leq_p B$ means f is computable in polynomial time and $x \in A$ iff $f(x) \in B$. Solving B then solves A, so B is at least as hard under this reduction. If $B \in P$ then $A \in P$; if A is NP-hard then B is NP-hard. $A \in P$ does not force $B \in P$, and the reduction alone does not place both problems in the same class. Polynomial reductions compose.

Question sources

Computer Science MCQ practice collection · Question 777

Question 85 | AM0778

Which listed term denotes decision problems that belong to NP and are at least as hard as every NP problem under polynomial-time many-one reductions?

A. P

B. NP-complete

C. PSPACE

D. EXPTIME

Hint

Separate resource bounds, certificate verification and reduction requirements. Use proved containments without assuming unresolved class separations.

Answer B: NP-complete

NP-completeness combines two conditions: the target problem belongs to NP, and every NP language reduces to it in polynomial time. That gives a precise meaning to hardest within NP under the chosen reductions. P, PSPACE and EXPTIME instead name resource-bounded language classes and do not by themselves assert that each member is hard for NP or belongs to NP.

Why each choice is right or wrong

A - Incorrect: P names a resource class, not the membership-plus-hardness condition.

B - Correct: NP-complete states both NP membership and hardness for all NP languages.

C - Incorrect: PSPACE membership alone does not give the specified NP completeness.

D - Incorrect: EXPTIME membership alone does not give the specified NP completeness.

Primary note proof

Study-note section AUT36

> X is NP-hard if every A∈NP satisfies A≤pX. It need not belong to NP and can even be undecidable. X is NP-complete if X∈NP and X is NP-hard. NP-complete languages lie inside NP and can be decided by finite exhaustive certificate search in exponential time. They are not known to require exponential time.

Question 86 | CS0247

Let a Grammar G = ({S}, {a,b}, S, P), where P: S -> aSb, S -> lambda. Which one of the following is NOT an element of the language L generated from G?

A. aabb

B. ab

C. lambda (empty string)

D. a

Hint

Apply the stated transition, closure or equivalence rule step by step; distinguish a guaranteed bound from a value for one particular machine.

Answer D: a

After n applications of S→aSb and a final S→λ the word is a^n b^n. Induction preserves equal counts in block order, including n=0. a has one a and no b and cannot be generated.

Why each choice is right or wrong

A - Incorrect: S⇒aSb⇒aaSbb⇒aabb.

B - Incorrect: S⇒aSb⇒ab.

C - Incorrect: S⇒λ directly.

D - Correct: Unequal counts violate the invariant of every terminal derivation.

Primary note proof

Study-note section AUT17

> Use a recursive rule to enforce matched structure and a base rule to stop. S→aSb|ε generates exactly $a^n b^n$ for n≥0: n recursive steps add n a's on the left and n b's on the right. Derive aabb by S⇒aSb⇒aaSbb⇒aabb. For n≥1 replace ε by base ab.

Question 87 | CS0249

Given input Alphabet sigma = {a, b, c, d} and empty string lambda. Which one of the following is true about sigma*?

A. sigma* = sigma+

B. sigma* = sigma+ union {lambda}

C. sigma* = sigma^1 union sigma^2 union sigma^3 union sigma+

D. sigma* = {lambda}

Hint

Distinguish symbols, finite strings, their lengths and sets of strings. Apply the operation to its stated operands, including empty cases.

Answer B: sigma* = sigma+ union {lambda}

Star allows every finite number of alphabet symbols, including zero. Positive closure allows all positive numbers. Their union with the singleton zero-length word gives exactly star. In C, unioning positive powers with Σ^+ still gives only Σ^+, missing λ.

Why each choice is right or wrong

A - Incorrect: Σ^+ omits λ, so it is smaller than Σ^*.

B - Correct: Partitions all words by zero versus positive length.

C - Incorrect: All terms already have positive length; λ is absent.

D - Incorrect: Omits every nonempty word such as a.

Primary note proof

Study-note section AUT03

> Σ^n contains words of exactly n symbols; for $|\Sigma|=k$, $|\Sigma^n|=k^n$, including $\Sigma^0=\{\varepsilon\}$. $\Sigma^*=\bigcup n\geq 0\Sigma^n$ and $\Sigma^+=\bigcup n\geq 1\Sigma^n$. Over a nonempty alphabet, Σ^+ excludes ε and $\Sigma^*=\Sigma^+\cup\{\varepsilon\}$. Σ^2 over {a,b} is {aa,ab,ba,bb}.

Study-note section AUT03

> For an arbitrary language L, $L^*=\bigcup n\geq 0 L^n$ and $L^+=LL^*$. Unlike alphabet positive closure, L^+ can contain ε when $\varepsilon\in L$. $\varnothing^*=\{\varepsilon\}$, $\varnothing^+=\varnothing$, and $\{\varepsilon\}^*=\{\varepsilon\}$. Union means membership in either set; intersection requires the same word in both, not concatenation. Complement is Σ^*-L and needs a fixed alphabet.

Question 88 | CS0250

Given input Alphabet sigma = {a, b, c, d} and empty string lambda. Which one of the following is equivalent to sigma+?

A. sigma

B. sigma+

C. {lambda}

D. sigma*

Hint

Distinguish symbols, finite strings, their lengths and sets of strings. Apply the operation to its stated operands, including empty cases.

Answer B: sigma+

Taken literally, B is an identity: $\Sigma+$ equals itself. Since the alphabet is nonempty and contains no empty symbol, Σ contains only length-one words, Σ^* additionally contains λ, and $\{\lambda\}$ contains no positive-length word. The identical expressions make B a definite answer as printed.

Why each choice is right or wrong

A - Incorrect: aa is in $\Sigma+$ but not in Σ.

B - Correct: Identical expression on both sides.

C - Incorrect: λ has length zero and is not a positive repetition.

D - Incorrect: Σ^* includes λ, unlike $\Sigma+$.

Primary note proof

Study-note section AUT03

Σ^n contains words of exactly n symbols; for $|\Sigma|=k$, $|\Sigma^n|=k^n$, including $\Sigma^0=\{\varepsilon\}$. $\Sigma^*=\bigcup n\geq 0\Sigma^n$ and $\Sigma^+=\bigcup n\geq 1\Sigma^n$. Over a nonempty alphabet, Σ^+ excludes ε and $\Sigma^*=\Sigma^+\cup\{\varepsilon\}$. Σ^2 over {a,b} is {aa,ab,ba,bb}.

Study-note section AUT03

For an arbitrary language L, $L^*=\bigcup n\geq 0L^n$ and $L^+=LL^*$. Unlike alphabet positive closure, L^+ can contain ε when $\varepsilon\in L$. $\varnothing^*=\{\varepsilon\}$, $\varnothing^+=\varnothing$, and $\{\varepsilon\}^*=\{\varepsilon\}$. Union means membership in either set;

> intersection requires the same word in both, not concatenation. Complement is Σ*−L and needs a fixed alphabet.

Computer Science Exit Exam practice collection · Question 250

Question 89 | CS0251

If Z=caddba, what is $|Z|^2$, the square of the numeric length of Z?

A. 3

B. 4

C. 2

D. 36

Hint

Distinguish symbols, finite strings, their lengths and sets of strings. Apply the operation to its stated operands, including empty cases.

Answer D: 36

String length counts every symbol occurrence, including repetitions. The word caddba has six positions, so $|Z|=6$ and $|Z|^2=6^2=36$. Counting distinct symbols would give four, which is not string length. Concatenating two copies gives length twelve, but that computes $|Z^2|$ instead; the revised stem expressly preserves the original placement of the exponent outside the bars.

Why each choice is right or wrong

A - Incorrect: Three is neither the length nor its square.

B - Incorrect: Four counts distinct letters rather than the squared length.

C - Incorrect: Two is the exponent, not the squared length.

D - Correct: Six positions squared gives 36.

Primary note proof

Study-note section AUT01

> An alphabet Σ is a finite set of symbols. A word/string is a finite ordered sequence of symbols from Σ; a language is a set of words, L⊆Σ*. An empty word ε, also written λ, has length zero. The empty language ∅ contains no words; {ε} contains one.

Study-note section AUT01

> Length counts occurrences, not distinct symbols: |caddba|=6, so $|caddba|^2$=36.

Question sources

Computer Science Exit Exam practice collection · Question 251

Question 90 | CS0252

What will be the value of Z^R (reverse) if string Z = caddba?

A. abddac

B. cad

C. abd

D. caddba

Hint

Distinguish symbols, finite strings, their lengths and sets of strings. Apply the operation to its stated operands, including empty cases.

Answer A: abddac

Reversal reads the characters in the opposite order without dropping any: c a d d b a becomes a b d d a c.

Why each choice is right or wrong

A - Correct: Produces every symbol in reverse order: abddac.

B - Incorrect: Only a three-symbol prefix; does not reverse the full word.

C - Incorrect: Only the first three reversed symbols; drops the remaining characters.

D - Incorrect: Original word differs from its reverse at the first symbol.

Primary note proof

Study-note section AUT02

> Concatenation xy writes x followed by y: cddc·ababb=cddcababb; order generally matters. εx=xε=x. Define $x^0=\varepsilon$ and x^n as n copies for n≥1. Reverse x^R reads symbols backward: caddba reverses to abddac; $(xy)^R=y^Rx^R$ and $(x^R)^R=x$.

Study-note section AUT02

> For languages, LM={xy:x∈L,y∈M}, $L^0=\{\varepsilon\}$, and $L^{n+1}=L^nL$. Thus {e,fgh}{c,d}={ec,ed,fghc,fghd}; fghe is absent.

Question sources

Computer Science Exit Exam practice collection · Question 252

Question 91 | CS0253

If we have two strings Z = cddc and W = ababb, then the concatenation ZW will be?

A. ZW = cddcababb

B. ZW = cdab

C. ZW = ababbcddc

D. ZW = ca

Hint

Distinguish symbols, finite strings, their lengths and sets of strings. Apply the operation to its stated operands, including empty cases.

Answer A: ZW = cddcababb.

AUT02 defines xy as all of x followed by all of y, preserving order and every symbol. Appending ababb to cddc yields cddcababb, of length 4+5=9. Reversing the operands produces a different string; selecting prefixes or first letters discards symbols and is not concatenation.

Why each choice is right or wrong

A - Correct: This preserves cddc followed by ababb, giving the required nine-symbol concatenation.

B - Incorrect: cdab discards symbols from both operands instead of retaining both complete strings.

C - Incorrect: ababbcddc is WZ, reversing the specified operand order.

D - Incorrect: ca retains only initial symbols and is not the concatenation of the full strings.

Primary note proof

Study-note section AUT02

> Concatenation xy writes x followed by y: cddc·ababb=cddcababb; order generally matters. εx=xε=x. Define $x^0=\varepsilon$ and x^n as n copies for n≥1. Reverse x^R reads symbols backward: caddba reverses to abddac; $(xy)^R=y^Rx^R$ and $(x^R)^R=x$.

Question 92 | CS0254

Given input alphabet sigma = {a, b, c, d} and empty string lambda. Which one of the following is FALSE about lambda?

A. lambda*ab = ab

B. For any string Z, Z^0 = lambda

C. lambda is an element of sigma*

D. lambda = 0

Hint

Distinguish symbols, finite strings, their lengths and sets of strings. Apply the operation to its stated operands, including empty cases.

Answer D: The empty word is not numeric zero.

AUT01 distinguishes the empty word λ from the numeric symbol 0. AUT02 gives λx=x and Z^0=λ, while AUT03 includes the empty word in Σ*. Thus the first three claims express the standard empty-word identities under the displayed concatenation notation, and D is the false equality.

Why each choice is right or wrong

A - Incorrect: Reading the displayed star as concatenation, the empty word followed by ab is ab.

B - Incorrect: Every string's zeroth concatenation power is the empty word.

C - Incorrect: Kleene closure of the alphabet includes its zero-length word λ.

D - Correct: This equality is false: λ is a zero-length word, not the numeric symbol 0.

Primary note proof

Study-note section AUT01

> An alphabet Σ is a finite set of symbols. A word/string is a finite ordered sequence of symbols from Σ; a language is a set of words, L⊆Σ*. An empty word ε, also written λ, has length zero. The empty language ∅ contains no words; {ε} contains one.

Study-note section AUT01

> Length counts occurrences, not distinct symbols: |caddba|=6, so $|caddba|^2$=36.

Study-note section AUT02

> Concatenation xy writes x followed by y: cddc·ababb=cddcababb; order generally matters. εx=xε=x. Define x^0=ε and x^n as n copies for n≥1. Reverse x^R reads symbols backward: caddba reverses to abddac; $(xy)^R$=y^Rx^R and $(x^R)^R$=x.

Study-note section AUT02

> For languages, LM={xy:x∈L,y∈M}, L^0={ε}, and L^{n+1}=L^nL. Thus {e,fgh}{c,d}={ec,ed,fghc,fghd}; fghe is absent.

Study-note section AUT03

> $Σ^n$ contains words of exactly n symbols; for |Σ|=k, $|Σ^n|$=k^n, including $Σ^0$={ε}. Σ*=∪n≥0$Σ^n$ and $Σ^+$=∪n≥1$Σ^n$. Over a nonempty alphabet, $Σ^+$ excludes ε and Σ*=$Σ^+$∪{ε}. $Σ^2$ over {a,b} is {aa,ab,ba,bb}.

Study-note section AUT03

> For an arbitrary language L, L*=∪n≥0L^n and L^+=LL*. Unlike alphabet positive closure, L^+ can contain ε when ε∈L. ∅*={ε}, $∅^+$=∅, and {ε}*={ε}. Union means membership in either set; intersection requires the same word in both, not concatenation. Complement is Σ*−L and needs a fixed alphabet.

Question sources

Computer Science Exit Exam practice collection · Question 254

Question 93 | CS0255

Which one of the following is FALSE about any language L?

A. L^3 = L^1 * L^1 * L^1

B. L^0 = lambda

C. L* = L^0 union L^1 union L^2 union L^3 ...

D. L+ = L^1 union L^2 union L^3 ...

Hint

Distinguish symbols, finite strings, their lengths and sets of strings. Apply the operation to its stated operands, including empty cases.

Answer B: L^0 is {λ}, not the word λ itself.

AUT02 defines $L^0=\{\varepsilon\}$; AUT01 equates λ with ε. Thus the literal equality $L^0=\lambda$ confuses a set with its sole word and is false unless braces are explicitly understood. Reading the binary stars in A as the displayed concatenation separators, A is the third-power definition; C and D are the unions defining star and positive closure in AUT03.

Why each choice is right or wrong

A - Incorrect: With the displayed binary stars denoting concatenation, three copies of L form L^3, so this is true.

B - Correct: This is the false statement: the zeroth power is the singleton language {λ}, not the word λ.

C - Incorrect: The union of all nonnegative language powers is the definition of Kleene closure, so this is true.

D - Incorrect: The union of positive language powers is positive closure, even if L itself contains ε.

Primary note proof

Study-note section AUT03

Σ^n contains words of exactly n symbols; for $|\Sigma|=k$, $|\Sigma^n|=k^n$, including $\Sigma^0=\{\varepsilon\}$. $\Sigma^*=\bigcup n\geq 0\Sigma^n$ and $\Sigma^+=\bigcup n\geq 1\Sigma^n$. Over a nonempty alphabet, Σ^+ excludes ε and $\Sigma^*=\Sigma^+\cup\{\varepsilon\}$. Σ^2 over {a,b} is {aa,ab,ba,bb}.

Study-note section AUT03

For an arbitrary language L, $L^*=\cup n\geq 0 L^n$ and $L^+=LL^*$. Unlike alphabet positive closure, L^+ can contain ε when $\varepsilon\in L$. $\varnothing^*=\{\varepsilon\}$, $\varnothing^+=\varnothing$, and $\{\varepsilon\}^*=\{\varepsilon\}$. Union means membership in either set; intersection requires the same word in both, not concatenation. Complement is Σ^*-L and needs a fixed alphabet.

Study-note section AUT02

Concatenation xy writes x followed by y: cddc·ababb=cddcababb; order generally matters. εx=xε=x. Define $x^0=\varepsilon$ and x^n as n copies for n≥1. Reverse x^R reads symbols backward: caddba reverses to abddac; $(xy)^R=y^Rx^R$ and $(x^R)^R=x$.

Study-note section AUT02

For languages, LM={xy:x∈L,y∈M}, $L^0=\{\varepsilon\}$, and $L^{n+1}=L^nL$. Thus {e,fgh}{c,d}={ec,ed,fghc,fghd}; fghe is absent.

Study-note section AUT01

An alphabet Σ is a finite set of symbols. A word/string is a finite ordered sequence of symbols from Σ; a language is a set of words, $L\subseteq\Sigma^*$. An empty word ε, also written λ, has length zero. The empty language ∅ contains no words; {ε} contains one.

Question 94 | CS0256

Given input alphabet sigma = {a, b, c, d}, which one of the following is an element of set sigma^2?

A. b

B. c

C. ac

D. aabbccdd

Hint

Distinguish symbols, finite strings, their lengths and sets of strings. Apply the operation to its stated operands, including empty cases.

Answer C: ac.

AUT03 defines Σ^n as the words containing exactly n alphabet symbols. The given alphabet includes a and c, so ac has two permitted symbols and belongs to Σ^2. Single-symbol choices have length one; aabbccdd has length eight. Membership depends on length and symbol validity, not on including all alphabet symbols.

Why each choice is right or wrong

A - Incorrect: b uses an allowed symbol but has length one rather than the required two.

B - Incorrect: c is a one-symbol word and therefore belongs to Σ^1, not Σ^2.

C - Correct: ac has exactly two symbols, both drawn from the given alphabet.

D - Incorrect: aabbccdd has eight symbols; using each symbol twice does not make it a length-two word.

Primary note proof

Study-note section AUT03

> Σ^n contains words of exactly n symbols; for $|\Sigma|=k$, $|\Sigma^n|=k^n$, including $\Sigma^0=\{\varepsilon\}$. $\Sigma^*=\bigcup n\geq 0\Sigma^n$ and $\Sigma^+=\bigcup n\geq 1\Sigma^n$. Over a nonempty alphabet, Σ^+ excludes ε and $\Sigma^*=\Sigma^+\cup\{\varepsilon\}$. Σ^2 over {a,b} is {aa,ab,ba,bb}.

Study-note section AUT03

> For an arbitrary language L, $L^*=\bigcup n\geq 0L^n$ and $L^+=LL^*$. Unlike alphabet positive closure, L^+ can contain ε when $\varepsilon\in L$. $\varnothing^*=\{\varepsilon\}$, $\varnothing^+=\varnothing$, and $\{\varepsilon\}^*=\{\varepsilon\}$. Union means membership in either set; intersection requires the same word in both, not concatenation. Complement is Σ^*-L and needs a fixed alphabet.

Question sources

Computer Science Exit Exam practice collection · Question 256

Question 95 | CS0260

In a Turing Machine, the transition a -> b, L means:

A. Read a, write b and move left

B. Delete a, read b and move left

C. Write a, read b and move left

D. Replace b by a and move left

Hint

Compare production restrictions, memory access and language-family containments. Distinguish an exact characterization from an included subclass.

Answer A: Read a, write b and move left

The TM transition reads the scanned a, replaces it with b, and moves the head one cell left. This is the transition ordering (read symbol, write symbol, movement), with next state specified by the destination vertex.

Why each choice is right or wrong

A - Correct: Matches the scanned symbol, replacement, and L direction.

B - Incorrect: b is written rather than read; no distinct delete-then-read instruction is specified.

C - Incorrect: Swaps read and write roles.

D - Incorrect: Replaces the wrong symbol in the wrong direction.

Primary note proof

Study-note section AUT27

> δ(q,a)=(p,b,L) means read a in q, write b, move one cell left and enter p. Accept/reject halting states have no further moves under this convention.

Computer Science Exit Exam practice collection · Question 260

Question 96 | NS0161

What is the difference between a DFA and an NFA? Are they equally powerful?

Hint

Apply the stated transition, closure or equivalence rule step by step; distinguish a guaranteed bound from a value for one particular machine.

Answer: DFA has one successor per state/symbol; NFA permits sets. They recognize the same languages.

AUT09 permits an NFA to have zero, one or several next states and states that DFA and NFA recognize exactly REG. Subset construction simulates the simultaneous NFA possibilities by DFA states.

Primary note proof

Study-note section AUT06

> A deterministic finite automaton (DFA) is $M=(Q,\Sigma,\delta,q_0,F)$, with finite nonempty Q, start $q_0 \in Q$, accepting set $F \subseteq Q$ and total $\delta: Q \times \Sigma \to Q$. Exactly one next state is specified per state/symbol pair; this does not mean the whole machine has one transition.

Study-note section AUT09

> A nondeterministic finite automaton (NFA) permits zero, one or many successors: $\delta: Q \times \Sigma \to P(Q)$.

Study-note section AUT09

> An NFA is not more expressive than a DFA: both recognize exactly REG. Nondeterminism can make a description smaller.

Study-note section AUT10

> ε-closure(T) contains T and every state reachable through ε moves. Start the DFA at ε-closure($\{q_0\}$); for each current subset T and symbol a compute ε-closure($\bigcup_{q \in T} \delta(q,a)$). A subset accepts iff it intersects F.

Question sources

Automata & Complexity Theory review questions · Question 1

Question 97 | NS0162

What is the pumping lemma used for? Demonstrate with an example.

Hint

Respect the quantifier order and length constraints. A valid nonmembership argument must address every allowed decomposition, not one convenient split.

Answer: The regular pumping lemma can disprove regularity, for example for $a^n b^n$.

AUT15 chooses $a^p b^p$ after assuming a pumping length p. Every legal nonempty y in the first p symbols contains only a, so pumping it out changes the a count without changing b. That contradicts regularity.

Primary note proof

Study-note section AUT15

> If L is regular, some $p \geq 1$ satisfies: every $s \in L$ with $|s| \geq p$ has a split $s=xyz$, $|xy| \leq p$, $|y| \geq 1$, and $xy^i z \in L$ for every $i \geq 0$.

Study-note section AUT15

> For $L=\{a^n b^n : n \geq 0\}$, choose $a^p b^p$. Every allowed $y=a^k$ with $k \geq 1$; pumping $i=0$ leaves fewer a's than b's. The contradiction excludes every DFA.

Question sources

Automata & Complexity Theory review questions · Question 2

Question 98 | NS0163

What is the difference between P and NP? Why does it matter?

Hint

Separate resource bounds, certificate verification and reduction requirements. Use proved containments without assuming unresolved class separations.

Answer: P is deterministic polynomial-time decision; NP admits polynomial certificates. Equality remains open.

AUT34 defines P by deterministic polynomial running time and NP by nondeterministic polynomial time or polynomial-size verifiable certificates. P is included in NP, and equality is unresolved. This matters for converting efficiently checked witnesses into efficiently found decisions.

Primary note proof

Study-note section AUT34

> Complexity classes here contain decision languages. P consists of deterministic polynomial-time decidable languages; NP consists of nondeterministic polynomial-time decidable languages, equivalently polynomially verifiable yes-instances with polynomial-size certificates. A verifier must accept some certificate exactly for yes-inputs; no certificate may falsely establish a no-instance. NP means nondeterministic polynomial, not non-polynomial.

Study-note section AUT34

> P⊆NP because a verifier can ignore its certificate and run the P algorithm. P=NP remains open; NP does not mean definitely hard or definitely outside P. Finding versus verifying is an intuition for witnesses, not a rule that all NP instances need exponential search.

Study-note section AUT36

> X is NP-hard if every A∈NP satisfies A≤pX. It need not belong to NP and can even be undecidable. X is NP-complete if X∈NP and X is NP-hard.

Question sources

Automata & Complexity Theory review questions · Question 3

Question 99 | NS0164

Why is the halting problem undecidable? Explain the contradiction.

Hint

Check whether the required procedure must halt on every input, and distinguish solving a task from recognizing its yes-instances.

Answer: A proposed halting decider yields a program contradicting its own prediction.

AUT30 constructs D(x) to loop when H(x,x) predicts halting and to halt otherwise. On D's own description, either prediction is contradicted. Therefore no general halting decider exists, although simulation recognizes halting instances.

Primary note proof

Study-note section AUT30

> HALT={⟨M,w⟩:M halts on w} is recognizable: simulate and accept upon any halt. Suppose a decider H determines halting. Construct D(x) that loops if H(x,x) says halt, otherwise halts. Running D on its own description contradicts H in both cases. Thus HALT is undecidable and witnesses RE beyond DECIDABLE. Its complement is not RE, or both recognizers would yield a decider.

Question sources

Automata & Complexity Theory review questions · Question 4

Question 100 | NS0165

What is the Chomsky hierarchy and why are the containments proper?

Hint

Check whether the required procedure must halt on every input, and distinguish solving a task from recognizing its yes-instances.

Answer: REG⊊CFL⊊CSL⊊RE by increasing generative power; separating examples witness proper inclusions.

AUT05 supplies the proper family hierarchy. Equal pairs separate CFL from REG; equal triples separate CSL from CFL. CSLs are decidable by AUT25, while HALT is RE but undecidable under AUT30, separating CSL from RE.

Primary note proof

Study-note section AUT05

> Type 3 regular grammars correspond to finite automata; type 2 CFGs to nondeterministic PDAs; type 1 context-sensitive/noncontracting grammars to nondeterministic LBAs; type 0 unrestricted grammars to Turing recognizers.

Study-note section AUT05

> Use REG ⊊ CFL ⊊ CSL ⊊ DECIDABLE ⊊ RE, under the usual convention allowing S→ε with S absent from right sides when needed.

Study-note section AUT26

> a*b* and $\{a^n b : n \geq 0\}$ are regular. $a^n b^n$ is CFL but not regular. Over a two-symbol alphabet, ww^R is CFL, ww is not CFL; both are decidable. $a^n b^n c^n$ is CSL but not CFL, and therefore decidable. Every finite language is regular. A stronger grammar or TM can still recognize any of these lower-family languages.

Study-note section AUT30

> Thus HALT is undecidable and witnesses RE beyond DECIDABLE.

Question sources

Automata & Complexity Theory review questions · Question 5

Question 101 | NS0166

Which of the following correctly orders automata from LEAST to MOST powerful?

A. NFA < DFA < PDA < TM

B. PDA < NFA < DFA < TM

C. DFA = NFA < PDA < LBA < TM

D. TM < LBA < PDA < DFA

Hint

Compare production restrictions, memory access and language-family containments. Distinguish an exact characterization from an included subclass.

Answer C: DFA=NFA < PDA < LBA < TM in language-recognition power.

AUT09 equates DFA and NFA power. AUT05 assigns finite automata, nondeterministic PDAs, nondeterministic LBAs and Turing recognizers to successively stronger language families. That gives C under the standard nondeterministic PDA/LBA family convention. The comparison is expressiveness, not a statement that stronger models always run faster.

Why each choice is right or wrong

A - Incorrect: NFA and DFA have equal power rather than the strict order shown.

B - Incorrect: PDAs recognize more than regular languages, so placing PDA below finite automata reverses the hierarchy.

C - Correct: This gives equal finite-automaton power followed by the standard strictly increasing PDA/LBA/TM families.

D - Incorrect: This reverses the standard language-recognition power hierarchy.

Primary note proof

Study-note section AUT05

> Type 3 regular grammars correspond to finite automata; type 2 CFGs to nondeterministic PDAs; type 1 context-sensitive/noncontracting grammars to nondeterministic LBAs; type 0 unrestricted grammars to Turing recognizers.

Study-note section AUT05

> Use REG ⊊ CFL ⊊ CSL ⊊ DECIDABLE ⊊ RE, under the usual convention allowing S→ε with S absent from right sides when needed.

Question sources

Automata & Complexity Theory review questions · Question 1

Question 102 | NS0167

Complexity theory primarily studies:

A. How to design finite automata

B. Resources (time and space) required to solve computational problems

C. How to convert NFA to DFA

D. The syntax of formal grammars

Hint

Check whether the required procedure must halt on every input, and distinguish solving a task from recognizing its yes-instances.

Answer B: Time and space resources for computational problems.

AUT33 defines time as computation steps and space as memory cells, and AUT34 groups decision problems by polynomial resource bounds. Complexity studies these resource requirements as a function of encoded input size. Designing automata or transforming grammars may be objects of study, but neither is the general defining purpose.

Why each choice is right or wrong

A - Incorrect: Finite-automaton design is one specific task rather than the general study of computational resources.

B - Correct: Complexity theory classifies time and space requirements relative to input size.

C - Incorrect: NFA determinization is a particular construction, not the broad subject of complexity theory.

D - Incorrect: Grammar syntax concerns formal language description rather than resource requirements in general.

Primary note proof

Study-note section AUT-S01

> Computability theory asks whether an effective algorithm can solve a problem at all. For a decision problem, a decision procedure must terminate with the correct yes-or-no result on every input.

Study-note section AUT-S01

> Computational complexity theory studies the time and memory resources required to solve problems as functions of encoded input size. Automata theory studies abstract machine models and the languages they recognize; these subjects overlap but ask different questions.

Question sources

Automata & Complexity Theory review questions · Question 2

Question 103 | NS0168

Given $\Sigma = \{a, b\}$, which of the following is in Σ^2 but NOT in Σ^1?

A. a

B. b

C. ε

D. ab

Hint

Distinguish symbols, finite strings, their lengths and sets of strings. Apply the operation to its stated operands, including empty cases.

Answer D: ab.

AUT03 defines Σ^n by exact word length. Over {a,b}, ab contains two permitted symbols and is not length one. The single letters a and b belong to Σ^1; ε has length zero. Thus only ab satisfies both membership in Σ^2 and exclusion from Σ^1.

Why each choice is right or wrong

A - Incorrect: a has length one and belongs to Σ^1 rather than Σ^2.

B - Incorrect: b has length one, violating the required exact length two.

C - Incorrect: Epsilon has length zero and is not in Σ^2.

D - Correct: ab has two permitted symbols and is not a one-symbol word.

Primary note proof

Study-note section AUT03

> Σ^n contains words of exactly n symbols; for $|\Sigma|=k$, $|\Sigma^n|=k^n$, including $\Sigma^0=\{\varepsilon\}$. $\Sigma^*=\bigcup n\geq 0\Sigma^n$ and $\Sigma^+=\bigcup n\geq 1\Sigma^n$. Over a nonempty alphabet, Σ^+ excludes ε and $\Sigma^*=\Sigma^+\cup\{\varepsilon\}$. Σ^2 over {a,b} is {aa,ab,ba,bb}.

Study-note section AUT03

> For an arbitrary language L, $L^*=\bigcup n\geq 0 L^n$ and $L^+=LL^*$. Unlike alphabet positive closure, L^+ can contain ε when $\varepsilon\in L$. $\varnothing^*=\{\varepsilon\}$, $\varnothing^+=\varnothing$, and $\{\varepsilon\}^*=\{\varepsilon\}$. Union means membership in either set; intersection requires the same word in both, not concatenation. Complement is Σ^*-L and needs a fixed alphabet.

Question sources

Automata & Complexity Theory review questions · Question 3

Question 104 | NS0169

The set Σ^* for $\Sigma = \{0, 1\}$ includes which of the following?

A. ε (empty string)

B. All binary strings of length ≥ 1 only

C. Only finite-length strings starting with 1

D. All strings NOT over {0,1}

Hint

Distinguish symbols, finite strings, their lengths and sets of strings. Apply the operation to its stated operands, including empty cases.

Answer A: The empty string is included.

AUT03 defines Σ^* as the union of all nonnegative powers, including $\Sigma^0=\{\varepsilon\}$. Therefore the empty word belongs to the binary closure. Positive-length-only and starting-with-one descriptions exclude valid members, and strings using symbols outside {0,1} are outside this universe. The wording of B must not erase its restrictive only.

Why each choice is right or wrong

A - Correct: The zero power contributes epsilon to the Kleene closure.

B - Incorrect: The word only excludes epsilon, so this is not a complete description of Σ^*.

C - Incorrect: Binary strings starting with 0 and epsilon also belong, so the starting-with-1 restriction is false.

D - Incorrect: Σ^* consists of words over the specified binary alphabet, not words outside it.

Primary note proof

Study-note section AUT03

> Σ^n contains words of exactly n symbols; for $|\Sigma|=k$, $|\Sigma^n|=k^n$, including $\Sigma^0=\{\varepsilon\}$. $\Sigma^*=\bigcup n\geq 0\Sigma^n$ and $\Sigma^+=\bigcup n\geq 1\Sigma^n$. Over a nonempty alphabet, Σ^+ excludes ε and $\Sigma^*=\Sigma^+\cup\{\varepsilon\}$. Σ^2 over {a,b} is {aa,ab,ba,bb}.

Study-note section AUT03

> For an arbitrary language L, $L^*=\bigcup n\geq 0 L^n$ and $L^+=LL^*$. Unlike alphabet positive closure, L^+ can contain ε when $\varepsilon\in L$. $\varnothing^*=\{\varepsilon\}$, $\varnothing^+=\varnothing$, and $\{\varepsilon\}^*=\{\varepsilon\}$. Union means membership in either set; intersection requires the same word in both, not concatenation. Complement is Σ^*-L and needs a fixed alphabet.

Question sources

Automata & Complexity Theory review questions · Question 4

Question 105 | NS0170

What is the difference between Σ^* and Σ^+?

A. Σ^* excludes strings of length 2 or more

B. Σ^+ includes the empty string but Σ^* does not

C. Σ^* includes the empty string (ε) but Σ^+ does not

D. They are identical

Hint

Distinguish symbols, finite strings, their lengths and sets of strings. Apply the operation to its stated operands, including empty cases.

Answer C: Σ^* includes ε; Σ^+ excludes it.

AUT03 explicitly gives $\Sigma^*=\Sigma^+\cup\{\varepsilon\}$ for a nonempty alphabet. Both operations allow arbitrarily long finite words, but only star includes length zero. This statement concerns alphabet closure; the note separately cautions that positive closure of an arbitrary language containing epsilon can itself include epsilon.

Why each choice is right or wrong

A - Incorrect: Σ^* contains words of every finite length, including length two and above.

B - Incorrect: This reverses which alphabet closure contains the empty word.

C - Correct: Star includes the zero-length word and positive alphabet closure omits it.

D - Incorrect: They differ at least by epsilon for the nonempty alphabet convention.

Primary note proof

Study-note section AUT03

> Σ^n contains words of exactly n symbols; for $|\Sigma|=k$, $|\Sigma^n|=k^n$, including $\Sigma^0=\{\varepsilon\}$. $\Sigma^*=\bigcup n\geq 0\Sigma^n$ and $\Sigma^+=\bigcup n\geq 1\Sigma^n$. Over a nonempty alphabet, Σ^+ excludes ε and $\Sigma^*=\Sigma^+\cup\{\varepsilon\}$. Σ^2 over {a,b} is {aa,ab,ba,bb}.

Study-note section AUT03

> For an arbitrary language L, $L^*=\bigcup n\geq 0 L^n$ and $L^+=LL^*$. Unlike alphabet positive closure, L^+ can contain ε when $\varepsilon\in L$. $\varnothing^*=\{\varepsilon\}$, $\varnothing^+=\varnothing$, and $\{\varepsilon\}^*=\{\varepsilon\}$. Union means membership in either set; intersection requires the same word in both, not concatenation. Complement is Σ^*-L and needs a fixed alphabet.

Question sources

Automata & Complexity Theory review questions · Question 5

Question 106 | NS0171

In the five-tuple $M = (Q, \Sigma, \delta, q_0, F)$ of an FSM, which component determines how the machine moves from state to state?

A. Q - the set of states

B. δ - the transition function

C. F - the set of accepting states

D. q_0 - the initial state

Hint

Read the transition domain and acceptance condition carefully. Track which inputs are consumed and evaluate the whole word under the stated model.

Answer B: δ, the transition function.

AUT06 defines $\delta:Q\times\Sigma\to Q$, mapping a current state and input symbol to the next state. That is precisely the movement rule asked for. Q lists available states, F marks acceptance and q_0 fixes the starting state; none of those alone specifies the transitions between states.

Why each choice is right or wrong

A - Incorrect: Q supplies state names but not the next-state rule for input symbols.

B - Correct: Delta maps the current state and input symbol to the next state.

C - Incorrect: F identifies acceptance rather than transitions between states.

D - Incorrect: The initial state specifies where processing starts, not how each symbol changes state.

Primary note proof

Study-note section AUT06

> A deterministic finite automaton (DFA) is $M=(Q,\Sigma,\delta,q_0,F)$, with finite nonempty Q, start $q_0\in Q$, accepting set $F\subseteq Q$ and total $\delta:Q\times\Sigma\to Q$. Exactly one next state is specified per state/symbol pair; this does not mean the whole machine has one transition. F may be empty, recognizing $\varnothing$.

Study-note section AUT06

> Start at q_0 and consume the entire input. Accept iff the ending state is in F; visiting an accepting state earlier is insufficient. ε is accepted exactly when $q_0\in F$. A nonaccepting sink loops on every symbol and cannot reach acceptance; it still finishes after finite input. Finite automata have finite memory encoded by states, not no state or no ability to remember any history.

Question sources

Automata & Complexity Theory review questions · Question 6

Question 107 | NS0172

What is the defining characteristic that makes an automaton 'deterministic'?

A. It has exactly one accepting state

B. It processes input from right to left

C. It never enters a dead state

D. For every (state, input) pair, there is exactly ONE next state

Hint

Read the transition domain and acceptance condition carefully. Track which inputs are consumed and evaluate the whole word under the stated model.

Answer D: One next state for every state/input-symbol pair.

AUT06 explicitly defines exactly one successor per state/symbol pair. Determinism does not constrain the number of final states, input-reading direction or whether a rejecting sink is reachable. The uniqueness concerns each transition choice, not the number of states or transitions in the entire automaton.

Why each choice is right or wrong

A - Incorrect: A DFA may have zero, one or several accepting states.

B - Incorrect: Right-to-left processing is not the definition of determinism.

C - Incorrect: Deterministic automata may legitimately have reachable rejecting sinks.

D - Correct: The next state is uniquely determined by the current state and current input symbol.

Primary note proof

Study-note section AUT06

> A deterministic finite automaton (DFA) is $M=(Q,\Sigma,\delta,q_0,F)$, with finite nonempty Q, start $q_0 \in Q$, accepting set $F \subseteq Q$ and total $\delta: Q \times \Sigma \to Q$. Exactly one next state is specified per state/symbol pair; this does not mean the whole machine has one transition. F may be empty, recognizing $\varnothing$.

Study-note section AUT06

> Start at q_0 and consume the entire input. Accept iff the ending state is in F; visiting an accepting state earlier is insufficient. ε is accepted exactly when $q_0 \in F$. A nonaccepting sink loops on every symbol and cannot reach acceptance; it still finishes after finite input. Finite automata have finite memory encoded by states, not no state or no ability to remember any history.

Question sources

Automata & Complexity Theory review questions · Question 7

Question 108 | NS0173

Over the alphabet Σ={a,b,c}, what is the minimum number of states in a complete DFA accepting exactly the strings that start with abc?

A. 3

B. 5

C. 4

D. 6

Hint

Read the transition domain and acceptance condition carefully. Track which inputs are consumed and evaluate the whole word under the stated model.

Answer B: 5

Before completing abc, the DFA must distinguish no matched symbol, a matched, and ab matched. It then needs an accepting state for all continuations after abc and a rejecting sink for any earlier mismatch. These five distinct situations require five states in a complete DFA. Including c in the alphabet makes the intended prefix language nonempty and the standard prefix-state construction applicable.

Why each choice is right or wrong

A - Incorrect: Three omits the accepting continuation and rejecting-mismatch situations.

B - Correct: Three incomplete-prefix stages plus accepting continuation and sink give five.

C - Incorrect: Four omits a necessary distinct situation in the complete DFA.

D - Incorrect: Six exceeds the five-state construction and is not minimal.

Primary note proof

Study-note section AUT08

> For a fixed valid word w of length n, a DFA for strings ending in w needs n+1 states representing the longest consumed suffix that is a prefix of w. Overlapping prefixes determine fallback transitions. Distinct prefixes are distinguishable by suitable continuations, proving the lower bound; do not add an unnecessary rejecting sink.

Study-note section AUT08

> For strings starting with w, a complete DFA ordinarily has n matched-prefix stages, an accepting continuation state and a rejecting sink: n+2 when n≥1 and the alphabet allows mismatches.

Question sources

Automata & Complexity Theory review questions · Question 8

Question 109 | NS0174

In a DFA, what happens after reaching a nonaccepting trap state while processing a finite input?

A. It immediately accepts the input

B. It restarts processing from the initial state

C. It stays there for every remaining input symbol and rejects after the input ends.

D. It transitions to the initial state on the next input

Hint

Read the transition domain and acceptance condition carefully. Track which inputs are consumed and evaluate the whole word under the stated model.

Answer C: It stays there for every remaining input symbol and rejects after the input ends.

A nonaccepting trap is a sink: every subsequent input symbol leaves the machine in that same state. It therefore cannot recover an accepting state. Once the finite remaining input is consumed, the DFA finishes and rejects. A self-loop transition does not imply an infinite computation after the input ends, nor does it restart processing or transfer to the start state.

Why each choice is right or wrong

A - Incorrect: The trap is nonaccepting, so it does not accept.

B - Incorrect: A sink stays in place rather than restarting.

C - Correct: It remains in the trap for the remaining symbols and rejects when input ends.

D - Incorrect: The next transition returns to the trap itself.

Primary note proof

Study-note section AUT06

> A deterministic finite automaton (DFA) is $M=(Q,\Sigma,\delta,q_0,F)$, with finite nonempty Q, start $q_0 \in Q$, accepting set $F \subseteq Q$ and total $\delta: Q \times \Sigma \to Q$. Exactly one next state is specified per state/symbol pair; this does not mean the whole machine has one transition. F may be empty, recognizing $\varnothing$.

Study-note section AUT06

> Start at q_0 and consume the entire input. Accept iff the ending state is in F; visiting an accepting state earlier is insufficient. ε is accepted exactly when $q_0 \in F$. A nonaccepting sink loops on every symbol and cannot reach acceptance; it still finishes after finite input. Finite automata have finite memory encoded by states, not no state or no ability to remember any history.

Question sources

Automata & Complexity Theory review questions · Question 9

Question 110 | NS0175

The transition function of a DFA is defined as:

A. $\delta: Q \times \Sigma \to Q$

B. $\delta: Q \times \Sigma \to 2^Q$

C. $\delta: Q \times \Sigma \times \Gamma \to Q \times \Gamma^* \times \{L,R\}$

D. $\delta: Q \times (\Sigma \cup \{\varepsilon\}) \to 2^Q$

Hint

Read the transition domain and acceptance condition carefully. Track which inputs are consumed and evaluate the whole word under the stated model.

Answer A: $\delta:Q\times\Sigma\to Q$.

AUT06 defines a total function from a state/input-symbol pair to one state. A set-valued codomain describes NFA choices; allowing epsilon in the input domain describes epsilon-NFA transitions. Stack alphabets and write/direction outputs belong to richer models and are not components of the ordinary DFA transition signature.

Why each choice is right or wrong

A - Correct: This is the exact state/symbol to unique next-state signature of a DFA.

B - Incorrect: A powerset codomain allows nondeterministic next-state choices.

C - Incorrect: The extra storage alphabet and write/direction outputs do not describe an ordinary finite automaton.

D - Incorrect: Epsilon input and set-valued successors describe an epsilon-NFA rather than a DFA.

Primary note proof

Study-note section AUT06

> A deterministic finite automaton (DFA) is $M=(Q,\Sigma,\delta,q_0,F)$, with finite nonempty Q, start $q_0\in Q$, accepting set $F\subseteq Q$ and total $\delta:Q\times\Sigma\to Q$. Exactly one next state is specified per state/symbol pair; this does not mean the whole machine has one transition. F may be empty, recognizing $\varnothing$.

Study-note section AUT06

> Start at q_0 and consume the entire input. Accept iff the ending state is in F; visiting an accepting state earlier is insufficient. ε is accepted exactly when $q_0\in F$. Finite automata have finite memory encoded by states, not no state or no ability to remember any history.

Question sources

Automata & Complexity Theory review questions · Question 10

Question 111 | NS0176

Which operation on regular languages gives all strings that are NOT in the original language?

A. Reverse (L^R)

B. Complement (Σ* - L)

C. Kleene Star (L*)

D. Concatenation

Hint

Track mandatory symbols and factors that may repeat or disappear. Use short test words to check both directions of each proposed language description.

Answer B: Complement, relative to the fixed alphabet universe.

AUT03 defines complement as $\Sigma^* - L$ and requires a fixed alphabet. This selects precisely the words in the universe absent from L. Reversal changes symbol order, star concatenates copies and concatenation joins words; none performs the required membership negation. Completing a DFA before swapping final states is the recognition construction in AUT14.

Why each choice is right or wrong

A - Incorrect: Reversal changes word order rather than selecting all words outside the language.

B - Correct: Complement contains exactly the universe's words that are not members of L.

C - Incorrect: Kleene star concatenates zero or more language words and does not negate membership.

D - Incorrect: Concatenation joins words from languages rather than forming the universe-relative exclusion.

Primary note proof

Study-note section AUT03

> Σ^n contains words of exactly n symbols; for $|\Sigma|=k$, $|\Sigma^n|=k^n$, including $\Sigma^0=\{\varepsilon\}$. $\Sigma^*=\bigcup n\geq 0\Sigma^n$ and $\Sigma^+=\bigcup n\geq 1\Sigma^n$. Over a nonempty alphabet, Σ^+ excludes ε and $\Sigma^*=\Sigma^+\cup\{\varepsilon\}$. Σ^2 over {a,b} is {aa,ab,ba,bb}.

Study-note section AUT03

> For an arbitrary language L, $L^*=\bigcup n\geq 0L^n$ and $L^+=LL^*$. Unlike alphabet positive closure, L^+ can contain ε when $\varepsilon\in L$. $\varnothing^*=\{\varepsilon\}$, $\varnothing^+=\varnothing$, and $\{\varepsilon\}^*=\{\varepsilon\}$. Union means membership in either set; intersection requires the same word in both, not concatenation. Complement is Σ^*-L and needs a fixed alphabet.

Study-note section AUT14

> Right-linear rules have form A→aB, A→a or permitted ε rules; left-linear rules put the single variable at the opposite end, A→Ba. Both consistent orientations generate REG; arbitrarily mixing them can generate nonregular languages, for example S→aA|ε, A→Sb generates a^nb^n. A CFG rule A→aBA is legal but not regular-grammar form.

Study-note section AUT14

> Regular languages are closed under union, concatenation, star, reversal, intersection, difference and complement.

Question sources

Automata & Complexity Theory review questions · Question 11

Question 112 | NS0177

The language L* (Kleene Star of L) is defined as:

A. $L^1 \cup L^2 \cup L^3 \cup ...$

B. $L \cap \Sigma^*$

C. All strings not in L

D. $L^0 \cup L^1 \cup L^2 \cup ...$ (includes empty string because $L^0 = \{\varepsilon\}$)

Hint

Distinguish symbols, finite strings, their lengths and sets of strings. Apply the operation to its stated operands, including empty cases.

Answer D: The union of all nonnegative language powers.

AUT03 defines L* by union over every n≥0, and AUT02 gives $L^0=\{\varepsilon\}$. Thus the zero power guarantees the empty word even when L is empty. A omits the zero power and instead describes positive closure; intersection with the universe and complement are different operations.

Why each choice is right or wrong

A - Incorrect: This omits L^0 and defines positive closure rather than general Kleene star.

B - Incorrect: Intersecting a language with its word universe simply retains L.

C - Incorrect: All words outside L define complement, not repeated concatenation.

D - Correct: The nonnegative-power union is the definition and its zeroth term contributes epsilon.

Primary note proof

Study-note section AUT03

> Σ^n contains words of exactly n symbols; for $|\Sigma|=k$, $|\Sigma^n|=k^n$, including $\Sigma^0=\{\varepsilon\}$. $\Sigma^*=\bigcup n\geq 0\Sigma^n$ and $\Sigma^+=\bigcup n\geq 1\Sigma^n$. Over a nonempty alphabet, Σ^+ excludes ε and $\Sigma^*=\Sigma^+\cup\{\varepsilon\}$. Σ^2 over {a,b} is {aa,ab,ba,bb}.

Study-note section AUT03

> For an arbitrary language L, $L^*=\bigcup n\geq 0 L^n$ and $L^+=LL^*$. Unlike alphabet positive closure, L^+ can contain ε when $\varepsilon\in L$. $\varnothing^*=\{\varepsilon\}$, $\varnothing^+=\varnothing$, and $\{\varepsilon\}^*=\{\varepsilon\}$. Union means membership in either set; intersection requires the same word in both, not concatenation. Complement is Σ^*-L and needs a fixed alphabet.

Study-note section AUT02

Concatenation xy writes x followed by y: cddc·ababb=cddcababb; order generally matters. εx=xε=x. Define $x^0=\varepsilon$ and x^n as n copies for n≥1. Reverse x^R reads symbols backward: caddba reverses to abddac; $(xy)^R=y^Rx^R$ and $(x^R)^R=x$.

Study-note section AUT02

For languages, $LM=\{xy:x\in L,y\in M\}$, $L^0=\{\varepsilon\}$, and $L^{n+1}=L^nL$. Thus {e,fgh}{c,d}={ec,ed,fghc,fghd}; fghe is absent.

Question sources

Automata & Complexity Theory review questions · Question 12

Question 113 | NS0178

In an NFA, the transition function maps each (state, input) pair to:

A. Exactly one next state

B. The initial state always

C. A SET of possible next states (including the empty set)

D. A symbol and a direction

Hint

Read the transition domain and acceptance condition carefully. Track which inputs are consumed and evaluate the whole word under the stated model.

Answer C: A set of possible successors, possibly empty.

AUT09 defines an NFA transition as a mapping into the powerset of Q, so zero, one or several successors are permitted. The empty set represents a stuck branch, not an invalid machine. A uniquely determined singleton is only a deterministic special case; fixed resets and tape write/direction outputs do not describe the NFA signature.

Why each choice is right or wrong

A - Incorrect: One successor is permitted but not required; NFA transitions may have zero or several.

B - Incorrect: An NFA transition need not return to the initial state.

C - Correct: The powerset codomain permits any subset of states, including the empty set.

D - Incorrect: Write-symbol and direction outputs are tape-machine operations, not NFA state-set transitions.

Primary note proof

Study-note section AUT09

> A nondeterministic finite automaton (NFA) permits zero, one or many successors: $\delta:Q\times\Sigma\to P(Q)$. An ε-NFA additionally permits moves without consuming input, using domain $Q\times(\Sigma\cup\{\varepsilon\})$. Some books include ε moves in the term NFA; state the convention. An NFA accepts iff at least one finite path consumes the complete word and finishes in F, including permitted ε moves before/after symbols.

Study-note section AUT09

> An NFA is not more expressive than a DFA: both recognize exactly REG. Nondeterminism can make a description smaller. A DFA is a special NFA after interpreting its unique successor as a singleton set.

Question sources

Automata & Complexity Theory review questions · Question 13

Question 114 | NS0179

An NFA accepts a string if:

A. ALL computation paths lead to an accepting state

B. AT LEAST ONE computation path leads to an accepting state

C. The majority of paths lead to accepting states

D. The last state visited is the accepting state

Hint

Read the transition domain and acceptance condition carefully. Track which inputs are consumed and evaluate the whole word under the stated model.

Answer B: At least one path consumes the whole word and finishes accepting.

AUT09 states existential acceptance over finite computation paths, with the entire word consumed and permitted epsilon moves included. B expresses that existential condition, interpreted with the full-input requirement. Failed branches do not cancel an accepting branch, and counting a majority or asking every path to accept gives different, incorrect conditions.

Why each choice is right or wrong

A - Incorrect: Requiring all paths would wrongly reject words with one accepting branch and another failing branch.

B - Correct: One complete accepting path suffices; it must consume the whole input.

C - Incorrect: Path majority is irrelevant; the acceptance condition is existential rather than statistical.

D - Incorrect: There is no single global last state across nondeterministic branches, and unread input cannot be ignored.

Primary note proof

Study-note section AUT09

> A nondeterministic finite automaton (NFA) permits zero, one or many successors: $\delta:Q\times\Sigma\to P(Q)$. An ε-NFA additionally permits moves without consuming input, using domain $Q\times(\Sigma\cup\{\varepsilon\})$. Some books include ε moves in the term NFA; state the convention. Question sources

Automata & Complexity Theory review questions · Question 14

Question 115 | NS0180

Which statement about DFAs and NFAs is CORRECT?

A. Every NFA can be converted to an equivalent DFA recognizing the same language

B. NFAs are strictly more powerful than DFAs

C. DFAs can recognize languages that NFAs cannot

D. NFAs cannot recognize regular languages

Hint

Apply the stated transition, closure or equivalence rule step by step; distinguish a guaranteed bound from a value for one particular machine.

Answer A: Every NFA has an equivalent DFA.

AUT09 says both machine types recognize exactly regular languages, and AUT10 constructs equivalent DFA states as reachable NFA-state subsets. Nondeterminism may reduce representation size but does not add expressive power. Therefore A is true while each claim that one family recognizes languages inaccessible to the other is false.

Why each choice is right or wrong

A - Correct: Subset construction produces a DFA accepting exactly the NFA's language.

B - Incorrect: Nondeterminism may improve succinctness but does not exceed regular-language power.

C - Incorrect: Every DFA is also an NFA special case, so no such exclusive DFA language exists.

D - Incorrect: NFAs recognize exactly the regular languages, the opposite of this claim.

Primary note proof

Study-note section AUT09

> A nondeterministic finite automaton (NFA) permits zero, one or many successors: $\delta:Q\times\Sigma\to P(Q)$. An ε-NFA additionally permits moves without consuming input, using domain $Q\times(\Sigma\cup\{\varepsilon\})$. Some books include ε moves in the term NFA; state the convention. An NFA accepts iff at least one finite path consumes the complete word and finishes in F, including permitted ε moves before/after symbols.

Study-note section AUT09

> An NFA is not more expressive than a DFA: both recognize exactly REG. Nondeterminism can make a description smaller. A DFA is a special NFA after interpreting its unique successor as a singleton set.

Study-note section AUT10

> ε-closure(T) contains T and every state reachable through ε moves. Start the DFA at ε-closure($\{q_0\}$); for each current subset T and symbol a compute ε-closure($\bigcup q\in T\delta(q,a)$). A subset accepts iff it intersects F. Explore only reachable subsets; the empty subset is the rejecting sink when reached. An n-state NFA yields at most 2^n DFA states, not necessarily exactly 2^n.

Question sources

Automata & Complexity Theory review questions · Question 15

Question 116 | NS0181

What is an ε-transition in an NFA?

A. A transition that rejects the current input

B. A transition that only occurs at the end of input

C. A transition to the dead state

D. A transition that occurs without consuming any input symbol

Hint

Read the transition domain and acceptance condition carefully. Track which inputs are consumed and evaluate the whole word under the stated model.

Answer D: A move that consumes no input symbol.

AUT09 explicitly defines epsilon moves as transitions without consuming input. They may occur before, between or after symbol-consuming transitions when the machine permits them. They do not inherently mean rejection or movement to a sink, and they do not waive the requirement that an accepting computation consume the full word.

Why each choice is right or wrong

A - Incorrect: An epsilon move is not intrinsically rejecting; its destination and later path determine acceptance.

B - Incorrect: Permitted epsilon moves can occur before or between input symbols as well as at the end.

C - Incorrect: Its destination need not be a dead state.

D - Correct: The machine changes state without consuming a symbol from the input.

Primary note proof

Study-note section AUT09

> A nondeterministic finite automaton (NFA) permits zero, one or many successors: $\delta:Q\times\Sigma\to P(Q)$. An ε-NFA additionally permits moves without consuming input, using domain $Q\times(\Sigma\cup\{\varepsilon\})$. Some books include ε moves in the term NFA; state the convention. An NFA accepts iff at least one finite path consumes the complete word and finishes in F, including permitted ε moves before/after symbols.

Question sources

Automata & Complexity Theory review questions · Question 16

Question 117 | NS0182

When converting an NFA with n states to an equivalent DFA, the DFA may have at most how many states?

A. n states

B. n^2 states

C. 2^n states (the power set of Q)

D. n+1 states

Hint

Apply the stated transition, closure or equivalence rule step by step; distinguish a guaranteed bound from a value for one particular machine.

Answer C: At most 2^n states.

AUT10 states the subset-construction bound explicitly. An n-element state set has 2^n subsets, and each DFA state denotes one subset. Only reachable subsets need be included, so the bound need not be attained. Linear, quadratic and n+1 bounds are not general worst-case guarantees for NFA determinization.

Why each choice is right or wrong

A - Incorrect: A deterministic equivalent may require more than the original n states.

B - Incorrect: A quadratic bound does not cover the general powerset worst case.

C - Correct: There are 2^n possible subsets of the n NFA states.

D - Incorrect: An n+1 bound is not sufficient for general subset construction.

Primary note proof

Study-note section AUT10

> ε-closure(T) contains T and every state reachable through ε moves. Start the DFA at ε-closure({q_0}); for each current subset T and symbol a compute ε-closure(∪q∈Tδ(q,a)). A subset accepts iff it intersects F. Explore only reachable subsets; the empty subset is the rejecting sink when reached. An n-state NFA yields at most 2^n DFA states, not necessarily exactly 2^n.

Question sources

Automata & Complexity Theory review questions · Question 17

Question 118 | NS0183

What does the regular expression (0+1)*1 describe?

A. All binary strings

B. All binary strings that END with '1'

C. All binary strings starting with '1'

D. All binary strings containing exactly one '1'

Hint

Apply the stated transition, closure or equivalence rule step by step; distinguish a guaranteed bound from a value for one particular machine.

Answer B: All binary strings ending in 1.

With + as union, (0+1)* generates any finite binary prefix, including empty. Concatenating the final 1 forces the whole word to end in 1. It does not constrain the beginning or total number of ones: 01 and 11 are included, while epsilon and words ending in 0 are not.

Why each choice is right or wrong

A - Incorrect: Epsilon and words ending in zero are binary strings excluded by the final mandatory 1.

B - Correct: An arbitrary binary prefix followed by 1 is precisely a binary word ending in 1.

C - Incorrect: The arbitrary prefix may begin with zero, as in 01.

D - Incorrect: The prefix may contain additional ones, so exactly-one is too restrictive.

Primary note proof

Study-note section AUT12

> Classical expressions use ∅, ε, symbols, union, concatenation and star. A union B is written A|B or A+B; postfix r^+ means one-or-more r repetitions and is a different use of +. Parenthesize when conventions might clash. Star binds tightest, concatenation next, union last. r? means r|ε; r^+=rr*.

Study-note section AUT12

> (a|b)*a denotes words ending a; 0*10* denotes exactly one 1; a*(b|c) gives zero-or-more a's then exactly one b or c, so aab belongs but aaa and aaabc do not.

Question sources

Automata & Complexity Theory review questions · Question 18

Question 119 | NS0184

Which regular expression describes the language of all strings over {a,b} with at least one 'a'?

A. (a+b)*a(a+b)*

B. b*ab*

C. (a+b)+

D. a(a+b)*

Hint

Track mandatory symbols and factors that may repeat or disappear. Use short test words to check both directions of each proposed language description.

Answer A: (a+b)*a(a+b)*.

AUT13 gives this construction explicitly for at least one a. The middle a guarantees existence, while both stars permit additional a or b anywhere. b*ab* permits exactly one a; positive closure also permits all-b words, and a(a+b)* requires the first symbol rather than merely some symbol to be a.

Why each choice is right or wrong

A - Correct: The required middle a guarantees existence while unrestricted sides allow all other positions.

B - Incorrect: b*ab* excludes words with multiple a symbols and therefore denotes exactly one a.

C - Incorrect: Positive closure admits nonempty all-b words, which contain no a.

D - Incorrect: This requires a at the beginning and excludes valid words such as ba.

Primary note proof

Study-note section AUT13

> To require at least one a anywhere over {a,b}, use (a|b)*a(a|b)*. b*ab* requires exactly one a. At least two zeros uses (0|1)*0(0|1)*0(0|1)*; the zeros need not be adjacent. Testing 010 distinguishes it from a requirement for substring 00. For S→aS|ε, any number of a's is generated, giving a*.

Question sources

Automata & Complexity Theory review questions · Question 19

Question 120 | NS0185

The regular expression 0*10* represents:

A. All binary strings

B. All binary strings starting with 1

C. All binary strings containing exactly one '1'

D. All binary strings ending with '0'

Hint

Apply the stated transition, closure or equivalence rule step by step; distinguish a guaranteed bound from a value for one particular machine.

Answer C: Exactly one 1, with any number of zeros on either side.

AUT12 explicitly interprets 0*10* as exactly one 1. Both stars contribute only zeros, including none, so they cannot add another 1. The word 1 is accepted, while 11 and epsilon are not. No constraint forces the first symbol to be 1 or the final symbol to be zero.

Why each choice is right or wrong

A - Incorrect: Many binary words, including epsilon and 11, are excluded.

B - Incorrect: Leading zeros are permitted, so accepted words need not start with 1.

C - Correct: Only the mandatory middle symbol is 1; all other generated symbols are zeros.

D - Incorrect: The trailing zero star can be empty, so accepted words may end in 1.

Primary note proof

Study-note section AUT12

> Classical expressions use ∅, ε, symbols, union, concatenation and star. A union B is written A|B or A+B; postfix r^+ means one-or-more r repetitions and is a different use of +. Parenthesize when conventions might clash. Star binds tightest, concatenation next, union last. r? means r|ε; r^+=rr*.

Study-note section AUT12

> (a|b)*a denotes words ending a; 0*10* denotes exactly one 1; a*(b|c) gives zero-or-more a's then exactly one b or c, so aab belongs but aaa and aaabc do not.

Question sources

Automata & Complexity Theory review questions · Question 20

Question 121 | NS0186

Which of the following languages CANNOT be described by a regular expression?

A. All strings over {a,b} starting with 'a'

B. All binary strings of even length

C. All strings containing at least two 'b's

D. $\{a^n b^n \mid n \geq 1\}$ - strings with equal a's and b's

Hint

Respect the quantifier order and length constraints. A valid nonmembership argument must address every allowed decomposition, not one convenient split.

Answer D: The equal-count language $a^n b^n$ is nonregular.

AUT15 uses $a^p b^p$ and shows that pumping any permitted initial a block breaks equal counts. Classical regular expressions cannot describe this language. Starting with a fixed symbol, even length and a minimum number of b occurrences require only finite-state information, so the other descriptions are regular.

Why each choice is right or wrong

A - Incorrect: A fixed starting symbol can be recognized by finitely many prefix states.

B - Incorrect: Even length needs only two parity states and is regular.

C - Incorrect: Counting b occurrences up to a threshold of two needs finitely many states.

D - Correct: Unbounded equality of separated counts defeats regular pumping and therefore classical regular expressions.

Primary note proof

Study-note section AUT15

> If L is regular, some $p \geq 1$ satisfies: every $s \in L$ with $|s| \geq p$ has a split $s=xyz$, $|xy| \leq p$, $|y| \geq 1$, and $xy^i z \in L$ for every $i \geq 0$.

Study-note section AUT15

> For $L=\{a^n b^n : n \geq 0\}$, choose $a^p b^p$. Every allowed $y=a^k$ with $k \geq 1$; pumping $i=0$ leaves fewer a's than b's. The contradiction excludes every DFA.

Question sources

Automata & Complexity Theory review questions · Question 21

Question 122 | NS0187

In the Chomsky hierarchy, which grammar type corresponds to Finite Automata?

A. Type 0 - Unrestricted Grammar

B. Type 3 - Regular Grammar

C. Type 2 - Context-Free Grammar

D. Type 1 - Context-Sensitive Grammar

Hint

Compare production restrictions, memory access and language-family containments. Distinguish an exact characterization from an included subclass.

Answer B: Type 3 regular grammars.

AUT05 directly pairs Type 3 regular grammars with finite automata. Other grammar types can generate regular sublanguages, but the question asks which family corresponds to the finite-automaton model, an exact-family comparison. Type 2, Type 1 and Type 0 correspond to progressively stronger stack, bounded-tape and unrestricted-tape recognition families.

Why each choice is right or wrong

A - Incorrect: Type 0 corresponds to unrestricted Turing recognition rather than exactly finite-automaton power.

B - Correct: Type 3 is the regular grammar family exactly matched by finite automata.

C - Incorrect: Type 2 corresponds to nondeterministic pushdown recognition.

D - Incorrect: Type 1 corresponds to nondeterministic linear-bounded recognition.

Primary note proof

Study-note section AUT05

> Type 3 regular grammars correspond to finite automata; type 2 CFGs to nondeterministic PDAs; type 1 context-sensitive/noncontracting grammars to nondeterministic LBAs; type 0 unrestricted grammars to Turing recognizers.

Study-note section AUT05

> Use REG ⊊ CFL ⊊ CSL ⊊ DECIDABLE ⊊ RE, under the usual convention allowing S→ε with S absent from right sides when needed.

Question sources

Automata & Complexity Theory review questions · Question 22

Question 123 | NS0188

A formal grammar is defined as a 4-tuple G = (V, Σ, P, S). What does 'P' represent?

A. The set of all accepting states

B. The power set of the terminal alphabet

C. The set of production rules (A → β)

D. The pushdown stack alphabet

Hint

Distinguish symbols, finite strings, their lengths and sets of strings. Apply the operation to its stated operands, including empty cases.

Answer C: The set of production rules.

AUT04 defines V as variables, Σ as terminals, P as productions and S as the start variable. Productions specify the allowed rewriting steps used to generate terminal words. Accepting states and stack alphabets belong to machine definitions, while an alphabet powerset is not the meaning of P in this grammar tuple.

Why each choice is right or wrong

A - Incorrect: Accepting states are a recognizer component, not the production component of a grammar.

B - Incorrect: P is not the powerset notation for the alphabet in this tuple.

C - Correct: P denotes the allowed grammar-production rewrite rules.

D - Incorrect: A stack alphabet belongs to PDA storage rather than the grammar's production set.

Primary note proof

Study-note section AUT04

> Write G=(V,Σ,P,S): finite variables V, terminals Σ disjoint from V, productions P and start variable S∈V. A production replaces its left side by its right side. The language is L(G)={w∈Σ*:S⇒*w}. A recognizer processes a word and accepts exactly the language members. Grammars generate languages; automata recognize languages, not grammars.

Study-note section AUT04

> Two grammars are equivalent when their generated languages are equal, regardless of rule counts or variable names. One common word, equal alphabets or one-way inclusion is insufficient.

Question sources

Automata & Complexity Theory review questions · Question 23

Question 124 | NS0189

In a RIGHT-LINEAR grammar, production rules have the form:

A. A → aB or A → a (terminal before optional non-terminal on right)

B. A → Ba or A → a (non-terminal before terminal)

C. A → α where α is any string of terminals and non-terminals

D. αAβ → αγβ

Hint

Track mandatory symbols and factors that may repeat or disappear. Use short test words to check both directions of each proposed language description.

Answer A: A→aB or A→a, with permitted ε rules where needed.

AUT14 places the optional single variable at the right end after the terminal. That gives A; B is the opposite left-linear orientation. An unrestricted string on the right is CFG form rather than necessarily regular, and a context-sensitive rewrite with surrounding context is a different grammar restriction. Epsilon conventions are handled separately.

Why each choice is right or wrong

A - Correct: The optional nonterminal follows the terminal at the right end of the production.

B - Incorrect: Putting the nonterminal before the terminal gives a left-linear orientation.

C - Incorrect: An arbitrary right-hand string can contain multiple variables and need not be regular-grammar form.

D - Incorrect: The context-sensitive contextual rewrite is not the defining right-linear production form.

Primary note proof

Study-note section AUT14

> Right-linear rules have form A→aB, A→a or permitted ε rules; left-linear rules put the single variable at the opposite end, A→Ba. Both consistent orientations generate REG; arbitrarily mixing them can generate nonregular languages, for example S→aA|ε, A→Sb generates $a^n b^n$. A CFG rule A→aBA is legal but not regular-grammar form.

Study-note section AUT14

> Regular languages are closed under union, concatenation, star, reversal, intersection, difference and complement.

Question sources

Automata & Complexity Theory review questions · Question 24

Question 125 | NS0190

Which production rule form is VALID in a Context-Free Grammar but NOT in a Regular Grammar?

A. A → a

B. A → aB

C. A → ε

D. A → aBA (two non-terminals on right-hand side)

Hint

Track mandatory symbols and factors that may repeat or disappear. Use short test words to check both directions of each proposed language description.

Answer D: A→aBA is context-free but not regular-grammar form.

AUT14 explicitly identifies A→aBA as legal CFG form but not regular form. A CFG restricts the left side to one variable while permitting a variable/terminal string on the right. The other choices are regular productions or permitted epsilon cases. Two right-hand nonterminals violate the regular linear restriction.

Why each choice is right or wrong

A - Incorrect: A→a is an ordinary regular production as well as context-free.

B - Incorrect: A→aB is exactly a right-linear regular production.

C - Incorrect: An epsilon rule is allowed under the note's regular-grammar convention.

D - Correct: The single-variable left side is CFG-valid, but two right-side variables violate regular linear form.

Primary note proof

Study-note section AUT14

> Right-linear rules have form A→aB, A→a or permitted ε rules; left-linear rules put the single variable at the opposite end, A→Ba. Both consistent orientations generate REG; arbitrarily mixing them can generate nonregular languages, for example S→aA|ε, A→Sb generates $a^n b^n$. A CFG rule A→aBA is legal but not regular-grammar form.

Study-note section AUT14

> Regular languages are closed under union, concatenation, star, reversal, intersection, difference and complement.

Question sources

Automata & Complexity Theory review questions · Question 25

Question 126 | NS0191

A grammar is said to be AMBIGUOUS if:

A. It generates infinitely many strings

B. Some string in the language has more than one parse tree

C. It contains left-recursive production rules

D. It uses both left-linear and right-linear rules

Hint

Compare production restrictions, memory access and language-family containments. Distinguish an exact characterization from an included subclass.

Answer B: Some generated word has more than one parse tree.

AUT18 defines ambiguity by two distinct parse trees for at least one word, equivalently two leftmost derivations. Infinite size, left recursion and mixed linear orientations concern other properties and do not establish this condition. One must exhibit competing trees, not merely different expansion orders of a single tree.

Why each choice is right or wrong

A - Incorrect: Infinite languages can have unambiguous grammars, so infinitude does not define ambiguity.

B - Correct: Multiple parse trees for one generated word are the precise ambiguity criterion.

C - Incorrect: Left recursion can encode unambiguous left associativity; it does not alone prove ambiguity.

D - Incorrect: Mixing linear orientations concerns grammar form and is not the parse-tree multiplicity definition.

Primary note proof

Study-note section AUT18

> A CFG is ambiguous when some word has two distinct parse trees, equivalently two different leftmost derivations. Different expansion orders that give the same tree do not prove ambiguity.

Study-note section AUT18

> Separate precedence levels: E→E+T|T, T→T*F|F, F→id|(E). Multiplication binds inside T before addition at E, and left recursion encodes left association. Uniqueness follows by the top-level last operator split and induction. S→SS|ε is already ambiguous for ε. S→A|B is ambiguous if A→ab and B→abB|ε both produce ab. Ambiguous grammar and inherently ambiguous language differ: another grammar may remove ambiguity.

Question sources

Automata & Complexity Theory review questions · Question 26

Question 127 | NS0192

In a derivation tree (parse tree), what do the LEAF NODES represent?

A. Non-terminal symbols that haven't been expanded yet

B. The start symbol S

C. Terminal symbols - the actual characters in the generated string

D. ε-transitions in the grammar

Hint

Apply the stated transition, closure or equivalence rule step by step; distinguish a guaranteed bound from a value for one particular machine.

Answer C: Terminal symbols, with an explicit ε leaf where that convention is used.

AUT16 describes complete parse trees with terminal leaves and sometimes an epsilon leaf for an empty production. Reading leaves left to right yields the generated word. Unexpanded variables belong to incomplete trees, and a start symbol is normally the root. Epsilon productions are not automaton transitions in this representation.

Why each choice is right or wrong

A - Incorrect: Unexpanded nonterminals indicate an incomplete tree rather than leaves of the completed derivation.

B - Incorrect: S is normally the root, not the general category of terminal leaves.

C - Correct: Terminal leaves spell the derived word; epsilon may be displayed for an empty production.

D - Incorrect: A parse tree records productions, not automaton epsilon-transition edges.

Primary note proof

Study-note section AUT16

> In a context-free grammar (CFG) each production has one variable on the left, $A \to \alpha$ with $\alpha \in (V \cup \Sigma)^*$. The left side therefore also belongs to $V \cup \Sigma$ and its string closure; alternatives stating these weaker memberships can all be true. A sentential form is any string derived from S, including terminal-only sentences and S itself.

Study-note section AUT16

> A leftmost derivation always replaces the leftmost variable; a rightmost one replaces the rightmost variable. This is not scanning the completed input in opposite directions. A complete parse tree has root S, internal variable nodes expanded by productions and terminal leaves, with ε leaves when that convention is used. Read the leaves left-to-right for the yielded word. The whole tree represents derivation structure; a path in a derivation graph is a different object.

Question sources

Automata & Complexity Theory review questions · Question 27

Question 128 | NS0193

What is the key difference between left derivation and right derivation?

A. Left derivation always expands the LEFTMOST non-terminal; right derivation expands the RIGHTMOST

B. Left derivation produces left-linear grammars; right produces right-linear grammars

C. Left derivation is used only for regular grammars

D. They produce different final strings for the same grammar

Hint

Apply the stated transition, closure or equivalence rule step by step; distinguish a guaranteed bound from a value for one particular machine.

Answer A: Expand the leftmost versus rightmost remaining nonterminal.

AUT16 defines the two derivations by which remaining variable is rewritten. Both can describe the same final word and even the same parse tree. They do not determine whether the grammar itself is left-linear or right-linear, and the distinction applies to CFGs generally rather than only regular grammars.

Why each choice is right or wrong

A - Correct: The choice of the leftmost or rightmost remaining variable is the defining difference.

B - Incorrect: Derivation order does not convert the production system into a left-linear or right-linear grammar.

C - Incorrect: Leftmost derivation is used for context-free grammars generally, not only regular ones.

D - Incorrect: Different expansion orders can generate the same terminal word and the same tree.

Primary note proof

Study-note section AUT16

> In a context-free grammar (CFG) each production has one variable on the left, $A \to \alpha$ with $\alpha \in (V \cup \Sigma)^*$. The left side therefore also belongs to $V \cup \Sigma$ and its string closure; alternatives stating these weaker memberships can all be true. A sentential form is any string derived from S, including terminal-only sentences and S itself.

Study-note section AUT16

> A leftmost derivation always replaces the leftmost variable; a rightmost one replaces the rightmost variable. This is not scanning the completed input in opposite directions. A complete parse tree has root S, internal variable nodes expanded by productions and terminal leaves, with ε leaves when that convention is used. Read the leaves left-to-right for the yielded word. The whole tree represents derivation structure; a path in a derivation graph is a different object.

Question sources

Automata & Complexity Theory review questions · Question 28

Question 129 | NS0194

The language $\{a^n b^n \mid n \geq 1\}$ is:

A. Regular - recognized by a DFA

B. Not a formal language

C. Context-Free but NOT Regular - recognized by a PDA, not a DFA

D. Context-Sensitive but not Context-Free

Hint

Respect the quantifier order and length constraints. A valid nonmembership argument must address every allowed decomposition, not one convenient split.

Answer C: Context-free but not regular.

AUT17 generates $a^n b^n$ with matched recursive additions, using ab as the base for n≥1. AUT15 proves the family nonregular by pumping the initial a block. Thus a PDA suffices but a DFA does not. It remains a formal language and is also CSL, so a description denying context-freeness is wrong.

Why each choice is right or wrong

A - Incorrect: The regular pumping argument rules out any DFA for unbounded equal counts.

B - Incorrect: This is a precisely specified set of words and therefore a formal language.

C - Correct: A CFG/PDA handles matched counts, while the language is not regular.

D - Incorrect: It is context-sensitive too, but denying its context-free status is false.

Primary note proof

Study-note section AUT17

> Use a recursive rule to enforce matched structure and a base rule to stop. $S \to aSb \mid \varepsilon$ generates exactly $a^n b^n$ for n≥0: n recursive steps add n a's on the left and n b's on the right. Derive aabb by $S \Rightarrow aSb \Rightarrow aaSbb \Rightarrow aabb$. For n≥1 replace ε by base ab.

Study-note section AUT15

> If L is regular, some p≥1 satisfies: every $s \in L$ with $|s| \geq p$ has a split $s=xyz$, $|xy| \leq p$, $|y| \geq 1$, and $xy^i z \in L$ for every i≥0.

Study-note section AUT15

> For $L=\{a^n b^n : n \geq 0\}$, choose $a^p b^p$. Every allowed $y=a^k$ with k≥1; pumping i=0 leaves fewer a's than b's. The contradiction excludes every DFA.

Study-note section AUT05

Type 3 regular grammars correspond to finite automata; type 2 CFGs to nondeterministic PDAs; type 1 context-sensitive/noncontracting grammars to nondeterministic LBAs; type 0 unrestricted grammars to Turing recognizers.

Study-note section AUT05

Use REG ⊊ CFL ⊊ CSL ⊊ DECIDABLE ⊊ RE, under the usual convention allowing S→ε with S absent from right sides when needed.

Question sources

Automata & Complexity Theory review questions · Question 29

Question 130 | NS0195

Every regular language is a context-free language. This means:

A. Every CFL can be described by a regular expression

B. Any language recognizable by a DFA/NFA can also be recognized by a PDA

C. Regular grammars are more powerful than CFGs

D. CFGs and regular grammars generate the same set of languages

Hint

Compare production restrictions, memory access and language-family containments. Distinguish an exact characterization from an included subclass.

Answer B: A PDA can also recognize every DFA/NFA language.

AUT05 places regular languages inside context-free languages, and AUT09 equates DFA with NFA power. Thus a PDA can recognize every finite-automaton language, for example by ignoring its extra stack. The containment is strict; it does not give regular expressions for every CFL or make regular and CFG language families equal.

Why each choice is right or wrong

A - Incorrect: The proper inclusion leaves CFLs that no classical regular expression describes.

B - Correct: Finite-automaton languages are included in the PDA-recognizable context-free family.

C - Incorrect: Regular grammars are less expressive, not more expressive, than CFGs.

D - Incorrect: The note gives a proper containment rather than equality of the two families.

Primary note proof

Study-note section AUT05

> Type 3 regular grammars correspond to finite automata; type 2 CFGs to nondeterministic PDAs; type 1 context-sensitive/noncontracting grammars to nondeterministic LBAs; type 0 unrestricted grammars to Turing recognizers.

Study-note section AUT05

> Use REG ⊊ CFL ⊊ CSL ⊊ DECIDABLE ⊊ RE, under the usual convention allowing S→ε with S absent from right sides when needed.

Question sources

Automata & Complexity Theory review questions · Question 30

Question 131 | NS0196

What additional component does a Pushdown Automaton (PDA) have that a Finite Automaton lacks?

A. A set of accepting states

B. A transition function

C. An input tape

D. A stack (LIFO memory)

Hint

Compare production restrictions, memory access and language-family containments. Distinguish an exact characterization from an included subclass.

Answer D: A stack.

AUT21 defines a PDA by adding a stack to finite control, with its own alphabet and initial symbol. Finite automata already have states, accepting states and transition rules and process input. The distinguishing unbounded LIFO storage is what supports matched-count recognition beyond finite-state memory.

Why each choice is right or wrong

A - Incorrect: Finite automata also have an accepting-state set.

B - Incorrect: Finite automata already use a transition function.

C - Incorrect: Both models process input; an input representation is not the added PDA memory.

D - Correct: The stack is the extra LIFO storage that distinguishes the PDA from finite control alone.

Primary note proof

Study-note section AUT21

> A nondeterministic pushdown automaton (PDA) adds a stack to finite control: $(Q,\Sigma,\Gamma,\delta,q_0,Z_0,F)$. Its transition relation maps (state,input symbol or ε,stack top) to possible (new state,replacement stack string) pairs.

Study-note section AUT-S02

> A stack is last-in, first-out: push adds an item at the top and pop removes the top item, so the most recently pushed item is removed first. A PDA accesses this top rather than an arbitrary interior position.

Study-note section AUT-S02

> A queue is first-in, first-out: insertion at the rear and removal at the front returns the oldest waiting item. A linked list can implement a storage discipline, but the implementation container is different from the abstract push/pop or enqueue/dequeue access rule.

Question sources

Automata & Complexity Theory review questions · Question 31

Question 132 | NS0197

The stack in a PDA operates as a:

A. Last-In-First-Out (LIFO) data structure

B. First-In-First-Out (FIFO) data structure

C. Random access memory

D. Circular queue

Hint

Compare production restrictions, memory access and language-family containments. Distinguish an exact characterization from an included subclass.

Answer A: Last in, first out.

AUT21 defines each PDA move using the current stack top and its replacement string. This top-only discipline means the most recently pushed item is the next removed: LIFO. A queue removes oldest items, random-access storage permits arbitrary addressing, and circular-queue organization is not the PDA stack model.

Why each choice is right or wrong

A - Correct: Top-only push/pop access removes the most recently pushed item first.

B - Incorrect: FIFO removes the oldest item and describes queue rather than stack behavior.

C - Incorrect: A PDA cannot arbitrarily access interior stack positions like random-access memory.

D - Incorrect: Circular queue organization does not express the top-only LIFO stack discipline.

Primary note proof

Study-note section AUT21

> A nondeterministic pushdown automaton (PDA) adds a stack to finite control: $(Q,\Sigma,\Gamma,\delta,q_0,Z_0,F)$. Its transition relation maps (state,input symbol or ε,stack top) to possible (new state,replacement stack string) pairs.

Study-note section AUT-S02

> A stack is last-in, first-out: push adds an item at the top and pop removes the top item, so the most recently pushed item is removed first. A PDA accesses this top rather than an arbitrary interior position.

Study-note section AUT-S02

> A queue is first-in, first-out: insertion at the rear and removal at the front returns the oldest waiting item. A linked list can implement a storage discipline, but the implementation container is different from the abstract push/pop or enqueue/dequeue access rule.

Question sources

Automata & Complexity Theory review questions · Question 32

Question 133 | NS0198

A PDA formally defined as a 7-tuple includes which of the following that a DFA does NOT have?

A. A set of states Q

B. An input alphabet Σ

C. A stack alphabet Γ and initial stack symbol Z

D. A set of accepting states F

Hint

Compare production restrictions, memory access and language-family containments. Distinguish an exact characterization from an included subclass.

Answer C: A stack alphabet and initial stack symbol.

AUT21 gives the PDA tuple $(Q,\Sigma,\Gamma,\delta,q_0,Z_0,F)$. Compared with a DFA, Γ and Z_0 describe its added stack storage. States, input symbols and accepting states occur in both models. Their presence is not what expands the recognizer beyond finite-state control.

Why each choice is right or wrong

A - Incorrect: Both DFA and PDA models have a finite control-state set Q.

B - Incorrect: Both machines process symbols from an input alphabet Σ.

C - Correct: Γ and Z_0 specify stack storage, which an ordinary DFA lacks.

D - Incorrect: Accepting-state sets occur in both models and do not distinguish stack memory.

Primary note proof

Study-note section AUT21

> A nondeterministic pushdown automaton (PDA) adds a stack to finite control: $(Q,\Sigma,\Gamma,\delta,q_0,Z_0,F)$. Its transition relation maps (state,input symbol or ε,stack top) to possible (new state,replacement stack string) pairs. Fix which end denotes the top before tracing. Replacing X by X leaves the stack unchanged; ε input means consume no symbol, while replacing X by ε pops it. These are different uses of ε.

Question sources

Automata & Complexity Theory review questions · Question 33

Question 134 | NS0199

The transition function of a PDA takes which inputs and produces which outputs?

A. (state, input) → next state

B. (state, input symbol or ε, top of stack) → (new state, new stack string)

C. (state, input) → set of states

D. (state, stack top, next input) → (write symbol, direction)

Hint

Compare production restrictions, memory access and language-family containments. Distinguish an exact characterization from an included subclass.

Answer B: State, input-or-ε and stack top map to possible new states and replacement stack strings.

AUT21 defines a PDA move by the current state, consumed symbol or epsilon and top stack symbol. Its possible outputs combine a new state with a replacement stack string. Set-valued nondeterminism is understood even though B abbreviates an individual result. The alternatives lacking stack access or using tape directions describe other models.

Why each choice is right or wrong

A - Incorrect: This omits the stack top and replacement string essential to PDA behavior.

B - Correct: This includes the current stack top and replacement string; nondeterminism permits a set of such results.

C - Incorrect: A state-set output without stack operations describes finite-state nondeterminism instead.

D - Incorrect: Writing a tape symbol and moving a head is TM-style machinery, not PDA stack replacement.

Primary note proof

Study-note section AUT21

> A nondeterministic pushdown automaton (PDA) adds a stack to finite control: $(Q,\Sigma,\Gamma,\delta,q_0,Z_0,F)$. Its transition relation maps (state,input symbol or ε,stack top) to possible (new state,replacement stack string) pairs. Fix which end denotes the top before tracing. Replacing X by X leaves the stack unchanged; ε input means consume no symbol, while replacing X by ε pops it. These are different uses of ε.

Question sources

Automata & Complexity Theory review questions · Question 34

Question 135 | NS0200

Which of the following languages can a PDA recognize but a DFA CANNOT?

A. All binary strings ending with '1'

B. All strings over {a,b} starting with 'ab'

C. $\{a^n b^n \mid n \geq 1\}$ - strings with equal number of a's and b's

D. All strings of even length over {a,b}

Hint

Respect the quantifier order and length constraints. A valid nonmembership argument must address every allowed decomposition, not one convenient split.

Answer C: The nonregular equal-count language $a^n b^n$.

AUT22 supplies the push-one/pop-one PDA procedure for equal a/b counts, and AUT15 excludes a DFA. Fixed suffixes, fixed prefixes and length parity require only finite memory, so both machine types can recognize those. C alone describes a language in PDA capability but outside DFA capability.

Why each choice is right or wrong

A - Incorrect: A fixed final symbol is a regular condition recognized by a DFA.

B - Incorrect: A fixed starting prefix needs only finitely many match stages and is regular.

C - Correct: A PDA matches unbounded equal counts using its stack, while regular pumping rules out a DFA.

D - Incorrect: Even length needs only a finite parity state, so a DFA already suffices.

Primary note proof

Study-note section AUT22

> For $a^n b^n$, push one X per a, switch to a b-reading phase, pop one X per b, and accept when input ends at the bottom marker. Reject a after entering the b phase and b when no X remains. Handle ε explicitly if n=0 is permitted. A stack counts without storing the full input as random-access memory.

Study-note section AUT15

> If L is regular, some $p \geq 1$ satisfies: every $s \in L$ with $|s| \geq p$ has a split $s=xyz$, $|xy| \leq p$, $|y| \geq 1$, and $xy^i z \in L$ for every $i \geq 0$.

Study-note section AUT15

> For $L=\{a^n b^n : n \geq 0\}$, choose $a^p b^p$. Every allowed $y=a^k$ with $k \geq 1$; pumping i=0 leaves fewer a's than b's. The contradiction excludes every DFA.

Question sources

Automata & Complexity Theory review questions · Question 35

Question 136 | NS0201

The language $\{a^n b^n c^n \mid n \geq 1\}$ is NOT a context-free language. This means:

A. It can be recognized by a PDA

B. It can be described by a context-free grammar

C. It is not a formal language

D. No PDA can recognize it; it requires at least a Linear Bounded Automaton (LBA)

Hint

Respect the quantifier order and length constraints. A valid nonmembership argument must address every allowed decomposition, not one convenient split.

Answer D: No PDA recognizes it; an LBA suffices in the listed hierarchy.

AUT24 proves three equal counts non-context-free, and AUT25 recognizes them by marking matched triples within the input region. Thus no ordinary single-stack PDA recognizes the language, while an LBA does. It is still a precisely defined formal language; non-context-freeness is a family boundary rather than failure to be a language.

Why each choice is right or wrong

A - Incorrect: PDA-recognizable languages are context-free, contradicting the stated non-CFL property.

B - Incorrect: A CFG would make it context-free, which the pumping proof rules out.

C - Incorrect: It remains a formal language despite lying outside the context-free family.

D - Correct: No PDA suffices; bounded triple marking provides an LBA recognizer in the next listed family.

Primary note proof

Study-note section AUT25

> A context-sensitive rule $\alpha A \beta \to \alpha \gamma \beta$ replaces A in context, with γ nonempty. Equivalently, noncontracting grammar presentations preserve/increase total length, with the isolated ε exception. The condition is on the complete sides, not an unrelated comparison $|\beta| \geq |\alpha|$.

Study-note section AUT25

> A linear bounded automaton (LBA) is a TM with O(n) tape cells on length-n input; the standard CSL characterization uses nondeterministic LBAs. For $a^n b^n c^n$ first verify a*b*c* order, repeatedly mark one unmarked a, b and c, and reject missing/excess symbols.

Study-note section AUT25

> Thus every CSL is decidable.

Study-note section AUT24

If L is context-free, some p ensures each sufficiently long $s \in L$ has $s=uvxyz$ with $|vxy| \le p$, $|vy| \ge 1$ and $uv^ixy^iz \in L$ for every $i \ge 0$. The two pieces v and y are pumped together; either may be empty, not both. A non-CFL proof must defeat every allowed decomposition.

Study-note section AUT24

For $s=a^pb^pc^p$, the window vxy cannot contain both an a and a c. Pumping affects at most two blocks and at least one count. Use i=0 or 2: the unaffected third block retains p while another count changes, or symbol order breaks. Hence $a^nb^nc^n$ is not CFL.

Question sources

Automata & Complexity Theory review questions · Question 36

Question 137 | NS0202

In a Context-Sensitive Grammar, the production rule $\alpha A \beta \rightarrow \alpha \gamma \beta$ requires:

A. $|\gamma| < |A|$ (right side shorter than left)

B. $|\alpha\gamma\beta| \geq |\alpha A \beta|$ (right side no shorter than left side)

C. α and β must be empty strings

D. γ must be a single terminal symbol

Hint

Compare production restrictions, memory access and language-family containments. Distinguish an exact characterization from an included subclass.

Answer B: The complete right-hand side cannot be shorter.

AUT25 explains contextual rules with a nonempty replacement γ, equivalently noncontracting full-side length under the isolated epsilon convention. The comparison must include the complete left and right sides, making B correct. Context α and β need not vanish, and γ may contain more than a single terminal.

Why each choice is right or wrong

A - Incorrect: A shorter replacement contradicts the noncontracting context-sensitive requirement.

B - Correct: The full right-hand side must be at least as long as the full left-hand side.

C - Incorrect: Context can be present; requiring empty α and β is not the context-sensitive rule.

D - Incorrect: Gamma is nonempty but need not be exactly one terminal.

Primary note proof

Study-note section AUT25

> A context-sensitive rule $\alpha A \beta \rightarrow \alpha \gamma \beta$ replaces A in context, with γ nonempty. Equivalently, noncontracting grammar presentations preserve/increase total length, with the isolated ε exception. The condition is on the complete sides, not an unrelated comparison $|\beta| \geq |\alpha|$.

Study-note section AUT25

> A linear bounded automaton (LBA) is a TM with O(n) tape cells on length-n input; the standard CSL characterization uses nondeterministic LBAs. For $a^n b^n c^n$ first verify a*b*c* order, repeatedly mark one unmarked a, b and c, and reject missing/excess symbols.

Study-note section AUT25

> Thus every CSL is decidable.

Question sources

Automata & Complexity Theory review questions · Question 37

Question 138 | NS0203

The Turing Machine transition function δ(q, a) = (p, b, L) means:

A. In state q reading symbol a: go to state p, write b, move head LEFT

B. In state q reading symbol a: go to state p, write b, move head RIGHT

C. In state q reading symbol a: go to state p, push b onto stack, move LEFT

D. In state q reading symbol a: delete b, move LEFT, enter state p

Hint

Compare production restrictions, memory access and language-family containments. Distinguish an exact characterization from an included subclass.

Answer A: Write b, move left, and enter p after reading a in q.

AUT27 directly interprets δ(q,a)=(p,b,L). The current scanned symbol a is replaced with b, the head shifts one cell left and control enters p. L fixes the direction; there is no stack push operation, and deletion is not the meaning of writing b.

Why each choice is right or wrong

A - Correct: This exactly preserves the specified new state, written symbol and leftward head movement.

B - Incorrect: R would indicate right movement; the given L specifies left.

C - Incorrect: The TM writes b on tape rather than pushing onto a separate stack.

D - Incorrect: The transition writes b; it does not mean delete b.

Primary note proof

Study-note section AUT27

> δ(q,a)=(p,b,L) means read a in q, write b, move one cell left and enter p. Accept/reject halting states have no further moves under this convention.

Question sources

Automata & Complexity Theory review questions · Question 38

Question 139 | NS0204

Which of the following is TRUE about Turing Machines?

A. A TM has a finite tape of fixed length

B. A TM can only move the head in one direction

C. A TM can simulate any algorithm - it is the most powerful computational model

D. A TM is equivalent in power to a PDA

Hint

Compare production restrictions, memory access and language-family containments. Distinguish an exact characterization from an included subclass.

Answer C: A TM models general effective algorithmic computation.

AUT28 identifies Turing completeness with simulating general TM computation and relates effective procedures to the Church-Turing thesis. C expresses this ordinary model comparison, not omnipotence over undecidable tasks or a speed guarantee. A standard tape is unbounded, heads may move both directions, and TMs exceed single-stack PDA recognition power.

Why each choice is right or wrong

A - Incorrect: A standard TM tape is unbounded rather than fixed to a finite length.

B - Incorrect: Standard TM transitions may move the head left or right.

C - Correct: Under the effective-algorithm interpretation, TM computation captures general algorithmic procedures.

D - Incorrect: TMs recognize languages beyond the context-free languages of ordinary PDAs.

Primary note proof

Study-note section AUT28

> An off-line TM has a read-only input tape and separate read/write work tape. Multitape, multihead, two-way-infinite-tape and nondeterministic TMs have the same language-recognition power as standard TMs, though simulation costs differ. Two unbounded stacks can simulate a tape. Turing completeness means ability to simulate general TM computation, not polynomial speed or literally using infinitely many cells in a finite run. The Church-Turing thesis connects effective procedures to this formal model; it is not a proved runtime theorem.

Question sources

Automata & Complexity Theory review questions · Question 39

Question 140 | NS0205

Which option summarizes the pumping lemma for regular languages, rather than a separate consequence for a chosen recognizing DFA?

A. Every string in L can be pumped to produce longer strings still in L

B. Any sufficiently long string s in L can be split as xyz where the middle part y can be 'pumped' (repeated any number of times) and stay in L

C. L is infinite if and only if a string in L is longer than the number of states

D. All strings in L have the same length

Hint

Respect the quantifier order and length constraints. A valid nonmembership argument must address every allowed decomposition, not one convenient split.

Answer B: Any sufficiently long string s in L can be split as xyz where the middle part y can be 'pumped' (repeated any number of times) and stay in L

For each regular language there is a pumping length p. Every accepted word of length at least p has a decomposition xyz with $|xy| \le p$ and $|y| > 0$ such that xy^iz remains accepted for every $i \ge 0$. The threshold and nonempty repeated part matter; short words need not be pumpable. The infinitude criterion involving a DFA's state count is a separate consequence, while a regular language can contain words of many different lengths.

Why each choice is right or wrong

A - Incorrect: The lemma applies only above a length threshold and pumps a suitable part, not every word without qualification.

B - Correct: This states the sufficiently-long-word split and repeatable middle part; the formal bounds are supplied in the explanation.

C - Incorrect: A fixed-DFA infinitude criterion is a consequence rather than the pumping lemma's quantified statement.

D - Incorrect: Regular languages need not have constant word length; 0* contains arbitrarily many lengths.

Primary note proof

Study-note section AUT15

> If L is regular, some $p \ge 1$ satisfies: every $s \in L$ with $|s| \ge p$ has a split $s=xyz$, $|xy| \le p$, $|y| \ge 1$, and $xy^iz \in L$ for every $i \ge 0$.

Study-note section AUT15

> For $L=\{a^nb^n : n \ge 0\}$, choose a^pb^p. Every allowed $y=a^k$ with $k \ge 1$; pumping $i=0$ leaves fewer a's than b's. The contradiction excludes every DFA.

Question sources

Automata & Complexity Theory review questions · Question 40

Question 141 | NS0206

The language $L = \{a^n b^n c^n \mid n \geq 1\}$ is NOT context-free. Which technique proves this?

A. The Pumping Lemma for Regular Languages

B. The Chomsky hierarchy alone

C. Constructing a PDA and showing it fails

D. The Pumping Lemma for Context-Free Languages - any pumping violates the equal-count constraint

Hint

Respect the quantifier order and length constraints. A valid nonmembership argument must address every allowed decomposition, not one convenient split.

Answer D: The CFL pumping lemma, defeating every permitted decomposition.

AUT24 chooses $a^p b^p c^p$ and shows the bounded vxy window cannot cover both a and c blocks. Pumping changes at most two counts or breaks block order, defeating every allowed decomposition. A failed individual PDA is not a proof against all PDAs, and regular pumping excludes only regularity, not the stronger CFL property.

Why each choice is right or wrong

A - Incorrect: Regular pumping disproves regularity and does not by itself establish non-context-freeness.

B - Incorrect: The hierarchy alone does not prove the specific language lies outside CFL.

C - Incorrect: Failure of one proposed PDA does not rule out every possible PDA.

D - Correct: The CFL pumping proof breaks every legal decomposition by changing counts or symbol order.

Primary note proof

Study-note section AUT24

> If L is context-free, some p ensures each sufficiently long $s \in L$ has $s=uvxyz$ with $|vxy| \leq p$, $|vy| \geq 1$ and $uv^i xy^i z \in L$ for every $i \geq 0$. The two pieces v and y are pumped together; either may be empty, not both. A non-CFL proof must defeat every allowed decomposition.

Study-note section AUT24

> For $s=a^p b^p c^p$, the window vxy cannot contain both an a and a c. Pumping affects at most two blocks and at least one count. Use i=0 or 2: the unaffected third block retains p while another count changes, or symbol order breaks. Hence $a^n b^n c^n$ is not CFL.

Question sources

Automata & Complexity Theory review questions · Question 41

Question 142 | NS0207

'Turing Completeness' means a system:

A. Can simulate a Turing Machine and thus compute anything computable

B. Solves problems in polynomial time

C. Uses an infinite amount of memory

D. Is equivalent to a Pushdown Automaton

Hint

Compare production restrictions, memory access and language-family containments. Distinguish an exact characterization from an included subclass.

Answer A: Ability to simulate general Turing-machine computation.

AUT28 defines Turing completeness by general TM simulation. This says which effective computations can be expressed, not whether they run in polynomial time. A finite execution uses finitely many cells even though the model permits unbounded memory. Single-stack PDA equivalence is weaker than Turing universality.

Why each choice is right or wrong

A - Correct: Simulation of general TM computation is the definition of Turing completeness.

B - Incorrect: Universality does not guarantee a polynomial-time algorithm for every computable problem.

C - Incorrect: A finite run need not and cannot literally use infinitely many cells.

D - Incorrect: An ordinary PDA has less expressive recognition power than a TM.

Primary note proof

Study-note section AUT28

> An off-line TM has a read-only input tape and separate read/write work tape. Multitape, multihead, two-way-infinite-tape and nondeterministic TMs have the same language-recognition power as standard TMs, though simulation costs differ. Two unbounded stacks can simulate a tape. Turing completeness means ability to simulate general TM computation, not polynomial speed or literally using infinitely many cells in a finite run. The Church-Turing thesis connects effective procedures to this formal model; it is not a proved runtime theorem.

Question sources

Automata & Complexity Theory review questions · Question 42

Question 143 | NS0208

The complexity class P contains problems that are:

A. Hard to solve and hard to verify

B. Solvable in polynomial time by a deterministic Turing Machine

C. Solvable only by nondeterministic machines

D. Requiring exponential space to solve

Hint

Separate resource bounds, certificate verification and reduction requirements. Use proved containments without assuming unresolved class separations.

Answer B: Deterministic polynomial-time decidable problems.

AUT34 defines P by deterministic polynomial-time decision relative to input length. It is a solvability upper bound, not a requirement of hardness, nondeterminism or exponential space. A problem in P may also have nondeterministic algorithms, but it is the existence of a deterministic polynomial-time decider that establishes membership.

Why each choice is right or wrong

A - Incorrect: P is defined by efficient deterministic decision, not by hardness of solving or verification.

B - Correct: This is the exact deterministic polynomial-time definition of P.

C - Incorrect: Problems in P have deterministic algorithms and are not solvable only nondeterministically.

D - Incorrect: Exponential space is not a requirement for a polynomial-time computation.

Primary note proof

Study-note section AUT34

> Complexity classes here contain decision languages. P consists of deterministic polynomial-time decidable languages; NP consists of nondeterministic polynomial-time decidable languages, equivalently polynomially verifiable yes-instances with polynomial-size certificates. A verifier must accept some certificate exactly for yes-inputs; no certificate may falsely establish a no-instance. NP means nondeterministic polynomial, not non-polynomial.

Study-note section AUT34

> P⊆NP because a verifier can ignore its certificate and run the P algorithm. P=NP remains open; NP does not mean definitely hard or definitely outside P.

Question sources

Automata & Complexity Theory review questions · Question 43

Question 144 | NS0209

The key property of problems in class NP is:

A. They can be solved in polynomial time by a deterministic TM

B. They require exponential time to verify solutions

C. Given a potential solution, it can be VERIFIED in polynomial time

D. They require polynomial space but exponential time

Hint

Separate resource bounds, certificate verification and reduction requirements. Use proved containments without assuming unresolved class separations.

Answer C: Polynomial-time verification of polynomial-size yes-certificates.

AUT34 equates NP with polynomially verifiable yes-instances using polynomial-size certificates. A verifier must not certify no-instances. Polynomial-time deterministic solving defines P and is not known for every NP problem; exponential verification or execution bounds are not part of NP's defining certificate condition.

Why each choice is right or wrong

A - Incorrect: Deterministic polynomial-time solution defines P; whether it covers all NP is unresolved.

B - Incorrect: NP verification is polynomial for an appropriate certificate rather than requiring exponential time.

C - Correct: A polynomial-size yes-certificate can be checked in polynomial time, the equivalent NP definition.

D - Incorrect: NP does not require exponential running time; it includes the polynomial-time languages.

Primary note proof

Study-note section AUT34

> Complexity classes here contain decision languages. P consists of deterministic polynomial-time decidable languages; NP consists of nondeterministic polynomial-time decidable languages, equivalently polynomially verifiable yes-instances with polynomial-size certificates. A verifier must accept some certificate exactly for yes-inputs; no certificate may falsely establish a no-instance. NP means nondeterministic polynomial, not non-polynomial.

Study-note section AUT34

> P⊆NP because a verifier can ignore its certificate and run the P algorithm. P=NP remains open; NP does not mean definitely hard or definitely outside P.

Question sources

Automata & Complexity Theory review questions · Question 44

Question 145 | NS0210

If a problem is NP-COMPLETE, it means:

A. It is in NP but not in P

B. It is the easiest problem in NP

C. It is NP-hard but might not be in NP

D. It is both in NP AND NP-hard; every problem in NP reduces to it in polynomial time

Hint

Separate resource bounds, certificate verification and reduction requirements. Use proved containments without assuming unresolved class separations.

Answer D: Both NP membership and NP-hardness under polynomial reductions.

AUT36 defines NP-complete as being in NP and hard for every NP language under polynomial reduction. It does not assert exclusion from P, since P versus NP is open. NP-hard alone need not even be decidable, while complete problems are the hardest in NP under the stated reduction, not its easiest members.

Why each choice is right or wrong

A - Incorrect: NP-completeness does not prove exclusion from P; that would settle the open P-versus-NP question.

B - Incorrect: Completeness concerns hardness for the whole class, not easiest membership.

C - Incorrect: This describes NP-hardness without the required NP-membership condition.

D - Correct: Both membership and polynomial-reduction hardness for every NP problem are required.

Primary note proof

Study-note section AUT36

> X is NP-hard if every $A \in NP$ satisfies $A \leq_p X$. It need not belong to NP and can even be undecidable. X is NP-complete if $X \in NP$ and X is NP-hard. NP-complete languages lie inside NP and can be decided by finite exhaustive certificate search in exponential time. They are not known to require exponential time.

Question sources

Automata & Complexity Theory review questions · Question 45

Question 146 | NS0211

Which is an established reason for the foundational significance of Boolean satisfiability (SAT) in NP-completeness theory?

A. It was the FIRST problem proven NP-complete (Cook-Levin theorem); every NP problem reduces to SAT

B. It can be solved in polynomial time

C. It is in class P

D. It requires exponential space to verify

Hint

Distinguish a foundational hardness proof, efficient certificate verification and an unproved efficient solving algorithm.

Answer A: It was the FIRST problem proven NP-complete (Cook-Levin theorem); every NP problem reduces to SAT

The Cook-Levin theorem made SAT the first problem proved NP-complete: its proof encodes an arbitrary nondeterministic polynomial-time computation as a Boolean formula. Hence every NP decision problem has a polynomial-time reduction to SAT. This starts the chain of later hardness reductions. A satisfying assignment can be checked in polynomial time. Whether SAT itself has a deterministic polynomial-time algorithm is unresolved, so neither membership in P nor such an algorithm is an established reason.

Why each choice is right or wrong

A - Correct: Cook-Levin established the first NP-complete problem and reductions from every problem in NP.

B - Incorrect: A general deterministic polynomial-time SAT algorithm is not established; one would imply P=NP.

C - Incorrect: SAT membership in P is unresolved, so this is not an established statement.

D - Incorrect: An assignment can be verified in polynomial time, without requiring exponential verification space.

Primary note proof

Study-note section AUT-S03

> Boolean satisfiability was the first problem proved NP-complete, through the Cook-Levin theorem. Its hardness proof starts directly from an arbitrary nondeterministic polynomial-time computation and constructs a Boolean formula that is satisfiable exactly when an accepting computation exists.

Study-note section AUT-S03

> This starting point matters: once one NP-complete problem is available, later hardness proofs can reduce that known problem to a new target. Membership in NP remains a separate

obligation. Checking a satisfying assignment is efficient; whether finding one is always polynomial-time remains unresolved.

Study-note section AUT36

SAT asks whether a Boolean formula has a satisfying assignment; Cook-Levin establishes SAT NP-complete. CNF-SAT and 3-SAT are NP-complete versions.

Question sources

Automata & Complexity Theory review questions · Question 46

Question 147 | NS0212

Which containment chain is established unconditionally, without assuming answers to the open equalities among these classes? Here EXP means EXPTIME.

A. NP ⊆ P ⊆ PSPACE ⊆ EXP

B. P ⊆ NP ⊆ PSPACE ⊆ EXP

C. PSPACE ⊆ NP ⊆ P ⊆ EXP

D. EXP ⊆ PSPACE ⊆ NP ⊆ P

Hint

Separate resource bounds, certificate verification and reduction requirements. Use proved containments without assuming unresolved class separations.

Answer B: P⊆NP⊆PSPACE⊆EXPTIME.

The established resource-class chain is P⊆NP⊆PSPACE⊆EXPTIME. These subset relations need not all be strict: the adjacent equalities named in the note remain unresolved. A reverse relation such as NP⊆P cannot therefore be selected as an unconditional theorem. Reversing the entire chain would additionally put EXPTIME inside P, contradicting the known strict separation P⊊EXPTIME. The revised scope asks for proved inclusion, not for a speculative equality.

Why each choice is right or wrong

A - Incorrect: This includes NP⊆P, which would settle the open P-versus-NP question rather than state a known unconditional chain.

B - Correct: P⊆NP⊆PSPACE⊆EXPTIME is the established chain.

C - Incorrect: This requires reverse containments that are not established unconditionally.

D - Incorrect: Reversing the entire chain would imply EXPTIME⊆P, contradicting the known strict time-hierarchy separation.

Primary note proof

Study-note section AUT39

> Use L⊆NL⊆P⊆NP⊆PSPACE⊆EXPTIME⊆EXPSPACE. Here L/NL use logarithmic workspace; EXPTIME is ⋃kTIME(2^(n^k)), an upper-bound class that also contains P, not a statement that every member requires exponential time.

Study-note section AUT39

> P versus NP, NP versus PSPACE and PSPACE versus EXPTIME remain unresolved. coNP contains complements of NP languages; P⊆NP∩coNP, and NP=coNP is open.

Question sources

Automata & Complexity Theory review questions · Question 47

Question 148 | NS0213

If problem A is REDUCIBLE to problem B in polynomial time ($A \leq_p B$), what can we conclude?

A. A is at least as hard as B

B. A and B are in the same complexity class

C. B is at least as hard as A; an efficient algorithm for B gives an efficient algorithm for A

D. B can be solved in the same time as A

Hint

Separate resource bounds, certificate verification and reduction requirements. Use proved containments without assuming unresolved class separations.

Answer C: B is at least as hard as A; solving B efficiently solves A efficiently.

AUT35 defines $A \leq pB$ by a polynomial-time transformation preserving membership. Compute that transformation and run B's algorithm to solve A. Therefore the target B is at least as hard under this reduction. The reduction does not force equal complexity classes, a reverse reduction or an algorithm for B from A alone.

Why each choice is right or wrong

A - Incorrect: This reverses the hardness direction implied by reducing A to B.

B - Incorrect: A one-way reduction does not place both languages in the same complexity class.

C - Correct: The polynomial mapping followed by a fast B solver gives a fast A solver.

D - Incorrect: A solver for A alone does not invert the reduction to provide a B solver.

Primary note proof

Study-note section AUT35

> $A \leq pB$ means f is computable in polynomial time and $x \in A$ iff $f(x) \in B$. Solving B then solves A, so B is at least as hard under this reduction. If $B \in P$ then $A \in P$; if A is NP-hard then B is NP-hard. $A \in P$ does not force $B \in P$, and the reduction alone does not place both problems in the same class. Polynomial reductions compose.

Question sources

Automata & Complexity Theory review questions · Question 48

Question 149 | NS0214

For standard finite encoded instances, how is the exact optimization task of finding a shortest tour visiting every city once and returning to the start classified?

A. P - solvable efficiently

B. PSPACE-complete

C. Not a formal computational problem

D. NP-hard; this classification does not establish an exponential-time lower bound.

Hint

Separate resource bounds, certificate verification and reduction requirements. Use proved containments without assuming unresolved class separations.

Answer D: NP-hard; this classification does not establish an exponential-time lower bound.

Finding the shortest tour is an optimization problem and is NP-hard. The related question whether a tour of cost at most a given bound exists is a decision problem and is NP-complete. These statements do not prove that every exact algorithm must take exponential time or resolve P versus NP. The option retains the established hardness classification without overstating a lower bound.

Why each choice is right or wrong

A - Incorrect: A general polynomial-time exact algorithm is not the classification established in the note.

B - Incorrect: PSPACE-complete is not the supplied classification of this optimization task.

C - Incorrect: The finite encoded task is a well-defined computational optimization problem.

D - Correct: Shortest-tour optimization is NP-hard; hardness alone gives no exponential lower bound.

Primary note proof

Study-note section AUT36

> TSP decision asks whether a tour of cost at most B exists; it is NP-complete for standard finite encoded inputs. Finding the shortest tour is optimization and NP-hard; call it NP-complete only after specifying a decision formulation.

Question sources

Automata & Complexity Theory review questions · Question 49

Question 150 | NS0215

Which statement about P vs NP is CORRECT?

A. It has been proven that P ≠ NP

B. It is an UNSOLVED open question - one of the most important problems in computer science

C. It has been proven that P = NP

D. The question is irrelevant since all real-world problems are in P

Hint

Separate resource bounds, certificate verification and reduction requirements. Use proved containments without assuming unresolved class separations.

Answer B: P versus NP remains open.

AUT34 explicitly says P=NP remains open, and AUT39 lists the separation among unresolved questions. Therefore neither equality nor inequality is proved in this source. The inclusion P⊆NP is known, but does not decide equality. Real-world problem encodings and resource requirements do not make the theoretical question irrelevant.

Why each choice is right or wrong

A - Incorrect: The note states that the separation is unresolved, not proved.

B - Correct: Whether P and NP are equal is an open question.

C - Incorrect: The note does not establish equality and explicitly calls it unresolved.

D - Incorrect: The note gives hard and undecidable problems, refuting the claim that all real-world problems fall in P.

Primary note proof

Study-note section AUT34

> Complexity classes here contain decision languages. P consists of deterministic polynomial-time decidable languages; NP consists of nondeterministic polynomial-time decidable languages, equivalently polynomially verifiable yes-instances with polynomial-size certificates. A verifier must accept some certificate exactly for yes-inputs; no certificate may falsely establish a no-instance. NP means nondeterministic polynomial, not non-polynomial.

Study-note section AUT34

> P⊆NP because a verifier can ignore its certificate and run the P algorithm. P=NP remains open; NP does not mean definitely hard or definitely outside P.

Study-note section AUT39

> Use L⊆NL⊆P⊆NP⊆PSPACE⊆EXPTIME⊆EXPSPACE. Here L/NL use logarithmic workspace; EXPTIME is ⋃kTIME(2^(n^k)), an upper-bound class that also contains P, not a statement that every member requires exponential time.

Study-note section AUT39

P versus NP, NP versus PSPACE and PSPACE versus EXPTIME remain unresolved. coNP contains complements of NP languages; P⊆NP∩coNP, and NP=coNP is open.

Question sources

Automata & Complexity Theory review questions · Question 50

Question 151 | NS0287

Which automaton is powerful enough to recognize the language L = {$a^n b^n c^n$ | n ≥ 1}?

A. DFA

B. Linear Bounded Automaton (LBA)

C. NFA

D. Pushdown Automaton (PDA)

Hint

Respect the quantifier order and length constraints. A valid nonmembership argument must address every allowed decomposition, not one convenient split.

Answer B: A linear bounded automaton.

An LBA checks block order then repeatedly marks one a, one b and one c, rejecting unmatched symbols. The language is not context-free, ruling out a PDA and therefore finite automata too.

Why each choice is right or wrong

A - Incorrect: A DFA recognizes only regular languages, too weak for this non-CFL language.

B - Correct: An LBA can match the three counts by marking symbols within the bounded input region.

C - Incorrect: NFA power equals DFA power and cannot reach this context-sensitive non-CFL language.

D - Incorrect: A PDA recognizes CFLs, whereas this equal-three-count language is not context-free.

Primary note proof

Study-note section AUT25

A context-sensitive rule αAβ→αγβ replaces A in context, with γ nonempty. Equivalently, noncontracting grammar presentations preserve/increase total length, with the isolated ε exception. The condition is on the complete sides, not an unrelated comparison |β|≥|α|.

Study-note section AUT25

A linear bounded automaton (LBA) is a TM with O(n) tape cells on length-n input; the standard CSL characterization uses nondeterministic LBAs. For $a^n b^n c^n$ first verify a*b*c* order, repeatedly mark one unmarked a, b and c, and reject missing/excess symbols.

Study-note section AUT25

Thus every CSL is decidable.

Study-note section AUT24

If L is context-free, some p ensures each sufficiently long $s \in L$ has $s=uvxyz$ with $|vxy| \le p$, $|vy| \ge 1$ and $uv^ixy^iz \in L$ for every $i \ge 0$. The two pieces v and y are pumped together; either may be empty, not both. A non-CFL proof must defeat every allowed decomposition.

Study-note section AUT24

For $s=a^pb^pc^p$, the window vxy cannot contain both an a and a c. Pumping affects at most two blocks and at least one count. Use i=0 or 2: the unaffected third block retains p while another count changes, or symbol order breaks. Hence $a^nb^nc^n$ is not CFL.

Question sources

Computer Science Exit Exam · 2018 · Question 4

Question 152 | NS0309

Which of the following statements is TRUE?

A. Every regular language is context-free.

B. Every context-free language is regular.

C. Every context-sensitive language is regular.

D. Every recursively enumerable language is recursive

Hint

Compare production restrictions, memory access and language-family containments. Distinguish an exact characterization from an included subclass.

Answer A: Every regular language is context-free.

AUT05 gives REG⊊CFL⊊CSL⊊DECIDABLE⊊RE, immediately establishing A. Reverse inclusions for CFL or CSL into REG fail. AUT29 explains that RE strictly exceeds decidable/recursive languages, so not every RE language is recursive. Strictness is essential to rejecting the three converse-style claims.

Why each choice is right or wrong

A - Correct: REG is a proper subfamily of CFL, so every regular language is context-free.

B - Incorrect: Matched equal counts supply CFLs that are not regular.

C - Incorrect: CSL includes nonregular and even non-CFL languages.

D - Incorrect: Some Turing-recognizable languages, such as HALT, are not recursive.

Primary note proof

Study-note section AUT05

> Type 3 regular grammars correspond to finite automata; type 2 CFGs to nondeterministic PDAs; type 1 context-sensitive/noncontracting grammars to nondeterministic LBAs; type 0 unrestricted grammars to Turing recognizers.

Study-note section AUT05

> Use REG ⊊ CFL ⊊ CSL ⊊ DECIDABLE ⊊ RE, under the usual convention allowing S→ε with S absent from right sides when needed.

Question sources

Computer Science Exit Exam · 2018 · Question 30

Question 153 | NS0322

In the CNF-first route for converting a CFG into Greibach normal form, which initial normalization is performed before the later ordering, substitution and left-recursion work?

A. Convert the grammar into CNF

B. If any production rule in the grammar is not in GNF form, convert it.

C. Convert the grammar into GNF

D. If the grammar exists left recursion, eliminate it.

Hint

Compare production restrictions, memory access and language-family containments. Distinguish an exact characterization from an included subclass.

Answer A: Convert the grammar into CNF

The specified route begins by putting the grammar into Chomsky normal form. Later ordering and substitution arrange terminal-leading productions and eliminate left recursion as required for Greibach form. CNF is an intermediate normalization in this particular route, not a universal prerequisite for every GNF construction. The other conversion choices state the goal broadly rather than identify this route's initial normalization.

Why each choice is right or wrong

A - Correct: CNF conversion is the initial normalization in the selected route.

B - Incorrect: Converting arbitrary offending rules does not identify the route's initial normalization.

C - Incorrect: GNF conversion is the overall goal, not this preliminary operation.

D - Incorrect: Left recursion must be handled later in this chosen route.

Primary note proof

Study-note section AUT20

> Some algorithms first convert to CNF; this is a method choice, not a universally mandatory first step.

Question sources

Computer Science Exit Exam · 2018 · Question 47

Question 154 | NS0336

A recognizer for a language L halts and accepts every member, but may reject or run forever on nonmembers. L is known to be undecidable. Which listed grammar family can nevertheless generate exactly L?

A. Context-free

B. Context-sensitive

C. Unrestricted (Type 0)

D. Regular

Hint

Check whether the required procedure must halt on every input, and distinguish solving a task from recognizing its yes-instances.

Answer C: Unrestricted (Type 0)

The recognizer accepts every member, so L is Turing-recognizable even though no decider exists for it. Type 0 unrestricted grammars generate exactly the Turing-recognizable languages and can therefore generate L. Regular, context-free and context-sensitive languages are all decidable under the stated hierarchy, so none of those grammar families can generate this known undecidable language. The distinction is recognition versus guaranteed decision, not running speed.

Why each choice is right or wrong

A - Incorrect: Every context-free language is decidable, whereas the given L is not.

B - Incorrect: Every context-sensitive language is decidable, excluding the stated L.

C - Correct: Type 0 grammars correspond to Turing recognizers, including recognizable undecidable languages.

D - Incorrect: Every regular language is decidable, whereas the given L is not.

Primary note proof

Study-note section AUT29

> A decider halts on every input and accepts exactly its language; these languages are recursive/decidable. A recognizer must halt and accept every member, but on a nonmember may halt-reject or loop. Its languages are recursively enumerable (RE), Turing-recognizable or semidecidable. Looping is nonacceptance, not a rejecting halt. An undecidable language may still have a recognizer.

Study-note section AUT29

> Every decidable language is RE, and the containment is strict.

Study-note section AUT05

Type 3 regular grammars correspond to finite automata; type 2 CFGs to nondeterministic PDAs; type 1 context-sensitive/noncontracting grammars to nondeterministic LBAs; type 0 unrestricted grammars to Turing recognizers.

Study-note section AUT05

Use REG ⊊ CFL ⊊ CSL ⊊ DECIDABLE ⊊ RE, under the usual convention allowing S→ε with S absent from right sides when needed.

Question sources

Computer Science Exit Exam · 2018 · Question 66

Question 155 | NS0353

ou have given that Grammar G1 −({S, A, B}, {a, b}, S, {S → AB, A → a, B → b}).
Which one is terminal symbol in the give?

A. a,b

B. S

C. S → AB, A → a, B → b

D. S,A,B

Hint

Distinguish symbols, finite strings, their lengths and sets of strings. Apply the operation to its stated operands, including empty cases.

Answer A: a and b are the terminal symbols.

AUT04 separates the variable set from the terminal alphabet in G. The stem explicitly declares {S,A,B} as variables and {a,b} as terminals. The production rules are rewrites, not symbols, and uppercase S is the start variable. Therefore a,b is the terminal-symbol choice without needing any derivation calculation.

Why each choice is right or wrong

A - Correct: These are exactly the two symbols in the supplied terminal alphabet {a,b}.

B - Incorrect: S is the start variable rather than a terminal.

C - Incorrect: These are production rules, not terminal symbols.

D - Incorrect: S,A,B is the declared variable set rather than the terminal alphabet.

Primary note proof

Study-note section AUT04

> Write G=(V,Σ,P,S): finite variables V, terminals Σ disjoint from V, productions P and start variable S∈V. A production replaces its left side by its right side. The language is L(G)={w∈Σ*:S⇒*w}. A recognizer processes a word and accepts exactly the language members. Grammars generate languages; automata recognize languages, not grammars.

Study-note section AUT04

> Two grammars are equivalent when their generated languages are equal, regardless of rule counts or variable names. One common word, equal alphabets or one-way inclusion is insufficient.

Question sources

Computer Science Exit Exam · 2018 · Question 90

Question 156 | NS0356

The language $L = \{ww^R \mid w \in \{a, b\}^*\}$ (even-length palindromes) is:

A. Regular

B. Non-deterministic CFL but not deterministic

C. Deterministic CFL

D. Context-sensitive but not context-free

Hint

Compare production restrictions, memory access and language-family containments. Distinguish an exact characterization from an included subclass.

Answer B: A nondeterministic CFL that is not deterministic context-free.

AUT22 gives the NPDA for binary ww^R by guessing the midpoint and states that without a marker it is not deterministic context-free. The alphabet {a,b} is explicit here, excluding the unary regular exception. A visible center marker would allow a DPDA, but no such marker occurs in the given language.

Why each choice is right or wrong

A - Incorrect: Binary unmarked even palindromes are not regular; the unary exception does not apply.

B - Correct: An NPDA guesses the midpoint, while the unmarked binary language is not deterministic context-free.

C - Incorrect: Deterministic recognition requires a visible midpoint marker for the contrasting construction in AUT22.

D - Incorrect: The language is context-free, so denying context-freeness is false even though it is also CSL.

Primary note proof

Study-note section AUT22

> For even palindromes ww^R over {a,b}, push the first half, nondeterministically guess its midpoint, then pop matching symbols. No center marker makes that language context-free but not deterministic context-free. With a marker wcw^R the switch point is visible and a DPDA suffices. Unary even palindromes are merely even-length words and regular. A PDA cannot compare two arbitrary halves in the same forward order: $\{ww : w \in \{a,b\}^*\}$ is the copy language, not the palindrome language.

Compiler Design

Questions & Worked Answers

200 questions

Question 1 | Q01406

Which grammar gives multiple parse trees for the same string?

A. Unambiguous

B. Regular

C. Ambiguous

D. All of the above

Hint

Identify each activity's input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer C: An ambiguous grammar.

COMP10 defines ambiguity by the existence of one terminal string with two different parse trees. This is exactly the property asked for. An unambiguous grammar excludes it. Being regular describes a grammar class rather than guaranteeing multiple trees, so it does not make all the listed descriptions correct.

Why each choice is right or wrong

A - Incorrect: Unambiguous means each generated string has a unique parse tree, directly contradicting the property.

B - Incorrect: Regularity restricts grammar form; it does not require multiple parse trees for a string.

C - Correct: Ambiguity is precisely the existence of multiple parse trees for the same terminal string.

D - Incorrect: Unambiguous grammars do not have the stated property, so all cannot be correct.

Primary note proof

Study-note section COMP10

> A grammar is ambiguous if at least one terminal string has two different parse trees, equivalently two leftmost derivations. Merely changing derivation order on the same tree does not establish ambiguity. E→E+E|E*E|id allows different trees for id+id*id.

Study-note section COMP10

> Use E→E+T|T, T→T*F|F, F→(E)|id to give * higher precedence and both operators left associativity. For subtraction, a−b−c then groups (a−b)−c. The dangling-else grammar permits

else to attach to either nested if; a nearest-unmatched-if rule or grammar rewrite resolves it. Taking a leftmost derivation by itself does not resolve ambiguous interpretation.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Compiler Design module | PDF page 9 | lines 6-16

Grammars
• Every programming language has grammar rules
• Parsers or syntax analyzers are generated for a particular grammar
• CFG are used for syntax specification of programming languages
Context Free Grammar (CFG)
• Is denoted as G = (N, T , P, S)
• N : finite set of non-terminals
• T : finite set of terminals
• S ∈ N: The start symbol
• P : Finite set of productions, each of the form A→α, where A∈N and α ∈ (N U T)*

Compiler Design module | PDF page 9 | lines 22-27

Derivation Trees
• Derivations can be displayed as trees
• Internal nodes of the tree are all non-terminals
• Leaves are all terminals
• The yield of a derivation tree is the list of the labels of all the leaves read from left to right.

Question sources

Compiler Design review questions · Question 14

Question 2 | Q01416

Leaf nodes in a parse tree indicate?

A. sub-terminals

B. half-terminals

C. non-terminals

D. terminals

Hint

Identify each activity's input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer D: terminals

PDF p. 9 explicitly states that internal nodes are non-terminals and leaves are terminals. Thus the leaf labels in this module's derivation trees are terminals, not the grammar variables expanded at internal nodes.

Why each choice is right or wrong

A - Incorrect: Sub-terminals is not a category in the module's CFG or tree definitions (p. 9).

B - Incorrect: Half-terminals is not a category in those definitions (p. 9).

C - Incorrect: Non-terminals label internal nodes, not leaves (p. 9).

D - Correct: The module expressly assigns terminals to leaves (p. 9).

Primary note proof

Study-note section COMP09

> A context-free grammar G=(N,T,P,S) has nonterminals N, terminals T, productions P and start S. A production A→α rewrites one nonterminal. A sentential form is any string of terminals/nonterminals derivable from S; a sentence contains only terminals. A leftmost derivation rewrites the leftmost remaining nonterminal; a rightmost one rewrites the rightmost.

Study-note section COMP09

> A parse tree shows grammar productions: root S, internal nonterminals, and terminal leaves, with ε sometimes shown for empty productions. Its left-to-right yield is the input. An AST omits grammar scaffolding and punctuation; expression operands are leaves and operators internal nodes. The parser can build either representation, depending on implementation.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Compiler Design module | PDF page 9 | lines 22-27

> Derivation Trees
> • Derivations can be displayed as trees

> • Leaves are all terminals
> • The yield of a derivation tree is the list of the labels of all the leaves read from left to right.

Question sources

Compiler Design review questions · Question 24

Question 3 | Q00047

Which one of the following is not the task of lexical analyzer?

A. Group characters into lexemes

B. Output a sequence of tokens

C. Read the input characters

D. Build syntax tree

Hint

Identify each activity's input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer D: Build syntax tree

Scanning reads characters and represents matched lexemes as tokens (PDF pp. 5, 8). Syntax analysis then groups those tokens and produces a parse tree. Building that tree is therefore the non-lexical task.

Why each choice is right or wrong

A - Incorrect: Grouping characters into matched lexemes belongs to scanning (pp. 5, 8).

B - Incorrect: A sequence of tokens is the scanner's stated output (p. 8).

C - Incorrect: Reading the stream of source characters is explicitly lexical analysis.

D - Correct: Constructing the syntactic tree belongs to syntax analysis.

Primary note proof

Study-note section COMP04

> Keywords, identifiers, literals, operators and punctuation are token classes. Whitespace and comments are usually skipped while line/column positions are retained. In indentation-sensitive or newline-sensitive languages, layout can carry tokens. Parse-tree construction is a parser task; scanning can intern identifier spellings, but declaration scope and types need later analysis.

Study-note section COMP09

> A parse tree shows grammar productions: root S, internal nonterminals, and terminal leaves, with ε sometimes shown for empty productions. Its left-to-right yield is the input.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Compiler Design module | PDF page 5 | lines 3-11

> 1. Lexical / Linear Analysis (scanning)
> - Scans the source code as a stream of characters
> - Represent lexemes in the form of tokens as:
> <token-name, attribute-value>
> - Token

• smallest meaningful element that a compiler understands.
- Eg.
• Identifiers, Keywords, Literals, Operators and Special symbols.
- Blanks, new lines, comments will be removed from the source program.

Compiler Design module | PDF page 8 | lines 4-9

What is Lexical Analysis
• The first phase of a compiler
• The input is a high level language program
• The output is a sequence of tokens
• Strips off blanks, tabs, newlines, and comments from the source program
• Keeps track of line numbers

Compiler Design module | PDF page 5 | lines 12-18

2. Syntax / Hierarchical Analysis - Parsing
• Tokens are grouped hierarchically into nested collections with collective meaning.
• The result is generally a parse tree.
• expressions, statements, declarations etc... are identified by using the results of lexical analysis.
• Most syntactic errors in the source program are caught in this phase.
• Syntactic rules of the source language are given via a Grammar.

Question sources

MOE Computer Science Exit Exam · 2016 · Question 47

Question 4 | Q00054

Which statement is false about a compiler parser that constructs a parse tree and supports syntax-error diagnosis and recovery?

A. Parser builds the parse tree

B. Parser attempts to correct or recover few errors

C. Parser cannot perform context free syntax analysis

D. Parser produces appropriate error messages

Hint

Identify each activity’s input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer C: Parser cannot perform context free syntax analysis

A parser analyzes the token stream against the context-free syntax and builds its structural representation. In a compiler with syntax diagnostics and recovery, it can report an unexpected token and try to resume at a useful boundary. Therefore the claim that it cannot perform context-free syntax analysis reverses its defining role. Building a parse tree, reporting syntax errors and attempting the specified recovery behavior are compatible responsibilities.

Why each choice is right or wrong

A - Incorrect: Building a parse tree represents the grammar structure recognized by syntax analysis.

B - Incorrect: Error recovery may skip to a synchronization token or make a limited local repair.

C - Correct: Context-free syntax analysis is the parser's defining task, so denying it is false.

D - Incorrect: Syntax diagnostics identify unexpected or missing tokens with useful source locations.

Primary note proof

Study-note section COMP09

> A context-free grammar G=(N,T,P,S) has nonterminals N, terminals T, productions P and start S. A production A→α rewrites one nonterminal.

Study-note section COMP09

> A parse tree shows grammar productions: root S, internal nonterminals, and terminal leaves, with ε sometimes shown for empty productions. Its left-to-right yield is the input.

Study-note section COMP39

> Panic-mode recovery skips input until a synchronizing token such as ; or } permits parsing to resume. Phrase-level recovery makes a local insertion/deletion. Report the location and cause while avoiding cascades of misleading diagnostics. Lexical, syntax and semantic phases each detect their own errors; error handling is a shared service.

2. Syntax / Hierarchical Analysis - Parsing
• Tokens are grouped hierarchically into nested collections with collective meaning.
• The result is generally a parse tree.
• expressions, statements, declarations etc... are identified by using the results of lexical analysis.
• Most syntactic errors in the source program are caught in this phase.
• Syntactic rules of the source language are given via a Grammar.

Question sources

MOE Computer Science Exit Exam · 2016 · Question 54

Question 5 | Q00058

For an infix source expression targeting a postfix stack evaluator, which notation conversion prepares it for evaluation?

A. Convert infix notation to postfix notation

B. Convert postfix notation to prefix notation

C. Evaluate infix notation to prefix notation

D. Convert postfix to infix notation

Hint

Track where each computed value comes from and when each production action runs. Distinguish the representation from its attached information.

Answer A: Convert infix notation to postfix notation

A postfix evaluator reads operands before the operator that combines them. Converting an infix expression to postfix therefore supplies the required input order for the specified stack target. For example, the tree for a−4+c yields a 4 − c + in postorder. This is a choice of representation for this evaluator, rather than a mandatory strategy for every compiler.

Why each choice is right or wrong

A - Correct: Infix-to-postfix supplies the required target order.

B - Incorrect: Neither source nor target matches this direction.

C - Incorrect: Prefix is not the specified target.

D - Incorrect: This reverses the specified translation direction.

Primary note proof

Study-note section COMP25

A syntax-directed translation scheme embeds executable actions in productions; the actions run while translating a source program, not while generating the compiler. Attributes may compute types, values, AST pointers or generated code. The scheme defines an input-to-output translation, not merely an input language.

Study-note section COMP25

Create an identifier leaf with mkleaf(id,entry), a number with mkleaf(num,value), and an operator node with mknode(op,left,right). For a−4+c, construct +(−(a,4),c). Postorder traversal prints postfix: a 4 − c +. A stack evaluator pushes operands and pops right then left operands for an operator. Infix-to-postfix is useful for stack machines but not mandatory for all compilers.

MOE Computer Science Exit Exam · 2016 · Question 58

Question 6 | Q00335

Which named transformation directly replaces an expression whose operands are compile-time constants with its computed value?

A. Pee hole optimization

B. Constant folding

C. Invariant computation

D. Code hoisting

Hint

Trace whether computation is evaluated, moved, shared or removed. Preserve observable effects and use the stated arithmetic and target assumptions.

Answer B: Constant folding

Constant folding evaluates an expression from operands known at compilation and substitutes its value, such as replacing 3*4 with 12. This removes that expression's run-time arithmetic. A peephole pass describes a small inspection region and may perform several transformations; it is not the particular evaluation rule. Loop-invariant computation can remain unknown until execution, and hoisting moves safe invariant work rather than necessarily computing a compile-time value.

Why each choice is right or wrong

A - Incorrect: Peephole identifies a short-window optimization method, not specifically constant-expression evaluation.

B - Correct: Constant folding computes a known constant expression during compilation.

C - Incorrect: An invariant may depend on a run-time input even though it stays unchanged across a loop.

D - Incorrect: Hoisting moves a computation to a preheader; it need not evaluate it at compilation.

Primary note proof

Study-note section COMP30

> Constant folding evaluates constant expressions during compilation: 3*4→12.

Study-note section COMP32

> A loop-invariant expression has unchanged inputs during a loop. Hoist it to a preheader only when evaluation is safe on the paths where it will newly run.

Study-note section COMP31

> Peephole optimization examines short instruction windows.

Question 7 | Q00337

Which listed deterministic parser families can evaluate synthesized attributes for suitable grammars and semantic actions? Select all that apply.

A. Ambiguous grammar

B. LR grammar

C. LL grammar

D. None

Hint

Track where each computed value comes from and when each production action runs. Distinguish the representation from its attached information.

Answer B, C: LR grammar; LL grammar

Synthesized attributes flow from child nodes to their parent. LR parsers naturally compute these during reduction, after the right-hand-side children have been recognized. Suitable LL implementations can also compute them after their recursive child calls return. Ambiguity is a property of grammar interpretation, not a deterministic parser family or attribute-evaluation method. Thus both LR and LL are valid families for this task.

Why each choice is right or wrong

A - Incorrect: Ambiguity is not a deterministic parser family or evaluation mechanism.

B - Correct: LR reduction actions can compute parent values from children.

C - Correct: Suitable LL actions can compute values after child processing.

D - Incorrect: Both LR and LL provide supported implementations.

Primary note proof

Study-note section COMP24

> A syntax-directed definition is a CFG with attributes on grammar symbols and semantic rules on productions. An annotated parse tree displays computed attribute values; it is not itself an inherited or synthesized attribute. Synthesized attributes flow from children to a parent; inherited attributes carry context from parent or siblings.

Study-note section COMP24

> For E→E1+T, E.val=E1.val+T.val synthesizes an expression value. A declaration's type environment passed into its body is inherited. S-attributed definitions use only synthesized attributes and fit LR reduction-time evaluation naturally; suitable LL parsers can also compute them. L-attributed definitions restrict dependencies so a left-to-right traversal can evaluate inherited context. Attribute dependency cycles can prevent evaluation.

Question sources

Computer Science model exam · Question 68

University of Gondar model exam · Question 68

Question 8 | Q00338

Identifiers consist of one Letter followed by zero or more Letters or Digits. Which expressions denote exactly that language? Select all that apply. Here + means one-or-more, | alternation, and _ a literal underscore.

A. Letter(Letter+|Digit*)*

B. Letter(Letter|Digit)+

C. Letter(Letter|Digit)*

D. Letter(_Digit)*

Hint

Follow the representation at each construction step and apply the pattern or state-set rules consistently, including empty cases.

Answer A, C: Letter(Letter+|Digit*)*; Letter(Letter|Digit)*

C directly expresses a leading letter followed by any sequence of letters and digits. A is equivalent: its outer star may take zero blocks, and repeated letter or digit blocks can generate every such suffix. B excludes a one-letter identifier because its suffix uses plus. D permits literal underscores and restricted digit blocks, so it does not denote the specified identifier language.

Why each choice is right or wrong

A - Correct: Its repeated blocks generate every allowed suffix, including the empty suffix.

B - Incorrect: The trailing plus excludes a one-letter identifier.

C - Correct: This directly states the required pattern.

D - Incorrect: Its literal underscores violate the specified alphabet and its restricted suffix misses identifiers.

Primary note proof

Study-note section COMP05

> Regular expressions use concatenation, alternation r|s, Kleene star r* for zero or more, and r+ for one or more. In a simplified alphabet, identifier = Letter(Letter|Digit)*; it permits a single letter and forbids a leading digit.

Study-note section COMP05

> Letter(Letter+|Digit*)* denotes the same language as Letter(Letter|Digit)* under ordinary regular-expression semantics: repeated blocks can contain any trailing letter/digit sequence. These two regular expressions are equivalent. Regular patterns handle ordinary tokens; arbitrary balanced nesting generally needs grammar/stack structure.

Computer Science model exam · Question 69

University of Gondar model exam · Question 69

Question 9 | Q00339

What is the process of finding a parse tree for a string of tokens called?

A. Recognizing

B. Parsing

C. Tokenizing

D. Analyzing

Hint

Identify each activity's input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer B: Parsing

Parsing is explicitly the process of constructing a parse tree for a sentence generated by a grammar (PDF p. 10). That is the operation named in the question; token production precedes it (p. 8).

Why each choice is right or wrong

A - Incorrect: The module does not use Recognizing as the name of this construction (p. 10).

B - Correct: Parsing matches the express definition (p. 10).

C - Incorrect: Tokenizing produces the token stream, rather than its parse tree (p. 8).

D - Incorrect: Analyzing is a broad description; the defined specific process is Parsing (p. 10).

Primary note proof

Study-note section COMP09

> A context-free grammar G=(N,T,P,S) has nonterminals N, terminals T, productions P and start S. A production A→α rewrites one nonterminal. A sentential form is any string of terminals/nonterminals derivable from S; a sentence contains only terminals. A leftmost derivation rewrites the leftmost remaining nonterminal; a rightmost one rewrites the rightmost.

Study-note section COMP09

> A parse tree shows grammar productions: root S, internal nonterminals, and terminal leaves, with ε sometimes shown for empty productions. Its left-to-right yield is the input. An AST omits grammar scaffolding and punctuation; expression operands are leaves and operators internal nodes. The parser can build either representation, depending on implementation.

What is Lexical Analysis
- The first phase of a compiler
- The input is a high level language program
- The output is a sequence of tokens
- Strips off blanks, tabs, newlines, and comments from the source program
- Keeps track of line numbers

Question sources

Computer Science model exam · Question 70

University of Gondar model exam · Question 70

Question 10 | Q00340

Which compiler phase groups source characters into lexemes and classifies them as identifier, keyword, literal or operator tokens?

A. Interpretation analysis

B. Lexical analysis

C. Syntax analysis

D. General syntax analysis

Hint

Identify each activity's input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer B: Lexical analysis

Lexical analysis groups the source character sequence into lexemes and emits token categories with attributes. Syntax analysis instead combines already recognized tokens into larger grammatical structures such as expressions and statements. Specifying characters and token categories resolves the original mixture of lexical classification and parsing terminology. The generic interpretation and syntax labels do not describe the requested character-to-token phase.

Why each choice is right or wrong

A - Incorrect: Interpretation executes a representation rather than classifying lexemes.

B - Correct: Lexical analysis turns character sequences into tokens.

C - Incorrect: Syntax analysis groups tokens into grammatical structures.

D - Incorrect: This syntax label concerns parsing rather than lexical classification.

Primary note proof

Study-note section COMP41

> Grouping characters into token classes is lexical analysis; grouping tokens into expressions and statements is syntax analysis.

Study-note section COMP41

> Trees store hierarchical constructs, while a symbol table stores declaration metadata.

Module passages - related reading

Question sources

Computer Science model exam · Question 71

University of Gondar model exam · Question 71

Question 11 | Q00532

For a register-based target compiler, which choice most completely lists general code-generator tasks?

A. Instruction selection

B. Register allocation and assignment

C. Instruction ordering

D. All

Hint

Identify each activity’s input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer D: All

COMP34 separates selecting target operations, deciding storage in registers, assigning physical registers, and scheduling instructions. The three concrete choices name these standard code-generation tasks. Since the question offers an aggregate covering them, that aggregate is the complete answer; each individual choice supplies only part of the requested task list.

Why each choice is right or wrong

A - Incorrect: True as one component, but incomplete as the requested full selection. Instruction selection chooses which target instructions implement the intermediate operations.

B - Incorrect: True as one component, but incomplete as the requested full selection. Register allocation and physical assignment decide where values reside and which registers hold them.

C - Incorrect: True as one component, but incomplete as the requested full selection. Instruction ordering schedules computations while preserving data and control dependencies.

D - Correct: All three listed activities belong to the code-generator task set described in COMP34.

Primary note proof

Study-note section COMP34

> Code generation lowers checked IR to a target form. Instruction selection chooses target operations; register allocation chooses where values reside; scheduling orders instructions while respecting dependencies; storage layout assigns offsets and follows ABI requirements. Register assignment names actual physical registers after allocation decisions.

Study-note section COMP34

> For t=a+b, a simple target could emit LOAD R1,a; LOAD R2,b; ADD R3,R1,R2; STORE t,R3. Other targets may combine loads with arithmetic or keep t in a register. Machine idioms, register availability and instruction order affect execution time.

Compiler Design module | PDF page 18 | lines 11-22

Register Allocation
• Registers hold values
• Example
- a = c + d
- e = a + b
- f = e - 1

• With the assumption that a and e die after use
• Temporary a can be reused after e=a+b, same wz a
• Can allocate a,e and f all to one register(r1)
- r1 = r2 + r3
- r1 = r1 + r4
- r1 = r1 - 1

Question sources

Computer Science model exam · 2015 · Question 1

Question 12 | Q00537

What is the term for an actual occurrence of a character sequence in source text that matches a token pattern, such as total or 42?

A. Pattern

B. Lexemes

C. Tokens

D. All

Hint

Identify each activity’s input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer B: Lexemes

A lexeme is the actual character sequence occurring in source text. A token is the category and optional attribute emitted for that occurrence, while a pattern defines which spellings are members of the category. For example, total is a lexeme classified as an identifier token. These are related but distinct objects, so the aggregate choice cannot name the concrete occurrence.

Why each choice is right or wrong

A - Incorrect: A pattern describes possible spellings.

B - Correct: Lexeme names the actual matched source sequence.

C - Incorrect: Token names the category and optional attribute.

D - Incorrect: The three concepts are distinct, not synonymous.

Primary note proof

Study-note section COMP04

A token is a category with optional attribute, such as (ID, symbol-entry) or (INT_LITERAL,42). A lexeme is the actual character sequence, such as total or 42. A pattern specifies which lexemes belong to a token class. The scanner emits an ordered token stream, not an unordered mathematical set.

Study-note section COMP04

Keywords, identifiers, literals, operators and punctuation are token classes. Whitespace and comments are usually skipped while line/column positions are retained. In indentation-sensitive or newline-sensitive languages, layout can carry tokens. Parse-tree construction is a parser task; scanning can intern identifier spellings, but declaration scope and types need later analysis.

Study-note section COMP41

Grouping characters into token classes is lexical analysis; grouping tokens into expressions and statements is syntax analysis.

Study-note section COMP41

Trees store hierarchical constructs, while a symbol table stores declaration metadata.

Tokens, Patterns, and Lexemes
• Token
- A string of characters which logically belong together
- Classes of similar lexemes
l identifier, keywords, constants etc.
• Pattern

- A rule which describes a token
- Lexeme
- The sequence of characters matched by a pattern to form the token

Question sources

Computer Science model exam · 2015 · Question 6

Question 13 | Q00561

Which one of the following are the specific character strings that make up a token?

A. Token

B. Lexemes

C. Lexical units

D. Pattern

Hint

Identify each activity’s input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer B: Lexemes

A lexeme is the sequence of characters matched by a pattern to form a token (PDF p. 8). A token instead denotes a class of similar lexemes, and a pattern specifies the rule. “Specific character strings” therefore identifies lexemes.

Why each choice is right or wrong

A - Incorrect: Token names the class in the module’s token/lexeme distinction (p. 8).

B - Correct: Lexemes are the actual matched sequences (p. 8).

C - Incorrect: Lexical units is not the defined name for specific strings in this passage (p. 8).

D - Incorrect: A pattern is the matching rule, not its particular match (p. 8).

Primary note proof

Study-note section COMP04

A token is a category with optional attribute, such as (ID, symbol-entry) or (INT_LITERAL,42). A lexeme is the actual character sequence, such as total or 42. A pattern specifies which lexemes belong to a token class. The scanner emits an ordered token stream, not an unordered mathematical set.

Study-note section COMP04

Keywords, identifiers, literals, operators and punctuation are token classes. Whitespace and comments are usually skipped while line/column positions are retained. In indentation-sensitive

or newline-sensitive languages, layout can carry tokens. Parse-tree construction is a parser task; scanning can intern identifier spellings, but declaration scope and types need later analysis.

Computer Science model exam · 2015 · Question 30

Question 14 | Q00578

Which one of the following are the program properties that can be checked at run time?

A. Static checking

B. Dynamic semantics

C. Other Static Checks

D. None

Hint

Ask whether the required information is a declaration’s identity and attributes, program structure or the ordered source tokens.

Answer B: Dynamic semantics

Semantic checks are static when done during compilation and dynamic when done during run-time (PDF p. 14). Interpreting “Dynamic semantics” as the option’s name for run-time semantic checking, B fits; static checking and other static checks occur during compilation.

Why each choice is right or wrong

A - Incorrect: Static checking is done at compilation, not run-time (p. 14).

B - Correct: B corresponds to the module’s run-time dynamic semantic checks (p. 14).

C - Incorrect: Other static checks retain the compile-time timing (p. 14).

D - Incorrect: None does not fit because the dynamic check category is present (p. 14).

Primary note proof

Study-note section COMP21

Static checks occur before execution: type compatibility, duplicate declarations within a restricted scope, valid names, argument counts, return compatibility and control-flow placement. A break is valid only in constructs allowed by the language; in C/C++ it can exit a loop or switch. A compiler may annotate an AST or create typed IR; there is no mandatory uniquely named output tree.

Study-note section COMP21

Dynamic checks depend on runtime values, such as some bounds and null checks. Static analysis can prove some accesses safe or faulty; “all memory errors cannot be statically checked” is too strong. Unreachable code is not universally a semantic error: some languages reject it in specified cases, others merely warn or optimize it away.

• Type Checks: incompatible operands
• Flow Control Check
• Uniqueness Check
• Name Related Check

Question sources

Computer Science model exam · 2015 · Question 47

Question 15 | Q00610

For a language with insignificant whitespace and comments, which choice most completely lists the scanner’s secondary tasks?

A. Stripping out blanks, tabs, new lines

B. Stripping out comments

C. Error reporting

D. All

Hint

Identify each activity’s input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer D: All

COMP04 says scanners usually skip whitespace and comments while retaining source positions. COMP39 adds that lexical analysis detects its own errors and that error handling is shared. These establish all three listed secondary scanner duties under the ordinary language convention. Layout-sensitive languages are an explicit exception in COMP04, not evidence that scanners never perform these tasks.

Why each choice is right or wrong

A - Incorrect: True as one component, but incomplete as the requested full selection. Ordinary scanners skip blanks, tabs and newlines while retaining positions; layout-sensitive languages need special handling.

B - Incorrect: True as one component, but incomplete as the requested full selection. Comments are normally discarded instead of being delivered as ordinary parser tokens.

C - Incorrect: True as one component, but incomplete as the requested full selection. Lexical errors require reporting, with positions retained to locate the offending source text.

D - Correct: Together the choices cover normal whitespace removal, comment removal and lexical error reporting.

Primary note proof

Study-note section COMP04

> Keywords, identifiers, literals, operators and punctuation are token classes. Whitespace and comments are usually skipped while line/column positions are retained. In indentation-sensitive or newline-sensitive languages, layout can carry tokens. Parse-tree construction is a parser task; scanning can intern identifier spellings, but declaration scope and types need later analysis.

Study-note section COMP39

> Report the location and cause while avoiding cascades of misleading diagnostics. Lexical, syntax and semantic phases each detect their own errors; error handling is a shared service.

2. Syntax / Hierarchical Analysis - Parsing
• Tokens are grouped hierarchically into nested collections with collective meaning.
• The result is generally a parse tree.
• expressions, statements, declarations etc... are identified by using the results of lexical analysis.
• Most syntactic errors in the source program are caught in this phase.
• Syntactic rules of the source language are given via a Grammar.

Question sources

Computer Science model exam · 2015 · Question 79

Question 16 | Q00613

Which one of the following is the parse tree showing the values of attributes at each node?

A. Inherited attribute

B. Synthesized attribute

C. Annotated parse tree

D. A&B

Hint

Track where each computed value comes from and when each production action runs. Distinguish the representation from its attached information.

Answer C: An annotated parse tree.

COMP24 directly calls a parse tree displaying computed attribute values an annotated parse tree. Inherited and synthesized classify how attribute information flows; neither is the name of the entire displayed tree. Combining those attribute categories still does not name the representation described in the question.

Why each choice is right or wrong

A - Incorrect: An inherited attribute carries contextual information; it is not a parse tree displaying values.

B - Incorrect: A synthesized attribute carries a value upward, rather than naming the annotated tree.

C - Correct: This is the note's precise name for a parse tree showing attribute values at nodes.

D - Incorrect: Combining two attribute categories does not give the name of the displayed tree.

Primary note proof

Study-note section COMP24

> A syntax-directed definition is a CFG with attributes on grammar symbols and semantic rules on productions. An annotated parse tree displays computed attribute values; it is not itself an inherited or synthesized attribute. Synthesized attributes flow from children to a parent; inherited attributes carry context from parent or siblings.

Study-note section COMP24

> For E→E1+T, E.val=E1.val+T.val synthesizes an expression value. A declaration's type environment passed into its body is inherited. S-attributed definitions use only synthesized attributes and fit LR reduction-time evaluation naturally; suitable LL parsers can also compute them. L-attributed definitions restrict dependencies so a left-to-right traversal can evaluate inherited context. Attribute dependency cycles can prevent evaluation.

Question sources

Computer Science model exam · 2015 · Question 82

Question 17 | Q00631

Which one of the following can be applied directly after intermediate code generation to improve the intermediate representation?

A. Peephole optimization

B. Constant Propagation

C. Dead code elimination

D. All

Hint

Trace whether computation is evaluated, moved, shared or removed. Preserve observable effects and use the stated arithmetic and target assumptions.

Answer D: All

Optimization changes intermediate code to remove inefficiencies (PDF p. 7). The module lists peephole transformations and constant propagation (p. 18), and elimination of never-executed or unreachable statements (p. 18). Each can improve an intermediate representation before target code is emitted; no exclusive ordering among those transformations is specified.

Why each choice is right or wrong

A - Incorrect: Peephole transformation improves instruction sequences (p. 18).

B - Incorrect: Constant propagation is a listed optimization technique (p. 18).

C - Incorrect: Removing unreachable intermediate statements is dead code elimination (p. 18).

D - Correct: All three fit the optimization of intermediate code described on p. 7.

Primary note proof

Study-note section COMP30

Constant folding evaluates constant expressions during compilation: 3*4→12. Constant propagation substitutes known values: x=3; y=x+2 becomes y=3+2 before folding. Copy propagation substitutes a copied name while its source remains unchanged. Dead-code elimination removes unreachable code or computations whose values are unused and whose evaluation has no necessary side effects.

Study-note section COMP31

Common-subexpression elimination reuses an earlier value only if operand values and relevant memory remain unchanged. A DAG can represent sharing. Algebraic simplification removes identities when valid: integer x+0→x. Strength reduction replaces an operation with an equivalent cheaper form, such as unsigned x*8→x<<3 for a valid width and shift count. Target costs determine whether it is actually cheaper.

Study-note section COMP31

Peephole optimization examines short instruction windows. It can remove redundant loads/stores, replace machine idioms and shorten jump chains: jump L1 where L1 immediately jumps L2 can become jump L2. Local optimization is a wider category; peephole optimization is a concrete method within the relevant scope.

Techniques
• Common sub-expression elimination
- Repeated appearance computed previously
• Strength reduction
- Replacement of expensive expressions with simple ones
• Code movement
- Moving a block of code outside a loop
• Dead code elimination
- Eliminated code statements that are either never executed or unreachable

Question sources

Computer Science model exam · 2015 · Question 100

Question 18 | Q00652

Which compiler structure associates declared identifier names or identities with attributes such as type, scope and storage location, irrespective of its container implementation?

A. Literal Table

B. Symbol table

C. Hash table

D. All

Hint

Ask whether the required information is a declaration’s identity and attributes, program structure or the ordered source tokens.

Answer B: Symbol table

A symbol table maps identifier names or declaration identities to attributes such as type, scope and storage location. A hash table is one possible implementation of that mapping, not its semantic role. Literal tables concern literal values, and punctuation need not have symbol records at all. Restricting the question to identifier metadata avoids claiming that every token kind uses the same table.

Why each choice is right or wrong

A - Incorrect: A literal table concerns literal values.

B - Correct: The symbol table provides this mapping.

C - Incorrect: Hashing is an implementation technique rather than the semantic role.

D - Incorrect: The structures have different roles.

Primary note proof

Study-note section COMP19

A symbol table maps names or symbol identities to attributes: type, scope, width, storage offset, parameter signature, constant information or linkage. A hash table gives expected O(1) insertion/lookup with suitable hashing; a stack of scope tables supports lexical nesting. Search the nearest scope first, insert declarations in the current scope, and remove visibility when leaving it.

Study-note section COMP19

Scanning may intern a spelling first; semantic analysis determines the declaration and type. Implementations differ, so first interaction is conventional rather than universal. Not every punctuation token needs a symbol-table entry; literals may use a separate literal table. A hash table is an implementation, not the information's semantic role.

Study-note section COMP41

Grouping characters into token classes is lexical analysis; grouping tokens into expressions and statements is syntax analysis.

Study-note section COMP41

Trees store hierarchical constructs, while a symbol table stores declaration metadata.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Compiler Design module | PDF page 6 | lines 2-10

3. Semantic Analysis
• Certain checks are performed to make sure that the components of the program fit together meaningfully.
• Unlike parsing, this phase checks for semantic errors in the source program (e.g. type mismatch)
- Type checking of various programming language constructs is one of the most important tasks.
• Stores type information in the symbol table or the syntax tree.
- Types of variables, function parameters, array dimensions, etc.

Compiler Design module | PDF page 17 | lines 2-15

Declarations
• Involves allocation of space in memory &
• Entry of type and name in symbol table
• Off set variable (Offset=0) is used to denote the base address
int a; float b;
Allocation process: { offset = 0 }
int a;
id.type = int
id.width = 2
offset = offset + id.width { offset = 2 }
float b;
id.type=float

id.width=4
offset = offset +id.width { offset = 6 }

Compiler Design module | PDF page 8 | lines 10-18

Tokens, Patterns, and Lexemes
• Token
- A string of characters which logically belong together
- Classes of similar lexemes

l identifier, keywords, constants etc.
• Pattern
- A rule which describes a token

• Lexeme
- The sequence of characters matched by a pattern to form the token

Question sources

Computer Science model exam · 2015 · Question 121

Question 19 | Q00754

The output of lexical analyzer is*

A. Syntax tree

B. Strings of characters

C. A set of tokens

D. set of regular expressions

Hint

Identify each activity's input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer C: A set of tokens

The output of lexical analysis is expressly a sequence of tokens (PDF p. 8). C is the only option naming that output, although "set" should be read informally: order matters, so the module's precise word is sequence.

Why each choice is right or wrong

A - Incorrect: The parse tree is produced by syntax analysis.

B - Incorrect: Characters are the scanner input, not its classified output.

C - Correct: Tokens are the output elements (p. 8).

D - Incorrect: Patterns describe tokens; they are not the source-specific output sequence (p. 8).

Primary note proof

Study-note section COMP04

A token is a category with optional attribute, such as (ID, symbol-entry) or (INT_LITERAL,42). A lexeme is the actual character sequence, such as total or 42. A pattern specifies which lexemes belong to a token class. The scanner emits an ordered token stream, not an unordered mathematical set.

Study-note section COMP04

Keywords, identifiers, literals, operators and punctuation are token classes. Whitespace and comments are usually skipped while line/column positions are retained. In indentation-sensitive or newline-sensitive languages, layout can carry tokens. Parse-tree construction is a parser task; scanning can intern identifier spellings, but declaration scope and types need later analysis.

What is Lexical Analysis
• The first phase of a compiler
• The input is a high level language program
• The output is a sequence of tokens
• Strips off blanks, tabs, newlines, and comments from the source program
• Keeps track of line numbers

Compiler Design module | PDF page 5 | lines 12-18

2. Syntax / Hierarchical Analysis - Parsing
• Tokens are grouped hierarchically into nested collections with collective meaning.
• The result is generally a parse tree.
• expressions, statements, declarations etc... are identified by using the results of lexical analysis.
• Most syntactic errors in the source program are caught in this phase.
• Syntactic rules of the source language are given via a Grammar.

Question sources

Computer Science model exam 2 · Question 95

Question 20 | Q00755

Which of the following is NOT the primary role of code generator in compiler design? *

A. instruction selection

B. Declaration of variables

C. instruction ordering

D. A Register allocation

Hint

Identify what the representation stores, what it omits and which later transformations it must support; separate a representation property from an algorithmic task.

Answer B: Declaration of variables

Code generation lowers checked intermediate code into target operations. It selects instructions, allocates registers and orders instructions subject to dependencies. Declarations instead establish source names, types and storage information during analysis; generating code may use that information without declaring the variables again. Thus the declaration activity is outside the primary code-generator task set, while the other three choices describe target implementation decisions.

Why each choice is right or wrong

A - Incorrect: Instruction selection chooses target operations implementing the IR.

B - Correct: Processing source declarations belongs to analysis and symbol-table/type handling.

C - Incorrect: Instruction ordering schedules target computations while preserving dependencies.

D - Incorrect: Register allocation decides where intermediate values reside.

Primary note proof

Study-note section COMP26

> IR separates source analysis from target implementation, allowing optimizers and backends to be reused. It should be easy to generate, analyze, transform and lower.

Study-note section COMP26

> Ordinary TAC arithmetic has at most one operation, two sources and one destination: t1=c*d; t2=b+t1; a=t2. Quadruples store (op,arg1,arg2,result); triples omit an explicit result field and refer to instruction positions. Indirect triples reference a separate ordering list, easing rearrangement. Trees describe expressions; DAGs share common subexpressions, while quadruples/triples are instruction-record structures.

Study-note section COMP34

> Code generation lowers checked IR to a target form. Instruction selection chooses target operations; register allocation chooses where values reside; scheduling orders instructions while respecting dependencies; storage layout assigns offsets and follows ABI requirements. Register assignment names actual physical registers after allocation decisions.

Study-note section COMP34

> For t=a+b, a simple target could emit LOAD R1,a; LOAD R2,b; ADD R3,R1,R2; STORE t,R3. Other targets may combine loads with arithmetic or keep t in a register. Machine idioms, register availability and instruction order affect execution time.

Computer Science model exam 2 · Question 96

Question 21 | Q00756

Which one of the following is different from the others?

A. quadruples

B. triples

C. tree

D. indirect triples

Hint

Identify what the representation stores, what it omits and which later transformations it must support; separate a representation property from an algorithmic task.

Answer C: tree

Quadruples, triples, indirect triples, trees and DAGs all implement three-address code (PDF p. 16). Quadruples and triples have numbered record fields, and indirect triples use pointers; tree is the hierarchical representation. C is the natural odd one out under that structural distinction.

Why each choice is right or wrong

A - Incorrect: Quadruples are instruction records with four fields (p. 16).

B - Incorrect: Triples are instruction records with three fields (p. 16).

C - Correct: Tree is the hierarchical structure among the options (p. 16).

D - Incorrect: Indirect triples retain a pointer-based triple representation (p. 16).

Primary note proof

Study-note section COMP26

> IR separates source analysis from target implementation, allowing optimizers and backends to be reused. It should be easy to generate, analyze, transform and lower.

Study-note section COMP26

> Ordinary TAC arithmetic has at most one operation, two sources and one destination: t1=c*d; t2=b+t1; a=t2. Question sources

Computer Science model exam 2 · Question 97

Question 22 | Q00757

A compiler computes expression-type attributes and checks compatibility as grammar productions are processed. Which offered description most specifically identifies this mechanism?

A. During lexical analysis

B. During syntax analysis

C. During syntax directed translation

D. During code optimization

Hint

Check operand compatibility and permitted conversions under the stated language rules; distinguish grammatical structure from semantic meaning.

Answer C: During syntax directed translation

The compiler in the scenario evaluates type attributes and applies compatibility checks as grammar productions are processed. This is syntax-directed translation: semantic rules or actions are attached to grammatical structure. Pure lexical analysis only recognizes tokens, and pure syntax recognition alone does not establish operand-type compatibility. Optimization transforms an already analyzed representation. Parsing can invoke these semantic actions, so the mechanism is more precise than naming syntax analysis alone.

Why each choice is right or wrong

A - Incorrect: Token recognition alone does not compute full expression-type compatibility.

B - Incorrect: Pure syntax recognition checks grammar; the scenario additionally attaches semantic computations.

C - Correct: Syntax-directed semantic actions compute and check attributes associated with productions.

D - Incorrect: Optimization transforms analyzed code rather than naming the stated checking mechanism.

Primary note proof

Study-note section COMP24

> A syntax-directed definition is a CFG with attributes on grammar symbols and semantic rules on productions.

Study-note section COMP25

> A syntax-directed translation scheme embeds executable actions in productions; the actions run while translating a source program, not while generating the compiler. Attributes may compute types, values, AST pointers or generated code.

Study-note section COMP22

A type checker verifies that operations are defined for their operands. In a simple strict language, integer mod requires two integers; array indexing requires an array and integer index; an if condition requires Boolean; assignment requires equal or convertible types. Function calls check parameter count and compatibility, and returns match result types.

Question sources

Computer Science model exam 2 · Question 98

Question 23 | Q00758

In a conventional pipeline that lowers TAC further to native code or VM instructions, which representation is intermediate rather than the final emitted target?

A. Three address code

B. Assembly language

C. Absolute machine code

D. Byte Code

Hint

Identify what the representation stores, what it omits and which later transformations it must support; separate a representation property from an algorithmic task.

Answer A: Three address code

Three-address code is intermediate in the specified pipeline: analysis and optimization transform it before code generation lowers it further. Assembly, absolute machine code and VM bytecode can each be final target forms for an appropriate compiler. This pipeline-specific distinction does not assert that TAC could never be another translator's target; it identifies the expressly stated intermediate role here.

Why each choice is right or wrong

A - Correct: TAC is lowered further in this pipeline.

B - Incorrect: Assembly can be a final emitted target.

C - Incorrect: Absolute machine code can be a final target.

D - Incorrect: VM bytecode can be a final target.

Primary note proof

Study-note section COMP34

> Code generation lowers checked IR to a target form. Instruction selection chooses target operations; register allocation chooses where values reside; scheduling orders instructions while respecting dependencies; storage layout assigns offsets and follows ABI requirements. Register assignment names actual physical registers after allocation decisions.

Study-note section COMP34

> For t=a+b, a simple target could emit LOAD R1,a; LOAD R2,b; ADD R3,R1,R2; STORE t,R3. Other targets may combine loads with arithmetic or keep t in a register. Machine idioms, register availability and instruction order affect execution time.

a. Register allocation and assignment

Question sources

Computer Science model exam 2 · Question 99

Question 24 | Q00759

Which of the following is NOT important property of intermediate code representation?

A. Ease of generation

B. Ease of manipulation

C. Register allocation

D. Level of abstraction

Hint

Identify what the representation stores, what it omits and which later transformations it must support; separate a representation property from an algorithmic task.

Answer C: Register allocation

An intermediate representation should be convenient to generate, analyze and transform, and its abstraction should suit optimization and target lowering. Those are design properties of the representation. Register allocation is an algorithmic backend task that chooses locations for values; it is not itself a property such as ease of generation or abstraction level. An IR can carry information useful to that task without making allocation a representation property.

Why each choice is right or wrong

A - Incorrect: Ease of generation is a useful IR design property.

B - Incorrect: Ease of manipulation supports analysis and transformation passes.

C - Correct: Register allocation is a backend decision over values rather than an IR property.

D - Incorrect: Abstraction level determines which source and target details the representation exposes.

Primary note proof

Study-note section COMP26

> IR separates source analysis from target implementation, allowing optimizers and backends to be reused. It should be easy to generate, analyze, transform and lower.

Study-note section COMP26

> Ordinary TAC arithmetic has at most one operation, two sources and one destination: t1=c*d; t2=b+t1; a=t2. Question sources

Computer Science model exam 2 · Question 100

Question 25 | Q00903

What is the main purpose of syntax-directed translation in a compiler?

A. To interleave semantic analysis with syntax analysis using attributes attached to grammar symbols

B. To generate optimized machine code directly

C. .
To tokenize the source code

D. To replace the parser with a finite automaton

Hint

Track where each computed value comes from and when each production action runs. Distinguish the representation from its attached information.

Answer A: To interleave semantic analysis with syntax analysis using attributes attached to grammar symbols

A syntax-directed definition is a CFG with attributes and rules; attributes attach to symbols and rules to productions (PDF p. 12). Actions execute according to the parsing mechanism. This is the grammar-based integration of semantic processing described in A, rather than a direct optimized-machine-code replacement for the remaining phases.

Why each choice is right or wrong

A - Correct: A matches the attribute/rule and parsing-action definitions (p. 12).

B - Incorrect: Machine-code conversion is a later code-generation task (p. 7), not the definition of SDT.

C - Incorrect: Tokenization is lexical analysis (p. 8).

D - Incorrect: The module retains the grammar/parsing mechanism; it does not replace it with an automaton (p. 12).

Primary note proof

Study-note section COMP24

A syntax-directed definition is a CFG with attributes on grammar symbols and semantic rules on productions. An annotated parse tree displays computed attribute values; it is not itself an

inherited or synthesized attribute. Synthesized attributes flow from children to a parent; inherited attributes carry context from parent or siblings.

Study-note section COMP24

For E→E1+T, E.val=E1.val+T.val synthesizes an expression value. A declaration's type environment passed into its body is inherited. S-attributed definitions use only synthesized attributes and fit LR reduction-time evaluation naturally; suitable LL parsers can also compute them. L-attributed definitions restrict dependencies so a left-to-right traversal can evaluate inherited context. Attribute dependency cycles can prevent evaluation.

Computer Science Exit Exam · 2018 · Question 16

Question 26 | Q00908

Straight directed translation uses:

A. Purely lexical rules

B. Backtracking algorithms

C. ¢.
Grammar without attributes

D. Grammar with sematic rule

Hint

Track where each computed value comes from and when each production action runs. Distinguish the representation from its attached information.

Answer D: Grammar with sematic rule

Interpreting the apparent typo “Straight directed translation” as syntax-directed translation, the module defines it through actions on productions and a CFG with attributes and semantic rules (PDF p. 12). D is the only option that retains this grammar-plus-rule structure.

Why each choice is right or wrong

A - Incorrect: Pure lexical rules omit the production-associated semantic actions (p. 12).

B - Incorrect: Backtracking is not the defining mechanism; actions follow the chosen parser (p. 12).

C - Incorrect: A grammar without attributes omits the defining additions in a syntax-directed definition (p. 12).

D - Correct: A grammar with semantic rules matches the definition (p. 12).

Primary note proof

Study-note section COMP24

> A syntax-directed definition is a CFG with attributes on grammar symbols and semantic rules on productions. An annotated parse tree displays computed attribute values; it is not itself an inherited or synthesized attribute. Synthesized attributes flow from children to a parent; inherited attributes carry context from parent or siblings.

Study-note section COMP24

> For E→E1+T, E.val=E1.val+T.val synthesizes an expression value. A declaration’s type environment passed into its body is inherited. S-attributed definitions use only synthesized attributes and fit LR reduction-time evaluation naturally; suitable LL parsers can also compute them. L-attributed definitions restrict dependencies so a left-to-right traversal can evaluate inherited context. Attribute dependency cycles can prevent evaluation.

Syntax Directed Translation
• Attaching actions to the grammar rules(productions).
• Actions are executed during the compilation
- Not during the generation of the compiler
• Actions are executed according to the parsing mechanism.
Syntax Directed Definitions
• Is a generalization of a context free grammar
• Is a CFG with attributes and rules
• Attributes are associated with grammar symbols and rules with productions
• Attributes may be:
- Numbers
- Types
- Strings etc

Question sources

Computer Science Exit Exam · 2018 · Question 21

Question 27 | Q00911

Which one of the following is a top-down parser without backtracking?

A. LR parser

B. Brute force parser

C. Operator precedence parser

D. Predictive parser

Hint

Use construction direction, lookahead and grammar restrictions. Distinguish algorithm families, implementations and coverage before comparing them.

Answer D: A predictive parser.

COMP11 defines predictive parsing by choosing productions with lookahead without backtracking. This supplies both requirements in the stem: top-down direction and absence of backtracking. LR and operator-precedence parsing belong to bottom-up approaches; brute-force top-down trial does not provide the no-backtracking guarantee.

Why each choice is right or wrong

A - Incorrect: LR parsing reduces input bottom-up rather than expanding the start symbol top-down.

B - Incorrect: Brute-force production trials can require backtracking and do not meet the defining predictive constraint.

C - Incorrect: Operator-precedence parsing is a bottom-up technique rather than predictive top-down expansion.

D - Correct: Predictive parsing uses lookahead to choose productions without backtracking, exactly as COMP11 states.

Primary note proof

Study-note section COMP11

> Top-down parsing starts with S and expands productions toward the input, usually constructing a leftmost derivation. Recursive descent typically has one procedure per nonterminal. A general recursive-descent implementation can backtrack; a predictive parser chooses a production using lookahead without backtracking. LL(1) scans Left to right, produces a Leftmost derivation and uses one lookahead token.

Study-note section COMP15

> Bottom-up parsing starts from input and reduces toward S, constructing a rightmost derivation in reverse.

Study-note section COMP-S01

> Operator-precedence parsing is a restricted bottom-up expression-parsing method using a stack and precedence relations. With a suitable expression grammar, the stack retains unfinished surrounding expressions while nested parentheses are processed.

LR Parsing
• LR(k) - Left to right scanning with Rightmost derivation in reverse, k being the number of lookahead tokens.
Types of LR Parsers
• LR (0) , SLR (1) , LALR (1) , CLR (1)

LL	LR
Leftmost derivation	Rightmost derivation in reverse
Starts with root non-terminal on stack	Ends with root non-terminal on the stack
Builds the parse tree top-down	Builds the parse tree bottom-up
Expands the non-terminals	Reduces the non-terminals

Question sources

Computer Science Exit Exam · 2018 · Question 24

Question 28 | Q00940

If input is "a" is for syntax tree, which function is used to create tree?

A. mknode(num, value)

B. mkleaf(num, value)

C. mkleaf(id, entry)

D. mknode(op, left, right)

Hint

Track where each computed value comes from and when each production action runs. Distinguish the representation from its attached information.

Answer C: mkleaf(id, entry)

For the expression a-4+c the first construction is P1=mkleaf(id,entrya) (PDF p. 13). Since a is an identifier, its node stores a pointer to the identifier’s symbol-table entry. Numeric leaf construction is instead used for 4; operator nodes connect child nodes.

Why each choice is right or wrong

A - Incorrect: The module uses mkleaf, not mknode, for a numeric constant, and a is not a number (p. 13).

B - Incorrect: This creates a numeric leaf, suitable for 4 rather than identifier a (p. 13).

C - Correct: This is exactly the identifier-leaf constructor used for a (p. 13).

D - Incorrect: This makes an operator node with two children, not an identifier leaf (pp. 12-13).

Primary note proof

Study-note section COMP25

A syntax-directed translation scheme embeds executable actions in productions; the actions run while translating a source program, not while generating the compiler. Attributes may compute types, values, AST pointers or generated code. The scheme defines an input-to-output translation, not merely an input language.

Study-note section COMP25

Create an identifier leaf with mkleaf(id,entry), a number with mkleaf(num,value), and an operator node with mknode(op,left,right). For a−4+c, construct +(−(a,4),c). Postorder traversal prints postfix: a 4 − c +. A stack evaluator pushes operands and pops right then left operands for an operator. Infix-to-postfix is useful for stack machines but not mandatory for all compilers.

Computer Science Exit Exam · 2018 · Question 53

Question 29 | Q00945

Which statement is WRONGLY described about code generation?

A. Code generation can be considered as the start phase of compilation

B. The target program is the output of the code generator

C. Checked intermediate code is supplied as input to the code generator.

D. It used to produce the target code for three-address statements.

Hint

Identify each activity's input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer A: Code generation can be considered as the start phase of compilation

Lexical analysis begins the standard pipeline by recognizing tokens. Code generation occurs after analysis and IR construction, lowering checked IR to a target form. Its output is target code, which may be assembly or an object form, and it can translate three-address statements. Therefore calling code generation the start phase is the wrong description. The input option is read as checked IR suitable for lowering, without claiming a compiler can prove the absence of every program defect.

Why each choice is right or wrong

A - Correct: Code generation follows the frontend and IR; it is not the initial scanning phase.

B - Incorrect: The generator produces code in a target representation.

C - Incorrect: Checked intermediate code supplies the operations and metadata to lower.

D - Incorrect: Three-address statements can be lowered into target instructions.

Primary note proof

Study-note section COMP03

> The conventional sequence is lexical analysis → syntax analysis → semantic analysis → intermediate-code generation → optimization → target-code generation. Scanning turns characters into tokens; parsing builds structure; semantics checks declarations and types; synthesis produces implementation code. A phase is a logical activity; a pass is a traversal that can combine activities.

Study-note section COMP34

> Code generation lowers checked IR to a target form.

Question sources

Computer Science Exit Exam · 2018 · Question 58

Question 30 | Q00973

Which of the following is NOT a task of the lexical analyzer?

A. Generating parse trees

B. Correlating errors with line numbers

C. Entering identifiers into the symbol table

D. Stripping whitespace and comments

Hint

Identify each activity's input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer A: Generating parse trees

Scanning turns characters into tokens, usually skips insignificant whitespace and comments, and retains source positions for diagnostics. A scanner may also intern identifier spellings in a symbol table; later semantic processing adds scope and declaration information. Parse-tree construction belongs to syntax analysis because it arranges the token stream according to grammar productions. It is consequently the activity outside the scanner's listed responsibilities.

Why each choice is right or wrong

A - Correct: Parse trees represent grammar structure built by parsing.

B - Incorrect: Tracking token positions and line numbers supports scanner diagnostics.

C - Incorrect: Scanner-side interning can enter identifier spellings, distinct from later declaration analysis.

D - Incorrect: Ordinary scanners discard insignificant whitespace and comments.

Primary note proof

Study-note section COMP04

Keywords, identifiers, literals, operators and punctuation are token classes. Whitespace and comments are usually skipped while line/column positions are retained. In indentation-sensitive or newline-sensitive languages, layout can carry tokens. Parse-tree construction is a parser task; scanning can intern identifier spellings, but declaration scope and types need later analysis.

Study-note section COMP09

A parse tree shows grammar productions: root S, internal nonterminals, and terminal leaves, with ε sometimes shown for empty productions. Its left-to-right yield is the input.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Science Exit Exam · 2018 · Question 86

Question 31 | Q01165

Which analysis used to read the sequence of the characters from the source program?

A. a | Lexical Analysis A

B. i? Syntax Analysis ><

C. /@| Semantic Analysis x

D. | All of the above x

Hint

Identify each activity's input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer A: a | Lexical Analysis A

PDF p. 5 explicitly says lexical analysis scans source code as a stream of characters; syntax groups tokens, and semantics checks meaningful compatibility (p. 6).

Why each choice is right or wrong

A - Correct: Lexical analysis explicitly reads the character stream.

B - Incorrect: Syntax analysis works on tokens grouped hierarchically.

C - Incorrect: Semantic analysis performs meaning/type checks (p. 6).

D - Incorrect: The raw-character scanning responsibility is assigned specifically to lexical analysis, not all three phases (pp. 5-6).

Primary note proof

Study-note section COMP04

> A token is a category with optional attribute, such as (ID, symbol-entry) or (INT_LITERAL,42). A lexeme is the actual character sequence, such as total or 42. A pattern specifies which lexemes belong to a token class. The scanner emits an ordered token stream, not an unordered mathematical set.

Study-note section COMP04

> Keywords, identifiers, literals, operators and punctuation are token classes. Whitespace and comments are usually skipped while line/column positions are retained. In indentation-sensitive or newline-sensitive languages, layout can carry tokens. Parse-tree construction is a parser task; scanning can intern identifier spellings, but declaration scope and types need later analysis.

Question 32 | Q01193

What is the bottom-up parsing method also known as?

A. Recursive descent parsing

B. Predictive parsing

C. Shift-reduce parsing

D. All of them

Hint

Use construction direction, lookahead and grammar restrictions. Distinguish algorithm families, implementations and coverage before comparing them.

Answer C: Shift-reduce parsing

Bottom-up parsing starts with input symbols and reduces recognized right-hand sides until it reaches the start symbol. A shift-reduce parser implements this by shifting input onto a stack and reducing handles. Recursive descent expands from a start-symbol procedure and is top-down; predictive parsing is a top-down approach that uses lookahead to choose productions. Therefore the aggregate alternative cannot apply to methods with these different construction directions.

Why each choice is right or wrong

A - Incorrect: Recursive descent expands productions from nonterminals and is top-down.

B - Incorrect: Predictive parsing chooses top-down productions using lookahead.

C - Correct: Shifting input and reducing handles is the bottom-up shift-reduce method.

D - Incorrect: The list includes top-down methods, so not all are bottom-up.

Primary note proof

Study-note section COMP11

> Top-down parsing starts with S and expands productions toward the input, usually constructing a leftmost derivation. Recursive descent typically has one procedure per nonterminal. A general recursive-descent implementation can backtrack; a predictive parser chooses a production using lookahead without backtracking. LL(1) scans Left to right, produces a Leftmost derivation and uses one lookahead token.

Study-note section COMP15

> Bottom-up parsing starts from input and reduces toward S, constructing a rightmost derivation in reverse.

Question sources

Computer Science model exam 2 · Question 14

Question 33 | Q01222

How many tokens are in the C++ loop header for (int i = 0; i <= 10; i++)? Ignore whitespace and count <= and ++ as single operator tokens.

A. 4

B. 5

C. 9

D. 14

Hint

Follow the representation at each construction step and apply the pattern or state-set rules consistently, including empty cases.

Answer D: 14

The tokens are for, (, int, i, =, 0, ;, i, <=, 10, ;, i, ++,). There are fourteen occurrences. Whitespace contributes nothing, but both semicolons and both parentheses count. Longest match makes <= and ++ one token each; it does not merge neighboring identifiers or discard repeated tokens. The numerical option therefore gives the unique count.

Why each choice is right or wrong

A - Incorrect: Four omits most token occurrences.

B - Incorrect: Five misses operators, punctuation and operands.

C - Incorrect: Nine is below the fourteen-token count.

D - Correct: The complete sequence contains fourteen tokens.

Primary note proof

Study-note section COMP07

> At each input position, choose the longest matching lexeme; if equal lengths match multiple flex rules, choose the earliest rule. Thus ifx is an identifier rather than if followed by x; <= and ++ are each one operator token.

Study-note section COMP07

> There are 14 tokens, irrespective of spacing. The increment operator is one token.

Computer Science model exam 2 · Question 43

Question 34 | Q01243

Identify the correct definition of lexical analysis.

A. Breaking a sequence of characters into packets.

B. Breaking a sequence of characters into groups.

C. Breaking a sequence of characters into tokens.

D. Breaking a sequence of characters into lines.

Hint

Identify each activity's input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer C: Breaking a sequence of characters into tokens.

Lexical analysis takes a source program and outputs a sequence of tokens (PDF p. 8). Thus its relevant grouping units are tokens, rather than network packets, arbitrary groups, or source lines.

Why each choice is right or wrong

A - Incorrect: Packets are not the compiler units described on p. 8.

B - Incorrect: Groups is too unspecific; the defined output units are tokens (p. 8).

C - Correct: Breaking the character sequence into tokens matches scanning (pp. 5, 8).

D - Incorrect: Lines are tracked and whitespace stripped; they are not the primary output units (p. 8).

Primary note proof

Study-note section COMP04

A token is a category with optional attribute, such as (ID, symbol-entry) or (INT_LITERAL,42). A lexeme is the actual character sequence, such as total or 42. A pattern specifies which lexemes belong to a token class. The scanner emits an ordered token stream, not an unordered mathematical set.

Study-note section COMP04

Keywords, identifiers, literals, operators and punctuation are token classes. Whitespace and comments are usually skipped while line/column positions are retained. In indentation-sensitive or newline-sensitive languages, layout can carry tokens. Parse-tree construction is a parser task; scanning can intern identifier spellings, but declaration scope and types need later analysis.

Computer Science model exam 2 · Question 64

Question 35 | Q01254

What does a top-down parser generate?

A. Rightmost derivation in reverse.

B. Rightmost derivation.

C. Leftmost derivation in reverse.

D. Leftmost derivation.

Hint

Use construction direction, lookahead and grammar restrictions. Distinguish algorithm families, implementations and coverage before comparing them.

Answer D: Leftmost derivation.

The module says top-down parsing builds from the start symbol (PDF p. 10), and the LL/LR comparison pairs top-down LL with leftmost derivation and bottom-up LR with rightmost derivation in reverse (p. 11). D matches the top-down direction.

Why each choice is right or wrong

A - Incorrect: Rightmost derivation in reverse is the LR/bottom-up entry (p. 11).

B - Incorrect: Rightmost derivation alone is not the listed top-down entry (p. 11).

C - Incorrect: The top-down derivation is leftmost in the forward direction, not reversed (p. 11).

D - Correct: Leftmost derivation is explicitly the LL/top-down entry (p. 11).

Primary note proof

Study-note section COMP11

> Top-down parsing starts with S and expands productions toward the input, usually constructing a leftmost derivation. Recursive descent typically has one procedure per nonterminal. A general recursive-descent implementation can backtrack; a predictive parser chooses a production using lookahead without backtracking. LL(1) scans Left to right, produces a Leftmost derivation and uses one lookahead token.

Study-note section COMP11

> A nonrecursive predictive parser stores grammar symbols on an explicit stack and consults a table. It is another implementation of predictive parsing, not a wholly different language class. Table-driven and recursive predictive implementations can both be linear for a fixed suitable grammar. Efficiency cannot be ranked from their names alone.

Question sources

Computer Science model exam 2 · Question 75

Question 36 | Q01257

For line 3, fro ((I = o, I;, in the displayed C program, classify only lexical and syntactic well-formedness. Treat fro and o as legal identifier spellings and leave declaration/type diagnostics outside this question.

A. Syntax error, with no lexical error established.

B. No compilation error.

C. Only lexical error.

D. Both lexical and syntax error.

Hint

Identify each activity’s input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer A: Syntax error, with no lexical error established.

The characters fro and o form valid identifier lexemes, so their spellings do not establish a lexical error. The displayed line nevertheless has mismatched parentheses and an invalid token arrangement, establishing a syntax error. Under this restricted lexical/syntactic classification, A is correct. Declaration or type diagnostics may arise in a real compiler, but are outside the expressly stated classification scope.

Why each choice is right or wrong

A - Correct: The arrangement is syntactically invalid without an established lexical fault.

B - Incorrect: Mismatched delimiters prevent syntactic validity.

C - Incorrect: Legal identifier spellings do not establish a lexical error.

D - Incorrect: A syntax error exists but no lexical error is established.

Primary note proof

Study-note section COMP08

> A lexical error prevents forming a legal token, such as an invalid character or unterminated literal. A syntax error is an illegal token arrangement, such as a missing delimiter. A semantic error violates name, scope or type rules after grammatical recognition.

Study-note section COMP08

> In the malformed C line fro ((I = o, I;, fro and lowercase o are legal identifier lexemes. Misspelling for does not turn fro into a lexical error; mismatched syntax is definite, and undeclared o can also produce a semantic diagnostic.

Computer Science model exam 2 · Question 78

Question 37 | Q01397

Which tool is used for grouping of characters in tokens in the compiler?

A. Parser

B. Code optimizer

C. Code generator

D. Scanner

Hint

Identify each activity's input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer D: Scanner

Lexical analysis is called scanning on PDF p. 5 and outputs tokens on p. 8. Hence the scanner is the component that groups source characters into tokens, before the parser handles token structure.

Why each choice is right or wrong

A - Incorrect: The parser groups tokens into syntactic constructs.

B - Incorrect: The optimizer improves intermediate code (p. 7).

C - Incorrect: The generator converts intermediate code to machine code (p. 7).

D - Correct: Scanner is the component associated with lexical analysis (pp. 5, 8).

Primary note proof

Study-note section COMP04

A token is a category with optional attribute, such as (ID, symbol-entry) or (INT_LITERAL,42). A lexeme is the actual character sequence, such as total or 42. A pattern specifies which lexemes belong to a token class. The scanner emits an ordered token stream, not an unordered mathematical set.

Compiler Design review questions · Question 5

Question 38 | Q01399

When parsing techniques are classified by the direction in which they construct the parse tree, how many broad categories are there?

A. three types

B. four types

C. two types

D. five types

Hint

Use construction direction, lookahead and grammar restrictions. Distinguish algorithm families, implementations and coverage before comparing them.

Answer C: two types

Construction direction gives two broad categories. Top-down parsing expands from the start symbol toward the input, while bottom-up parsing reduces input toward the start symbol. Recursive descent, predictive parsing and LR are algorithms or families within that classification rather than additional directions. Counting named algorithms would give a different and open-ended taxonomy, so the revised question explicitly counts only the broad construction directions.

Why each choice is right or wrong

A - Incorrect: Three is not the number of construction directions in this two-way taxonomy.

B - Incorrect: Four may count selected algorithms, but it does not count the two broad directions.

C - Correct: The directions are top-down and bottom-up.

D - Incorrect: Five is not the number of construction directions.

Primary note proof

Study-note section COMP-S01

> The common two-way classification of parsing is by construction direction: top-down parsing expands from the start symbol, while bottom-up parsing reduces the input toward that symbol. This counts broad directions, not the number of parser algorithms or implementations.

> ● Top down parsing (predictive parsers)
> • LL(1)
> ● Bottom up parsing (SR parsers)
> • LR(1)

Question sources

Compiler Design review questions · Question 7

Question 39 | Q01400

In which parsing, the parser constructs the parse tree from the start symbol and transforms it into the input symbol.

A. Bottom-up parsing

B. Top-down parsing

C. None of the above

D. Both a and b

Hint

Use construction direction, lookahead and grammar restrictions. Distinguish algorithm families, implementations and coverage before comparing them.

Answer B: Top-down parsing

Top-down parsing starts from the start symbol and transforms it into the input (PDF p. 10). Bottom-up parsing starts with input symbols and constructs toward the start symbol. The stem is an almost verbatim description of the first direction.

Why each choice is right or wrong

A - Incorrect: Bottom-up starts from input symbols, the opposite endpoint (p. 10).

B - Correct: Top-down starts from the start symbol as requested (p. 10).

C - Incorrect: The described category is explicitly present, so none is false (p. 10).

D - Incorrect: Both is false because the two categories have opposite starting points (p. 10).

Primary note proof

Study-note section COMP11

> Top-down parsing starts with S and expands productions toward the input, usually constructing a leftmost derivation. Recursive descent typically has one procedure per nonterminal. A general recursive-descent implementation can backtrack; a predictive parser chooses a production using lookahead without backtracking. LL(1) scans Left to right, produces a Leftmost derivation and uses one lookahead token.

Study-note section COMP11

> A nonrecursive predictive parser stores grammar symbols on an explicit stack and consults a table. It is another implementation of predictive parsing, not a wholly different language class. Table-driven and recursive predictive implementations can both be linear for a fixed suitable grammar. Efficiency cannot be ranked from their names alone.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Compiler Design module | PDF page 10 | lines 18-23

Top Down Parsing
• The parse tree is created top to bottom
• Starts from the start symbol and transform it to the input
Bottom Up Parsing
• Starts with the input symbols and tries to construct the parse tree up to the start symbol.
• One way of reducing a sentence is to follow the right most derivation in reverse

Question sources

Compiler Design review questions · Question 8

Question 40 | Q01401

Which derivation is generated by the top-down parser?

A. Right-most derivation in reverse

B. Left-most derivation in reverse

C. Right-most derivation

D. Left-most derivation

Hint

Use construction direction, lookahead and grammar restrictions. Distinguish algorithm families, implementations and coverage before comparing them.

Answer D: Left-most derivation

The LL/top-down column uses leftmost derivation, while the LR/bottom-up column uses rightmost derivation in reverse (PDF p. 11). Consequently a top-down parser generates a forward leftmost derivation.

Why each choice is right or wrong

A - Incorrect: This is the bottom-up LR direction (p. 11).

B - Incorrect: The LL entry is leftmost without reversal (p. 11).

C - Incorrect: Rightmost is not the listed top-down derivation (p. 11).

D - Correct: Leftmost is explicitly the top-down/LL entry (p. 11).

Primary note proof

Study-note section COMP11

Top-down parsing starts with S and expands productions toward the input, usually constructing a leftmost derivation. Recursive descent typically has one procedure per nonterminal. A general recursive-descent implementation can backtrack; a predictive parser chooses a production using lookahead without backtracking. LL(1) scans Left to right, produces a Leftmost derivation and uses one lookahead token.

Study-note section COMP11

A nonrecursive predictive parser stores grammar symbols on an explicit stack and consults a table. It is another implementation of predictive parsing, not a wholly different language class. Table-driven and recursive predictive implementations can both be linear for a fixed suitable grammar. Efficiency cannot be ranked from their names alone.

• LR (0) , SLR (1) , LALR (1) , CLR (1)
LL LR
Leftmost derivation Rightmost derivation in reverse
Starts with root non-terminal on stack Ends with root non-terminal on the stack
Builds the parse tree top-down Builds the parse tree bottom-up
Expands the non-terminals Reduces the non-terminals

Compiler Design module | PDF page 10 | lines 18-23

Top Down Parsing
• The parse tree is created top to bottom
• Starts from the start symbol and transform it to the input
Bottom Up Parsing
• Starts with the input symbols and tries to construct the parse tree up to the start symbol.
• One way of reducing a sentence is to follow the right most derivation in reverse

Question sources

Compiler Design review questions · Question 9

Question 41 | Q01402

Which derivation is generated by the bottom-up parser?

A. Right-most derivation in reverse

B. Left-most derivation in reverse

C. Right-most derivation

D. Left-most derivation

Hint

Use construction direction, lookahead and grammar restrictions. Distinguish algorithm families, implementations and coverage before comparing them.

Answer A: Right-most derivation in reverse

PDF p. 10 describes bottom-up parsing as reducing input symbols toward the start symbol, following a rightmost derivation in reverse. PDF p. 11 repeats this as the definition of LR parsing. Thus A gives both the correct derivation kind and direction.

Why each choice is right or wrong

A - Correct: Rightmost derivation in reverse is explicitly stated (pp. 10-11).

B - Incorrect: Leftmost in reverse is not the module's bottom-up rule (p. 11).

C - Incorrect: Rightmost without reversal would expand rather than describe the stated reductions (pp. 10-11).

D - Incorrect: Leftmost is paired with LL/top-down parsing (p. 11).

Primary note proof

Study-note section COMP15

> Bottom-up parsing starts from input and reduces toward S, constructing a rightmost derivation in reverse. A handle is a production RHS occurrence whose reduction is the next step of that reverse derivation. Not every substring matching a RHS is a handle in the current context.

Study-note section COMP15

> Shift pushes the next input token and a state; reduce replaces a recognized RHS by its LHS and consults GOTO; accept recognizes completion; error reports an invalid situation. For A→XYZ, pop three grammar symbols and their states, expose state q, then push A and GOTO[q,A]. "Go" is not a separate standard shift-reduce ACTION, although GOTO is essential table machinery.

Compiler Design review questions · Question 10

Question 42 | Q01403

Among these named deterministic parser methods, which has the broadest grammar coverage under the standard SLR(1), LALR(1) and canonical LR(1) comparison?

A. Operator Precedence

B. SLR

C. Canonical LR

D. LALR

Hint

Use construction direction, lookahead and grammar restrictions. Distinguish algorithm families, implementations and coverage before comparing them.

Answer C: Canonical LR

Canonical LR(1) keeps context-specific lookahead and covers at least the grammars handled by SLR(1) and LALR(1), with strictly greater coverage in the standard comparison.
Operator-precedence parsing is a more restricted expression-parsing method. This is a comparison of grammar coverage, not speed, implementation simplicity or table size. Canonical LR may require larger tables and still does not parse every unambiguous context-free grammar.

Why each choice is right or wrong

A - Incorrect: Operator-precedence parsing applies to a more restricted grammar family.

B - Incorrect: SLR(1) uses less context-specific reduction information and has narrower grammar coverage.

C - Correct: Canonical LR(1) has the broadest coverage among the named methods.

D - Incorrect: Merging LR(1) cores for LALR(1) can lose distinctions needed by some LR(1) grammars.

Primary note proof

Study-note section COMP-S01

> In the standard comparison by grammar coverage, canonical LR(1) is more general than the restricted operator-precedence method. Together with SLR(1)⊆LALR(1)⊆LR(1), this makes canonical LR(1) the broadest of those named deterministic parsing methods. Broader coverage does not mean faster execution or smaller tables.

Study-note section COMP17

> The standard grammar-class hierarchy is LR(0)⊆SLR(1)⊆LALR(1)⊆LR(1), with increasing capability and often table size.

Compiler Design review questions · Question 11

Question 43 | Q01404

The output of the lexical analyzer is _____

A. string character

B. a syntax tree

C. a set of RE

D. a set of tokens

Hint

Identify each activity's input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer D: a set of tokens

The lexical analyzer's output is a sequence of tokens (PDF p. 8). Among the options only D identifies these elements; "set" is informal wording for the ordered stream.

Why each choice is right or wrong

A - Incorrect: Source characters are scanned as input.

B - Incorrect: The syntax tree belongs to parsing.

C - Incorrect: Regular expressions are not the listed scanner output; patterns are rules (p. 8).

D - Correct: Tokens are explicitly the scanner output (p. 8).

Primary note proof

Study-note section COMP04

> A token is a category with optional attribute, such as (ID, symbol-entry) or (INT_LITERAL,42). A lexeme is the actual character sequence, such as total or 42. A pattern specifies which lexemes belong to a token class. The scanner emits an ordered token stream, not an unordered mathematical set.

Study-note section COMP04

> Keywords, identifiers, literals, operators and punctuation are token classes. Whitespace and comments are usually skipped while line/column positions are retained. In indentation-sensitive or newline-sensitive languages, layout can carry tokens. Parse-tree construction is a parser task; scanning can intern identifier spellings, but declaration scope and types need later analysis.

• Lexeme

- The sequence of characters matched by a pattern to form the token

Question sources

Compiler Design review questions · Question 12

Question 44 | Q01405

Which is the least sufficient Chomsky grammar family for ordinary token patterns specified by classical regular expressions, rather than a purpose-based grammar name?

A. Lexical Grammar

B. Context-free Grammar

C. Syntactic Grammar

D. Regular Grammar

Hint

Use construction direction, lookahead and grammar restrictions. Distinguish algorithm families, implementations and coverage before comparing them.

Answer D: Regular Grammar

Ordinary regular-expression token patterns describe regular languages, whose least sufficient Chomsky family is regular grammar. A lexical grammar names a specification by purpose, whereas this question asks for its formal family. Context-free grammars are more expressive than required and typically model nested syntax. Syntactic grammar is another purpose label rather than the specific formal family matching the regular token patterns.

Why each choice is right or wrong

A - Incorrect: Lexical grammar is a purpose label, not the requested family.

B - Incorrect: CFGs are stronger than these regular patterns require.

C - Incorrect: Syntactic grammar is a purpose label.

D - Correct: Regular grammars generate exactly regular token languages.

Primary note proof

Study-note section COMP-S03

Classical regular expressions, consistently right-linear regular grammars and finite automata describe the same regular-language family. Thus an ordinary token pattern specified by a regular expression also has a regular grammar and an equivalent finite-state recognizer.

Study-note section COMP-S03

This equivalence concerns expressive power, not spelling of the specification or implementation size. Context-free grammars can also describe regular languages, but their larger family is needed for syntax with unbounded nested structure rather than ordinary regular token patterns.

Study-note section COMP18

Regular patterns are chiefly lexical specifications; CFGs chiefly describe nested syntax.

MOE Computer Science Exit Exam · 2016 · Question 93

Question 45 | Q01407

In Compiler lexical analyzer is used for?

A. removing comments

B. removing whitespace

C. breaking the syntaxes in the set of tokens

D. All of the mentioned

Hint

Identify each activity's input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer D: All of the mentioned

Lexical analysis scans source characters into tokens and removes blanks/newlines/comments (PDF pp. 5, 8). Thus comment removal, whitespace removal, and tokenization all belong to the scanner in this module, making D the inclusive choice.

Why each choice is right or wrong

A - Incorrect: Comment removal is expressly stated (p. 8).

B - Incorrect: Whitespace stripping is expressly stated (p. 8).

C - Incorrect: Interpreting "syntaxes" as source text, tokenization is the lexical role.

D - Correct: All combines the three documented responsibilities (pp. 5, 8).

Primary note proof

Study-note section COMP04

> A token is a category with optional attribute, such as (ID, symbol-entry) or (INT_LITERAL,42). A lexeme is the actual character sequence, such as total or 42. A pattern specifies which lexemes belong to a token class. The scanner emits an ordered token stream, not an unordered mathematical set.

Study-note section COMP04

> Keywords, identifiers, literals, operators and punctuation are token classes. Whitespace and comments are usually skipped while line/column positions are retained. Compiler Design review questions · Question 15

Question 46 | Q01408

Which is considered as the sequence of characters in a token?

A. Mexeme

B. Lexeme

C. Texeme

D. Pattern

Hint

Identify each activity’s input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer B: Lexeme

PDF p. 8 calls the matched character sequence a Lexeme. A pattern is the rule that matches that sequence, rather than the concrete spelling itself.

Why each choice is right or wrong

A - Incorrect: Mexeme is not a defined tokenization term (p. 8).

B - Correct: Lexeme is the exact defined term (p. 8).

C - Incorrect: Texeme is not a defined tokenization term (p. 8).

D - Incorrect: Pattern is a rule describing a token, not the matched sequence (p. 8).

Primary note proof

Study-note section COMP04

A token is a category with optional attribute, such as (ID, symbol-entry) or (INT_LITERAL,42). A lexeme is the actual character sequence, such as total or 42. A pattern specifies which lexemes belong to a token class. The scanner emits an ordered token stream, not an unordered mathematical set.

Study-note section COMP04

Keywords, identifiers, literals, operators and punctuation are token classes. Whitespace and comments are usually skipped while line/column positions are retained. In indentation-sensitive or newline-sensitive languages, layout can carry tokens. Parse-tree construction is a parser task; scanning can intern identifier spellings, but declaration scope and types need later analysis.

Question 47 | Q01409

Which part of the compiler highly used the grammar concept?

A. Code optimization

B. Code generation

C. Parser

D. Lexical Analysis

Hint

Identify each activity’s input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer C: Parser

PDF p. 9 explicitly states that parsers/syntax analyzers are generated for a particular grammar and CFGs specify programming-language syntax. This directly connects the parser to the grammar concept asked about.

Why each choice is right or wrong

A - Incorrect: Optimization is defined through removal of inefficiencies, not grammar-based recognition (p. 7).

B - Incorrect: Generation converts intermediate code to machine code (p. 7).

C - Correct: Parser generation and syntax specification are explicitly grammar-based (p. 9).

D - Incorrect: Lexical patterns classify tokens (p. 8); the cited grammar emphasis is the parser (p. 9).

Primary note proof

Study-note section COMP04

> Keywords, identifiers, literals, operators and punctuation are token classes. Whitespace and comments are usually skipped while line/column positions are retained. In indentation-sensitive or newline-sensitive languages, layout can carry tokens. Parse-tree construction is a parser task; scanning can intern identifier spellings, but declaration scope and types need later analysis.

Study-note section COMP09

> A parse tree shows grammar productions: root S, internal nonterminals, and terminal leaves, with ε sometimes shown for empty productions. Its left-to-right yield is the input.

Compiler Design review questions · Question 17

Question 48 | Q01410

Which phase of the compiler checks the grammar of the programming?

A. Code Optimization

B. Semantic Analysis

C. Code Generation

D. Syntax Analysis

Hint

Identify each activity's input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer D: Syntax Analysis

Syntax analysis groups tokens into nested constructs, catches syntactic errors, and uses source-language grammar rules (PDF p. 5). Therefore it checks grammatical program structure; semantic checks, optimization and target-code generation perform different work.

Why each choice is right or wrong

A - Incorrect: Optimization removes intermediate-code inefficiencies (p. 7).

B - Incorrect: Semantic analysis checks meaningful compatibility and types (p. 6).

C - Incorrect: Code generation emits machine code from intermediate code (p. 7).

D - Correct: Syntax analysis is explicitly governed by grammar rules.

Primary note proof

Study-note section COMP04

> Keywords, identifiers, literals, operators and punctuation are token classes. Whitespace and comments are usually skipped while line/column positions are retained. In indentation-sensitive or newline-sensitive languages, layout can carry tokens. Parse-tree construction is a parser task; scanning can intern identifier spellings, but declaration scope and types need later analysis.

Compiler Design review questions · Question 18

Question 49 | Q01411

Which listed data structure supplies declaration names, scopes and types to semantic analysis?

A. Yacc

B. Lex

C. Symbol Table

D. Type Checking

Hint

Check operand compatibility and permitted conversions under the stated language rules; distinguish grammatical structure from semantic meaning.

Answer C: Symbol Table

A symbol table supplies the identities and attributes needed to resolve names and check types during semantic analysis. Type checking is an important activity using that information, but is not itself the requested data structure. Yacc and Lex generate parsers and scanners respectively. This narrower role makes the symbol table unique without denying that several components contribute to semantic processing.

Why each choice is right or wrong

A - Incorrect: Yacc is a parser generator.

B - Incorrect: Lex is a scanner generator.

C - Correct: The symbol table stores declaration and type metadata.

D - Incorrect: Type checking is an activity, not the information structure.

Primary note proof

Study-note section COMP19

> A symbol table maps names or symbol identities to attributes: type, scope, width, storage offset, parameter signature, constant information or linkage.

Study-note section COMP39

> Lex/flex generates scanners from patterns and actions. Yacc means Yet Another Compiler Compiler; Yacc/Bison generates parsers from grammar rules and semantic actions.

Study-note section COMP22

> A type checker verifies that operations are defined for their operands.

Question 50 | Q01412

Which phase of the compiler is also known as Scanner?

A. Syntax Analysis

B. Lexical Analysis

C. Semantic Analysis

D. Code generation

Hint

Identify each activity's input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer B: Lexical Analysis

The module labels lexical/linear analysis "scanning" (PDF p. 5). Its scanner reads characters into tokens (p. 8), so B names the phase associated with Scanner.

Why each choice is right or wrong

A - Incorrect: Syntax analysis is called parsing.

B - Correct: Lexical analysis is explicitly scanning.

C - Incorrect: Semantic analysis checks types/meaning (p. 6).

D - Incorrect: Code generation converts intermediate code to machine code (p. 7).

Primary note proof

Study-note section COMP04

A token is a category with optional attribute, such as (ID, symbol-entry) or (INT_LITERAL,42). A lexeme is the actual character sequence, such as total or 42. A pattern specifies which lexemes belong to a token class. The scanner emits an ordered token stream, not an unordered mathematical set.

Study-note section COMP04

Keywords, identifiers, literals, operators and punctuation are token classes. Whitespace and comments are usually skipped while line/column positions are retained. In indentation-sensitive or newline-sensitive languages, layout can carry tokens. Parse-tree construction is a parser task; scanning can intern identifier spellings, but declaration scope and types need later analysis.

1. Lexical / Linear Analysis (scanning)
- Scans the source code as a stream of characters
- Represent lexemes in the form of tokens as:
<token-name, attribute-value>
- Token
• smallest meaningful element that a compiler understands.
- Eg.
• Identifiers, Keywords, Literals, Operators and Special symbols.
- Blanks, new lines, comments will be removed from the source program.

Compiler Design module | PDF page 8 | lines 4-9

What is Lexical Analysis
• The first phase of a compiler
• The input is a high level language program
• The output is a sequence of tokens
• Strips off blanks, tabs, newlines, and comments from the source program
• Keeps track of line numbers

Question sources

Compiler Design review questions · Question 20

Question 51 | Q01413

Which phase of the compiler is also known as Parser?

A. Code Optimization

B. Semantic Analysis

C. Syntax Analysis

D. Lexical Analysis

Hint

Identify each activity's input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer C: Syntax Analysis

Syntax/hierarchical analysis is explicitly labeled Parsing (PDF p. 5); p. 9 equates parsers with syntax analyzers. Thus the phase known as Parser is syntax analysis.

Why each choice is right or wrong

A - Incorrect: Optimization improves intermediate code (p. 7).

B - Incorrect: Semantic analysis checks meaningful compatibility (p. 6).

C - Correct: Syntax analysis is expressly Parsing (pp. 5, 9).

D - Incorrect: Lexical analysis is scanning, preceding parsing.

Primary note proof

Study-note section COMP04

> Keywords, identifiers, literals, operators and punctuation are token classes. Whitespace and comments are usually skipped while line/column positions are retained. In indentation-sensitive or newline-sensitive languages, layout can carry tokens. Parse-tree construction is a parser task; scanning can intern identifier spellings, but declaration scope and types need later analysis.

Study-note section COMP09

> A parse tree shows grammar productions: root S, internal nonterminals, and terminal leaves, with ε sometimes shown for empty productions. Its left-to-right yield is the input.

Compiler Design review questions · Question 21

Question 52 | Q01414

Which of the following parser is a top-down parser?

A. An LALR parser

B. A LR parser

C. Operator precedence parser

D. Recursive descent parser

Hint

Use construction direction, lookahead and grammar restrictions. Distinguish algorithm families, implementations and coverage before comparing them.

Answer D: Recursive descent.

COMP11 introduces recursive descent as a top-down implementation, normally with one procedure per nonterminal. It expands the start symbol toward the input. LR and LALR instead use bottom-up reductions, and operator-precedence parsing is also bottom-up. Therefore only recursive descent names the top-down family among these options.

Why each choice is right or wrong

A - Incorrect: LALR is an LR bottom-up family, using merged LR item states.

B - Incorrect: LR recognizes input through bottom-up shifts and reductions.

C - Incorrect: Operator-precedence parsing reduces expressions bottom-up rather than expanding productions top-down.

D - Correct: Recursive descent implements top-down parsing through procedures corresponding to nonterminals.

Primary note proof

Study-note section COMP11

Top-down parsing starts with S and expands productions toward the input, usually constructing a leftmost derivation. Recursive descent typically has one procedure per nonterminal. A general recursive-descent implementation can backtrack; a predictive parser chooses a production using

lookahead without backtracking. LL(1) scans Left to right, produces a Leftmost derivation and uses one lookahead token.

Study-note section COMP15

Bottom-up parsing starts from input and reduces toward S, constructing a rightmost derivation in reverse.

Study-note section COMP-S01

Operator-precedence parsing is a restricted bottom-up expression-parsing method using a stack and precedence relations. With a suitable expression grammar, the stack retains unfinished surrounding expressions while nested parentheses are processed.

Question 53 | Q01415

Keywords are recognized in a compiler during -

A. the code generation

B. the data flow analysis

C. the lexical analysis of the program

D. the program parsing

Hint

Identify each activity's input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer C: the lexical analysis of the program

Keywords are listed among the token categories identified during lexical analysis (PDF pp. 5, 8). Recognizing a reserved spelling therefore occurs in the lexical classification of the program rather than later target generation or parsing.

Why each choice is right or wrong

A - Incorrect: Generation acts on intermediate code, not raw keyword spellings (p. 7).

B - Incorrect: Data-flow analysis is not identified as keyword recognition.

C - Correct: Keywords are explicitly lexical token classes (pp. 5, 8).

D - Incorrect: Parsing groups the already-produced tokens.

Primary note proof

Study-note section COMP04

> A token is a category with optional attribute, such as (ID, symbol-entry) or (INT_LITERAL,42). A lexeme is the actual character sequence, such as total or 42. A pattern specifies which lexemes belong to a token class. The scanner emits an ordered token stream, not an unordered mathematical set.

Study-note section COMP04

> Keywords, identifiers, literals, operators and punctuation are token classes. Whitespace and comments are usually skipped while line/column positions are retained. In indentation-sensitive or newline-sensitive languages, layout can carry tokens. Parse-tree construction is a parser task; scanning can intern identifier spellings, but declaration scope and types need later analysis.

Compiler Design review questions · Question 23

Question 54 | Q01417

Which names denote the graph whose vertices are basic blocks and edges are possible next-block control transfers? Select all that apply. In A, control graph abbreviates control-flow graph.

A. Control graph

B. DAG

C. Flow graph

D. Hamilton graph

Hint

Identify what the representation stores, what it omits and which later transformations it must support; separate a representation property from an algorithmic task.

Answer A, C: Control graph; Flow graph

A control-flow graph represents basic blocks as vertices and possible execution transfers, including fall-through, as edges. With the stated abbreviation, both control graph and flow graph name that representation. An expression DAG instead represents shared computations and value dependencies. A Hamiltonian-path label concerns a graph property rather than the compiler representation of block successors. Thus A and C are both valid names.

Why each choice is right or wrong

A - Correct: The declared abbreviation denotes the specified graph.

B - Incorrect: An expression DAG records value dependencies, not block successors.

C - Correct: Flow graph conventionally names this representation.

D - Incorrect: Hamiltonian paths do not define the block-successor representation.

Primary note proof

Study-note section COMP28

> A basic block is a maximal straight-line instruction sequence entered at its beginning and exited at its end. Leaders are the first instruction, every jump target, and each instruction after a branch. Start a block at each leader and continue until the next leader.

Study-note section COMP28

> A control-flow graph has blocks as vertices and possible next-block transfers as edges, including fall-through. A node D dominates N when every entry-to-N path passes through D. For an edge N→H where H dominates N, H is a loop header of a natural loop. This structure supports loop analysis. An expression DAG records value dependencies, not arbitrary control flow.

Compiler Design review questions · Question 25

Question 55 | Q01420

In the compiler, the function of using intermediate code is:

A. to improve the register allocation

B. to increase the error reporting & recovery.

C. to make semantic analysis easier.

D. to increase the chances of re-using the machine-independent code optimizer in other compilers.

Hint

Identify what the representation stores, what it omits and which later transformations it must support; separate a representation property from an algorithmic task.

Answer D: Reuse the machine-independent optimizer across compilers.

COMP26 explains that IR separates source analysis from target implementation, making optimizers and backends reusable. This directly supports reusing a machine-independent optimizer in different compilers. An IR can support allocation and analysis, but none of the other proposed improvements is its defining architectural function, nor does merely introducing IR guarantee them.

Why each choice is right or wrong

A - Incorrect: Allocation may analyze IR, but improved allocation is not the portability function identified here.

B - Incorrect: Error reporting and recovery are shared compiler services, not the defining purpose of introducing IR.

C - Incorrect: Semantic analysis normally establishes source correctness before lowering; IR is not introduced chiefly to simplify it.

D - Correct: Separating source and target through IR enables reuse of machine-independent optimization passes.

Primary note proof

Study-note section COMP26

> IR separates source analysis from target implementation, allowing optimizers and backends to be reused. It should be easy to generate, analyze, transform and lower.

Study-note section COMP26

> Ordinary TAC arithmetic has at most one operation, two sources and one destination: t1=c*d; t2=b+t1; a=t2. Quadruples store (op,arg1,arg2,result); triples omit an explicit result field and refer to instruction positions. Indirect triples reference a separate ordering list, easing rearrangement. Trees describe expressions; DAGs share common subexpressions, while quadruples/triples are instruction-record structures.

Question 56 | Q01421

How many categories result when optimizations are divided solely by whether they depend on the target machine?

A. two types

B. three types

C. four types

D. five types

Hint

Trace whether computation is evaluated, moved, shared or removed. Preserve observable effects and use the stated arithmetic and target assumptions.

Answer A: two types

The stated criterion divides optimizations into machine-dependent and machine-independent categories, giving two categories. Other taxonomies use different criteria, such as local, global and loop scope, and need not have the same count. Individual transformations are not additional categories under this binary division. Naming the criterion fixes the count without claiming a universal number of optimization types across all classifications.

Why each choice is right or wrong

A - Correct: The two categories are machine-dependent and machine-independent.

B - Incorrect: Three fits another possible scope taxonomy.

C - Incorrect: This binary division does not yield four categories.

D - Incorrect: This binary division does not yield five categories.

Primary note proof

Study-note section COMP32

> A loop-invariant expression has unchanged inputs during a loop. Hoist it to a preheader only when evaluation is safe on the paths where it will newly run. Induction variables change by a loop-invariant increment, such as i=i+1. For repeated t=4*i, maintain a running t increased by 4 when equivalent, reducing repeated multiplication.

Study-note section COMP32

> Loop fusion or jamming combines loops with compatible bounds and safe dependence order. Unrolling replicates a body to reduce branch overhead and expose parallelism; handle remaining iterations and increased code size. Loop-invariant code motion, fusion, unrolling and strength reduction are different transformations. A finite taxonomy needs a criterion: machine dependent/independent versus local/global/loop are different classifications.

Question sources

Compiler Design review questions · Question 29

Question 57 | Q01422

The value of which variable is updated inside the loop by a loop-invariant value?

A. loop

B. strength

C. induction

D. invariable

Hint

Trace whether computation is evaluated, moved, shared or removed. Preserve observable effects and use the stated arithmetic and target assumptions.

Answer C: An induction variable.

COMP32 defines induction variables as values changed by a loop-invariant increment, such as i=i+1. This matches an update inside a loop by an invariant amount. A loop-invariant value itself stays unchanged; strength is part of the term strength reduction, and loop alone names a construct rather than this variable class.

Why each choice is right or wrong

A - Incorrect: Loop names the repeated control construct rather than the variable category defined by invariant increments.

B - Incorrect: Strength refers to replacing costly operations, not to this variable classification.

C - Correct: An induction variable is updated by a loop-invariant increment during loop iterations.

D - Incorrect: An invariant value remains unchanged, unlike the updated variable described in the stem.

Primary note proof

Study-note section COMP32

> A loop-invariant expression has unchanged inputs during a loop. Hoist it to a preheader only when evaluation is safe on the paths where it will newly run. Induction variables change by a loop-invariant increment, such as i=i+1. For repeated t=4*i, maintain a running t increased by 4 when equivalent, reducing repeated multiplication.

Study-note section COMP32

> Loop fusion or jamming combines loops with compatible bounds and safe dependence order. Unrolling replicates a body to reduce branch overhead and expose parallelism; handle remaining iterations and increased code size. Loop-invariant code motion, fusion, unrolling and strength reduction are different transformations. A finite taxonomy needs a criterion: machine dependent/independent versus local/global/loop are different classifications.

Question sources

Compiler Design review questions · Question 30

Question 58 | Q01423

Which compiler runs on one machine and generates code for multiple machines?

A. Multipass compiler

B. Cross compiler

C. Optimizing compiler

D. Onepass compiler

Hint

Identify each activity's input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer B: Cross compiler

A cross-compiler runs on platform A and generates executable code for another platform B (PDF p. 3). B matches the host/target distinction. The module's definition concerns a different target platform; it does not require one executable to support several targets simultaneously.

Why each choice is right or wrong

A - Incorrect: Multipass is not the host/target distinction described on p. 3.

B - Correct: Cross compiler is explicitly the platform-A to platform-B translator (p. 3).

C - Incorrect: Optimizing refers to improving code (p. 7), not the host/target relationship.

D - Incorrect: Onepass is not the documented host/target category.

Primary note proof

Study-note section COMP02

A preprocessor handles directives such as file inclusion and macros. An assembler translates assembly to object code. A linker combines object files and libraries, resolves external symbols and performs relocation. A loader maps an executable into memory and starts it. Compilation alone does not necessarily produce a ready executable.

Study-note section COMP02

A cross-compiler runs on a host platform and generates code for a different target. Multiple targets require appropriate backends, not a special definition of cross-compilation. A retargetable compiler supports changing target descriptions. Incremental compilation recompiles affected fragments or dependent units after edits; it is more than literally replacing changed lines. One-pass versus multipass counts traversals, not supported targets.

Module passages - related reading

Question sources

Compiler Design review questions · Question 31

Question 59 | Q01425

Which phenomenon happens when the non-terminal on the left side is repeated as the first symbol on the right side?

A. Left-most derivation

B. Left recursion

C. Left factoring

D. Left parsing

Hint

Use construction direction, lookahead and grammar restrictions. Distinguish algorithm families, implementations and coverage before comparing them.

Answer B: Immediate left recursion.

COMP12 writes immediate left recursion as A→Aα: the production's left-hand nonterminal occurs first on its right-hand side. This is precisely the pattern in the question. Leftmost derivation chooses which nonterminal to expand; left factoring extracts a shared prefix. Neither is the repeated-leftmost-self-reference property.

Why each choice is right or wrong

A - Incorrect: Leftmost derivation chooses the leftmost remaining nonterminal to rewrite, regardless of self-reference.

B - Correct: A production beginning with its own left-hand nonterminal is immediate left recursion.

C - Incorrect: Left factoring extracts common prefixes from alternatives and does not define recursive self-reference.

D - Incorrect: Left parsing is not the note's name for the production pattern described.

Primary note proof

Study-note section COMP12

Immediate left recursion has A→Aα. For A→Aα|β, where β does not start with A, introduce a new nonterminal A′ and use:
A→βA′
A′→αA′|ε
This preserves the generated language; tree shape changes, so semantic actions must preserve intended associativity. Indirect left recursion follows a cycle through other nonterminals and also needs removal for ordinary predictive descent.

Study-note section COMP12

Left factoring rewrites A→αβ|αγ using:
A→αA′
A′→β|γ
It postpones a choice until after the common prefix. It does not by itself remove ambiguity or guarantee LL(1). LR parsers can handle suitable left-recursive grammars; ordinary unmodified recursive descent can recurse forever before consuming input.

Top Down Parsing
• The parse tree is created top to bottom
• Starts from the start symbol and transform it to the input
Bottom Up Parsing

• Starts with the input symbols and tries to construct the parse tree up to the start symbol.
• One way of reducing a sentence is to follow the right most derivation in reverse

Question sources

Compiler Design review questions · Question 33

Question 60 | Q01428

The compiler can detect what type of errors?

A. neither logical nor grammatical error

B. logical errors only

C. grammatical errors only

D. both grammatical and logical errors

Hint

Identify each activity's input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer C: grammatical errors only

PDF p. 5 says syntax analysis catches syntactic errors, so grammar violations are detectable. PDF p. 6 adds semantic type mismatches; it does not claim detection of arbitrary mistakes in the intended algorithm. Among the offered grammatical-versus-logical choices, C fits if "logical" means wrong intended algorithm rather than all semantic errors.

Why each choice is right or wrong

A - Incorrect: Neither conflicts with the documented detection of syntactic errors.

B - Incorrect: Logical-only omits the explicitly detected grammatical errors.

C - Correct: Grammatical errors are expressly detected; the intended-algorithm interpretation of logical makes this the matching choice.

D - Incorrect: The module does not claim that general intended-algorithm errors are detected.

Primary note proof

Study-note section COMP08

A lexical error prevents forming a legal token, such as an invalid character or unterminated literal. A syntax error is an illegal token arrangement, such as a missing delimiter. A semantic error violates name, scope or type rules after grammatical recognition. A wrong algorithm can compile successfully; compilers do not detect all logical mistakes.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Compiler Design module | PDF page 5 | lines 12-18

2. Syntax / Hierarchical Analysis - Parsing
• Tokens are grouped hierarchically into nested collections with collective meaning.
• The result is generally a parse tree.
• expressions, statements, declarations etc... are identified by using the results of lexical analysis.
• Most syntactic errors in the source program are caught in this phase.
• Syntactic rules of the source language are given via a Grammar.

Compiler Design module | PDF page 6 | lines 2-10

3. Semantic Analysis
• Certain checks are performed to make sure that the components of the program fit together meaningfully.
• Unlike parsing, this phase checks for semantic errors in the source program (e.g. type mismatch)
- Type checking of various programming language constructs is one of the most important tasks.
• Stores type information in the symbol table or the syntax tree.
- Types of variables, function parameters, array dimensions, etc.

Question sources

Compiler Design review questions · Question 36

Question 61 | Q01430

Which method merges the multiple loops into the single one?

A. Constant Folding

B. Loop rolling

C. Loop fusion or jamming

D. None of the above

Hint

Trace whether computation is evaluated, moved, shared or removed. Preserve observable effects and use the stated arithmetic and target assumptions.

Answer C: Loop fusion, also called jamming.

COMP32 explicitly defines loop fusion or jamming as combining loops with compatible bounds and safe dependence order. That is the requested merging transformation. Constant folding evaluates constant expressions, while loop rolling does not name this fusion of separate loops. Fusion must preserve dependence order; it is not automatically legal for arbitrary loops.

Why each choice is right or wrong

A - Incorrect: Constant folding evaluates constant expressions at compile time; it does not combine loop bodies.

B - Incorrect: Loop rolling is not the note's named transformation for merging separate compatible loops.

C - Correct: Fusion or jamming combines compatible loops into one while preserving required dependence order.

D - Incorrect: The explicit fusion/jamming option already names the requested transformation.

Primary note proof

Study-note section COMP32

> A loop-invariant expression has unchanged inputs during a loop. Hoist it to a preheader only when evaluation is safe on the paths where it will newly run. Induction variables change by a loop-invariant increment, such as i=i+1. For repeated t=4*i, maintain a running t increased by 4 when equivalent, reducing repeated multiplication.

Study-note section COMP32

> Loop fusion or jamming combines loops with compatible bounds and safe dependence order. Unrolling replicates a body to reduce branch overhead and expose parallelism; handle remaining iterations and increased code size. Loop-invariant code motion, fusion, unrolling and strength reduction are different transformations. A finite taxonomy needs a criterion: machine dependent/independent versus local/global/loop are different classifications.

Compiler Design review questions · Question 38

Question 62 | Q01431

Which parser is known as the shift-reduce parser?

A. Bottom-up parser

B. Top-down parser

C. Both Top-down and bottom-up

D. None of the Above

Hint

Use construction direction, lookahead and grammar restrictions. Distinguish algorithm families, implementations and coverage before comparing them.

Answer A: Bottom-up parser

PDF p. 10 names bottom-up parsing as SR parsing and describes reductions from the input to the start symbol. Interpreting SR as shift-reduce, A is the matching category; top-down is instead predictive.

Why each choice is right or wrong

A - Correct: Bottom-up is explicitly the SR category (p. 10).

B - Incorrect: Top-down is labeled predictive, not SR (p. 10).

C - Incorrect: Both collapses two categories the module distinguishes (p. 10).

D - Incorrect: The bottom-up category is present (p. 10), so none is false.

Primary note proof

Study-note section COMP15

> Bottom-up parsing starts from input and reduces toward S, constructing a rightmost derivation in reverse. A handle is a production RHS occurrence whose reduction is the next step of that reverse derivation. Not every substring matching a RHS is a handle in the current context.

Study-note section COMP15

> Shift pushes the next input token and a state; reduce replaces a recognized RHS by its LHS and consults GOTO; accept recognizes completion; error reports an invalid situation. For A→XYZ, pop three grammar symbols and their states, expose state q, then push A and GOTO[q,A]. “Go” is not a separate standard shift-reduce ACTION, although GOTO is essential table machinery.

Question sources

Compiler Design review questions · Question 39

Question 63 | Q01433

The full form of YACC is:

A. Yet Another Computer Computer

B. Yet Another Computer Compiler

C. Yet Another Compiler Computer

D. Yet Another Compiler Compiler

Hint

Identify each activity’s input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer D: Yet Another Compiler Compiler.

COMP39 expands Yacc as Yet Another Compiler Compiler and describes Yacc/Bison as generating parsers from grammar rules and semantic actions. The other expansions interchange computer and compiler and do not match the note. The name refers to a parser generator, distinct from Lex/flex scanner generation.

Why each choice is right or wrong

A - Incorrect: Computer Computer replaces both required occurrences of Compiler and is not the stated expansion.

B - Incorrect: The first noun must be Compiler, not Computer.

C - Incorrect: The final noun must also be Compiler, not Computer.

D - Correct: This matches the exact Yacc expansion given in COMP39.

Primary note proof

Study-note section COMP39

Panic-mode recovery skips input until a synchronizing token such as ; or } permits parsing to resume. Phrase-level recovery makes a local insertion/deletion. Report the location and cause while avoiding cascades of misleading diagnostics. Lexical, syntax and semantic phases each detect their own errors; error handling is a shared service.

Study-note section COMP39

Lex/flex generates scanners from patterns and actions. Yacc means Yet Another Compiler Compiler; Yacc/Bison generates parsers from grammar rules and semantic actions. Typical specification files have definitions, %% rules, and %% user code. Classic Yacc uses LALR; Bison supports additional LR and generalized modes. Scanner generation does not replace the CFG parser.

Grammars
• Every programming language has grammar rules
• Parsers or syntax analyzers are generated for a particular grammar
• CFG are used for syntax specification of programming languages
Context Free Grammar (CFG)
• Is denoted as G = (N, T , P, S)
• N : finite set of non-terminals
• T : finite set of terminals
• S ∈ N: The start symbol
• P : Finite set of productions, each of the form A→α, where A∈N and α ∈ (N U T)*

Question sources

Compiler Design review questions · Question 41

Question 64 | Q01434

What type of conflicts can occur in the shift-reduce parsing? Select the most complete choice.

A. reduce/reduce

B. shift/reduce

C. Both shift/reduce and reduce/reduce

D. None of the above

Hint

Use construction direction, lookahead and grammar restrictions. Distinguish algorithm families, implementations and coverage before comparing them.

Answer C: Both shift/reduce and reduce/reduce

COMP17 distinguishes a shift/reduce conflict, where shifting competes with reduction, from reduce/reduce, where two reductions compete. Both can arise in shift-reduce table construction. The combined option therefore answers the question completely; either individual conflict is a valid example but omits the other named kind.

Why each choice is right or wrong

A - Incorrect: True as one component, but incomplete as the requested full selection. Two competing reductions form a reduce/reduce conflict, one of the listed possible types.

B - Incorrect: True as one component, but incomplete as the requested full selection. A shift competing with a reduction forms the other standard conflict type.

C - Correct: This aggregate includes both conflict types explicitly defined in COMP17.

D - Incorrect: Both listed kinds can occur, so denying every listed type is false.

Primary note proof

Study-note section COMP17

> SLR(1) uses LR(0) states and FOLLOW(A) for reduction by a completed A production. Canonical LR(1) attaches context-specific lookahead to items. LALR(1) merges canonical states with the same LR(0) core, combining lookaheads; merging can introduce reduce/reduce conflicts. The standard grammar-class hierarchy is LR(0)⊆SLR(1)⊆LALR(1)⊆LR(1), with increasing capability and often table size.

Study-note section COMP17

> A shift/reduce conflict offers both consuming a token and reducing; reduce/reduce offers two reductions. An SLR or LALR conflict does not by itself prove the grammar ambiguous. Canonical LR(1) handles LR(1) grammars, not every unambiguous CFG. Precedence and associativity can resolve suitable expression conflicts; changing parser names alone does not repair all ambiguity.

Starts with root non-terminal on stack Ends with root non-terminal on the stack
Builds the parse tree top-down Builds the parse tree bottom-up
Expands the non-terminals Reduces the non-terminals

Question sources

Compiler Design review questions · Question 42

Question 65 | Q01436

Which algorithm invokes a function GETREG()?

A. Code motion algorithm

B. Code optimization algorithm

C. Intermediate Code

D. Code generation algorithm

Hint

Match stored information to its lifetime, access path and calling-convention role; distinguish compile-time organization from run-time storage.

Answer D: A code-generation algorithm.

COMP35 directly associates getReg with a simple code-generation algorithm. It selects operand/result registers for a TAC instruction before loads and the target operation are emitted and descriptors are updated. Code motion and general optimization serve other transformation purposes; intermediate code is the input representation here rather than the algorithm making the register choice.

Why each choice is right or wrong

A - Incorrect: Code motion relocates computations; it is not the described getReg-driven emission algorithm.

B - Incorrect: Optimization is broader, but COMP35 specifically locates getReg in the target code-generation algorithm.

C - Incorrect: Intermediate code supplies instructions to the generator; it is not the algorithm invoking the register selector.

D - Correct: The note explicitly describes getReg as part of simple target code generation.

Primary note proof

Study-note section COMP35

A register descriptor records which current values are held in a register. An address descriptor for a name records all current locations containing its value, possibly memory and multiple registers. A memory copy can become stale after a register-only assignment. These are code-generator bookkeeping structures, not source-language types.

Study-note section COMP35

A simple code-generation algorithm calls getReg for a TAC instruction to select operand/result registers, emits necessary loads, emits the operation, then updates descriptors. Prefer an already suitable register or a reusable dead operand; otherwise choose a spill victim and store any live value lacking another current copy. At a block exit, preserve values needed by successors.

a. Register allocation and assignment

Compiler Design module | PDF page 18 | lines 11-22

Register Allocation
• Registers hold values
• Example
- a = c + d
- e = a + b
- f = e - 1

• With the assumption that a and e die after use
• Temporary a can be reused after e=a+b, same wz a
• Can allocate a,e and f all to one register(r1)
- r1 = r2 + r3
- r1 = r1 + r4
- r1 = r1 - 1

Question sources

Compiler Design review questions · Question 44

Question 66 | Q01438

The execution time of the code depends on? Select the most complete choice.

A. the usage of machine idioms

B. the way the registers are used

C. the orders in which the computations are performed

D. All of the mentioned

Hint

Identify each activity's input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer D: All of the mentioned

COMP34 states that machine idioms, register availability and instruction order affect execution time. These correspond to all three concrete choices. Better register use can reduce loads/spills; target idioms affect instruction cost, and legal scheduling changes execution efficiency. The aggregate is therefore the complete response rather than any one factor in isolation.

Why each choice is right or wrong

A - Incorrect: True as one component, but incomplete as the requested full selection. Choosing target machine idioms changes the operations emitted and their target costs.

B - Incorrect: True as one component, but incomplete as the requested full selection. Register use affects memory traffic and spills, which can change execution time.

C - Incorrect: True as one component, but incomplete as the requested full selection. The scheduling of computations affects execution efficiency while dependencies constrain legal orders.

D - Correct: COMP34 explicitly includes all three factors, so the aggregate is the complete answer.

Primary note proof

Study-note section COMP34

> Code generation lowers checked IR to a target form. Instruction selection chooses target operations; register allocation chooses where values reside; scheduling orders instructions while respecting dependencies; storage layout assigns offsets and follows ABI requirements. Register assignment names actual physical registers after allocation decisions.

Study-note section COMP34

> For t=a+b, a simple target could emit LOAD R1,a; LOAD R2,b; ADD R3,R1,R2; STORE t,R3. Other targets may combine loads with arithmetic or keep t in a register. Machine idioms, register availability and instruction order affect execution time.

Question sources

Compiler Design review questions · Question 46

Question 67 | Q01439

Which is the most specific named method for examining a short instruction window and replacing jump L1 with jump L2 when L1 immediately jumps to L2?

A. Latter optimization technique

B. Peephole optimization technique

C. Local optimization technique

D. Code optimization technique

Hint

Trace whether computation is evaluated, moved, shared or removed. Preserve observable effects and use the stated arithmetic and target assumptions.

Answer B: Peephole optimization technique

Peephole optimization examines a short instruction window and replaces it with an equivalent, preferable sequence. The described jump-chain rewrite is a direct example. Local optimization and code optimization are broader classifications that may include the transformation, but do not name the specific short-window method requested. Latter optimization is not a method defined in the supplied note.

Why each choice is right or wrong

A - Incorrect: Latter optimization does not name the specified method.

B - Correct: Peephole explicitly performs short-window jump-chain rewrites.

C - Incorrect: Local optimization is broader than the requested method.

D - Incorrect: Code optimization is broader than the requested method.

Primary note proof

Study-note section COMP31

> Peephole optimization examines short instruction windows. It can remove redundant loads/stores, replace machine idioms and shorten jump chains: jump L1 where L1 immediately jumps L2 can become jump L2.

Compiler Design review questions · Question 47

Question 68 | Q01440

Which of the following term is used to keep track of the location where the current values of the name are stored?

A. Register descriptor

B. Address descriptor

C. Allocation descriptor

D. Flag register

Hint

Match stored information to its lifetime, access path and calling-convention role; distinguish compile-time organization from run-time storage.

Answer B: An address descriptor.

COMP35 defines an address descriptor for a name as recording all current locations that contain its value, including memory and registers. That matches tracking where a name's current value is stored. A register descriptor instead records values held in a particular register, reversing the direction of the association.

Why each choice is right or wrong

A - Incorrect: A register descriptor maps a register to its current values rather than a name to all locations.

B - Correct: An address descriptor records the current memory and register locations holding a name's value.

C - Incorrect: Allocation descriptor is not the note's defined bookkeeping structure for name-to-location tracking.

D - Incorrect: A flag register stores machine status flags rather than all locations of a named value.

Primary note proof

Study-note section COMP35

> A register descriptor records which current values are held in a register. An address descriptor for a name records all current locations containing its value, possibly memory and multiple registers. A memory copy can become stale after a register-only assignment.

Question sources

Compiler Design review questions · Question 48

Question 69 | Q01441

In a nontrivial expression AST whose leaves are operands, which complete category of nodes carries operator symbols, including operators in nested subexpressions?

A. Root

B. Interior nodes

C. Leaves

D. Nodes

Hint

Identify each activity’s input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer B: Interior nodes

In an expression AST, leaves carry operands such as identifiers and constants, while nonleaf nodes carry the operators that combine child expressions. A nontrivial tree’s root can also be an operator, but naming only the root omits nested operators. Naming all nodes includes operand leaves. The complete category requested is therefore the interior nodes, which includes an operator root and any other nonleaf operator nodes.

Why each choice is right or wrong

A - Incorrect: The root alone omits operators in nested subexpressions.

B - Correct: Interior nodes are the complete nonleaf category carrying operators in this expression AST.

C - Incorrect: Leaves carry operands rather than combining operators.

D - Incorrect: All nodes includes operand leaves and is too broad.

Primary note proof

Study-note section COMP09

A context-free grammar G=(N,T,P,S) has nonterminals N, terminals T, productions P and start S. A production A→α rewrites one nonterminal. A sentential form is any string of terminals/nonterminals derivable from S; a sentence contains only terminals. A leftmost derivation rewrites the leftmost remaining nonterminal; a rightmost one rewrites the rightmost.

Study-note section COMP09

A parse tree shows grammar productions: root S, internal nonterminals, and terminal leaves, with ε sometimes shown for empty productions. Its left-to-right yield is the input. An AST omits grammar scaffolding and punctuation; expression operands are leaves and operators internal nodes. The parser can build either representation, depending on implementation.

Question 70 | Q01443

Which of the following is used in various stages or phases of the compiler?

A. Records

B. Program

C. Symbol Table

D. Table

Hint

Ask whether the required information is a declaration's identity and attributes, program structure or the ordered source tokens.

Answer C: Symbol Table

The module stores semantic type information in the symbol table (PDF p. 6), puts identifier-entry pointers in syntax-tree leaves (p. 13), and enters names/types during declarations (p. 17). These uses support the symbol table as a shared structure across compiler work.

Why each choice is right or wrong

A - Incorrect: Records is only a generic storage term, not the shared named structure in these passages.

B - Incorrect: Program is the object being compiled, not the metadata table.

C - Correct: Symbol Table is explicitly used in several contexts (pp. 6, 13, 17).

D - Incorrect: Table is nonspecific; Symbol Table is the documented structure.

Primary note proof

Study-note section COMP19

> A symbol table maps names or symbol identities to attributes: type, scope, width, storage offset, parameter signature, constant information or linkage.

Study-note section COMP03

> Symbol-table management and error reporting support multiple phases rather than forming one mandatory seventh final phase.

Study-note section COMP19

> Scanning may intern a spelling first; semantic analysis determines the declaration and type.

Compiler Design review questions · Question 51

Question 71 | Q01444

Which of the following structure has four fields?

A. Parse tree

B. Triples

C. Indirect Triples

D. Quadruples

Hint

Identify what the representation stores, what it omits and which later transformations it must support; separate a representation property from an algorithmic task.

Answer D: Quadruples

PDF p16 explicitly divides a quadruple into operator, arg1, arg2, and result: four fields. It contrasts triples with three fields.

Why each choice is right or wrong

A - Incorrect: A parse tree is a hierarchical representation, not the four-field instruction defined on p16.

B - Incorrect: P16 explicitly gives triples three fields.

C - Incorrect: P16 describes indirect triples through pointers, not a fourth result field.

D - Correct: P16 explicitly lists the four quadruple fields.

Primary note proof

Study-note section COMP26

> IR separates source analysis from target implementation, allowing optimizers and backends to be reused. It should be easy to generate, analyze, transform and lower.

Study-note section COMP26

> Ordinary TAC arithmetic has at most one operation, two sources and one destination: t1=c*d; t2=b+t1; a=t2. Quadruples store (op,arg1,arg2,result); triples omit an explicit result field and refer to instruction positions. Indirect triples reference a separate ordering list, easing rearrangement. Trees describe expressions; DAGs share common subexpressions, while quadruples/triples are instruction-record structures.

Question sources

Compiler Design review questions · Question 52

Question 72 | Q01445

What is the conventional name for the compact expression representation with operand leaves and operator interior nodes?

A. Syntax tree

B. Parser tree

C. Structured tree

D. Sematic tree

Hint

Identify each activity's input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer A: Syntax tree

The conventional expression AST places operands at leaves and operators at interior nodes, removing grammar scaffolding and punctuation. A parse tree instead records grammar productions: its internal nodes are nonterminals, and its yield includes the terminals of the source phrase. The other two names do not identify the conventional expression representation in this comparison. The syntax-tree choice supplies the specific structure described by the question.

Why each choice is right or wrong

A - Correct: An expression syntax tree places operands at leaves and operators at nonleaf nodes.

B - Incorrect: A parse tree's internal labels are grammar nonterminals, not generally expression operators.

C - Incorrect: This generic phrase does not specify the conventional expression AST representation requested.

D - Incorrect: Semantic annotation can be attached to representations, but this is not the conventional name for the described AST.

Primary note proof

Study-note section COMP09

> A context-free grammar G=(N,T,P,S) has nonterminals N, terminals T, productions P and start S. A production A→α rewrites one nonterminal. A sentential form is any string of terminals/nonterminals derivable from S; a sentence contains only terminals. A leftmost derivation rewrites the leftmost remaining nonterminal; a rightmost one rewrites the rightmost.

Study-note section COMP09

> A parse tree shows grammar productions: root S, internal nonterminals, and terminal leaves, with ε sometimes shown for empty productions. Its left-to-right yield is the input. An AST omits grammar scaffolding and punctuation; expression operands are leaves and operators internal nodes. The parser can build either representation, depending on implementation.

Compiler Design review questions · Question 53

Question 73 | Q01446

Which statement is an abstract form of intermediate code?

A. 3- address

B. 2-address

C. address

D. Intermediate code

Hint

Identify what the representation stores, what it omits and which later transformations it must support; separate a representation property from an algorithmic task.

Answer A: 3- address

PDF pp15-16 defines three-address code as a generic intermediate representation, X = Y op Z. Thus A names the supplied abstract statement form; D only repeats the general category.

Why each choice is right or wrong

A - Correct: P15 gives precisely this statement form.

B - Incorrect: No two-address intermediate statement form is supplied; it is not the form defined on p15.

C - Incorrect: A bare address is not the statement X = Y op Z.

D - Incorrect: This names the category rather than the particular statement form requested.

Primary note proof

Study-note section COMP26

> IR separates source analysis from target implementation, allowing optimizers and backends to be reused. It should be easy to generate, analyze, transform and lower.

Study-note section COMP26

> Ordinary TAC arithmetic has at most one operation, two sources and one destination: t1=c*d; t2=b+t1; a=t2. Question sources

Compiler Design review questions · Question 54

Question 74 | Q01447

Which mapping is described by the implementation of the syntax-directed translator?

A. Parse table

B. Input

C. Output

D. Input-Output

Hint

Track where each computed value comes from and when each production action runs. Distinguish the representation from its attached information.

Answer D: An input-to-output mapping.

COMP25 distinguishes translation from recognition: semantic actions compute an output, such as values, ASTs or code, from an input program. Accordingly the implemented translator defines an input-to-output mapping. A parse table may drive an implementation, but neither the table nor either endpoint alone names that mapping.

Why each choice is right or wrong

A - Incorrect: A parse table can guide recognition; it is not the translation mapping itself.

B - Incorrect: Input is only the domain side and omits the translated result.

C - Incorrect: Output is only the result side and omits the mapping from source inputs.

D - Correct: Syntax-directed translation relates each processed input to its computed translation output.

Primary note proof

Study-note section COMP25

A syntax-directed translation scheme embeds executable actions in productions; the actions run while translating a source program, not while generating the compiler. Attributes may compute types, values, AST pointers or generated code. The scheme defines an input-to-output translation, not merely an input language.

Study-note section COMP25

Create an identifier leaf with mkleaf(id,entry), a number with mkleaf(num,value), and an operator node with mknode(op,left,right). For a−4+c, construct +(−(a,4),c). Postorder traversal prints postfix: a 4 − c +. A stack evaluator pushes operands and pops right then left operands for an operator. Infix-to-postfix is useful for stack machines but not mandatory for all compilers.

Compiler Design module | PDF page 12 | lines 4-16

Syntax Directed Translation
• Attaching actions to the grammar rules(productions).
• Actions are executed during the compilation
- Not during the generation of the compiler
• Actions are executed according to the parsing mechanism.
Syntax Directed Definitions
• Is a generalization of a context free grammar
• Is a CFG with attributes and rules
• Attributes are associated with grammar symbols and rules with productions
• Attributes may be:
- Numbers
- Types
- Strings etc

Compiler Design module | PDF page 12 | lines 17-25

Syntax Directed Definition- Example
• Production Semantic Rules
• L → E return print(E.val)
• E → E1 + T E.val = E1.val + T.val
• E → T E.val = T.val
• T → T1 * F T.val = T1.val * F.val
• T → F T.val = F.val
• T → (E) F.val = E.val
• F → digit F.val = digit.lexval

Question sources

Compiler Design review questions · Question 55

Question 75 | Q01448

Which transition function moves the dot over a grammar symbol and takes closure to build successor states in the canonical LR(0) item collection?

A. FIRST

B. GOTO

C. COMPUTE

D. FOLLOW

Hint

Use construction direction, lookahead and grammar restrictions. Distinguish algorithm families, implementations and coverage before comparing them.

Answer B: GOTO

GOTO(I,X) advances the dot over X in eligible items and then takes closure, producing a successor item state. Repeating this over grammar symbols builds the canonical collection. The collection is the resulting set of item sets, not the function itself. FIRST and FOLLOW compute terminal sets for different parsing purposes; COMPUTE does not name the defined LR successor operation.

Why each choice is right or wrong

A - Incorrect: FIRST finds possible beginning terminals.

B - Correct: GOTO produces the successor item state.

C - Incorrect: COMPUTE is not the defined successor-state function.

D - Incorrect: FOLLOW finds possible following terminals.

Primary note proof

Study-note section COMP16

> Augment the grammar with S′→S. An LR(0) item A→α·β records progress through a production. CLOSURE(I) repeatedly adds B→·γ whenever an item has its dot before nonterminal B and B→γ is a production.

Study-note section COMP16

> GOTO(I,X) moves the dot past X in every eligible item and takes closure. Start with CLOSURE({S′→·S}); repeatedly compute nonempty GOTO sets for all grammar symbols until no new state appears. The resulting set of item sets is the canonical collection, not GOTO itself.

Question sources

Compiler Design review questions · Question 56

Question 76 | Q01449

Which of the following option is not a function of the shift-reduce parser?

A. Reduce

B. Accept

C. Go

D. Shift

Hint

Use construction direction, lookahead and grammar restrictions. Distinguish algorithm families, implementations and coverage before comparing them.

Answer C: “Go” is not a standard shift-reduce ACTION.

COMP15 lists shift, reduce, accept and error as standard shift-reduce actions. GOTO is essential after a reduction but is separate table machinery, not a distinct action called Go. Reading function as the standard action category yields the offered Go choice; the three other choices are explicitly standard actions.

Why each choice is right or wrong

A - Incorrect: Reduce is a standard action that replaces a recognized right-hand side by its left-hand nonterminal.

B - Incorrect: Accept is a standard action indicating successful completion of recognition.

C - Correct: Go is not one of the standard ACTION names; GOTO is separate transition-table machinery.

D - Incorrect: Shift is a standard action that consumes input and pushes a token with its state.

Primary note proof

Study-note section COMP15

Bottom-up parsing starts from input and reduces toward S, constructing a rightmost derivation in reverse. A handle is a production RHS occurrence whose reduction is the next step of that reverse derivation. Not every substring matching a RHS is a handle in the current context.

Study-note section COMP15

Shift pushes the next input token and a state; reduce replaces a recognized RHS by its LHS and consults GOTO; accept recognizes completion; error reports an invalid situation. For A→XYZ, pop three grammar symbols and their states, expose state q, then push A and GOTO[q,A]. “Go” is not a separate standard shift-reduce ACTION, although GOTO is essential table machinery.

Question sources

Compiler Design review questions · Question 57

Question 77 | Q01450

Which listed grammar classes guarantee no adjacent nonterminals on a production right-hand side? Select all that apply. Regular means consistently right-linear; irregular means arbitrary unrestricted.

A. Arbitrary unrestricted grammar

B. Right-linear regular grammar

C. Operator grammar

Hint

Use construction direction, lookahead and grammar restrictions. Distinguish algorithm families, implementations and coverage before comparing them.

Answer B, C: Right-linear regular grammar; Operator grammar

An operator grammar explicitly forbids adjacent nonterminals on a right-hand side. A consistently right-linear regular grammar has at most one nonterminal in such a rule, so it also guarantees the restriction. Arbitrary unrestricted grammars have no comparable adjacency guarantee. The property is therefore shared by the two specified classes and cannot be used to identify only operator grammar.

Why each choice is right or wrong

A - Incorrect: An unrestricted grammar can contain adjacent nonterminals.

B - Correct: A right-linear regular rule has at most one nonterminal.

C - Correct: Operator grammars forbid adjacent nonterminals by definition.

Primary note proof

Study-note section COMP18

> LL, LR and recursive-descent parsers can all handle nested parentheses for suitable grammars. An explicit or implicit stack, not the LR label alone, supports unbounded nesting. Both LL and LR can use parsing tables. Deterministic LL/LR grammars must be unambiguous; a general ambiguous grammar requires rewriting, disambiguation policy or a generalized method such as GLR.

Study-note section COMP18

> An operator grammar conventionally forbids adjacent nonterminals on a RHS and usually ε productions. Operator-precedence parsing additionally requires conflict-free precedence relations. Ordinary right-linear regular grammars also lack adjacent nonterminals, so that property alone does not uniquely identify the operator-grammar category. Regular patterns are chiefly lexical specifications; CFGs chiefly describe nested syntax.

Grammars
• Every programming language has grammar rules
• Parsers or syntax analyzers are generated for a particular grammar
• CFG are used for syntax specification of programming languages
Context Free Grammar (CFG)
• Is denoted as G = (N, T , P, S)
• N : finite set of non-terminals
• T : finite set of terminals
• S ∈ N: The start symbol
• P : Finite set of productions, each of the form A→α, where A∈N and α ∈ (N U T)*

Question sources

Compiler Design review questions · Question 58

Question 78 | Q01488

In an implementation where the scanner interns identifier spellings in a symbol table before returning their tokens, which phase first interacts with that table?

A. Syntax analysis

B. Parsing

C. Scanning

D. Semantic analysis

Hint

Ask whether the required information is a declaration’s identity and attributes, program structure or the ordered source tokens.

Answer C: Scanning

Interning associates an identifier spelling with a table entry while scanning its characters and returning the identifier token. Under this explicit implementation convention, scanning is the first phase to interact with the table. Parsing and semantic analysis use or enrich this information later; semantic analysis resolves declaration identity and type. This establishes an ordering for the stated implementation rather than a universal compiler requirement.

Why each choice is right or wrong

A - Incorrect: Syntax analysis receives tokens after this scanner has interned identifiers.

B - Incorrect: Parsing is syntax analysis and occurs after the stated interning.

C - Correct: Scanning performs the stipulated initial interning.

D - Incorrect: Semantic analysis enriches name/type information after that initial interaction.

Primary note proof

Study-note section COMP19

Scanning may intern a spelling first; semantic analysis determines the declaration and type. Implementations differ, so first interaction is conventional rather than universal.

Study-note section COMP04

A token is a category with optional attribute, such as (ID, symbol-entry) or (INT_LITERAL,42). A lexeme is the actual character sequence, such as total or 42. A pattern specifies which lexemes belong to a token class. The scanner emits an ordered token stream, not an unordered mathematical set.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Compiler Design module | PDF page 5 | lines 3-11

1. Lexical / Linear Analysis (scanning)
- Scans the source code as a stream of characters
- Represent lexemes in the form of tokens as:
<token-name, attribute-value>
- Token
• smallest meaningful element that a compiler understands.
- Eg.
• Identifiers, Keywords, Literals, Operators and Special symbols.
- Blanks, new lines, comments will be removed from the source program.

Compiler Design module | PDF page 6 | lines 2-10

3. Semantic Analysis
• Certain checks are performed to make sure that the components of the program fit together meaningfully.
• Unlike parsing, this phase checks for semantic errors in the source program (e.g. type mismatch)
- Type checking of various programming language constructs is one of the most important tasks.
• Stores type information in the symbol table or the syntax tree.
- Types of variables, function parameters, array dimensions, etc.

Question sources

Mock exam 1 · Question 4

Question 79 | Q01489

What is the name given to the sequence of alphabets that are identified as a token?

A. Lexeme

B. Prefix

C. Pattern

D. Grammar

Hint

Identify each activity's input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer A: Lexeme

PDF p8 calls the sequence of characters matched by a pattern to form a token a lexeme. Interpreting alphabets as characters makes A exact.

Why each choice is right or wrong

A - Correct: Matches the p8 definition.

B - Incorrect: Prefix is not the defined name for the matched sequence.

C - Incorrect: P8 defines a pattern as a rule, not the matched sequence.

D - Incorrect: P9 uses grammar for syntactic production rules, not a token occurrence.

Primary note proof

Study-note section COMP04

> A token is a category with optional attribute, such as (ID, symbol-entry) or (INT_LITERAL,42). A lexeme is the actual character sequence, such as total or 42. A pattern specifies which lexemes belong to a token class. The scanner emits an ordered token stream, not an unordered mathematical set.

Study-note section COMP04

> Keywords, identifiers, literals, operators and punctuation are token classes. Whitespace and comments are usually skipped while line/column positions are retained. In indentation-sensitive or newline-sensitive languages, layout can carry tokens. Parse-tree construction is a parser task; scanning can intern identifier spellings, but declaration scope and types need later analysis.

Question sources

Mock exam 1 · Question 5

Question 80 | Q01490

In a compiler where semantic analysis annotates an existing AST with resolved declarations and checked types, what is its resulting program representation?

A. Language constructs

B. Unannotated concrete syntax tree

C. AST annotated with resolved declarations and checked types

D. Token

Hint

Ask whether the required information is a declaration's identity and attributes, program structure or the ordered source tokens.

Answer C: AST annotated with resolved declarations and checked types

The stated implementation resolves names and checks types on an existing abstract syntax tree, so its result is that AST with semantic annotations. An unannotated syntax tree omits the newly checked information; language constructs is too generic to identify the representation. Tokens are the scanner's earlier output. Other compilers may produce typed IR, but the question specifies the retained-tree implementation.

Why each choice is right or wrong

A - Incorrect: Language constructs does not identify the specified annotated representation.

B - Incorrect: An unannotated concrete syntax tree is not the specified result.

C - Correct: The result is the AST enriched with checked semantic information.

D - Incorrect: Tokens precede syntax and semantic analysis.

Primary note proof

Study-note section COMP21

> Static checks occur before execution: type compatibility, duplicate declarations within a restricted scope, valid names, argument counts, return compatibility and control-flow placement. A break is valid only in constructs allowed by the language; in C/C++ it can exit a loop or switch. A compiler may annotate an AST or create typed IR; there is no mandatory uniquely named output tree.

Study-note section COMP21

> Dynamic checks depend on runtime values, such as some bounds and null checks. Static analysis can prove some accesses safe or faulty; "all memory errors cannot be statically checked" is too strong. Unreachable code is not universally a semantic error: some languages reject it in specified cases, others merely warn or optimize it away.

2. Syntax / Hierarchical Analysis - Parsing
• Tokens are grouped hierarchically into nested collections with collective meaning.
• The result is generally a parse tree.
• expressions, statements, declarations etc... are identified by using the results of lexical analysis.
• Most syntactic errors in the source program are caught in this phase.
• Syntactic rules of the source language are given via a Grammar.

Question sources

Mock exam 1 · Question 6

Question 81 | SM0026

For const int x=8; const int y=16; if(x>y){int z=x+y;}, which techniques directly apply to evaluating the condition from known constants and removing its unreachable branch? Select all that apply. Distinguish constant evaluation from algebraic identity simplification.

A. Arithmetic simplification

B. Dead code elimination

C. Code motion

D. Compile time evaluation

Hint

Trace whether computation is evaluated, moved, shared or removed. Preserve observable effects and use the stated arithmetic and target assumptions.

Answer B, D: Dead code elimination; Compile time evaluation

With x=8 and y=16, the condition x>y evaluates to false during compilation. The branch body is consequently unreachable and can be removed. These are compile-time evaluation and dead-code elimination, respectively. No computation needs to move to another program location, and the decisive evaluation is not an algebraic identity such as x+0→x. Both direct transformations belong in the answer.

Why each choice is right or wrong

A - Incorrect: No algebraic identity rewrite is the decisive step.

B - Correct: The constant-false branch is unreachable and removable.

C - Incorrect: Code motion does not describe evaluating or deleting the branch.

D - Correct: Known constants permit compile-time evaluation of the condition.

Primary note proof

Study-note section COMP30

> For const int x=8,y=16; if(x>y){int z=x+y;}, propagate the constants, fold 8>16 to false, then remove the unreachable branch. Both compile-time evaluation and dead-code elimination apply.

Study-note section COMP31

> Algebraic simplification removes identities when valid: integer x+0→x.

Question 82 | SM0041

Which one of the following phases is done BEFORE the semantic analysis phase of the compiling process?

A. Syntax analysis

B. Intermediate code generation

C. Code generation

D. Code optimization

Hint

Identify each activity's input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer A: Syntax analysis

PDF pp5-7 orders syntax analysis before semantic analysis, followed by intermediate generation, optimization, and code generation.

Why each choice is right or wrong

A - Correct: Syntax analysis appears on p5 before semantics on p6.

B - Incorrect: Intermediate generation follows semantic analysis on p6.

C - Incorrect: Code generation is phase 6 on p7.

D - Incorrect: Optimization is phase 5 on p7, after semantics.

Primary note proof

Study-note section COMP03

> The conventional sequence is lexical analysis → syntax analysis → semantic analysis → intermediate-code generation → optimization → target-code generation. Scanning turns characters into tokens; parsing builds structure; semantics checks declarations and types; synthesis produces implementation code. A phase is a logical activity; a pass is a traversal that can combine activities.

Study-note section COMP03

> The front end handles source-language rules; a middle end analyzes and transforms IR; the backend handles target details. Symbol-table management and error reporting support multiple phases rather than forming one mandatory seventh final phase. Optimization can occur at several levels, including after instruction selection. "Final phase" means code generation in the standard six-phase teaching pipeline.

Which phase of the compiling process is considered the FINAL phase?

A. Intermediate code generation

B. Semantic analysis

C. Code optimization

D. Code generation

Hint

Identify each activity's input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer D: Code generation in the conventional pipeline.

COMP03 calls code generation the final phase of the standard six-phase teaching pipeline. Intermediate generation, semantic analysis and optimization precede it there. Some implementations perform later target optimization, but that does not change the conventional phase answer requested here; the note explicitly records that distinction.

Why each choice is right or wrong

A - Incorrect: Intermediate-code generation precedes optimization and target-code generation in the conventional sequence.

B - Incorrect: Semantic analysis checks names and types before intermediate and target synthesis.

C - Incorrect: Optimization precedes final code generation in the simplified six-phase teaching pipeline.

D - Correct: COMP03 explicitly names code generation as final under this standard pipeline convention.

Primary note proof

Study-note section COMP03

> The conventional sequence is lexical analysis → syntax analysis → semantic analysis → intermediate-code generation → optimization → target-code generation. Scanning turns characters into tokens; parsing builds structure; semantics checks declarations and types; synthesis produces implementation code. A phase is a logical activity; a pass is a traversal that can combine activities.

Question 84 | SM0093

Which one of the following is used for the purpose of syntax analysis?

A. Loader

B. Linker

C. Parser

D. Scanner

Hint

Identify each activity’s input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer C: Parser

PDF p10 defines parsing as constructing a parse tree, and p5 labels syntax analysis Parsing. P3 assigns distinct object-code roles to loader and linker.

Why each choice is right or wrong

A - Incorrect: P3 loads an executable into memory.

B - Incorrect: P3 merges object files.

C - Correct: Parsing is syntax analysis (p5).

D - Incorrect: Scanning produces tokens (p8), prior to parsing.

Primary note proof

Study-note section COMP02

A preprocessor handles directives such as file inclusion and macros. An assembler translates assembly to object code. A linker combines object files and libraries, resolves external symbols and performs relocation. A loader maps an executable into memory and starts it.

Study-note section COMP03

Scanning turns characters into tokens; parsing builds structure; semantics checks declarations and types; synthesis produces implementation code.

MOE Computer Science Exit Exam · Question 26-3

Computer Science Exit Exam practice collection · Question 266

Question 85 | SM0216

Which output does syntax analysis produce when it retains every grammar production and terminal occurrence, including punctuation, without semantic attribute annotation?

A. Concrete syntax tree (parse tree)

B. Annotated parse tree

C. Abstract syntax tree

D. Pattern

Hint

Track where each computed value comes from and when each production action runs. Distinguish the representation from its attached information.

Answer A: Concrete syntax tree (parse tree)

A concrete syntax or parse tree records the grammar productions used, with nonterminal interiors and terminal leaves. Because the specified representation retains grammar scaffolding and punctuation, it is not the abstract syntax tree that omits those details. Semantic attribute values would make an annotated tree, which this question excludes. A lexical pattern is a specification for tokens rather than the parsed program representation.

Why each choice is right or wrong

A - Correct: A full syntax/parse tree records the retained grammar detail.

B - Incorrect: Semantic attribute annotation is expressly excluded.

C - Incorrect: An AST omits the scaffolding and punctuation retained here.

D - Incorrect: A pattern specifies lexical membership rather than parsed program structure.

Primary note proof

Study-note section COMP24

A syntax-directed definition is a CFG with attributes on grammar symbols and semantic rules on productions. An annotated parse tree displays computed attribute values; it is not itself an inherited or synthesized attribute.

Study-note section COMP09

A parse tree shows grammar productions: root S, internal nonterminals, and terminal leaves, with ε sometimes shown for empty productions. Its left-to-right yield is the input. An AST omits grammar scaffolding and punctuation; expression operands are leaves and operators internal nodes. The parser can build either representation, depending on implementation.

Question 86 | SM0219

For a fixed suitable grammar, which listed approaches can be efficient top-down parsers using prediction without backtracking? Select all that apply.

A. Recursive-descent parser

B. Shift-reduce parser

C. Non-recursive predictive parser

D. LR parser

Hint

Use construction direction, lookahead and grammar restrictions. Distinguish algorithm families, implementations and coverage before comparing them.

Answer A, C: Recursive-descent parser; Non-recursive predictive parser

Recursive descent can use lookahead to predict productions without backtracking. Nonrecursive predictive parsing implements the same top-down strategy with an explicit stack and table. Both can run linearly for a fixed suitable grammar. Shift-reduce and LR instead work bottom-up, reducing input toward the start symbol, so they do not meet the specified parsing direction even if they are efficient.

Why each choice is right or wrong

A - Correct: Predictive recursive descent is a supported efficient top-down implementation.

B - Incorrect: Shift-reduce is bottom-up.

C - Correct: Nonrecursive prediction is a supported efficient top-down implementation.

D - Incorrect: LR is bottom-up.

Primary note proof

Study-note section COMP11

> Top-down parsing starts with S and expands productions toward the input, usually constructing a leftmost derivation. Recursive descent typically has one procedure per nonterminal. A general recursive-descent implementation can backtrack; a predictive parser chooses a production using lookahead without backtracking. LL(1) scans Left to right, produces a Leftmost derivation and uses one lookahead token.

Study-note section COMP11

> A nonrecursive predictive parser stores grammar symbols on an explicit stack and consults a table. It is another implementation of predictive parsing, not a wholly different language class. Table-driven and recursive predictive implementations can both be linear for a fixed suitable grammar. Efficiency cannot be ranked from their names alone.

Study-note section COMP15

> Bottom-up parsing starts from input and reduces toward S, constructing a rightmost derivation in reverse.

Computer Science Exit Exam · Sene 2016 · Question 6-3

Question 87 | SM0224

Which abstract data structure naturally represents hierarchical source-program constructs with parent/child relationships, as in a parse tree or AST?

A. 2D-array

B. Stack

C. Tree

D. Queue

Hint

Identify each activity’s input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer C: Tree

A tree represents the hierarchy of program constructs through parent/child relationships. Parse trees preserve grammar detail, while ASTs retain the essential expression and statement structure. Arrays may implement node storage, and stacks or queues may support traversal, but those container roles do not make them the requested hierarchical model. The structure being represented, rather than the storage allocation technique, determines this answer.

Why each choice is right or wrong

A - Incorrect: A 2D array is not the requested abstract hierarchical model.

B - Incorrect: A stack supports processing order rather than the full parent/child model.

C - Correct: A tree directly models hierarchical constructs.

D - Incorrect: A queue supports work ordering rather than the hierarchy itself.

Primary note proof

Study-note section COMP41

> Grouping characters into token classes is lexical analysis; grouping tokens into expressions and statements is syntax analysis.

Study-note section COMP41

> Trees store hierarchical constructs, while a symbol table stores declaration metadata.

Study-note section COMP09

> A context-free grammar G=(N,T,P,S) has nonterminals N, terminals T, productions P and start S. A production A→α rewrites one nonterminal. A sentential form is any string of terminals/nonterminals derivable from S; a sentence contains only terminals. A leftmost derivation rewrites the leftmost remaining nonterminal; a rightmost one rewrites the rightmost.

Study-note section COMP09

> A parse tree shows grammar productions: root S, internal nonterminals, and terminal leaves, with ε sometimes shown for empty productions. Its left-to-right yield is the input. An AST omits grammar scaffolding and punctuation; expression operands are leaves and operators internal nodes. The parser can build either representation, depending on implementation.

Question sources

Computer Science Exit Exam · Sene 2016 · Question 8-2

Computer Science Exit Exam practice collection · Question 142

Question 88 | SM0238

In which phase of the compilation process does the source program get broken into its constituent parts?

A. Semantic Analysis

B. Syntax Analysis

C. Synthesis

D. Lexical Analysis

Hint

Identify each activity's input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer D: Lexical Analysis

PDF p5 scans characters into lexemes represented as tokens. These constituent lexical units precede hierarchical grouping during parsing.

Why each choice is right or wrong

A - Incorrect: P6 checks meaningful compatibility after lexical decomposition.

B - Incorrect: Parsing groups already recognized tokens (p5).

C - Incorrect: P3 calls synthesis machine dependent; it is not the scanning stage.

D - Correct: P5 decomposes the character stream into tokens.

Primary note proof

Study-note section COMP04

A token is a category with optional attribute, such as (ID, symbol-entry) or (INT_LITERAL,42). A lexeme is the actual character sequence, such as total or 42. A pattern specifies which lexemes belong to a token class. The scanner emits an ordered token stream, not an unordered mathematical set.

Study-note section COMP04

Keywords, identifiers, literals, operators and punctuation are token classes. Whitespace and comments are usually skipped while line/column positions are retained. In indentation-sensitive or newline-sensitive languages, layout can carry tokens. Parse-tree construction is a parser task; scanning can intern identifier spellings, but declaration scope and types need later analysis.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Compiler Design module | PDF page 5 | lines 3-11

1. Lexical / Linear Analysis (scanning)
- Scans the source code as a stream of characters
- Represent lexemes in the form of tokens as:
<token-name, attribute-value>
- Token
• smallest meaningful element that a compiler understands.
- Eg.
• Identifiers, Keywords, Literals, Operators and Special symbols.
- Blanks, new lines, comments will be removed from the source program.

Compiler Design module | PDF page 5 | lines 12-18

2. Syntax / Hierarchical Analysis - Parsing
• Tokens are grouped hierarchically into nested collections with collective meaning.
• The result is generally a parse tree.
• expressions, statements, declarations etc... are identified by using the results of lexical analysis.
• Most syntactic errors in the source program are caught in this phase.
• Syntactic rules of the source language are given via a Grammar.

Question sources

Computer Science Exit Exam · Sene 2016 · Question 12-3

Computer Science Exit Exam practice collection · Question 269

Question 89 | SM0265

Which described check requires runtime values rather than being solely a static check? In D, the index depends on input and no static proof of its bounds is available.

A. Type checking for compatibility

B. Uniqueness checks like redefined variables

C. Checking that break is inside an allowed loop or switch

D. Checking an input-dependent array index against runtime bounds, with no static proof available

Hint

Ask whether the required information is a declaration's identity and attributes, program structure or the ordered source tokens.

Answer D: Checking an input-dependent array index against runtime bounds, with no static proof available

Type compatibility, duplicate declarations and valid placement of break can be checked from the source program and its declarations. The specified array index depends on runtime input, and no static bounds proof is available, so its validity requires a runtime check. This does not claim that every memory access fault is inherently undetectable statically; the explicit value-dependent case supplies the distinction.

Why each choice is right or wrong

A - Incorrect: Type compatibility is a static semantic check.

B - Incorrect: Duplicate declarations can be checked statically within the relevant scope.

C - Incorrect: Placement in an allowed loop or switch is a static check.

D - Correct: The stipulated input-dependent bounds need runtime validation.

Primary note proof

Study-note section COMP21

> Static checks occur before execution: type compatibility, duplicate declarations within a restricted scope, valid names, argument counts, return compatibility and control-flow placement. A break is valid only in constructs allowed by the language; in C/C++ it can exit a loop or switch. A compiler may annotate an AST or create typed IR; there is no mandatory uniquely named output tree.

Study-note section COMP21

> Dynamic checks depend on runtime values, such as some bounds and null checks. Static analysis can prove some accesses safe or faulty; "all memory errors cannot be statically checked" is too

strong. Unreachable code is not universally a semantic error: some languages reject it in specified cases, others merely warn or optimize it away.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Compiler Design module | PDF page 14 | lines 16-23

Static Checking
• The compiler must check the semantic conventions of the source language
• Static Checking: ensures that certain kind of errors are detected and reported
• Example
• Type Checks: incompatible operands
• Flow Control Check
• Uniqueness Check
• Name Related Check

Compiler Design module | PDF page 14 | lines 2-15

• Type Errors:
- Improper or inconsistent operations during program execution
• Type-safety:
- Absence of type errors

Type Checking
• Semantic checks to enforce the type safety of the program
• Semantic Checks
- Static - done during compilation
- Dynamic - done during run-time
• Examples
- Unary and binary operators
- Number and type of arguments
- Return statement with return type
- Compatible assignment

Question sources

Computer Science Exit Exam · Sene 2016 · Question 21-2

Computer Science Exit Exam practice collection · Question 271

Question 90 | SM0285

Which tool is used to collect codes separately compiled or assembled in different object files into a file that is directly executable?

A. Linker

B. Loader

C. Assembler

D. Preprocessor

Hint

Identify each activity's input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer A: Linker

A linker combines separately compiled object files and required libraries, resolves their external symbol references and relocates addresses to produce the executable form. An assembler translates assembly into object code before this combination. A loader places the resulting executable in memory and starts it. A preprocessor handles source directives before compilation. These tool roles distinguish object-file combination from translation, source expansion and program loading.

Why each choice is right or wrong

A - Correct: The linker combines object files, resolves symbols and performs relocation.

B - Incorrect: The loader maps an already produced executable into memory.

C - Incorrect: An assembler translates assembly source into object code.

D - Incorrect: A preprocessor handles source directives rather than combining object files.

Primary note proof

Study-note section COMP02

> A preprocessor handles directives such as file inclusion and macros. An assembler translates assembly to object code. A linker combines object files and libraries, resolves external symbols and performs relocation. A loader maps an executable into memory and starts it. Compilation alone does not necessarily produce a ready executable.

Study-note section COMP02

> A cross-compiler runs on a host platform and generates code for a different target. Multiple targets require appropriate backends, not a special definition of cross-compilation. A retargetable compiler supports changing target descriptions. Incremental compilation recompiles affected fragments or dependent units after edits; it is more than literally replacing changed lines. One-pass versus multipass counts traversals, not supported targets.

Module passages - related reading

Computer Science Exit Exam practice collection · Question 272

Question 91 | SS059

Among phases of compiling process, in which phase a sequence of characters are converted into a tokens?

A. Code optimization

B. Syntax analysis

C. Semantic analysis

D. Lexical analysis

Hint

Identify each activity's input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer D: Lexical analysis

PDF pp5,8 gives lexical analysis a character-stream input and a sequence-of-tokens output.

Why each choice is right or wrong

A - Incorrect: Optimization changes intermediate code (p7).

B - Incorrect: Syntax analysis groups tokens already recognized (p5).

C - Incorrect: Semantic analysis checks meaningful fit (p6).

D - Correct: The exact input-output description is on p8.

Primary note proof

Study-note section COMP04

> A token is a category with optional attribute, such as (ID, symbol-entry) or (INT_LITERAL,42). A lexeme is the actual character sequence, such as total or 42. A pattern specifies which lexemes belong to a token class. The scanner emits an ordered token stream, not an unordered mathematical set.

Study-note section COMP04

National Computer Science Exit Exam · Question 61

National Computer Science Exit Exam

Question 92 | AM0779

Which phase of the compiler is responsible for recognizing tokens and building a symbol table?

A. Lexical Analysis

B. Syntax Analysis

C. Semantic Analysis

D. Code Generation

Hint

Ask whether the required information is a declaration’s identity and attributes, program structure or the ordered source tokens.

Answer A: Lexical Analysis

Token recognition uniquely identifies lexical analysis on p5. However, p6 and p17 assign type/name entries to semantic and declaration processing, so building the symbol table must mean contributing lexical identifier entries, not constructing every attribute exclusively.

Why each choice is right or wrong

A - Correct: P5 explicitly recognizes tokens; A is supported for that decisive responsibility.

B - Incorrect: Parsing groups tokens rather than recognizing the character stream (p5).

C - Incorrect: P6 stores types in the symbol table but does not perform lexical token recognition.

D - Incorrect: P7 converts intermediate code into machine code.

Primary note proof

Study-note section COMP19

Scanning may intern a spelling first; semantic analysis determines the declaration and type. Implementations differ, so first interaction is conventional rather than universal.

Study-note section COMP04

A token is a category with optional attribute, such as (ID, symbol-entry) or (INT_LITERAL,42). A lexeme is the actual character sequence, such as total or 42. A pattern specifies which lexemes belong to a token class. The scanner emits an ordered token stream, not an unordered mathematical set.

• Involves allocation of space in memory &
• Entry of type and name in symbol table
• Off set variable (Offset=0) is used to denote the base address

```
int a; float b;
Allocation process: { offset = 0 }
int a;
id.type = int
id.width = 2
offset = offset + id.width { offset = 2 }
float b;
id.type=float
id.width=4
offset = offset +id.width { offset = 6 }
```

Question sources

Computer Science MCQ practice collection · Question 779

Question 93 | AM0780

What is the primary ordered output of lexical analysis passed to the parser?

A. Abstract Syntax Tree (AST)

B. Ordered token stream

C. Intermediate Code

D. Assembly Code

Hint

Identify each activity's input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer B: Ordered token stream

Lexical analysis groups characters into lexemes and emits an ordered token stream, including token categories and relevant attributes. The parser consumes that stream to build grammatical structure. A symbol table may be updated as an auxiliary service, but it is not the primary ordered output. ASTs, intermediate code and assembly belong to later processing stages in the conventional pipeline.

Why each choice is right or wrong

A - Incorrect: AST construction follows scanning during parsing or syntax-directed work.

B - Correct: The ordered token stream is the parser's input.

C - Incorrect: Intermediate code follows syntactic and semantic processing.

D - Incorrect: Assembly is a possible later target output.

Primary note proof

Study-note section COMP41

Grouping characters into token classes is lexical analysis; grouping tokens into expressions and statements is syntax analysis.

Study-note section COMP41

Trees store hierarchical constructs, while a symbol table stores declaration metadata.

Study-note section COMP04

A token is a category with optional attribute, such as (ID, symbol-entry) or (INT_LITERAL,42). A lexeme is the actual character sequence, such as total or 42. A pattern specifies which lexemes belong to a token class. The scanner emits an ordered token stream, not an unordered mathematical set.

Study-note section COMP04

Keywords, identifiers, literals, operators and punctuation are token classes. Whitespace and comments are usually skipped while line/column positions are retained. In indentation-sensitive or newline-sensitive languages, layout can carry tokens. Parse-tree construction is a parser task; scanning can intern identifier spellings, but declaration scope and types need later analysis.

Question 94 | AM0781

Which phase of the compiler is responsible for checking the correctness of the program's structure?

A. Lexical Analysis

B. Syntax Analysis

C. Semantic Analysis

D. Code Generation

Hint

Identify each activity's input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer B: Syntax Analysis

PDF p5 groups tokens by grammar and catches most syntactic errors. Program structure here means syntactic structure, so B applies.

Why each choice is right or wrong

A - Incorrect: Recognizes lexical units rather than their grammatical arrangement (p5).

B - Correct: Checks grammar-governed hierarchy and syntactic errors (p5).

C - Incorrect: Checks meaning and type mismatch (p6).

D - Incorrect: Translates intermediate code into machine code (p7).

Primary note proof

Study-note section COMP04

> Keywords, identifiers, literals, operators and punctuation are token classes. Whitespace and comments are usually skipped while line/column positions are retained. In indentation-sensitive or newline-sensitive languages, layout can carry tokens. Parse-tree construction is a parser task; scanning can intern identifier spellings, but declaration scope and types need later analysis.

Study-note section COMP09

> A parse tree shows grammar productions: root S, internal nonterminals, and terminal leaves, with ε sometimes shown for empty productions. Its left-to-right yield is the input.

Computer Science MCQ practice collection · Question 781

Question 95 | AM0782

Which component of the compiler generates an Abstract Syntax Tree (AST)?

A. Lexical Analyzer

B. Parser

C. Semantic Analyzer

D. Code Generator

Hint

Identify each activity's input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer B: Parser

PDF p5 gives parsing the tree-building role. P12 says syntax-directed actions execute according to parsing, and pp12-13 give operator/operand syntax-tree constructors. Together these support parser as the component building the abstract structural tree.

Why each choice is right or wrong

A - Incorrect: Lexical analysis emits tokens (p8).

B - Correct: Parsing builds a tree (p5), with syntax-directed tree constructors on pp12-13.

C - Incorrect: Semantic analysis may annotate the existing tree (p6); it is not the phase assigned general syntactic tree construction.

D - Incorrect: Code generation translates intermediate code (p7).

Primary note proof

Study-note section COMP04

Keywords, identifiers, literals, operators and punctuation are token classes. Whitespace and comments are usually skipped while line/column positions are retained. In indentation-sensitive or newline-sensitive languages, layout can carry tokens. Parse-tree construction is a parser task; scanning can intern identifier spellings, but declaration scope and types need later analysis.

Study-note section COMP09

A parse tree shows grammar productions: root S, internal nonterminals, and terminal leaves, with ε sometimes shown for empty productions. Its left-to-right yield is the input.

Computer Science MCQ practice collection · Question 792

Question 96 | AM0783

What does the semantic analysis phase of the compiler focus on?

A. Identifying syntax errors

B. Analyzing the meaning of program statements

C. Generating intermediate code

D. Translating source code to machine code

Hint

Ask whether the required information is a declaration's identity and attributes, program structure or the ordered source tokens.

Answer B: Analyzing the meaning of program statements

PDF p6 defines semantic analysis through meaningful fit and type-mismatch checks, directly supporting B.

Why each choice is right or wrong

A - Incorrect: Most syntactic errors are assigned to parsing on p5.

B - Correct: Meaningful compatibility is the explicit semantic task (p6).

C - Incorrect: Intermediate generation is separately headed on p6.

D - Incorrect: Machine-code translation is code generation (p7).

Primary note proof

Study-note section COMP21

> Static checks occur before execution: type compatibility, duplicate declarations within a restricted scope, valid names, argument counts, return compatibility and control-flow placement. A break is valid only in constructs allowed by the language; in C/C++ it can exit a loop or switch. A compiler may annotate an AST or create typed IR; there is no mandatory uniquely named output tree.

Study-note section COMP21

> Dynamic checks depend on runtime values, such as some bounds and null checks. Static analysis can prove some accesses safe or faulty; "all memory errors cannot be statically checked" is too strong. Unreachable code is not universally a semantic error: some languages reject it in specified cases, others merely warn or optimize it away.

Question sources

Computer Science MCQ practice collection · Question 783

Question 97 | AM0784

Which phase of the compiler performs type checking and enforces semantic rules?

A. Lexical Analysis

B. Syntax Analysis

C. Semantic Analysis

D. Code Generation

Hint

Check operand compatibility and permitted conversions under the stated language rules; distinguish grammatical structure from semantic meaning.

Answer C: Semantic Analysis

PDF p6 explicitly names type checking as one of the most important semantic-analysis tasks.

Why each choice is right or wrong

A - Incorrect: Scanning recognizes tokens (p5).

B - Incorrect: Parsing checks grammatical hierarchy (p5).

C - Correct: Type checking is explicitly here (p6).

D - Incorrect: Code generation converts intermediate code (p7).

Primary note proof

Study-note section COMP22

> A type checker verifies that operations are defined for their operands. In a simple strict language, integer mod requires two integers; array indexing requires an array and integer index; an if condition requires Boolean; assignment requires equal or convertible types. Function calls check parameter count and compatibility, and returns match result types.

Study-note section COMP22

> Type inference derives types from constraints: if x is integer and + expects numeric operands, infer the expression type from numeric promotion rules. It is a static technique even without explicit annotations. Operator overloading supplies multiple operation meanings, not a substitute for type checking. int x="hello" is a type mismatch in ordinary C++/Java; division by zero and bounds violations are not automatically operand-type mismatches.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Compiler Design module | PDF page 6 | lines 2-10

> 3. Semantic Analysis

Question 98 | AM0785

Which phase of the compiler translates the intermediate representation into the target machine code?

A. Lexical Analysis

B. Syntax Analysis

C. Semantic Analysis

D. Code Generation

Hint

Identify each activity's input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer D: Code Generation

PDF p7 states that code generation converts intermediate code to machine code.

Why each choice is right or wrong

A - Incorrect: Scanning works on source characters (p5).

B - Incorrect: Parsing groups tokens (p5).

C - Incorrect: Semantic analysis checks types and meaning (p6).

D - Correct: Matches the explicit conversion on p7.

Primary note proof

Study-note section COMP34

> Code generation lowers checked IR to a target form. Instruction selection chooses target operations; register allocation chooses where values reside; scheduling orders instructions while respecting dependencies; storage layout assigns offsets and follows ABI requirements. Register assignment names actual physical registers after allocation decisions.

Study-note section COMP34

> For t=a+b, a simple target could emit LOAD R1,a; LOAD R2,b; ADD R3,R1,R2; STORE t,R3. Other targets may combine loads with arithmetic or keep t in a register. Machine idioms, register availability and instruction order affect execution time.

Computer Science MCQ practice collection · Question 785

Computer Science MCQ practice collection · Question 794

Question 99 | AM0786

What is the primary goal of the code optimization phase in compiler design?

A. To reduce the size of the source code

B. To eliminate syntax errors

C. To improve the performance of the generated code

D. To generate human-readable code

Hint

Trace whether computation is evaluated, moved, shared or removed. Preserve observable effects and use the stated arithmetic and target assumptions.

Answer C: To improve the performance of the generated code

PDF p7 names improvement in time, space, or power; p17 adds faster execution, efficient memory, and preserving meaning. Thus improving generated-code performance is the best statement.

Why each choice is right or wrong

A - Incorrect: Source text length is not the optimization goal.

B - Incorrect: Syntax errors are caught by parsing (p5); optimization assumes meaningful code to improve.

C - Correct: Matches the performance goal on p17.

D - Incorrect: Human readability is not the goal listed on pp7,17.

Primary note proof

Study-note section COMP30

> Constant folding evaluates constant expressions during compilation: 3*4→12. Constant propagation substitutes known values: x=3; y=x+2 becomes y=3+2 before folding. Copy propagation substitutes a copied name while its source remains unchanged. Dead-code elimination removes unreachable code or computations whose values are unused and whose evaluation has no necessary side effects.

Question sources

Computer Science MCQ practice collection · Question 786

Question 100 | AM0787

For E→E+E|E*E|id, which technique resolves the ambiguity by requiring * to bind more tightly than + and both operators to associate left?

A. Parsing with explicit operator precedence and left-associativity rules

B. Lexical analysis

C. Semantic analysis

D. Leftmost derivation

Hint

Identify each activity’s input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer A: Parsing with explicit operator precedence and left-associativity rules

The grammar permits multiple groupings of expressions such as id+id*id. An explicit precedence and associativity policy selects multiplication before addition and left association within each level. A parser may enforce this through declarations or a grammar rewrite. Lexical analysis and generic semantic checking do not themselves establish that policy, and taking a leftmost derivation does not remove the competing parse trees.

Why each choice is right or wrong

A - Correct: The stated policy selects the intended grouping.

B - Incorrect: Token recognition does not determine operator grouping.

C - Incorrect: Generic semantic checking supplies no stated grouping policy.

D - Incorrect: An ambiguous grammar can have multiple leftmost derivations.

Primary note proof

Study-note section COMP10

A grammar is ambiguous if at least one terminal string has two different parse trees, equivalently two leftmost derivations. Merely changing derivation order on the same tree does not establish ambiguity. E→E+E|E*E|id allows different trees for id+id*id.

Study-note section COMP10

Use E→E+T|T, T→T*F|F, F→(E)|id to give * higher precedence and both operators left associativity. For subtraction, a−b−c then groups (a−b)−c. The dangling-else grammar permits else to attach to either nested if; a nearest-unmatched-if rule or grammar rewrite resolves it. Taking a leftmost derivation by itself does not resolve ambiguous interpretation.

Compiler Design module | PDF page 9 | lines 6-16

Grammars
• Every programming language has grammar rules
• Parsers or syntax analyzers are generated for a particular grammar
• CFG are used for syntax specification of programming languages
Context Free Grammar (CFG)
• Is denoted as G = (N, T , P, S)
• N : finite set of non-terminals
• T : finite set of terminals
• S ∈ N: The start symbol
• P : Finite set of productions, each of the form A→α, where A∈N and α ∈ (N U T)*

Compiler Design module | PDF page 10 | lines 11-17

Parsing
• Process of constructing parse tree for a sentence generated by a given grammar.
• 2 types of parsers
● Top down parsing (predictive parsers)
• LL(1)
● Bottom up parsing (SR parsers)
• LR(1)

Compiler Design module | PDF page 11 | lines 2-17

LL(1) Grammar
• L - left to right
• L - left most derivation
• 1 - number of look ahead
• First( ) and Follow( )
● the first terminal in a string and the terminal that follows a variable respectively.
LR Parsing
• LR(k) - Left to right scanning with Rightmost derivation in reverse, k being the number

of lookahead tokens.
Types of LR Parsers
• LR (0) , SLR (1) , LALR (1) , CLR (1)
LL LR
Leftmost derivation Rightmost derivation in reverse
Starts with root non-terminal on stack Ends with root non-terminal on the stack
Builds the parse tree top-down Builds the parse tree bottom-up
Expands the non-terminals Reduces the non-terminals

Question sources

Computer Science MCQ practice collection · Question 787

Question 101 | AM0788

What is the purpose of semantic rules in a programming language?

A. To define the syntax of the language

B. To specify the order of execution of statements

C. To enforce the correct use of language constructs

D. To optimize the generated code

Hint

Ask whether the required information is a declaration’s identity and attributes, program structure or the ordered source tokens.

Answer C: To enforce the correct use of language constructs

PDF p6 checks that program components fit together meaningfully and p14 requires semantic conventions to hold. C captures those constraints on use of language constructs.

Why each choice is right or wrong

A - Incorrect: Grammatical structure is assigned to syntax analysis (p5).

B - Incorrect: Execution order alone does not capture the type/compatibility constraints on pp6,14.

C - Correct: Correct semantic use follows the cited compatibility and convention checks.

D - Incorrect: Optimization is separately concerned with efficiency (p7).

Primary note proof

Study-note section COMP21

Static checks occur before execution: type compatibility, duplicate declarations within a restricted scope, valid names, argument counts, return compatibility and control-flow placement. A break is valid only in constructs allowed by the language; in C/C++ it can exit a loop

or switch. A compiler may annotate an AST or create typed IR; there is no mandatory uniquely named output tree.

Study-note section COMP21

Dynamic checks depend on runtime values, such as some bounds and null checks. Static analysis can prove some accesses safe or faulty; “all memory errors cannot be statically checked” is too strong. Unreachable code is not universally a semantic error: some languages reject it in specified cases, others merely warn or optimize it away.

Computer Science MCQ practice collection · Question 788

Question 102 | AM0789

Which of the following is responsible for recognizing keywords and identifiers in a programming language?

A. Lexical Analyzer

B. Parser

C. Semantic Analyzer

D. Code Generator

Hint

Identify each activity's input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer A: Lexical Analyzer

PDF p5 lists identifiers and keywords among lexical tokens, and p8 explains their token classes.

Why each choice is right or wrong

A - Correct: Recognizes the token classes explicitly listed on pp5,8.

B - Incorrect: Parser consumes tokens already recognized (p9).

C - Incorrect: Semantic analysis checks type and meaning (p6).

D - Incorrect: Code generation produces machine code (p7).

Primary note proof

Study-note section COMP04

> A token is a category with optional attribute, such as (ID, symbol-entry) or (INT_LITERAL,42). A lexeme is the actual character sequence, such as total or 42. A pattern specifies which lexemes belong to a token class. The scanner emits an ordered token stream, not an unordered mathematical set.

Study-note section COMP04

> Keywords, identifiers, literals, operators and punctuation are token classes. Whitespace and comments are usually skipped while line/column positions are retained. In indentation-sensitive or newline-sensitive languages, layout can carry tokens. Parse-tree construction is a parser task; scanning can intern identifier spellings, but declaration scope and types need later analysis.

Question 103 | AM0791

Which phase of the compiler is responsible for checking the syntax of the program?

A. Lexical Analysis

B. Syntax Analysis

C. Semantic Analysis

D. Code Generation

Hint

Identify each activity's input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer B: Syntax Analysis

PDF p5 names syntax analysis Parsing and assigns it grammatical hierarchy and most syntactic-error detection.

Why each choice is right or wrong

A - Incorrect: Scanning identifies lexemes, not grammar structure (p5).

B - Correct: Directly matches the syntax-checking phase on p5.

C - Incorrect: P6 concerns semantic errors such as type mismatch.

D - Incorrect: P7 concerns machine-code generation.

Primary note proof

Study-note section COMP04

Keywords, identifiers, literals, operators and punctuation are token classes. Whitespace and comments are usually skipped while line/column positions are retained. In indentation-sensitive or newline-sensitive languages, layout can carry tokens. Parse-tree construction is a parser task; scanning can intern identifier spellings, but declaration scope and types need later analysis.

Study-note section COMP09

A parse tree shows grammar productions: root S, internal nonterminals, and terminal leaves, with ε sometimes shown for empty productions. Its left-to-right yield is the input.

Module passages - related reading

Compiler Design module | PDF page 5 | lines 12-18

> 2. Syntax / Hierarchical Analysis - Parsing
> • Tokens are grouped hierarchically into nested collections with collective meaning.
> • The result is generally a parse tree.
> • expressions, statements, declarations etc... are identified by using the results of lexical analysis.
> • Most syntactic errors in the source program are caught in this phase.
> • Syntactic rules of the source language are given via a Grammar.

Question sources

Computer Science MCQ practice collection · Question 791

Question 104 | AM0793

What is the main goal of the semantic analysis phase in compiler design?

A. To check the syntax of the program

B. To generate intermediate code

C. To perform type checking and enforce semantic rules

D. To translate the source code to machine code

Hint

Check operand compatibility and permitted conversions under the stated language rules; distinguish grammatical structure from semantic meaning.

Answer C: To perform type checking and enforce semantic rules

PDF p6 checks meaningful fit, detects semantic errors, and explicitly emphasizes type checking.

Why each choice is right or wrong

A - Incorrect: Syntactic structure is checked in parsing (p5).

B - Incorrect: Intermediate generation is a separate phase (p6).

C - Correct: Matches both semantic compatibility and type checking on p6.

D - Incorrect: Machine-code conversion belongs to code generation (p7).

Primary note proof

Study-note section COMP22

> A type checker verifies that operations are defined for their operands. In a simple strict language, integer mod requires two integers; array indexing requires an array and integer index; an if condition requires Boolean; assignment requires equal or convertible types. Function calls check parameter count and compatibility, and returns match result types.

Study-note section COMP22

Type inference derives types from constraints: if x is integer and + expects numeric operands, infer the expression type from numeric promotion rules. It is a static technique even without explicit annotations. Operator overloading supplies multiple operation meanings, not a substitute for type checking. int x="hello" is a type mismatch in ordinary C++/Java; division by zero and bounds violations are not automatically operand-type mismatches.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Question sources

Computer Science MCQ practice collection · Question 793

Question 105 | AM0795

What is the purpose of an Abstract Syntax Tree (AST)?

A. To store the program's symbol table

B. To generate assembly code

C. To visualize the program's control flow

D. To represent the hierarchical structure of the program

Hint

Identify each activity’s input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer D: To represent the hierarchical structure of the program

PDF pp12-13 represents a-4+c through identifier/number leaves and operator nodes linked by child pointers. This encodes the expression hierarchy, supporting D.

Why each choice is right or wrong

A - Incorrect: P13 leaves may point to a symbol-table entry, but the whole tree is not the symbol table.

B - Incorrect: P7 assigns machine-code production to code generation; that is not the tree definition.

C - Incorrect: The illustrated tree encodes expression operators and operands, not control-flow paths.

D - Correct: Operator-child nesting on pp12-13 represents program syntax hierarchy.

Primary note proof

Study-note section COMP04

> Keywords, identifiers, literals, operators and punctuation are token classes. Whitespace and comments are usually skipped while line/column positions are retained. In indentation-sensitive or newline-sensitive languages, layout can carry tokens. Parse-tree construction is a parser task; scanning can intern identifier spellings, but declaration scope and types need later analysis.

Question sources

Computer Science MCQ practice collection · Question 795

Question 106 | AM0796

What does the symbol table in a compiler store?

A. Intermediate code

B. Machine code

C. Source code

D. Information about identifiers and their attributes

Hint

Ask whether the required information is a declaration's identity and attributes, program structure or the ordered source tokens.

Answer D: Information about identifiers and their attributes

PDF p17 puts names and types in the symbol table; p6 adds variables, function parameters, and array dimensions. P13 points identifier leaves to table entries. This is identifier information and attributes.

Why each choice is right or wrong

A - Incorrect: Intermediate code has separate statement representations (pp15-16).

B - Incorrect: Machine code is output of code generation (p7).

C - Incorrect: The cited table entries are names/types, not the full source text.

D - Correct: Names and type attributes are explicitly stored (pp6,17).

Primary note proof

Study-note section COMP19

A symbol table maps names or symbol identities to attributes: type, scope, width, storage offset, parameter signature, constant information or linkage. A hash table gives expected O(1) insertion/lookup with suitable hashing; a stack of scope tables supports lexical nesting. Search the nearest scope first, insert declarations in the current scope, and remove visibility when leaving it.

Study-note section COMP19

Scanning may intern a spelling first; semantic analysis determines the declaration and type. Implementations differ, so first interaction is conventional rather than universal. Not every

punctuation token needs a symbol-table entry; literals may use a separate literal table. A hash table is an implementation, not the information’s semantic role.

Question 107 | AM0797

Which phase of the compiler performs type checking?

A. Lexical Analysis

B. Syntax Analysis

C. Semantic Analysis

D. Code Generation

Hint

Check operand compatibility and permitted conversions under the stated language rules; distinguish grammatical structure from semantic meaning.

Answer C: Semantic Analysis

PDF p6 explicitly places type checking in semantic analysis.

Why each choice is right or wrong

A - Incorrect: Scanning turns characters into tokens (p5).

B - Incorrect: Parsing groups tokens and checks syntax (p5).

C - Correct: P6 explicitly names this task.

D - Incorrect: Generation converts intermediate to machine code (p7).

Primary note proof

Study-note section COMP22

> A type checker verifies that operations are defined for their operands. In a simple strict language, integer mod requires two integers; array indexing requires an array and integer index; an if condition requires Boolean; assignment requires equal or convertible types. Function calls check parameter count and compatibility, and returns match result types.

Question sources

Computer Science MCQ practice collection · Question 797

Question 108 | AM0798

What is the purpose of intermediate code in compiler design?

A. To optimize the program's execution

B. To generate assembly code

C. To represent the program's semantics in a platform-independent form

D. To visualize the program's control flow

Hint

Identify what the representation stores, what it omits and which later transformations it must support; separate a representation property from an algorithmic task.

Answer C: Represent program meaning in a reusable, substantially platform-independent intermediate form.

COMP26 identifies separation of source analysis and target implementation as IR's architectural purpose, allowing reuse across targets. C expresses that purpose best. Optimization and assembly generation are operations enabled by the representation, while a control-flow graph is one possible representation aspect. Platform independence is a design benefit here, not a claim that every IR has no target details.

Why each choice is right or wrong

A - Incorrect: Optimization is enabled by IR, but it is not the general representational purpose distinguishing this choice.

B - Incorrect: Assembly is one possible later output; an IR need not be tied to assembly generation.

C - Correct: A reusable representation of program semantics separates front-end meaning from target-specific implementation.

D - Incorrect: Control-flow visualization is one possible use and does not exhaust the purpose of IR.

Primary note proof

Study-note section COMP26

IR separates source analysis from target implementation, allowing optimizers and backends to be reused. It should be easy to generate, analyze, transform and lower.

Study-note section COMP26

Ordinary TAC arithmetic has at most one operation, two sources and one destination: t1=c*d; t2=b+t1; a=t2. Quadruples store (op,arg1,arg2,result); triples omit an explicit result field and refer to instruction positions. Indirect triples reference a separate ordering list, easing rearrangement. Trees describe expressions; DAGs share common subexpressions, while quadruples/triples are instruction-record structures.

- a = b + c , x = -y , if a > b goto L1
• LHS is the target
• RHS has at most two sources and one operator

Question sources

Computer Science MCQ practice collection · Question 798

Question 109 | AM0799

Which of the following is used to generate a lexical analyzer for a programming language?

A. Finite Automaton

B. Context-Free Grammar

C. Pushdown Automaton

D. Turing Machine

Hint

Follow the representation at each construction step and apply the pattern or state-set rules consistently, including empty cases.

Answer A: A finite automaton.

COMP06 describes converting regular expressions to an NFA and then a DFA. This is the automaton construction used for ordinary generated token recognizers. CFGs and pushdown machinery address nested syntax rather than the regular token-pattern mechanism; a Turing machine is not the specific scanner model in the supplied construction.

Why each choice is right or wrong

A - Correct: NFA/DFA finite automata implement recognition of regular token patterns in the stated generator pipeline.

B - Incorrect: CFGs describe nested syntactic structure rather than the regular scanner-automaton construction.

C - Incorrect: Pushdown machinery adds a stack for context-free structure and is not the ordinary token-recognizer construction.

D - Incorrect: A Turing machine is more general but is not the specific model used in this scanner-generation pipeline.

Primary note proof

Study-note section COMP06

> A common generator pipeline is regular expressions → NFA using Thompson construction → DFA using subset construction; minimization is optional. For concatenation rs, connect r's final state to s's start by ε. Alternation introduces branching ε paths; star adds a way to skip and repeat the fragment.

Study-note section COMP06

> The ε-closure of states includes those reachable by zero or more ε edges. A DFA state is a set of NFA states; its a-transition is ε-closure(move(set,a)). Start with the NFA start closure, repeatedly add unseen subsets, and mark subsets containing an NFA final state as accepting. Token identity and rule priority annotate accepting states; the empty subset acts as a dead state.

Question 110 | AM0800

What is the purpose of a lexical analyzer in a compiler?

A. To check the syntax of the program

B. To generate intermediate code

C. To perform type checking

D. To recognize and tokenize the input source code

Hint

Identify each activity's input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer D: To recognize and tokenize the input source code

PDF p8 gives the scanner a high-level source-program input and sequence-of-tokens output.

Why each choice is right or wrong

A - Incorrect: Syntax checking belongs to parsing (p5).

B - Incorrect: Intermediate generation is separate (p6).

C - Incorrect: Type checking belongs to semantic analysis (p6).

D - Correct: Directly matches p8 input and output.

Primary note proof

Study-note section COMP04

> A token is a category with optional attribute, such as (ID, symbol-entry) or (INT_LITERAL,42). A lexeme is the actual character sequence, such as total or 42. A pattern specifies which lexemes belong to a token class. The scanner emits an ordered token stream, not an unordered mathematical set.

Study-note section COMP04

> Keywords, identifiers, literals, operators and punctuation are token classes. Whitespace and comments are usually skipped while line/column positions are retained. Question sources

Computer Science MCQ practice collection · Question 800

Question 111 | AM0801

Which listed notation directly specifies ordinary token patterns using alternation, concatenation and repetition, rather than a general production notation or a tree of one program?

A. Regular Expressions

B. Context-Free Grammars

C. Backus-Naur Form (BNF)

D. Abstract Syntax Trees (AST)

Hint

Follow the representation at each construction step and apply the pattern or state-set rules consistently, including empty cases.

Answer A: Regular Expressions

Classical regular expressions combine alternation, concatenation and repetition to specify ordinary token patterns. CFGs and BNF are production-based grammar descriptions and can also describe regular languages, so mere expressive capability would not distinguish them. An AST represents the analyzed structure of a particular program. The revised comparison asks for the direct pattern notation characterized by its operators, making regular expressions the specific answer.

Why each choice is right or wrong

A - Correct: Regular expressions directly use the stated pattern-combination operators.

B - Incorrect: A CFG is a general production grammar, not the direct expression notation described.

C - Incorrect: BNF is a notation for context-free productions.

D - Incorrect: An AST represents one analyzed program structure rather than the permitted token patterns.

Primary note proof

Study-note section COMP05

> Regular expressions use concatenation, alternation r|s, Kleene star r* for zero or more, and r+ for one or more. In a simplified alphabet, identifier = Letter(Letter|Digit)*; it permits a single letter and forbids a leading digit. A C-like ASCII rule commonly also allows underscore: [A-Za-z_][A-Za-z0-9_]*
> State the convention instead of claiming this covers every language's identifiers.

Study-note section COMP-S02

> Backus-Naur form, or BNF, is a notation for context-free grammar production rules. It describes how syntactic constructs are formed; it is different from an abstract syntax tree representing one particular program.

Study-note section COMP09

> An AST omits grammar scaffolding and punctuation; expression operands are leaves and operators internal nodes. The parser can build either representation, depending on implementation.

Grammars
• Every programming language has grammar rules
• Parsers or syntax analyzers are generated for a particular grammar
• CFG are used for syntax specification of programming languages
Context Free Grammar (CFG)
• Is denoted as G = (N, T , P, S)
• N : finite set of non-terminals
• T : finite set of terminals
• S ∈ N: The start symbol
• P : Finite set of productions, each of the form A→α, where A∈N and α ∈ (N U T)*

Question sources

Computer Science MCQ practice collection · Question 801

Question 112 | AM0802

Which listed parsing approaches can handle arbitrarily nested parenthesized expressions for suitable grammars and stack-based implementations? Select all that apply.

A. LL Parsing

B. LR Parsing

C. Recursive Descent Parsing

D. Operator Precedence Parsing

Hint

Use construction direction, lookahead and grammar restrictions. Distinguish algorithm families, implementations and coverage before comparing them.

Answer A, B, C, D: LL Parsing; LR Parsing; Recursive Descent Parsing; Operator Precedence Parsing

Nested parentheses require remembering unfinished surrounding expressions. LL and LR parsers use a parsing stack, recursive descent uses the call stack, and suitable operator-precedence expression parsing also uses stack structure and precedence relations. Each can therefore handle the stipulated nested expressions for an appropriate grammar. The existence of nesting alone does not distinguish one of these parser families from the others.

Why each choice is right or wrong

A - Correct: LL can parse a suitable nested-expression grammar using its stack.

B - Correct: LR can recognize the nesting with bottom-up stack actions.

C - Correct: Recursive descent processes nested expressions through recursive calls.

D - Correct: A suitable operator-precedence parser supports parenthesized subexpressions.

Primary note proof

Study-note section COMP18

LL, LR and recursive-descent parsers can all handle nested parentheses for suitable grammars. An explicit or implicit stack, not the LR label alone, supports unbounded nesting.

Study-note section COMP-S01

Operator-precedence parsing is a restricted bottom-up expression-parsing method using a stack and precedence relations. With a suitable expression grammar, the stack retains unfinished surrounding expressions while nested parentheses are processed.

• F → digit F.val = digit.lexval

Question sources

Computer Science MCQ practice collection · Question 802

Question 113 | AM0803

Which parsing technique builds the parse tree from the bottom-up?

A. LL Parsing

B. LR Parsing

C. Recursive Descent Parsing

D. Top-Down Parsing

Hint

Use construction direction, lookahead and grammar restrictions. Distinguish algorithm families, implementations and coverage before comparing them.

Answer B: LR Parsing

LR parsing constructs the parse tree bottom-up, reducing handles that correspond to a rightmost derivation in reverse. LL methods construct from the start symbol toward the input and are top-down. Recursive descent normally implements one procedure per nonterminal, also expanding top-down. The generic top-down option states the opposite construction direction. These are implementation and derivation distinctions, not a ranking of their execution speed.

Why each choice is right or wrong

A - Incorrect: LL parsing expands a leftmost derivation from the start symbol.

B - Correct: LR parsing reduces input handles and builds bottom-up.

C - Incorrect: Recursive-descent procedures expand grammar nonterminals top-down.

D - Incorrect: Top-down construction starts from the root, the opposite direction.

Primary note proof

Study-note section COMP11

Top-down parsing starts with S and expands productions toward the input, usually constructing a leftmost derivation. Recursive descent typically has one procedure per nonterminal. A general

recursive-descent implementation can backtrack; a predictive parser chooses a production using lookahead without backtracking. LL(1) scans Left to right, produces a Leftmost derivation and uses one lookahead token.

Study-note section COMP15

Bottom-up parsing starts from input and reduces toward S, constructing a rightmost derivation in reverse.

Question sources

Computer Science MCQ practice collection · Question 803

Question 114 | AM0804

Which is the most specific listed name for a stack-based expression parsing method using pairwise operator-precedence relations in a suitable conflict-free operator grammar?

A. Precedence Parsing

B. Operator Precedence Parsing

C. LR Parsing

D. LL Parsing

Hint

Use construction direction, lookahead and grammar restrictions. Distinguish algorithm families, implementations and coverage before comparing them.

Answer B: Operator Precedence Parsing

Operator-precedence parsing applies precedence relations to a suitable operator grammar to choose expression parsing actions. The question specifies that concrete method rather than asking for a universal cure for shift/reduce conflicts. Precedence parsing is a broader label, while LR and LL name larger parser families without supplying these particular relations. Therefore B is the most specific match to the described technique.

Why each choice is right or wrong

A - Incorrect: Precedence parsing is broader than the specific method requested.

B - Correct: Operator-precedence parsing directly names this method.

C - Incorrect: LR alone does not specify the operator-precedence method.

D - Incorrect: LL alone does not specify the operator-precedence method.

Primary note proof

Study-note section COMP18

> An operator grammar conventionally forbids adjacent nonterminals on a RHS and usually ε productions. Operator-precedence parsing additionally requires conflict-free precedence relations.

Study-note section COMP-S01

> Operator-precedence parsing is a restricted bottom-up expression-parsing method using a stack and precedence relations. With a suitable expression grammar, the stack retains unfinished surrounding expressions while nested parentheses are processed.

Study-note section COMP11

Top-down parsing starts with S and expands productions toward the input, usually constructing a leftmost derivation. Recursive descent typically has one procedure per nonterminal. A general recursive-descent implementation can backtrack; a predictive parser chooses a production using lookahead without backtracking. LL(1) scans Left to right, produces a Leftmost derivation and uses one lookahead token.

Question sources

Computer Science MCQ practice collection · Question 804

Question 115 | AM0805

Which listed parsing categories have a standard table-driven implementation that uses lookahead to select the next parsing action? Select all that apply. For C, mean ordinary procedure-based recursive descent with choices encoded directly in code.

A. LL Parsing

B. LR Parsing

C. Recursive Descent Parsing

D. Top-Down Parsing

Hint

Use construction direction, lookahead and grammar restrictions. Distinguish algorithm families, implementations and coverage before comparing them.

Answer A, B, D: LL Parsing; LR Parsing; Top-Down Parsing

A nonrecursive LL parser consults a nonterminal/lookahead table to select productions. LR parsers use ACTION and GOTO tables for shifts, reductions and state changes. Table-driven predictive parsing is also a top-down implementation, so the broader D category applies. The stipulated ordinary recursive-descent alternative encodes decisions directly in procedures instead of consulting an explicit parsing table. Thus A, B and D are selected.

Why each choice is right or wrong

A - Correct: Table-driven LL selects productions from lookahead entries.

B - Correct: LR uses ACTION/GOTO tables.

C - Incorrect: The stipulated implementation encodes decisions in procedures rather than an explicit table.

D - Correct: Nonrecursive predictive parsing is a table-driven top-down method.

Primary note proof

Study-note section COMP18

> Both LL and LR can use parsing tables.

Study-note section COMP11

> A nonrecursive predictive parser stores grammar symbols on an explicit stack and consults a table.

Question sources

Computer Science MCQ practice collection · Question 805

Question 116 | AM0806

Which parsing technique is more suitable for handling left-recursive grammar rules?

A. LL Parsing

B. LR Parsing

C. Recursive Descent Parsing

D. Top-Down Parsing

Hint

Use construction direction, lookahead and grammar restrictions. Distinguish algorithm families, implementations and coverage before comparing them.

Answer B: LR parsing.

COMP12 states that suitable left-recursive grammars are handled by LR parsers, while ordinary unmodified recursive descent can recurse forever without consuming input. LL/top-down prediction generally needs left recursion removed first. This directly supports LR as the suitable choice, without claiming LR accepts every possible left-recursive grammar.

Why each choice is right or wrong

A - Incorrect: Ordinary LL prediction requires eliminating left recursion rather than directly exploiting it.

B - Correct: LR can directly handle suitable left-recursive grammar rules using bottom-up recognition.

C - Incorrect: Unmodified recursive descent can recurse indefinitely before consuming input on a left-recursive rule.

D - Incorrect: Ordinary top-down prediction needs recursion removal; it is not the suitable direct handling choice.

Primary note proof

Study-note section COMP12

Immediate left recursion has A→Aα. For A→Aα|β, where β does not start with A, introduce a new nonterminal A′ and use:
A→βA′
A′→αA′|ε
This preserves the generated language; tree shape changes, so semantic actions must preserve intended associativity. Indirect left recursion follows a cycle through other nonterminals and also needs removal for ordinary predictive descent.

Study-note section COMP12

Left factoring rewrites A→αβ|αγ using:
A→αA′
A′→β|γ
It postpones a choice until after the common prefix. It does not by itself remove ambiguity or guarantee LL(1). LR parsers can handle suitable left-recursive grammars; ordinary unmodified recursive descent can recurse forever before consuming input.

Computer Science MCQ practice collection · Question 806

Question 117 | AM0807

Which of the following is not a top-down parsing algorithm?

A. Recursive Descent Parsing

B. LL Parsing

C. Predictive Parsing

D. LR Parsing

Hint

Use construction direction, lookahead and grammar restrictions. Distinguish algorithm families, implementations and coverage before comparing them.

Answer D: LR Parsing

Recursive descent, LL parsing and predictive parsing all expand productions from the start symbol toward the input. Predictive parsing uses lookahead to avoid backtracking, while a general recursive-descent implementation may backtrack. LR parsing instead shifts input and reduces handles to build structure bottom-up. Its construction direction therefore excludes it from the top-down family, independent of whether either implementation uses a stack.

Why each choice is right or wrong

A - Incorrect: Recursive descent expands nonterminal procedures from the start symbol.

B - Incorrect: LL constructs a leftmost derivation top-down.

C - Incorrect: Prediction chooses a top-down production using lookahead.

D - Correct: LR is bottom-up, reducing handles from the input.

Primary note proof

Study-note section COMP11

> Top-down parsing starts with S and expands productions toward the input, usually constructing a leftmost derivation. Recursive descent typically has one procedure per nonterminal. A general recursive-descent implementation can backtrack; a predictive parser chooses a production using lookahead without backtracking. LL(1) scans Left to right, produces a Leftmost derivation and uses one lookahead token.

Study-note section COMP15

> Bottom-up parsing starts from input and reduces toward S, constructing a rightmost derivation in reverse.

Question sources

Computer Science MCQ practice collection · Question 807

Question 118 | AM0808

Which listed method can retain multiple parse possibilities for a general ambiguous CFG rather than requiring an ordinary deterministic LL/LR grammar?

A. LL Parsing

B. Generalized LR parsing (GLR)

C. Recursive Descent Parsing

D. Top-Down Parsing

Hint

Use construction direction, lookahead and grammar restrictions. Distinguish algorithm families, implementations and coverage before comparing them.

Answer B: Generalized LR parsing (GLR)

A general ambiguous grammar has multiple parse trees for at least one input. Generalized LR parsing can handle those possibilities, whereas ordinary deterministic LL/LR grammars must be unambiguous. A separate disambiguation policy may still be needed to select intended meaning. Recursive descent and top-down labels alone do not provide a generalized multi-parse method, so the GLR alternative uniquely answers the question.

Why each choice is right or wrong

A - Incorrect: Ordinary deterministic LL requires an unambiguous predictive grammar.

B - Correct: GLR is the generalized method identified for ambiguous grammars.

C - Incorrect: Ordinary recursive descent alone does not specify a generalized multi-parse algorithm.

D - Incorrect: Top-down direction alone does not handle general ambiguity.

Primary note proof

Study-note section COMP18

> LL, LR and recursive-descent parsers can all handle nested parentheses for suitable grammars. An explicit or implicit stack, not the LR label alone, supports unbounded nesting. Both LL and LR can use parsing tables. Deterministic LL/LR grammars must be unambiguous; a general ambiguous grammar requires rewriting, disambiguation policy or a generalized method such as GLR.

Study-note section COMP18

> An operator grammar conventionally forbids adjacent nonterminals on a RHS and usually ε productions. Operator-precedence parsing additionally requires conflict-free precedence relations. Ordinary right-linear regular grammars also lack adjacent nonterminals, so that property alone does not uniquely identify the operator-grammar category. Regular patterns are chiefly lexical specifications; CFGs chiefly describe nested syntax.

Computer Science MCQ practice collection · Question 808

Question 119 | AM0809

What is the main goal of a compiler?

A. Execution of programs

B. Translation of programs

C. Optimization of programs

D. Debugging of programs

Hint

Identify each activity’s input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer B: Translation of programs

PDF p2 defines a compiler as reading a program in one language and translating it to an equivalent program in another.

Why each choice is right or wrong

A - Incorrect: Execution is not the defining translation task on p2.

B - Correct: Exactly matches the compiler definition on p2.

C - Incorrect: Optimization is an application/stage, not the defining goal (pp2,7).

D - Incorrect: Testing may use compiler technology (p2), but debugging is not its defining goal.

Primary note proof

Study-note section COMP01

> A compiler translates a source program into an equivalent target representation while preserving defined observable behavior. The target may be machine code, assembly, bytecode or another source language. A transpiler is a source-to-source compiler, not a fundamentally separate noncompiler technology. A compiler preserves language semantics, not the programmer's unstated intention.

Study-note section COMP01

> An interpreter executes a program representation; it need not work one source line at a time. Systems can compile to bytecode and then interpret or JIT-compile it. AOT compilation happens before execution; JIT compilation happens during execution and may use runtime profiles. Neither is universally faster; startup cost, optimization and workload matter.

> What is Compiler
> • a program that reads a program written in one language and translates it into an equivalent program in another language.

Question sources

Computer Science MCQ practice collection · Question 809

Question 120 | AM0810

Which phase of the compiler analyzes the source code to identify the basic syntactic structures?

A. Lexical Analysis

B. Syntax Analysis

C. Semantic Analysis

D. Code Generation

Hint

Identify each activity's input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer B: Syntax Analysis

PDF p5 assigns identifying expressions, statements, and declarations through grammatical grouping to syntax analysis. Here syntactic structures means those higher-level constructs.

Why each choice is right or wrong

A - Incorrect: Scanning recognizes tokens, the lexical units used by parsing (p5).

B - Correct: P5 explicitly identifies expressions, statements and declarations here.

C - Incorrect: Semantic analysis checks meaningful compatibility (p6).

D - Incorrect: Code generation translates IC to machine code (p7).

Primary note proof

Study-note section COMP04

> Keywords, identifiers, literals, operators and punctuation are token classes. Whitespace and comments are usually skipped while line/column positions are retained. In indentation-sensitive or newline-sensitive languages, layout can carry tokens. Parse-tree construction is a parser task; scanning can intern identifier spellings, but declaration scope and types need later analysis.

Study-note section COMP09

> A parse tree shows grammar productions: root S, internal nonterminals, and terminal leaves, with ε sometimes shown for empty productions. Its left-to-right yield is the input.

Module passages - related reading

Question sources

Computer Science MCQ practice collection · Question 810

Question 121 | AM0811

Which phase of the compiler assigns meaning to the syntactic structures and performs type checking?

A. Lexical Analysis

B. Syntax Analysis

C. Semantic Analysis

D. Code Generation

Hint

Check operand compatibility and permitted conversions under the stated language rules; distinguish grammatical structure from semantic meaning.

Answer C: Semantic Analysis

PDF p6 explicitly checks meaningful fit and performs type checking, which identifies semantic analysis.

Why each choice is right or wrong

A - Incorrect: Lexical analysis recognizes tokens (p5).

B - Incorrect: Syntax analysis checks grammar structure (p5).

C - Correct: Matches both meaningful compatibility and type checking on p6.

D - Incorrect: Code generation converts intermediate code (p7).

Primary note proof

Study-note section COMP22

> A type checker verifies that operations are defined for their operands. In a simple strict language, integer mod requires two integers; array indexing requires an array and integer index; an if condition requires Boolean; assignment requires equal or convertible types. Function calls check parameter count and compatibility, and returns match result types.

Study-note section COMP22

> Type inference derives types from constraints: if x is integer and + expects numeric operands, infer the expression type from numeric promotion rules. It is a static technique even without explicit annotations. Operator overloading supplies multiple operation meanings, not a substitute for type checking. int x="hello" is a type mismatch in ordinary C++/Java; division by zero and bounds violations are not automatically operand-type mismatches.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Compiler Design module | PDF page 6 | lines 2-10

> 3. Semantic Analysis
> • Certain checks are performed to make sure that the components of the program fit

together meaningfully.
• Unlike parsing, this phase checks for semantic errors in the source program (e.g. type mismatch)
- Type checking of various programming language constructs is one of the most important tasks.
• Stores type information in the symbol table or the syntax tree.
- Types of variables, function parameters, array dimensions, etc.

Question sources

Computer Science MCQ practice collection · Question 811

Question 122 | AM0812

Which of the following represents the correct order of compiler phases?

A. Code Generation, Semantic Analysis, Lexical Analysis, Syntax Analysis

B. Lexical Analysis, Syntax Analysis, Semantic Analysis, Code Generation

C. Syntax Analysis, Lexical Analysis, Semantic Analysis, Code Generation

D. Semantic Analysis, Syntax Analysis, Lexical Analysis, Code Generation

Hint

Identify each activity's input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer B: Lexical Analysis, Syntax Analysis, Semantic Analysis, Code Generation

PDF pp5-7 orders lexical, syntax, semantic, intermediate generation, optimization, and generation. B preserves the relative order of the four listed phases, though it omits two intervening stages.

Why each choice is right or wrong

A - Incorrect: Starts with generation before analysis, reversing the pp5-7 sequence.

B - Correct: Preserves the pp5-7 relative order: lexical, syntax, semantic, generation.

C - Incorrect: Syntax must consume lexical tokens (p5), so it cannot precede lexical analysis.

D - Incorrect: Semantics is phase 3 after lexical and syntax analysis (pp5-6).

Primary note proof

Study-note section COMP03

The conventional sequence is lexical analysis → syntax analysis → semantic analysis → intermediate-code generation → optimization → target-code generation. Scanning turns characters into tokens; parsing builds structure; semantics checks declarations and types; synthesis produces implementation code. A phase is a logical activity; a pass is a traversal that can combine activities.

Study-note section COMP03

The front end handles source-language rules; a middle end analyzes and transforms IR; the backend handles target details. Symbol-table management and error reporting support multiple phases rather than forming one mandatory seventh final phase. Optimization can occur at several levels, including after instruction selection. “Final phase” means code generation in the standard six-phase teaching pipeline.

Question 123 | AM0813

Which data structure is commonly used in symbol tables during the compilation process?

A. Stack

B. Queue

C. Hash Table

D. Linked List

Hint

Ask whether the required information is a declaration's identity and attributes, program structure or the ordered source tokens.

Answer C: A hash table.

COMP19 explicitly says a hash table offers expected constant-time insertion and lookup with suitable hashing. That makes it the conventional structure for the name-to-attribute mapping. A stack can organize nested scope tables, and lists are possible implementation choices, but the common keyed lookup structure asked for here is the hash table.

Why each choice is right or wrong

A - Incorrect: A stack manages nested scope order, while the keyed mapping within a scope commonly uses hashing.

B - Incorrect: FIFO queue order does not directly provide the keyed lookup role of a symbol table.

C - Correct: Hashing commonly implements efficient name-to-attribute insertion and lookup.

D - Incorrect: A linked list is possible but does not provide the expected constant-time keyed lookup highlighted in COMP19.

Primary note proof

Study-note section COMP19

A symbol table maps names or symbol identities to attributes: type, scope, width, storage offset, parameter signature, constant information or linkage. A hash table gives expected O(1) insertion/lookup with suitable hashing; a stack of scope tables supports lexical nesting. Search the nearest scope first, insert declarations in the current scope, and remove visibility when leaving it.

Study-note section COMP19

Scanning may intern a spelling first; semantic analysis determines the declaration and type. Implementations differ, so first interaction is conventional rather than universal. Not every punctuation token needs a symbol-table entry; literals may use a separate literal table. A hash table is an implementation, not the information's semantic role.

Question 124 | AM0814

Which phase of the compiler performs optimization techniques to improve the efficiency of the generated code?

A. Lexical Analysis

B. Syntax Analysis

C. Semantic Analysis

D. Code Optimization

Hint

Trace whether computation is evaluated, moved, shared or removed. Preserve observable effects and use the stated arithmetic and target assumptions.

Answer D: Code Optimization

PDF p7 explicitly improves intermediate code by removing inefficiencies; p17 names faster execution and efficient memory as goals.

Why each choice is right or wrong

A - Incorrect: Lexical analysis tokenizes (p5).

B - Incorrect: Syntax analysis parses (p5).

C - Incorrect: Semantic analysis checks meaningful fit (p6).

D - Correct: The named improvement phase on pp7,17 is code optimization.

Primary note proof

Study-note section COMP30

> Constant folding evaluates constant expressions during compilation: 3*4→12. Constant propagation substitutes known values: x=3; y=x+2 becomes y=3+2 before folding. Copy propagation substitutes a copied name while its source remains unchanged. Dead-code elimination removes unreachable code or computations whose values are unused and whose evaluation has no necessary side effects.

Question sources

Computer Science MCQ practice collection · Question 814

Question 125 | AM0815

Which of the following is not a typical optimization performed by a compiler?

A. Constant Folding

B. Loop Unrolling

C. Dead Code Elimination

D. Syntax Analysis

Hint

Trace whether computation is evaluated, moved, shared or removed. Preserve observable effects and use the stated arithmetic and target assumptions.

Answer D: Syntax Analysis

Constant folding evaluates known expressions, loop unrolling replicates a loop body to reduce branch overhead, and dead-code elimination removes unnecessary computation when effects permit. Each transforms an existing program while preserving its required behavior. Syntax analysis instead checks and organizes grammatical structure in the frontend. It is necessary compiler work, but it is not an optimization transformation of the kind named by the other alternatives.

Why each choice is right or wrong

A - Incorrect: Constant folding replaces constant expressions with computed values.

B - Incorrect: Unrolling replicates loop iterations, handling remainders and code-size costs.

C - Incorrect: Dead-code elimination removes unreachable or unused effect-free computations.

D - Correct: Syntax analysis recognizes grammatical structure rather than optimizing code.

Primary note proof

Study-note section COMP30

Constant folding evaluates constant expressions during compilation: 3*4→12.

Study-note section COMP30

Dead-code elimination removes unreachable code or computations whose values are unused and whose evaluation has no necessary side effects.

Study-note section COMP32

Unrolling replicates a body to reduce branch overhead and expose parallelism; handle remaining iterations and increased code size.

Study-note section COMP03

The conventional sequence is lexical analysis → syntax analysis → semantic analysis → intermediate-code generation → optimization → target-code generation. Scanning turns characters into tokens; parsing builds structure; semantics checks declarations and types; synthesis produces implementation code.

Module passages - related reading

Computer Science MCQ practice collection · Question 815

Question 126 | AM0816

Which phase of the compiler generates the target code?

A. Lexical Analysis

B. Syntax Analysis

C. Semantic Analysis

D. Code Generation

Hint

Identify each activity's input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer D: Code Generation

PDF p7 states that code generation converts intermediate code to machine code, the target in this question.

Why each choice is right or wrong

A - Incorrect: Lexical analysis emits tokens (p8).

B - Incorrect: Syntax analysis emits a tree (p5).

C - Incorrect: Semantic analysis checks compatibility (p6).

D - Correct: Machine-code output is the explicit code-generation role (p7).

Primary note proof

Study-note section COMP34

> Code generation lowers checked IR to a target form. Instruction selection chooses target operations; register allocation chooses where values reside; scheduling orders instructions while respecting dependencies; storage layout assigns offsets and follows ABI requirements. Register assignment names actual physical registers after allocation decisions.

Study-note section COMP34

> For t=a+b, a simple target could emit LOAD R1,a; LOAD R2,b; ADD R3,R1,R2; STORE t,R3. Other targets may combine loads with arithmetic or keep t in a register. Machine idioms, register availability and instruction order affect execution time.

Question sources

Computer Science MCQ practice collection · Question 816

Question 127 | AM0817

Which of the following is an advantage of using an intermediate representation during the compilation process?

A. Faster compilation speed

B. Improved error detection

C. Portability across different platforms

D. Reduced memory usage

Hint

Identify what the representation stores, what it omits and which later transformations it must support; separate a representation property from an algorithmic task.

Answer C: Portability across platforms.

COMP26 explains that IR separates source analysis from target implementation, allowing optimizers and backends to be reused. This supports retargeting and portability across platforms. Introducing IR does not inherently promise faster compilation, better error detection or lower memory use; it can add processing stages and data structures while improving architecture.

Why each choice is right or wrong

A - Incorrect: An extra representation and processing stage do not inherently guarantee faster compilation.

B - Incorrect: Error detection depends on analyses and language rules; it is not the stated architectural advantage.

C - Correct: Separating source meaning from target lowering enables reuse across different platforms.

D - Incorrect: IR introduces storage and does not guarantee reduced compiler memory consumption.

Primary note proof

Study-note section COMP26

IR separates source analysis from target implementation, allowing optimizers and backends to be reused. It should be easy to generate, analyze, transform and lower.

Study-note section COMP26

Ordinary TAC arithmetic has at most one operation, two sources and one destination: t1=c*d; t2=b+t1; a=t2. Quadruples store (op,arg1,arg2,result); triples omit an explicit result field and refer to instruction positions. Indirect triples reference a separate ordering list, easing rearrangement. Trees describe expressions; DAGs share common subexpressions, while quadruples/triples are instruction-record structures.

Question sources

Computer Science MCQ practice collection · Question 817

Question 128 | AM0818

What is the shared compiler service that supports detecting, recovering from and reporting lexical, syntax and semantic errors?

A. Lexical Analysis

B. Syntax Analysis

C. Semantic Analysis

D. Error Handling

Hint

Identify each activity’s input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer D: Error Handling

Error handling and reporting is a shared service supporting multiple compilation phases. Scanning detects malformed tokens, parsing detects invalid token arrangements, and semantic analysis detects name, scope or type violations. These are contributors rather than one phase responsible for every error category. Naming the shared service makes D the appropriate complete answer without denying the diagnostic responsibilities of the other phases.

Why each choice is right or wrong

A - Incorrect: Lexical analysis handles lexical errors but is not the complete shared service.

B - Incorrect: Syntax analysis handles parsing errors but is not the complete shared service.

C - Incorrect: Semantic analysis handles semantic errors but is not the complete shared service.

D - Correct: Error handling names the shared support service.

Primary note proof

Study-note section COMP39

> Panic-mode recovery skips input until a synchronizing token such as ; or } permits parsing to resume. Phrase-level recovery makes a local insertion/deletion. Report the location and cause while avoiding cascades of misleading diagnostics. Lexical, syntax and semantic phases each detect their own errors; error handling is a shared service.

Study-note section COMP39

> Lex/flex generates scanners from patterns and actions. Yacc means Yet Another Compiler Compiler; Yacc/Bison generates parsers from grammar rules and semantic actions. Typical specification files have definitions, %% rules, and %% user code. Classic Yacc uses LALR; Bison supports additional LR and generalized modes. Scanner generation does not replace the CFG parser.

Question sources

Computer Science MCQ practice collection · Question 818

Question 129 | AM0819

Which of the following is true about syntax-directed translation?

A. It only involves the lexical analysis phase.

B. It involves the generation of intermediate code from the parse tree.

C. It is concerned with the optimization of the generated code.

D. It is performed during the code generation phase.

Hint

Track where each computed value comes from and when each production action runs. Distinguish the representation from its attached information.

Answer B: It can generate intermediate code using parse-tree structure and semantic actions.

COMP25 says syntax-directed actions may compute types, values, AST pointers or generated code. Generating IR from grammatical structure is therefore a supported use of syntax-directed translation. B describes that standard use without limiting it to lexical analysis or a single final phase. Optimization may use other analyses, and syntax-directed translation is not defined solely by optimization.

Why each choice is right or wrong

A - Incorrect: Syntax-directed translation is tied to grammatical productions and semantic actions, not solely tokenization.

B - Correct: Semantic actions associated with parsed structure can compute and emit an intermediate representation.

C - Incorrect: Optimization is not the defining task; translation actions can construct many forms of semantic output.

D - Incorrect: It is not restricted to final target-code generation; actions can run while parsing and constructing IR.

Primary note proof

Study-note section COMP25

A syntax-directed translation scheme embeds executable actions in productions; the actions run while translating a source program, not while generating the compiler. Attributes may compute types, values, AST pointers or generated code. The scheme defines an input-to-output translation, not merely an input language.

Study-note section COMP25

Create an identifier leaf with mkleaf(id,entry), a number with mkleaf(num,value), and an operator node with mknode(op,left,right). For a−4+c, construct +(−(a,4),c). Postorder traversal prints postfix: a 4 − c +. A stack evaluator pushes operands and pops right then left operands for an operator. Infix-to-postfix is useful for stack machines but not mandatory for all compilers.

Question sources

Computer Science MCQ practice collection · Question 819

Question 130 | AM0820

What is the general defining role of semantic rules attached to productions in a syntax-directed definition, rather than one possible specialized use?

A. To define the syntactic structure of the language.

B. To define computations of attributes such as types, values, environments and generated code.

C. To perform optimization techniques on the intermediate code.

D. To define the order of evaluation of expressions.

Hint

Track where each computed value comes from and when each production action runs. Distinguish the representation from its attached information.

Answer B: To define computations of attributes such as types, values, environments and generated code.

The grammar productions define syntactic structure, while semantic rules define computations of attributes associated with grammar symbols. Those attributes may represent types, values, environments or generated code. Assigning types and constraining evaluation dependencies are examples rather than exhaustive definitions. Optimization may occur in a particular translation, but is not the general defining role of all such rules.

Why each choice is right or wrong

A - Incorrect: Productions, rather than semantic rules, specify the grammatical structure.

B - Correct: Computing attributes is the general defining role.

C - Incorrect: Optimization is a possible specialized transformation, not the general definition.

D - Incorrect: Evaluation order is a specialized concern rather than the complete role.

Primary note proof

Study-note section COMP24

A syntax-directed definition is a CFG with attributes on grammar symbols and semantic rules on productions. An annotated parse tree displays computed attribute values; it is not itself an inherited or synthesized attribute. Synthesized attributes flow from children to a parent; inherited attributes carry context from parent or siblings.

Study-note section COMP24

For E→E1+T, E.val=E1.val+T.val synthesizes an expression value. A declaration's type environment passed into its body is inherited. S-attributed definitions use only synthesized attributes and fit LR reduction-time evaluation naturally; suitable LL parsers can also compute them. L-attributed definitions restrict dependencies so a left-to-right traversal can evaluate inherited context. Attribute dependency cycles can prevent evaluation.

Computer Science MCQ practice collection · Question 820

Question 131 | AM0821

Which phase of the compiler is responsible for type checking?

A. Lexical Analysis

B. Syntax Analysis

C. Semantic Analysis

D. Code Generation

Hint

Check operand compatibility and permitted conversions under the stated language rules; distinguish grammatical structure from semantic meaning.

Answer C: Semantic Analysis

PDF p6 explicitly names type checking as a major task of semantic analysis.

Why each choice is right or wrong

A - Incorrect: Lexical analysis recognizes tokens (p5).

B - Incorrect: Syntax analysis checks grammatical hierarchy (p5).

C - Correct: Type checking is explicitly assigned here (p6).

D - Incorrect: Code generation converts IC to machine code (p7).

Primary note proof

Study-note section COMP22

A type checker verifies that operations are defined for their operands. In a simple strict language, integer mod requires two integers; array indexing requires an array and integer index; an if condition requires Boolean; assignment requires equal or convertible types. Function calls check parameter count and compatibility, and returns match result types.

Study-note section COMP22

Type inference derives types from constraints: if x is integer and + expects numeric operands, infer the expression type from numeric promotion rules. It is a static technique even without explicit annotations. Operator overloading supplies multiple operation meanings, not a substitute for type checking. int x="hello" is a type mismatch in ordinary C++/Java; division by zero and bounds violations are not automatically operand-type mismatches.

Question sources

Computer Science MCQ practice collection · Question 821

Question 132 | AM0822

What is type checking in a compiler?

A. Verifying the syntax of the program.

B. Detecting lexical errors in the program.

C. Ensuring that the operations on variables are well-defined and compatible.

D. Generating the intermediate code for the program.

Hint

Check operand compatibility and permitted conversions under the stated language rules; distinguish grammatical structure from semantic meaning.

Answer C: Ensuring that the operations on variables are well-defined and compatible.

PDF p14 defines type checking as enforcing type safety and lists incompatible operands; p15 makes assignment produce type_error when the identifier and expression types differ. Thus C expresses compatible operations.

Why each choice is right or wrong

A - Incorrect: Grammatical syntax is handled by parsing (p5).

B - Incorrect: Token recognition is lexical analysis (p8), not type compatibility.

C - Correct: Compatible operations and assignments match pp14-15.

D - Incorrect: Intermediate generation is distinct from semantic checking (pp6,15).

Primary note proof

Study-note section COMP22

> A type checker verifies that operations are defined for their operands. In a simple strict language, integer mod requires two integers; array indexing requires an array and integer index; an if condition requires Boolean; assignment requires equal or convertible types. Function calls check parameter count and compatibility, and returns match result types.

Study-note section COMP22

> Type inference derives types from constraints: if x is integer and + expects numeric operands, infer the expression type from numeric promotion rules. It is a static technique even without explicit annotations. Operator overloading supplies multiple operation meanings, not a substitute for type checking. int x="hello" is a type mismatch in ordinary C++/Java; division by zero and bounds violations are not automatically operand-type mismatches.

Computer Science MCQ practice collection · Question 822

Question 133 | AM0823

Which of the following is an example of a static type checking technique?

A. Type inference

B. Dynamic typing

C. Run-time type checking

D. Operator overloading

Hint

Check operand compatibility and permitted conversions under the stated language rules; distinguish grammatical structure from semantic meaning.

Answer A: Type inference.

COMP22 defines type inference as deriving types from constraints and explicitly calls it static even without explicit type annotations. Dynamic typing and runtime checks concern execution-time behavior. Operator overloading defines several meanings for an operation, but is not a replacement for the checking technique itself. Thus only type inference is the named static technique.

Why each choice is right or wrong

A - Correct: Type inference derives expression types from constraints before execution and is explicitly a static technique.

B - Incorrect: Dynamic typing does not name the requested before-execution type-inference technique.

C - Incorrect: Runtime type checking occurs during execution, so it is not static checking.

D - Incorrect: Overloading supplies operation meanings; COMP22 distinguishes it from type checking itself.

Primary note proof

Study-note section COMP22

> A type checker verifies that operations are defined for their operands. In a simple strict language, integer mod requires two integers; array indexing requires an array and integer index; an if condition requires Boolean; assignment requires equal or convertible types. Function calls check parameter count and compatibility, and returns match result types.

Study-note section COMP22

> Type inference derives types from constraints: if x is integer and + expects numeric operands, infer the expression type from numeric promotion rules. It is a static technique even without explicit annotations. Operator overloading supplies multiple operation meanings, not a substitute for type checking. int x="hello" is a type mismatch in ordinary C++/Java; division by zero and bounds violations are not automatically operand-type mismatches.

Question sources

Computer Science MCQ practice collection · Question 823

Question 134 | AM0824

Which attribute is specifically recorded for each variable in a type-oriented symbol table and distinguishes its typing information from the name that identifies the entry?

A. To store the types of variables used in the program.

B. To store the names of variables used in the program.

C. To store the intermediate code generated during parsing.

D. To store the syntax rules of the programming language.

Hint

Ask whether the required information is a declaration's identity and attributes, program structure or the ordered source tokens.

Answer A: To store the types of variables used in the program.

A symbol table associates a name or declaration identity with attributes. In a type-oriented table, the relevant attribute is the variable's type, used to check whether operations and assignments are compatible. Names identify the records but do not themselves give typing information. Intermediate instructions and grammar rules belong to other representations and are not the per-variable typing attribute requested.

Why each choice is right or wrong

A - Correct: Variable types provide the requested typing attribute.

B - Incorrect: Names identify entries but are not their type attributes.

C - Incorrect: IR instructions are not the per-variable type attribute.

D - Incorrect: Syntax rules describe the language rather than variable types.

Primary note proof

Study-note section COMP19

A symbol table maps names or symbol identities to attributes: type, scope, width, storage offset, parameter signature, constant information or linkage. A hash table gives expected O(1) insertion/lookup with suitable hashing; a stack of scope tables supports lexical nesting. Search

the nearest scope first, insert declarations in the current scope, and remove visibility when leaving it.

Study-note section COMP19

Scanning may intern a spelling first; semantic analysis determines the declaration and type. Implementations differ, so first interaction is conventional rather than universal. Not every punctuation token needs a symbol-table entry; literals may use a separate literal table. A hash table is an implementation, not the information's semantic role.

E → id { E.type = lookup(id.entry) }
E→E1 mod E2 { E.type=if E1.type=int and E2.type= int
then int
else type_error }

Question sources

Computer Science MCQ practice collection · Question 824

Question 135 | AM0825

In ordinary C++ with no custom conversions, which offered example is specifically a type mismatch rather than a syntax, value-domain or layout issue?

A. Syntax error in an if-else statement.

B. Division of a number by zero.

C. int x="hello";

D. Incorrect indentation in the program.

Hint

Check operand compatibility and permitted conversions under the stated language rules; distinguish grammatical structure from semantic meaning.

Answer C: int x="hello";

An ordinary C++ declaration int x="hello" attempts to initialize an integer from a string literal and is a type mismatch under the stated rules. Division by zero can involve correctly typed operands and is instead a value-domain fault. Incorrect indentation is layout, while malformed if-else syntax concerns grammatical arrangement. The option illustrates an incompatible-type example.

Why each choice is right or wrong

A - Incorrect: This explicitly describes a syntax error rather than a type mismatch.

B - Incorrect: A zero divisor is a value issue even with compatible numeric types.

C - Correct: A string literal is not a compatible ordinary integer initializer.

D - Incorrect: Indentation does not establish an incompatible operand type.

Primary note proof

Study-note section COMP22

> A type checker verifies that operations are defined for their operands. In a simple strict language, integer mod requires two integers; array indexing requires an array and integer index; an if condition requires Boolean; assignment requires equal or convertible types. Function calls check parameter count and compatibility, and returns match result types.

Study-note section COMP22

> Type inference derives types from constraints: if x is integer and + expects numeric operands, infer the expression type from numeric promotion rules. It is a static technique even without explicit annotations. Operator overloading supplies multiple operation meanings, not a substitute for type checking. int x="hello" is a type mismatch in ordinary C++/Java; division by zero and bounds violations are not automatically operand-type mismatches.

Question sources

Computer Science MCQ practice collection · Question 825

Question 136 | AM0826

Which advantage of static type checking specifically concerns detecting incompatible operations before the program executes?

A. Improved program performance.

B. Enhanced code optimization.

C. Early detection of potential runtime errors.

D. Simplified debugging process.

Hint

Check operand compatibility and permitted conversions under the stated language rules; distinguish grammatical structure from semantic meaning.

Answer C: Early detection of potential runtime errors.

Static type checking can reject an incompatible operation during compilation, before that operation causes a run-time type error. This is the direct timing benefit asked for. Type information may also aid optimization, and diagnostics may make debugging easier, but those are additional consequences rather than the specific before-execution detection property. Type checking does not by itself guarantee faster code or eliminate all possible run-time errors.

Why each choice is right or wrong

A - Incorrect: Faster execution is not guaranteed and does not state detection before execution.

B - Incorrect: Optimization may use types but is a different benefit from the requested early rejection.

C - Correct: Compile-time rejection detects incompatible operations before execution.

D - Incorrect: Debugging may be easier, but that broad consequence does not specify the requested detection timing.

Primary note proof

Study-note section COMP22

> A type checker verifies that operations are defined for their operands. In a simple strict language, integer mod requires two integers; array indexing requires an array and integer index; an if condition requires Boolean; assignment requires equal or convertible types. Function calls check parameter count and compatibility, and returns match result types.

Study-note section COMP22

> Type inference derives types from constraints: if x is integer and + expects numeric operands, infer the expression type from numeric promotion rules. It is a static technique even without explicit annotations. Operator overloading supplies multiple operation meanings, not a substitute for type checking. int x="hello" is a type mismatch in ordinary C++/Java; division by zero and bounds violations are not automatically operand-type mismatches.

Question sources

Computer Science MCQ practice collection · Question 826

Question 137 | AM0827

What is the primary goal of type checking in a compiler?

A. To ensure syntactic correctness of the program.

B. To generate efficient machine code.

C. To enforce programming language rules and constraints.

D. To provide support for code reuse through libraries.

Hint

Check operand compatibility and permitted conversions under the stated language rules; distinguish grammatical structure from semantic meaning.

Answer C: To enforce programming language rules and constraints.

PDF p14 defines type checking as semantic checks enforcing type safety and says the compiler checks source-language semantic conventions. C is the offered broad rule-enforcement description, limited here to type constraints.

Why each choice is right or wrong

A - Incorrect: Syntax correctness is the parsing task (p5).

B - Incorrect: Machine-code efficiency is an optimization goal (pp7,17).

C - Correct: Type-related semantic conventions and constraints match p14.

D - Incorrect: Library reuse is not a type-checking goal stated in the module.

Primary note proof

Study-note section COMP22

> A type checker verifies that operations are defined for their operands. In a simple strict language, integer mod requires two integers; array indexing requires an array and integer index; an if condition requires Boolean; assignment requires equal or convertible types. Question sources

Computer Science MCQ practice collection · Question 827

Question 138 | AM0828

Which of the following is an example of a type coercion or type conversion?

A. Assigning a floating-point value to an integer variable.

B. Assigning a value to an uninitialized variable.

C. Declaring a variable without specifying its type.

D. Using an undeclared variable in the program.

Hint

Check operand compatibility and permitted conversions under the stated language rules; distinguish grammatical structure from semantic meaning.

Answer A: Converting a floating-point value when assigning to an integer variable, where the language permits it.

COMP23 gives C++ int x=3.14 as an ordinary conversion yielding 3 when representable. That is the listed example of conversion, with the language caveat that Java needs a permitted cast and C++ brace initialization rejects narrowing. The remaining choices concern initialization, inference or undeclared names rather than converting one value type to another.

Why each choice is right or wrong

A - Correct: Floating-to-integer assignment performs conversion where permitted; exact legality and precision loss depend on the language.

B - Incorrect: First assigning to a variable is initialization or assignment, not inherently a change of value type.

C - Incorrect: Omitting an explicit declaration type may invoke inference; it does not itself convert a value.

D - Incorrect: An undeclared name is a name-resolution problem rather than an example of value conversion.

Primary note proof

Study-note section COMP23

Coercion is an implicit conversion permitted by the language; a cast requests an explicit conversion. Widening often increases representable range, but can still lose precision: Java int→float is widening although large integers round. Java int→long is exact. Narrowing can lose range or fractional information.

Study-note section COMP23

In C++ ordinary int x=3.14 converts to 3 when representable; it is not inherently a type error. int x{3.14} is rejected as narrowing. C++ floating-to-integer conversion discards the fraction and has undefined behavior if the truncated value is unrepresentable. Java ordinary double→int assignment needs a permitted explicit cast. Mixing char and int is ordinarily valid after promotion in C++/Java; do not import a fictitious universal ban.

Computer Science MCQ practice collection · Question 828

Question 139 | CS0121

Which listed approaches are bottom-up and therefore are not top-down parsers? Select all that apply. Assume predictive recursive descent for A.

A. Recursive-descent parser

B. Shift-reduce parser

C. Non-recursive predictive parser

D. LR parser

Hint

Use construction direction, lookahead and grammar restrictions. Distinguish algorithm families, implementations and coverage before comparing them.

Answer B, D: Shift-reduce parser; LR parser

Shift-reduce parsing starts from the input and reduces recognized handles toward the start symbol. LR is a bottom-up family using that strategy. Recursive descent and nonrecursive prediction instead expand productions top-down for suitable grammars. Therefore both B and D fail the top-down description. This directional distinction avoids an unsupported efficiency ranking between recursive and table-driven predictive implementations.

Why each choice is right or wrong

A - Incorrect: Predictive recursive descent is top-down.

B - Correct: Shift-reduce is bottom-up.

C - Incorrect: Nonrecursive prediction is top-down.

D - Correct: LR is bottom-up.

Primary note proof

Study-note section COMP11

> Top-down parsing starts with S and expands productions toward the input, usually constructing a leftmost derivation. Recursive descent typically has one procedure per nonterminal. A general recursive-descent implementation can backtrack; a predictive parser chooses a production using lookahead without backtracking. LL(1) scans Left to right, produces a Leftmost derivation and uses one lookahead token.

Study-note section COMP15

> Bottom-up parsing starts from input and reduces toward S, constructing a rightmost derivation in reverse.

Parsing
• Process of constructing parse tree for a sentence generated by a given grammar.
• 2 types of parsers
● Top down parsing (predictive parsers)
• LL(1)
● Bottom up parsing (SR parsers)
• LR(1)

Compiler Design module | PDF page 11 | lines 2-17

LL(1) Grammar
• L - left to right
• L - left most derivation
• 1 - number of look ahead
• First( ) and Follow( )
● the first terminal in a string and the terminal that follows a variable respectively.
LR Parsing
• LR(k) - Left to right scanning with Rightmost derivation in reverse, k being the number of lookahead tokens.
Types of LR Parsers
• LR (0) , SLR (1) , LALR (1) , CLR (1)
LL LR
Leftmost derivation Rightmost derivation in reverse
Starts with root non-terminal on stack Ends with root non-terminal on the stack
Builds the parse tree top-down Builds the parse tree bottom-up
Expands the non-terminals Reduces the non-terminals

Question sources

Computer Science Exit Exam practice collection · Question 121

Question 140 | CS0267

Which one of the following is a type of compiler that compiles only the changed lines from source code and updates the object code accordingly?

A. Retargetable compiler

B. One pass compiler

C. Incremental compiler

D. Parallelizing compiler

Hint

Identify each activity’s input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer C: An incremental compiler.

COMP02 defines incremental compilation as recompiling affected fragments or dependent units after edits. This is the compiler category intended by updating code after source changes. The question's only changed lines wording is simplified: real dependency tracking can require recompiling more than literal edited lines. Retargeting and one-pass organization describe different properties.

Why each choice is right or wrong

A - Incorrect: Retargetable compilers support changing target descriptions rather than selecting edited source fragments.

B - Incorrect: One pass counts traversals of the program, not whether edits trigger selective recompilation.

C - Correct: Incremental compilation updates affected fragments after edits, accounting for dependencies beyond literal changed lines.

D - Incorrect: Parallelizing compilation is not the category defined by selective recompilation after source changes.

Primary note proof

Study-note section COMP02

> A preprocessor handles directives such as file inclusion and macros. An assembler translates assembly to object code. A linker combines object files and libraries, resolves external symbols and performs relocation. A loader maps an executable into memory and starts it. Compilation alone does not necessarily produce a ready executable.

Study-note section COMP02

> A cross-compiler runs on a host platform and generates code for a different target. Multiple targets require appropriate backends, not a special definition of cross-compilation. A retargetable compiler supports changing target descriptions. Incremental compilation recompiles affected fragments or dependent units after edits; it is more than literally replacing changed lines. One-pass versus multipass counts traversals, not supported targets.

- Source-to-source Compiler
- compiler that translates source code of one programming language to another

Question sources

Computer Science Exit Exam practice collection · Question 267

Question 141 | CS0268

Which technique of code optimization shifts computations from run time to compile time by evaluating constant expressions at compile time and replacing them with their values?

A. Copy propagation

B. Compile time evaluation

C. Code motion

D. Dead code elimination

Hint

Trace whether computation is evaluated, moved, shared or removed. Preserve observable effects and use the stated arithmetic and target assumptions.

Answer B: Compile time evaluation

PDF p18 lists constant folding and illustrates R2 = 3 * 2. Evaluating this constant expression early gives 6, eliminating that runtime computation. B describes this operation as compile time evaluation, although constant folding would be the module's exact name.

Why each choice is right or wrong

A - Incorrect: P18 copy propagation example copies r1 into r2, not evaluates a constant arithmetic expression.

B - Correct: Evaluating 3 * 2 to 6 is the constant-folding example on p18, matching the stem.

C - Incorrect: P18 code movement relocates a block outside a loop, not necessarily evaluating it at compilation.

D - Incorrect: P18 dead-code elimination removes unreachable statements, rather than computing constant values.

Primary note proof

Study-note section COMP30

Constant folding evaluates constant expressions during compilation: 3*4→12. Constant propagation substitutes known values: x=3; y=x+2 becomes y=3+2 before folding. Copy propagation substitutes a copied name while its source remains unchanged. Dead-code elimination removes unreachable code or computations whose values are unused and whose evaluation has no necessary side effects.

Module passages - related reading

  - r2 = r1

Compiler Design module | PDF page 18 | lines 2-10

Techniques
- Common sub-expression elimination
  - Repeated appearance computed previously
- Strength reduction
  - Replacement of expensive expressions with simple ones
- Code movement
  - Moving a block of code outside a loop
- Dead code elimination
  - Eliminated code statements that are either never executed or unreachable

Question sources

Computer Science Exit Exam practice collection · Question 268

Question 142 | NS0222

For const int x=8; const int y=16; if(x>y){int z=x+y;}, which techniques directly evaluate the known condition and remove its unreachable body? Select all that apply. Arithmetic simplification means algebraic identity rewriting here.

A. Code motion

B. Dead code elimination

C. Compile time evaluation

D. Arithmetic simplification

Hint

Trace whether computation is evaluated, moved, shared or removed. Preserve observable effects and use the stated arithmetic and target assumptions.

Answer B, C: Dead code elimination; Compile time evaluation

Both x and y are known constants, so evaluating 8>16 at compile time yields false. The body can never execute and dead-code elimination can remove it. These are distinct but compatible transformations, corresponding to B and C in this option order. Code motion relocates computations, while algebraic identity simplification is not the decisive operation on this constant-false condition.

Why each choice is right or wrong

A - Incorrect: No relocation is needed to evaluate or delete the branch.

B - Correct: The unreachable branch body can be removed.

C - Correct: The condition is evaluated from known constants at compile time.

D - Incorrect: No algebraic identity rewrite is the decisive step.

Primary note proof

Study-note section COMP30

> For const int x=8,y=16; if(x>y){int z=x+y;}, propagate the constants, fold 8>16 to false, then remove the unreachable branch. Both compile-time evaluation and dead-code elimination apply.

Study-note section COMP31

> Algebraic simplification removes identities when valid: integer x+0→x.

Question sources

Computer Science Exit Exam practice collection · Question 263

Question 143 | NS0223

What is the difference between a compiler and an interpreter?

Hint

Identify each activity's input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer: A compiler translates; an interpreter executes a representation.

COMP01 distinguishes translating source into an equivalent target from executing a program representation. Bytecode systems may combine compilation, interpretation and JIT, so the distinction is not simply all-at-once versus line-by-line execution.

Primary note proof

Study-note section COMP01

> A compiler translates a source program into an equivalent target representation while preserving defined observable behavior. The target may be machine code, assembly, bytecode or another source language. A transpiler is a source-to-source compiler, not a fundamentally separate noncompiler technology. A compiler preserves language semantics, not the programmer's unstated intention.

Study-note section COMP01

> An interpreter executes a program representation; it need not work one source line at a time. Systems can compile to bytecode and then interpret or JIT-compile it. AOT compilation happens before execution; JIT compilation happens during execution and may use runtime profiles. Neither is universally faster; startup cost, optimization and workload matter.

Question sources

Compiler Design review questions · Question 1

Question 144 | NS0224

What is the difference between lexical analysis and syntax analysis?

Hint

Identify each activity's input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer: Lexical analysis groups characters into tokens; syntax analysis groups tokens into structures.

COMP41 separates character-to-token classification from token-to-expression or statement structure. The scanner recognizes lexemes such as identifiers and operators and emits an ordered token stream. The parser checks how those tokens form grammatical constructs and can build a parse tree or AST; legal tokens can still appear in an illegal syntactic arrangement.

Primary note proof

Study-note section COMP04

> A token is a category with optional attribute, such as (ID, symbol-entry) or (INT_LITERAL,42). A lexeme is the actual character sequence, such as total or 42. A pattern specifies which lexemes belong to a token class.

Study-note section COMP04

> Keywords, identifiers, literals, operators and punctuation are token classes. Whitespace and comments are usually skipped while line/column positions are retained.

Study-note section COMP09

> A parse tree shows grammar productions: root S, internal nonterminals, and terminal leaves, with ε sometimes shown for empty productions. Its left-to-right yield is the input. An AST omits grammar scaffolding and punctuation; expression operands are leaves and operators internal nodes. The parser can build either representation, depending on implementation.

Question sources

Compiler Design review questions · Question 2

Question 145 | NS0225

What is the purpose of a symbol table?

Hint

Ask whether the required information is a declaration’s identity and attributes, program structure or the ordered source tokens.

Answer: A symbol table associates names with declaration attributes.

COMP19 maps names or identities to type, scope, width, offsets, signatures and linkage information. These records support declaration lookup and semantic checks; a hash table is one implementation rather than the purpose itself.

Primary note proof

Study-note section COMP19

> A symbol table maps names or symbol identities to attributes: type, scope, width, storage offset, parameter signature, constant information or linkage. A hash table gives expected O(1) insertion/lookup with suitable hashing; a stack of scope tables supports lexical nesting. Search the nearest scope first, insert declarations in the current scope, and remove visibility when leaving it.

Study-note section COMP19

> Scanning may intern a spelling first; semantic analysis determines the declaration and type. Implementations differ, so first interaction is conventional rather than universal. Not every punctuation token needs a symbol-table entry; literals may use a separate literal table. A hash table is an implementation, not the information’s semantic role.

Question sources

Compiler Design review questions · Question 3

Question 146 | NS0226

What is the difference between top-down and bottom-up parsing?

Hint

Use construction direction, lookahead and grammar restrictions. Distinguish algorithm families, implementations and coverage before comparing them.

Answer: Top-down expands from the start symbol; bottom-up reduces input toward it.

COMP15 describes bottom-up recognition as input reductions toward S, reversing a rightmost derivation. COMP11 describes top-down expansion from S toward the input, normally a leftmost derivation.

Primary note proof

Study-note section COMP11

> Top-down parsing starts with S and expands productions toward the input, usually constructing a leftmost derivation. Recursive descent typically has one procedure per nonterminal. A general recursive-descent implementation can backtrack; a predictive parser chooses a production using lookahead without backtracking. LL(1) scans Left to right, produces a Leftmost derivation and uses one lookahead token.

Study-note section COMP15

> Bottom-up parsing starts from input and reduces toward S, constructing a rightmost derivation in reverse. A handle is a production RHS occurrence whose reduction is the next step of that reverse derivation. Not every substring matching a RHS is a handle in the current context.

Question sources

Compiler Design review questions · Question 4

Question 147 | NS0227

What is intermediate code and why is it used?

Hint

Identify what the representation stores, what it omits and which later transformations it must support; separate a representation property from an algorithmic task.

Answer: IR separates source analysis from target lowering and enables reuse.

COMP26 defines IR's role in separating source meaning from target implementation so analysis, optimization and backends can be reused. ASTs, graphs, TAC and bytecode are possible forms. A useful IR is easy to generate, analyze, transform and lower; portability does not require every IR to exclude all target-specific details.

Primary note proof

Study-note section COMP26

> IR separates source analysis from target implementation, allowing optimizers and backends to be reused. It should be easy to generate, analyze, transform and lower.

Study-note section COMP26

> Ordinary TAC arithmetic has at most one operation, two sources and one destination: t1=c*d; t2=b+t1; a=t2. Quadruples store (op,arg1,arg2,result); triples omit an explicit result field and refer to instruction positions. Indirect triples reference a separate ordering list, easing rearrangement. Trees describe expressions; DAGs share common subexpressions, while quadruples/triples are instruction-record structures.

Question sources

Compiler Design review questions · Question 5

Question 148 | NS0228

Which of the following is NOT a valid token type produced during lexical analysis?

A. Keyword |

B. Parse tree node

C. Identifier |

D. Numeric literal

Hint

Identify each activity's input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer B: Parse-tree node is not a lexical token type.

COMP04 lists keywords, identifiers and literals among token classes. A parse-tree node belongs to the grammatical structure built after scanning, not the lexical class of a source lexeme. Consequently only parse-tree node is the invalid token-type choice, while the other three are ordinary scanner output categories.

Why each choice is right or wrong

A - Incorrect: Keywords are explicitly listed as a valid lexical token class.

B - Correct: Parse-tree nodes represent grammatical structure, not a lexical token category emitted by a scanner.

C - Incorrect: Identifiers are an ordinary lexical token class.

D - Incorrect: Numeric literals are literals and therefore valid token categories.

Primary note proof

Study-note section COMP04

> A token is a category with optional attribute, such as (ID, symbol-entry) or (INT_LITERAL,42). A lexeme is the actual character sequence, such as total or 42. A pattern specifies which lexemes belong to a token class. The scanner emits an ordered token stream, not an unordered mathematical set.

Study-note section COMP04

> Keywords, identifiers, literals, operators and punctuation are token classes. Whitespace and comments are usually skipped while line/column positions are retained. In indentation-sensitive or newline-sensitive languages, layout can carry tokens. Parse-tree construction is a parser task; scanning can intern identifier spellings, but declaration scope and types need later analysis.

Question sources

Compiler Design review questions · Question 1

Question 149 | NS0229

What algorithm is commonly used to convert a Non-deterministic Finite Automaton (NFA) to a Deterministic Finite Automaton (DFA) in lexer construction?

A. Thompson's construction |

B. Subset construction (Powerset construction)

C. Cocke-Younger-Kasami (CYK) |

D. Earley's algorithm

Hint

Follow the representation at each construction step and apply the pattern or state-set rules consistently, including empty cases.

Answer B: Subset (powerset) construction.

COMP06 distinguishes Thompson construction, which builds an NFA from a regular expression, from subset construction, which determinizes the NFA. Each DFA state represents an NFA-state subset, with epsilon closure when needed. CYK and Earley are grammar-parsing algorithms rather than this automaton determinization, so the powerset option is the relevant stage.

Why each choice is right or wrong

A - Incorrect: Thompson construction goes from regular expression to NFA rather than NFA to DFA.

B - Correct: Subset construction creates DFA states from sets of NFA states.

C - Incorrect: CYK performs CFG membership parsing and does not determinize a lexical NFA.

D - Incorrect: Earley is a grammar-parsing method rather than the stated NFA-to-DFA construction.

Primary note proof

Study-note section COMP06

> A common generator pipeline is regular expressions → NFA using Thompson construction → DFA using subset construction; minimization is optional.

Study-note section COMP06

> The ε-closure of states includes those reachable by zero or more ε edges. A DFA state is a set of NFA states; its a-transition is ε-closure(move(set,a)). Start with the NFA start closure, repeatedly add unseen subsets, and mark subsets containing an NFA final state as accepting. Token identity and rule priority annotate accepting states; the empty subset acts as a dead state.

Study-note section COMP-S02

> CYK and Earley are context-free grammar parsing algorithms. They determine grammatical structure or membership of an input sequence. They are different tasks from Thompson construction, which builds a token-recognizing NFA from a regular expression, and subset construction, which turns an NFA into a DFA.

Question sources

Compiler Design review questions · Question 2

Question 150 | NS0230

Given the grammar: E → E + T | T, T → T * F | F, F → (E) | id - this grammar enforces:

A. Right-associativity for both + and * |

B. Left-associativity for both + and *, with * having higher precedence than +

C. Right-associativity for + and left-associativity for * |

D. No precedence or associativity rules

Hint

Identify each activity's input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer B: Both operators associate left; multiplication has higher precedence.

COMP10 states exactly these productions and their effect. Multiplication occurs within T below the addition level E, so it binds more tightly. The recursive operand on the left of E→E+T and T→T*F enforces left association for each operator. Parentheses in F can override the default grouping.

Why each choice is right or wrong

A - Incorrect: The recursive nonterminal is on the left, producing left rather than right association.

B - Correct: Separate T multiplication and E addition levels give higher multiplication precedence and left association.

C - Incorrect: Addition is left-recursive too, so it does not have the claimed right association.

D - Incorrect: The grammar explicitly encodes both precedence levels and associativity.

Primary note proof

Study-note section COMP10

> Use E→E+T|T, T→T*F|F, F→(E)|id to give * higher precedence and both operators left associativity. For subtraction, a−b−c then groups (a−b)−c.

Question sources

Compiler Design review questions · Question 3

Question 151 | NS0231

For a reduced CFG (all symbols reachable and productive), which conditions prevent it from being LL(1)? Select all that apply. In A, overlap means a shared terminal in competing RHS FIRST sets.

A. Two productions for the same non-terminal have overlapping FIRST sets |

B. The grammar contains a left-recursive rule

C. The grammar is ambiguous |

D. A and B only

Hint

Use construction direction, lookahead and grammar restrictions. Distinguish algorithm families, implementations and coverage before comparing them.

Answer A, B, C: Two productions for the same non-terminal have overlapping FIRST sets |; The grammar contains a left-recursive rule; The grammar is ambiguous |

A shared FIRST terminal for alternatives of one nonterminal creates a predictive-table collision. Reachable left recursion prevents ordinary LL(1) prediction, and an ambiguous useful grammar cannot have a unique LL(1) parse. Thus A, B and C are all obstructions. The combined D alternative wrongly says only A and B, excluding ambiguity, so it is not a complete correct selection.

Why each choice is right or wrong

A - Correct: Shared FIRST terminals create competing table entries.

B - Correct: Reachable left recursion rules out ordinary LL(1) parsing.

C - Correct: A useful ambiguous grammar is not LL(1).

D - Incorrect: The word only wrongly excludes the valid ambiguity obstruction.

Primary note proof

Study-note section COMP14

> For every A→α, put it in M[A,a] for each terminal a in FIRST(α). If α is nullable, also enter it under every symbol in FOLLOW(A). More than one production in a cell is a conflict. Pairwise SELECT sets must be disjoint; SELECT(α)=FIRST(α)−{ε}, plus FOLLOW(A) when α is nullable. This also detects two nullable alternatives.

Study-note section COMP12

> Indirect left recursion follows a cycle through other nonterminals and also needs removal for ordinary predictive descent.

Study-note section COMP12

> LR parsers can handle suitable left-recursive grammars; ordinary unmodified recursive descent can recurse forever before consuming input.

Study-note section COMP18

> Deterministic LL/LR grammars must be unambiguous; a general ambiguous grammar requires rewriting, disambiguation policy or a generalized method such as GLR.

Question sources

Compiler Design review questions · Question 4

Question 152 | NS0232

Which of the following is an example of a synthesized attribute in attribute grammars?

A. The type of an expression computed from its sub-expressions |

B. The scope environment passed down to a block

C. The inherited type context for a function body |

D. The enclosing loop level passed to a break statement

Hint

Track where each computed value comes from and when each production action runs. Distinguish the representation from its attached information.

Answer A: Expression type computed from subexpressions is synthesized.

COMP24 defines synthesized attributes by flow from children to a parent. Computing an expression's type from its subexpressions fits this direction. Scope, type context and enclosing-loop information passed down from surrounding constructs instead supply inherited context. The direction of dependency, rather than the fact that types are involved, distinguishes these choices.

Why each choice is right or wrong

A - Correct: The parent expression derives its type from child subexpressions, which is synthesized upward flow.

B - Incorrect: A scope environment passed down to a block is inherited contextual information.

C - Incorrect: A type context supplied to a function body flows from its surroundings, so it is inherited.

D - Incorrect: Enclosing-loop context is passed inward to a break statement rather than synthesized from its children.

Primary note proof

Study-note section COMP24

> A syntax-directed definition is a CFG with attributes on grammar symbols and semantic rules on productions. An annotated parse tree displays computed attribute values; it is not itself an inherited or synthesized attribute. Synthesized attributes flow from children to a parent; inherited attributes carry context from parent or siblings.

Study-note section COMP24

For E→E1+T, E.val=E1.val+T.val synthesizes an expression value. A declaration's type environment passed into its body is inherited. S-attributed definitions use only synthesized attributes and fit LR reduction-time evaluation naturally; suitable LL parsers can also compute them. L-attributed definitions restrict dependencies so a left-to-right traversal can evaluate inherited context. Attribute dependency cycles can prevent evaluation.

Question sources

Compiler Design review questions · Question 5

Question 153 | NS0233

What is the primary purpose of Three-Address Code (TAC) as an intermediate representation?

A. To directly execute on the target CPU |

B. To provide a machine-independent representation suitable for optimization and code generation

C. To replace the symbol table |

D. To encode only arithmetic expressions

Hint

Identify what the representation stores, what it omits and which later transformations it must support; separate a representation property from an algorithmic task.

Answer B: An optimization-friendly intermediate representation for later target generation.

COMP26 gives reuse and separation as the purpose of IR and describes TAC as simple instruction records. TAC is normally not directly executed by a native CPU, does not replace declaration metadata and is not limited to arithmetic: branches and assignments are also representable. B states its architectural optimization/code-generation role most directly.

Why each choice is right or wrong

A - Incorrect: TAC is normally intermediate and requires lowering rather than direct execution on the target CPU.

B - Correct: TAC provides analyzable intermediate operations supporting reuse, optimization and later target-code generation.

C - Incorrect: A symbol table retains declaration metadata and is not replaced by the instruction representation.

D - Incorrect: TAC can encode control transfers and other operations, not only arithmetic expressions.

Primary note proof

Study-note section COMP26

IR separates source analysis from target implementation, allowing optimizers and backends to be reused. It should be easy to generate, analyze, transform and lower.

Study-note section COMP26

Ordinary TAC arithmetic has at most one operation, two sources and one destination: t1=c*d; t2=b+t1; a=t2. Quadruples store (op,arg1,arg2,result); triples omit an explicit result field and refer to instruction positions. Indirect triples reference a separate ordering list, easing rearrangement. Trees describe expressions; DAGs share common subexpressions, while quadruples/triples are instruction-record structures.

Question sources

Compiler Design review questions · Question 6

Question 154 | NS0234

The 'maximal munch' rule in lexical analysis means:

A. The lexer always produces the shortest possible token |

B. The lexer always produces the longest possible token matching the current position

C. Keyword tokens are prioritized over identifiers |

D. Comments are included in the token stream

Hint

Follow the representation at each construction step and apply the pattern or state-set rules consistently, including empty cases.

Answer B: Choose the longest matching lexeme at the current position.

COMP07 defines longest matching lexeme selection at each input position. Equal-length matches use rule order, which is a separate tie-breaking rule; keywords do not override a longer identifier such as ifx. Comments are normally skipped rather than retained merely because maximal munch is used. This establishes B as the definition.

Why each choice is right or wrong

A - Incorrect: Shortest-match selection is the opposite of maximal munch.

B - Correct: The lexer consumes the longest available match beginning at the current input position.

C - Incorrect: Keyword priority can break equal-length rule ties but does not define longest match.

D - Incorrect: Comment retention is independent of longest match; ordinary comments are skipped.

Primary note proof

Study-note section COMP07

> At each input position, choose the longest matching lexeme; if equal lengths match multiple flex rules, choose the earliest rule. Thus ifx is an identifier rather than if followed by x; <= and ++ are each one operator token. An implementation may recognize an identifier first and then consult a keyword table.

Question sources

Compiler Design review questions · Question 7

Question 155 | NS0235

In bottom-up parsing, a 'shift-reduce conflict' occurs when:

A. There are two possible reductions for the same stack top |

B. The parser cannot decide whether to shift the next input token or reduce the current stack contents

C. The grammar is left-recursive |

D. The FOLLOW set is empty

Hint

Use construction direction, lookahead and grammar restrictions. Distinguish algorithm families, implementations and coverage before comparing them.

Answer B: A competing shift and reduction on the same situation.

COMP17 defines a shift/reduce conflict as a choice between consuming a token and reducing. Two competing reductions describe reduce/reduce instead. Left recursion may be entirely acceptable to LR, and an empty FOLLOW set is not the definition of this table conflict. The conflict concerns competing actions for the same state and lookahead.

Why each choice is right or wrong

A - Incorrect: Two possible reductions define a reduce/reduce conflict, a different conflict type.

B - Correct: The same parser situation permits both shifting input and reducing the recognized right-hand side.

C - Incorrect: LR can handle suitable left recursion; that property does not itself define a shift/reduce conflict.

D - Incorrect: FOLLOW-set emptiness does not express competing shift and reduction actions.

Primary note proof

Study-note section COMP17

> SLR(1) uses LR(0) states and FOLLOW(A) for reduction by a completed A production. Canonical LR(1) attaches context-specific lookahead to items. LALR(1) merges canonical states with the same LR(0) core, combining lookaheads; merging can introduce reduce/reduce conflicts. The standard grammar-class hierarchy is LR(0)⊆SLR(1)⊆LALR(1)⊆LR(1), with increasing capability and often table size.

Study-note section COMP17

> A shift/reduce conflict offers both consuming a token and reducing; reduce/reduce offers two reductions. An SLR or LALR conflict does not by itself prove the grammar ambiguous. Canonical LR(1) handles LR(1) grammars, not every unambiguous CFG. Precedence and associativity can resolve suitable expression conflicts; changing parser names alone does not repair all ambiguity.

Question sources

Compiler Design review questions · Question 8

Question 156 | NS0236

Which optimization technique moves loop-invariant computations outside the loop body?

A. Strength reduction |

B. Loop unrolling

C. Loop-invariant code motion (LICM) |

D. Dead code elimination

Hint

Trace whether computation is evaluated, moved, shared or removed. Preserve observable effects and use the stated arithmetic and target assumptions.

Answer C: Loop-invariant code motion.

COMP32 explains that an expression whose inputs remain unchanged can be moved to a preheader when safe on newly executed paths. That is loop-invariant code motion. Strength reduction changes operation cost, unrolling replicates the body, and dead-code elimination removes unused or unreachable work. Hoisting also requires safety, not merely unchanged operands.

Why each choice is right or wrong

A - Incorrect: Strength reduction substitutes a cheaper equivalent operation rather than necessarily moving it outside a loop.

B - Incorrect: Unrolling replicates loop bodies instead of hoisting invariant computations.

C - Correct: LICM moves invariant computations to an appropriate outside location when executing them there is safe.

D - Incorrect: Dead-code elimination removes unnecessary computations rather than relocating a needed invariant value.

Primary note proof

Study-note section COMP32

> A loop-invariant expression has unchanged inputs during a loop. Hoist it to a preheader only when evaluation is safe on the paths where it will newly run. Induction variables change by a loop-invariant increment, such as i=i+1. For repeated t=4*i, maintain a running t increased by 4 when equivalent, reducing repeated multiplication.

Study-note section COMP32

> Loop fusion or jamming combines loops with compatible bounds and safe dependence order. Unrolling replicates a body to reduce branch overhead and expose parallelism; handle remaining iterations and increased code size. Loop-invariant code motion, fusion, unrolling and strength reduction are different transformations. A finite taxonomy needs a criterion: machine dependent/independent versus local/global/loop are different classifications.

Question sources

Compiler Design review questions · Question 9

Question 157 | NS0237

What does 'register spilling' mean in the context of register allocation?

A. Allocating the same register to two variables |

B. Storing a variable in memory instead of a register because no register is available

C. Using floating-point registers for integer values |

D. Eliminating unnecessary register copies

Hint

Match stored information to its lifetime, access path and calling-convention role; distinguish compile-time organization from run-time storage.

Answer B: Store selected values in memory and insert loads/stores when registers do not suffice.

COMP36 says spilling places selected values in memory when the register assignment cannot fit available registers. Loads and stores then connect memory-resident values to instructions needing registers. Register sharing can be legal for nonoverlapping live ranges, while copy elimination and choosing a different register class are separate operations rather than this storage fallback.

Why each choice is right or wrong

A - Incorrect: Register sharing may be legal for disjoint live ranges and does not itself describe spilling.

B - Correct: Spilling moves selected values to memory because a feasible register-only assignment is unavailable.

C - Incorrect: Using another register class is not the definition of writing spilled values to memory.

D - Incorrect: Removing redundant register copies is a different optimization from memory-backed spilling.

Primary note proof

Study-note section COMP36

> A value is live where it can be used before redefinition. In the interference model, values that must coexist in distinct registers are connected by an edge; each register is a color. Nonoverlapping live ranges may share a register. If a valid assignment cannot fit the available registers, spilling places selected values in memory and inserts loads/stores.

Study-note section COMP36

The general graph k-colorability decision problem is NP-complete for fixed k≥3; optimal register assignment/spill minimization is a hard optimization problem in general, so practical allocators use heuristics.

Question sources

Compiler Design review questions · Question 10

Question 158 | NS0238

For Java numeric conversions such as int→long and int→float, which statement correctly describes widening?

A. Converting a wider type to a narrower type, possibly losing information |

B. Converting to a numeric type with a wider representable range; some widening conversions can still lose precision.

C. Declaring a variable with an explicit type annotation |

D. Assigning a value to a pointer of a different type

Hint

Check operand compatibility and permitted conversions under the stated language rules; distinguish grammatical structure from semantic meaning.

Answer B: Converting to a numeric type with a wider representable range; some widening conversions can still lose precision.

Java int→long is widening and exact, while int→float is also widening even though some large integer values round. Widening therefore does not universally guarantee preservation of every bit of precision. Narrowing goes toward a more restricted representation; type annotations and arbitrary pointer changes are separate concepts. Option B captures the relevant larger-range conversion without making the false no-loss promise.

Why each choice is right or wrong

A - Incorrect: This describes narrowing rather than widening.

B - Correct: Widening can increase range while still losing precision, as int→float illustrates.

C - Incorrect: An explicit annotation declares a type rather than converting a value.

D - Incorrect: An arbitrary pointer-type change does not define Java numeric widening.

Primary note proof

Study-note section COMP23

Coercion is an implicit conversion permitted by the language; a cast requests an explicit conversion. Widening often increases representable range, but can still lose precision: Java int→float is widening although large integers round. Java int→long is exact. Narrowing can lose range or fractional information.

Study-note section COMP23

> In C++ ordinary int x=3.14 converts to 3 when representable; it is not inherently a type error. int x{3.14} is rejected as narrowing. C++ floating-to-integer conversion discards the fraction and has undefined behavior if the truncated value is unrepresentable. Java ordinary double→int assignment needs a permitted explicit cast. Mixing char and int is ordinarily valid after promotion in C++/Java; do not import a fictitious universal ban.

Question sources

Compiler Design review questions · Question 11

Question 159 | NS0239

Which of the following data structures is most commonly used to implement a symbol table for fast insertion and lookup?

A. Sorted linked list |

B. Hash table

C. Binary search tree |

D. Stack

Hint

Ask whether the required information is a declaration’s identity and attributes, program structure or the ordered source tokens.

Answer B: A hash table.

COMP19 directly identifies hashing as giving expected constant-time insertion and lookup under suitable hashing. A stack supports nested scope order but is not the primary keyed mapping. Lists and trees are possible alternatives, yet neither is the specific common expected-constant-time structure emphasized in the note and requested by the stem.

Why each choice is right or wrong

A - Incorrect: A sorted linked list generally requires linear search and does not supply the highlighted expected constant lookup.

B - Correct: Hash tables commonly implement expected O(1) symbol insertion and lookup.

C - Incorrect: A search tree is possible, but the note specifically identifies hashing for the usual fast keyed implementation.

D - Incorrect: A stack organizes scope nesting rather than providing fast arbitrary name lookup within a scope.

Primary note proof

Study-note section COMP19

> A symbol table maps names or symbol identities to attributes: type, scope, width, storage offset, parameter signature, constant information or linkage. A hash table gives expected O(1)

insertion/lookup with suitable hashing; a stack of scope tables supports lexical nesting. Search the nearest scope first, insert declarations in the current scope, and remove visibility when leaving it.

Study-note section COMP19

Scanning may intern a spelling first; semantic analysis determines the declaration and type. Implementations differ, so first interaction is conventional rather than universal. Not every punctuation token needs a symbol-table entry; literals may use a separate literal table. A hash table is an implementation, not the information’s semantic role.

Question sources

Compiler Design review questions · Question 12

Question 160 | NS0240

A grammar is said to be 'left-factored' when:

A. All productions are left-recursive |

B. Productions for the same non-terminal that share a common prefix are rewritten to factor out the prefix

C. The grammar has no ε-productions |

D. The grammar can be parsed by a bottom-up parser only

Hint

Use construction direction, lookahead and grammar restrictions. Distinguish algorithm families, implementations and coverage before comparing them.

Answer B: Common prefixes are factored out of alternatives.

COMP12 rewrites A→αβ|αγ as A→αA′ and A′→β|γ. The transformation postpones the alternative choice until after consuming the common prefix. It does not mean making productions left-recursive, removing all epsilon rules or restricting parsing to bottom-up methods; left factoring alone also does not guarantee LL(1).

Why each choice is right or wrong

A - Incorrect: Left recursion and left factoring are distinct properties and transformations.

B - Correct: Factoring extracts shared prefixes and delays selection between the remaining suffix alternatives.

C - Incorrect: Factoring does not require removing every epsilon production.

D - Incorrect: Factored grammars can support top-down prediction; bottom-up exclusivity is not a defining condition.

Primary note proof

Study-note section COMP12

> Left factoring rewrites A→αβ|αγ using:
> A→αA′
> A′→β|γ
> It postpones a choice until after the common prefix. It does not by itself remove ambiguity or guarantee LL(1). LR parsers can handle suitable left-recursive grammars; ordinary unmodified recursive descent can recurse forever before consuming input.

Question sources

Compiler Design review questions · Question 13

Question 161 | NS0241

What is 'constant propagation' in compiler optimization?

A. Evaluating constant expressions at compile time |

B. Replacing uses of a variable with its known constant value at each program point

C. Removing code that has no effect on program output |

D. Moving constants from memory to registers

Hint

Trace whether computation is evaluated, moved, shared or removed. Preserve observable effects and use the stated arithmetic and target assumptions.

Answer B: Replace uses with their known constant values.

COMP30 gives x=3; y=x+2 becoming y=3+2 before folding. Replacing x by its known value is propagation; evaluating 3+2 is folding. Removing unnecessary code or choosing register locations addresses different transformations. The program-point qualification matters because the value must still be known on all relevant incoming paths.

Why each choice is right or wrong

A - Incorrect: Evaluating an already constant expression is constant folding, which can follow propagation.

B - Correct: Propagation substitutes a variable’s established constant value at uses where that fact holds.

C - Incorrect: Removing effect-free unused or unreachable work is dead-code elimination.

D - Incorrect: Memory-to-register placement is not the substitution of a known compile-time value.

Primary note proof

Study-note section COMP30

> Constant folding evaluates constant expressions during compilation: 3*4→12. Constant propagation substitutes known values: x=3; y=x+2 becomes y=3+2 before folding. Copy propagation substitutes a copied name while its source remains unchanged. Dead-code elimination removes unreachable code or computations whose values are unused and whose evaluation has no necessary side effects.

Question sources

Compiler Design review questions · Question 14

Question 162 | NS0242

In an LR parsing table, what does a 'reduce/reduce conflict' indicate?

A. Two different productions can both be used to reduce the same stack contents with the same lookahead |

B. The parser must both shift and reduce on the same input symbol

C. The grammar has a dangling else problem |

D. The grammar contains ε-productions

Hint

Use construction direction, lookahead and grammar restrictions. Distinguish algorithm families, implementations and coverage before comparing them.

Answer A: Two competing reductions for the same parser state/lookahead.

COMP17 defines reduce/reduce as two reductions being available. In a parsing table that means the same state and lookahead permit different completed productions. A shift competing with reduction is another conflict type. Dangling else is a grammar ambiguity example, and epsilon productions alone do not guarantee any reduce/reduce collision.

Why each choice is right or wrong

A - Correct: The table offers two different production reductions for the same state and lookahead.

B - Incorrect: Simultaneous shift and reduce actions define shift/reduce rather than reduce/reduce.

C - Incorrect: Dangling else commonly creates an attachment ambiguity, not the definition of two competing reductions.

D - Incorrect: Epsilon rules can appear in conflict-free grammars and do not alone imply this collision.

Primary note proof

Study-note section COMP17

> SLR(1) uses LR(0) states and FOLLOW(A) for reduction by a completed A production. Canonical LR(1) attaches context-specific lookahead to items. LALR(1) merges canonical states with the same LR(0) core, combining lookaheads; merging can introduce reduce/reduce conflicts. The standard grammar-class hierarchy is LR(0)⊆SLR(1)⊆LALR(1)⊆LR(1), with increasing capability and often table size.

Study-note section COMP17

> A shift/reduce conflict offers both consuming a token and reducing; reduce/reduce offers two reductions. An SLR or LALR conflict does not by itself prove the grammar ambiguous. Canonical LR(1) handles LR(1) grammars, not every unambiguous CFG. Precedence and associativity can resolve suitable expression conflicts; changing parser names alone does not repair all ambiguity.

Question sources

Compiler Design review questions · Question 15

Question 163 | NS0243

Which compiler phase is primarily responsible for detecting the incompatible assignment in the Java declaration int x = "hello";?

A. Lexical analysis |

B. Syntax analysis

C. Semantic analysis |

D. Code generation

Hint

Check operand compatibility and permitted conversions under the stated language rules; distinguish grammatical structure from semantic meaning.

Answer C: Semantic analysis |

The declaration has recognizable tokens and a valid declaration-shaped syntax, but assigns a string to an integer variable. Under Java's type rules this violates assignment compatibility, so semantic analysis and type checking identify the error. Scanning recognizes the identifier, type keyword and literal; parsing organizes them. Code generation uses the checked representation later. The named language removes any assumption that every statically typed language has identical implicit conversions.

Why each choice is right or wrong

A - Incorrect: The individual tokens are recognizable; the error is their type compatibility.

B - Incorrect: The declaration's grammar structure is not the primary problem.

C - Correct: Semantic type checking rejects the string-to-integer assignment.

D - Incorrect: Code generation follows the frontend type check rather than defining this compatibility rule.

Primary note proof

Study-note section COMP08

> A lexical error prevents forming a legal token, such as an invalid character or unterminated literal. A syntax error is an illegal token arrangement, such as a missing delimiter. A semantic error violates name, scope or type rules after grammatical recognition. A wrong algorithm can compile successfully; compilers do not detect all logical mistakes.

Study-note section COMP22

> int x="hello" is a type mismatch in ordinary C++/Java; division by zero and bounds violations are not automatically operand-type mismatches.

Question sources

Compiler Design review questions · Question 16

Question 164 | NS0244

In Thompson's construction for building an NFA from a regular expression, the NFA for the concatenation r1r2 is built by:

A. Merging the start states of both NFAs |

B. Adding an ε-transition from the accepting state(s) of the NFA for r1 to the start state of the NFA for r2

C. Creating a new start state with ε-transitions to both NFAs |

D. Taking the cross product of the two NFAs

Hint

Follow the representation at each construction step and apply the pattern or state-set rules consistently, including empty cases.

Answer B: Connect the first fragment’s accepting end to the second start with ε.

COMP06 directly gives the concatenation rule: connect r’s final state to s’s start by epsilon. This forces any complete path through the first fragment to continue through the second in order. Branching epsilon paths instead implement alternation; merged starts and product constructions do not implement the specified Thompson concatenation step.

Why each choice is right or wrong

A - Incorrect: Merging starts does not force a complete r1 match followed by an r2 match.

B - Correct: The epsilon connection joins the first accepting end to the second start without consuming input.

C - Incorrect: A new branching start with epsilon alternatives implements union rather than concatenation.

D - Incorrect: A state cross product is not the Thompson fragment connection for concatenation.

Primary note proof

Study-note section COMP06

> A common generator pipeline is regular expressions → NFA using Thompson construction → DFA using subset construction; minimization is optional. For concatenation rs, connect r’s final state to s’s start by ε. Alternation introduces branching ε paths; star adds a way to skip and repeat the fragment.

Study-note section COMP06

> The ε-closure of states includes those reachable by zero or more ε edges. A DFA state is a set of NFA states; its a-transition is ε-closure(move(set,a)). Start with the NFA start closure, repeatedly add unseen subsets, and mark subsets containing an NFA final state as accepting. Token identity and rule priority annotate accepting states; the empty subset acts as a dead state.

Question sources

Compiler Design review questions · Question 17

Question 165 | NS0245

What is the 'dangling else' problem?

A. An else branch that can never be reached due to preceding conditions |

B. Ambiguity in grammars that allows an else to be matched with either of two if statements

C. An else clause that lacks a body |

D. An else used outside an if statement

Hint

Identify each activity's input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer B: Ambiguous attachment of else to one of two nested ifs.

COMP10 describes an else that can attach to either nested if and resolves it with nearest-unmatched-if policy or a grammar rewrite. That grammatical ambiguity is the dangling-else problem. It does not mean unreachable code, a missing body or an else outside any if, which are different semantic or syntactic situations.

Why each choice is right or wrong

A - Incorrect: Unreachability concerns control-flow feasibility, not the competing grammatical attachment of else.

B - Correct: The ambiguity is whether else belongs to the inner or outer unmatched if.

C - Incorrect: A missing else body is a syntax defect rather than the classic attachment ambiguity.

D - Incorrect: An else outside any if is not the two-attachment situation defining dangling else.

Primary note proof

Study-note section COMP10

> The dangling-else grammar permits else to attach to either nested if; a nearest-unmatched-if rule or grammar rewrite resolves it. Taking a leftmost derivation by itself does not resolve ambiguous interpretation.

Question sources

Compiler Design review questions · Question 18

Question 166 | NS0246

Which representation explicitly uses basic blocks as vertices and possible transfers as edges, making it the direct structural basis for dominator and natural-loop analysis?

A. Abstract Syntax Tree (AST) |

B. Three-Address Code (TAC)

C. Static Single Assignment (SSA) form |

D. Control Flow Graph (CFG)

Hint

Identify what the representation stores, what it omits and which later transformations it must support; separate a representation property from an algorithmic task.

Answer D: Control Flow Graph (CFG)

A control-flow graph explicitly records basic blocks and their possible successor transfers. Dominator relationships describe which blocks occur on every path to another block; back edges to dominating headers identify natural loops. TAC can populate the blocks, and SSA can coexist with this graph, but neither alone names the requested vertex/edge structure. An AST emphasizes source syntax rather than this control-flow representation.

Why each choice is right or wrong

A - Incorrect: An AST represents source hierarchy rather than the specified block-transfer graph.

B - Incorrect: TAC gives instructions, not by itself the requested graph.

C - Incorrect: SSA is a definition-naming discipline that can coexist with a CFG.

D - Correct: A CFG explicitly provides the specified blocks, edges and path structure.

Primary note proof

Study-note section COMP28

> A basic block is a maximal straight-line instruction sequence entered at its beginning and exited at its end. Leaders are the first instruction, every jump target, and each instruction after a branch. Start a block at each leader and continue until the next leader.

Study-note section COMP28

> A control-flow graph has blocks as vertices and possible next-block transfers as edges, including fall-through. A node D dominates N when every entry-to-N path passes through D. For an edge N→H where H dominates N, H is a loop header of a natural loop. This structure supports loop analysis. An expression DAG records value dependencies, not arbitrary control flow.

Question sources

Compiler Design review questions · Question 19

Question 167 | NS0247

In Static Single Assignment (SSA) form, what is the purpose of a 'φ (phi) function'?

A. To represent a conditional branch in the control flow graph |

B. To select the correct version of a variable at join points where multiple control flow paths merge

C. To mark the entry point of a function |

D. To represent a loop-back edge in the CFG

Hint

Identify what the representation stores, what it omits and which later transformations it must support; separate a representation property from an algorithmic task.

Answer B: Select the incoming variable version corresponding to the predecessor taken.

COMP27 defines phi at a join as choosing an incoming value according to the actual predecessor path. It is not a conditional branch instruction, a function-entry marker or a back edge, and does not average its operands. The function reconciles distinct definition names when different paths reach the same use.

Why each choice is right or wrong

A - Incorrect: A phi function selects an incoming value; it does not transfer control between blocks.

B - Correct: It merges definition versions by selecting the value associated with the predecessor actually taken.

C - Incorrect: Function entry is a control-flow location, not the value-selection purpose of phi.

D - Incorrect: A back edge represents loop control transfer rather than a merge of SSA values.

Primary note proof

Study-note section COMP27

> A conditional expression can generate if a<b goto Ltrue; goto Lfalse; labels join control paths. Short-circuit AND evaluates the right operand only after a true left operand; OR only after a false one. Translating both eagerly can change side effects. For a zero-based array with element width w and lower bound L, element i uses base+(i−L)*w, assuming fixed-width contiguous storage.

Study-note section COMP27

> SSA gives each definition a distinct name. At a join, x3=φ(x1 from B1,x2 from B2) chooses the incoming value according to the predecessor actually taken; it is not an arithmetic average. SSA is a naming discipline over IR and commonly coexists with a control-flow graph.

Question sources

Compiler Design review questions · Question 20

Question 168 | NS0248

The FOLLOW set of the start symbol S always contains:

A. ε (epsilon) |

B. The end-of-input marker $

C. The first terminal of every production |

D. Nothing; FOLLOW(S) is always empty

Hint

Use construction direction, lookahead and grammar restrictions. Distinguish algorithm families, implementations and coverage before comparing them.

Answer B: The end-of-input marker $.

COMP13 explicitly places $ in FOLLOW(S), representing that a completed start-symbol derivation can be followed by end of input. FOLLOW never contains epsilon. Possible initial terminals belong to FIRST, not automatically FOLLOW. Therefore the marker is guaranteed even when other following terminals depend on the grammar.

Why each choice is right or wrong

A - Incorrect: FOLLOW contains terminals and possibly the end marker, never epsilon.

B - Correct: The end-of-input marker is placed in FOLLOW of the start symbol by initialization.

C - Incorrect: Initial terminals are FIRST information and are not automatically following terminals.

D - Incorrect: FOLLOW(S) is not empty because it contains the end marker.

Primary note proof

Study-note section COMP13

> FIRST(α) contains terminals that can begin strings derived from α, plus ε when α can vanish. For a sequence, add FIRST of each symbol except ε, continue while symbols are nullable, and add ε only if every symbol is nullable.

Study-note section COMP13

> FOLLOW(A) contains possible next terminals after A, plus end marker $ where appropriate; never ε. Put $ in FOLLOW(S). For B→αAβ, add FIRST(β)−{ε} to FOLLOW(A); if β is nullable, add FOLLOW(B). Repeat all rules until no sets grow.

Question sources

Compiler Design review questions · Question 21

Question 169 | NS0249

For an unsigned fixed-width integer x with width greater than three and modular arithmetic, which optimization replaces x = x * 8 with x = x << 3?

A. Constant folding |

B. Dead code elimination

C. Strength reduction |

D. Loop unrolling

Hint

Trace whether computation is evaluated, moved, shared or removed. Preserve observable effects and use the stated arithmetic and target assumptions.

Answer C: Strength reduction |

The transformation replaces multiplication by a power of two with an equivalent shift under the stated unsigned model. This is strength reduction when the target makes that replacement cheaper. It does not evaluate a constant-only expression because x remains variable, does not remove an unused statement, and does not replicate loop iterations. The explicit arithmetic model matters because signed-language overflow or shift rules can make a superficially similar rewrite invalid.

Why each choice is right or wrong

A - Incorrect: The operand x remains variable, so this is not evaluation of an all-constant expression.

B - Incorrect: The assignment remains and still computes a needed result.

C - Correct: Replacing an operation by an equivalent cheaper form is strength reduction.

D - Incorrect: No loop body is replicated.

Primary note proof

Study-note section COMP31

> Algebraic simplification removes identities when valid: integer x+0→x. Strength reduction replaces an operation with an equivalent cheaper form, such as unsigned x*8→x<<3 for a valid width and shift count. Target costs determine whether it is actually cheaper.

Study-note section COMP33

> Signed C/C++ overflow and shift rules differ from unsigned modular arithmetic; a mathematical identity is not automatically a legal transformation.

Study-note section COMP32

> Unrolling replicates a body to reduce branch overhead and expose parallelism; handle remaining iterations and increased code size.

Question sources

Compiler Design review questions · Question 22

Question 170 | NS0250

In a compiler's code generator, 'calling convention' refers to:

A. The order in which source files are compiled |

B. The agreed-upon protocol for how functions pass arguments, return values, and manage the stack

C. The naming convention for generated labels |

D. The format of debug information in the object file

Hint

Match stored information to its lifetime, access path and calling-convention role; distinguish compile-time organization from run-time storage.

Answer B: The protocol for arguments, results, registers and stack management.

COMP37 defines the locations of arguments/results, saved-register responsibilities, stack alignment and frame duties as the calling convention. These permit caller and callee to agree on the runtime call interface. Source-file build order, label spelling and debug format concern other compiler/toolchain conventions rather than this execution protocol.

Why each choice is right or wrong

A - Incorrect: Compilation order concerns build organization rather than the runtime interface between callers and callees.

B - Correct: The calling convention specifies argument/result passing and register/stack responsibilities.

C - Incorrect: Label naming is separate from the runtime storage and control-transfer call protocol.

D - Incorrect: Debug information format is not the protocol used to invoke and return from functions.

Primary note proof

Study-note section COMP37

> Static storage lasts throughout execution; stack frames support nested calls and recursion; heap storage supports lifetimes beyond a call. A frame may contain parameters, return address, saved registers, locals and temporaries. Sizes, alignment and offsets are target-dependent; a two-byte int is an example, not a C++ guarantee.

Study-note section COMP37

> A calling convention specifies argument and result locations, caller/callee-saved registers, stack alignment and frame responsibilities. Escape analysis asks whether an object/reference can

outlive or be accessed outside a region such as its allocating call. Proven nonescaping allocations may use stack storage or be eliminated by scalar replacement, provided identity and lifetime semantics remain correct.

Question sources

Compiler Design review questions · Question 23

Question 171 | NS0251

What does 'peephole optimization' involve?

A. Optimizing entire functions at once |

B. Examining and replacing small sequences of generated instructions with more efficient equivalents

C. Inlining small functions at call sites |

D. Eliminating unreachable basic blocks

Hint

Trace whether computation is evaluated, moved, shared or removed. Preserve observable effects and use the stated arithmetic and target assumptions.

Answer B: Examine short instruction sequences and replace them with better equivalents.

COMP31 defines peephole optimization by short instruction windows and lists redundant-load removal, machine idioms and jump-chain shortening. B states that method directly. Whole-function optimization has a broader scope; inlining changes calls to bodies, and unreachable-block removal is a particular control-flow simplification rather than the definition of examining small windows.

Why each choice is right or wrong

A - Incorrect: Whole-function scope is broader than the short instruction windows defining peephole optimization.

B - Correct: The optimizer inspects short instruction sequences and substitutes equivalent more efficient forms.

C - Incorrect: Inlining expands calls into bodies rather than defining the local instruction-window method.

D - Incorrect: Unreachable-block removal is one control-flow optimization, not the defining peephole inspection mechanism.

Primary note proof

Study-note section COMP31

> Peephole optimization examines short instruction windows. It can remove redundant loads/stores, replace machine idioms and shorten jump chains: jump L1 where L1 immediately jumps L2 can become jump L2.

Question sources

Compiler Design review questions · Question 24

Question 172 | NS0252

Which statement correctly compares LALR(1) with SLR(1) and canonical LR(1), allowing the case where no equal-core canonical states need merging?

A. LALR(1) is weaker than SLR(1) |

B. LALR(1) has no more states than canonical LR(1) and can resolve some conflicts SLR(1) cannot.

C. LALR(1) and SLR(1) produce identical parsing tables for all grammars |

D. LALR(1) requires more lookahead than SLR(1)

Hint

Use construction direction, lookahead and grammar restrictions. Distinguish algorithm families, implementations and coverage before comparing them.

Answer B: LALR(1) has no more states than canonical LR(1) and can resolve some conflicts SLR(1) cannot.

LALR combines lookaheads of canonical LR(1) states with equal LR(0) cores. This gives no more states than the canonical machine, with a reduction when distinct equal-core states merge. LALR can handle some grammars beyond SLR because its lookaheads are more precise. Both use one lookahead token, and their tables are not identical for every grammar.

Why each choice is right or wrong

A - Incorrect: The hierarchy places SLR within LALR rather than the reverse.

B - Correct: This states both the correct state-count bound and the greater parsing capability.

C - Incorrect: The methods can use different reduction lookaheads and tables.

D - Incorrect: Both use one lookahead token.

Primary note proof

Study-note section COMP17

> SLR(1) uses LR(0) states and FOLLOW(A) for reduction by a completed A production. Canonical LR(1) attaches context-specific lookahead to items. LALR(1) merges canonical states with the same LR(0) core, combining lookaheads; merging can introduce reduce/reduce conflicts. The standard grammar-class hierarchy is LR(0)⊆SLR(1)⊆LALR(1)⊆LR(1), with increasing capability and often table size.

Study-note section COMP17

> A shift/reduce conflict offers both consuming a token and reducing; reduce/reduce offers two reductions. An SLR or LALR conflict does not by itself prove the grammar ambiguous. Canonical LR(1) handles LR(1) grammars, not every unambiguous CFG. Precedence and associativity can resolve suitable expression conflicts; changing parser names alone does not repair all ambiguity.

Question sources

Compiler Design review questions · Question 25

Question 173 | NS0253

In data flow analysis, 'live variable analysis' is a:

A. Forward may-analysis |

B. Backward may-analysis

C. Forward must-analysis |

D. Backward must-analysis

Hint

Track which facts can hold along one path and which must hold along every path. Apply the specified direction, transfer rule and join operation.

Answer B: Backward may-analysis.

COMP29 explicitly calls liveness backward may-analysis. A value is live if some future path reads it before redefinition, so information flows backward from successor uses and combines possible uses rather than requiring every path. This distinguishes both the direction and may-versus-must dimensions requested by the options.

Why each choice is right or wrong

A - Incorrect: May is appropriate, but liveness propagates from future uses backward rather than forward.

B - Correct: Liveness asks whether some future path uses a value before redefinition, a backward may property.

C - Incorrect: Both direction and must quantification differ from the liveness definition.

D - Incorrect: Backward direction fits, but liveness requires a possible use, not use on every path.

Primary note proof

Study-note section COMP29

> Liveness is backward may-analysis: a value might be read before redefinition on some future path. OUT[B]=union of IN over successors; IN[B]=USE[B]∪(OUT[B]−DEF[B]). Iterate to a fixed point. Liveness supports register allocation and dead-value removal. Definite-assignment analysis asks whether initialization occurs on every path before use; reaching definitions alone does not prove this.

Question sources

Compiler Design review questions · Question 26

Question 174 | NS0254

The 'closure' operation in NFA-to-DFA subset construction computes:

A. The set of all NFA states reachable from a given set of states using only ε-transitions |

B. The set of all NFA states reachable using any number of any transitions

C. The minimal DFA equivalent to the NFA |

D. The FIRST set of a non-terminal

Hint

Follow the representation at each construction step and apply the pattern or state-set rules consistently, including empty cases.

Answer A: States reachable by zero or more ε transitions.

COMP06 defines epsilon closure as all states reachable without consuming input through zero or more epsilon edges. Zero moves includes the starting set itself. Arbitrary labeled transitions would consume symbols and belong to a different reachability relation; minimization and FIRST-set computation are separate algorithms. A therefore matches the closure used in subset construction.

Why each choice is right or wrong

A - Correct: Epsilon closure includes the starting set and every state reachable using only epsilon edges.

B - Incorrect: Arbitrary symbol transitions consume input and are not part of epsilon closure.

C - Incorrect: Closure supplies subsets during determinization; it does not itself minimize the resulting DFA.

D - Incorrect: FIRST is a grammar lookahead set, not epsilon reachability among NFA states.

Primary note proof

Study-note section COMP06

> A common generator pipeline is regular expressions → NFA using Thompson construction → DFA using subset construction; minimization is optional. For concatenation rs, connect r's final state to s's start by ε. Alternation introduces branching ε paths; star adds a way to skip and repeat the fragment.

Study-note section COMP06

> The ε-closure of states includes those reachable by zero or more ε edges. A DFA state is a set of NFA states; its a-transition is ε-closure(move(set,a)). Start with the NFA start closure, repeatedly add unseen subsets, and mark subsets containing an NFA final state as accepting. Token identity and rule priority annotate accepting states; the empty subset acts as a dead state.

Question sources

Compiler Design review questions · Question 27

Question 175 | NS0255

For a real-machine backend, which listed optimization chiefly depends on the target's instruction latencies and execution resources?

A. Constant folding |

B. Dead code elimination

C. Instruction scheduling |

D. Loop-invariant code motion

Hint

Trace whether computation is evaluated, moved, shared or removed. Preserve observable effects and use the stated arithmetic and target assumptions.

Answer C: Instruction scheduling |

Instruction scheduling chooses a legal instruction order while considering target resources and latencies. It is therefore the target-dependent backend choice in this comparison. Constant folding computes known expressions, dead-code elimination removes unnecessary computation while preserving effects, and loop-invariant motion relocates safe unchanged expressions. Their validity depends on program semantics, but these three need not be organized around a particular processor's scheduling resources.

Why each choice is right or wrong

A - Incorrect: Folding evaluates known expressions from program semantics rather than scheduling machine resources.

B - Incorrect: Dead-code elimination uses reachability, use and side-effect information.

C - Correct: Instruction scheduling considers target execution resources and instruction latencies.

D - Incorrect: Invariant motion uses loop values, paths and safety conditions rather than target issue scheduling.

Primary note proof

Study-note section COMP-S04

> Instruction scheduling orders selected target instructions while preserving dependencies. A target-aware scheduler also considers instruction latencies and the processor resources needed by each operation. This is a backend optimization whose performance choices depend on the target machine, even when a reusable scheduling framework serves many targets.

Study-note section COMP-S04

> By contrast, constant folding, dead-code elimination and safe loop-invariant motion can be expressed on a target-neutral IR using values, control flow and side-effect rules. Target costs can still influence whether a legal transformation is worthwhile. Machine independence therefore describes the abstraction of a pass, not freedom from all language semantics or implementation costs.

Question sources

Compiler Design review questions · Question 28

Question 176 | NS0256

In a context-free grammar, a 'sentential form' is:

A. A string consisting only of terminal symbols |

B. Any string of terminals and non-terminals derivable from the start symbol

C. A string that cannot be further reduced |

D. The right-hand side of a production rule

Hint

Identify each activity's input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer B: Any terminal/nonterminal string derivable from the start symbol.

COMP09 defines a sentential form as any string of terminals and nonterminals derivable from S. Terminal-only sentences are a special case, not the full definition. A production right side need not itself be reachable from S, and irreducibility does not define derivability. B captures the required reachability and permits both kinds of symbols.

Why each choice is right or wrong

A - Incorrect: Terminal-only strings are sentences, a subset of sentential forms rather than their full definition.

B - Correct: Derivability from the start symbol with terminals and possibly nonterminals is the defining property.

C - Incorrect: A sentential form can still contain expandable nonterminals; inability to reduce is not required.

D - Incorrect: A right-hand side is not necessarily reachable from the grammar's start symbol.

Primary note proof

Study-note section COMP09

> A context-free grammar G=(N,T,P,S) has nonterminals N, terminals T, productions P and start S. A production A→α rewrites one nonterminal. A sentential form is any string of terminals/nonterminals derivable from S; a sentence contains only terminals. A leftmost derivation rewrites the leftmost remaining nonterminal; a rightmost one rewrites the rightmost.

Study-note section COMP09

> A parse tree shows grammar productions: root S, internal nonterminals, and terminal leaves, with ε sometimes shown for empty productions. Its left-to-right yield is the input. An AST omits grammar scaffolding and punctuation; expression operands are leaves and operators internal nodes. The parser can build either representation, depending on implementation.

Question sources

Compiler Design review questions · Question 29

Question 177 | NS0257

What is 'function inlining' and what is its primary risk?

A. Replacing a function call with the function body; risk is incorrect semantics |

B. Replacing a function call with the function body; risk is increased code size (code bloat)

C. Moving a function to a different module; risk is linker errors |

D. Specializing a function for specific argument values; risk is type errors

Hint

Match stored information to its lifetime, access path and calling-convention role; distinguish compile-time organization from run-time storage.

Answer B: Replace a call with its body; excessive code size is a risk.

COMP38 defines inlining as substituting a suitably renamed body while preserving argument evaluation, returns and side effects. It can remove call overhead but increase code size and instruction-cache pressure. Correct inlining preserves semantics; corruption is an implementation bug rather than its defining trade-off. Moving modules or specializing arguments describes different transformations.

Why each choice is right or wrong

A - Incorrect: Inlining must preserve semantics; incorrect behavior is a bug rather than the normal primary trade-off stated here.

B - Correct: Body substitution can reduce call overhead while increasing generated code size.

C - Incorrect: Moving a function between modules is not call-site body substitution.

D - Incorrect: Argument specialization is a different optimization and does not define general function inlining.

Primary note proof

Study-note section COMP38

> Inlining replaces a call with a suitably renamed copy of its body, preserving argument evaluation, returns and side effects. It can remove call overhead and expose optimization opportunities, but may increase code size and instruction-cache pressure. A recursive function cannot simply be expanded without limit.

Study-note section COMP38

> Virtual dispatch chooses an overridden method based on a receiver’s runtime class. A common implementation uses a per-class virtual-method table and an object pointer to the table; the call loads the selected entry. This is an implementation strategy, not a universal language requirement. Name mangling distinguishes linker symbols, often for overloads; it is not itself runtime method selection. Proven receiver types may permit devirtualization.

Question sources

Compiler Design review questions · Question 30

Question 178 | NS0258

Which of the following best describes the 'handle' in bottom-up parsing?

A. The leftmost terminal in the input string |

B. A substring of the current sentential form that matches the right-hand side of a production and whose reduction leads to a valid parse

C. The top element of the parsing stack |

D. The lookahead token used for parsing decisions

Hint

Use construction direction, lookahead and grammar restrictions. Distinguish algorithm families, implementations and coverage before comparing them.

Answer B: The RHS occurrence whose next reverse-rightmost reduction leads toward the valid parse.

COMP15 defines a handle as a production RHS occurrence whose reduction is the next reverse-rightmost derivation step. B is the closest complete description: its valid-parse condition must mean that next legitimate step, not merely any matching substring. Neither a single stack item nor the lookahead alone specifies that contextual production occurrence.

Why each choice is right or wrong

A - Incorrect: The leftmost terminal need not be the handle and does not identify a production RHS occurrence.

B - Correct: Read valid reduction as the next reverse-rightmost step; contextual validity distinguishes a handle from arbitrary matches.

C - Incorrect: A handle can span multiple symbols and is not simply the top stack element.

D - Incorrect: Lookahead guides action selection but is not the substring being reduced.

Primary note proof

Study-note section COMP15

> Bottom-up parsing starts from input and reduces toward S, constructing a rightmost derivation in reverse. A handle is a production RHS occurrence whose reduction is the next step of that reverse derivation. Not every substring matching a RHS is a handle in the current context.

Study-note section COMP15

> Shift pushes the next input token and a state; reduce replaces a recognized RHS by its LHS and consults GOTO; accept recognizes completion; error reports an invalid situation. For A→XYZ, pop three grammar symbols and their states, expose state q, then push A and GOTO[q,A]. “Go” is not a separate standard shift-reduce ACTION, although GOTO is essential table machinery.

Question sources

Compiler Design review questions · Question 31

Question 179 | NS0259

In the context of code generation, what is a 'basic block'?

A. A block of memory allocated on the heap |

B. A maximal straight-line sequence of instructions with one entry point and one exit point

C. A function or procedure in the source code |

D. A group of related variable declarations

Hint

Identify what the representation stores, what it omits and which later transformations it must support; separate a representation property from an algorithmic task.

Answer B: A maximal straight-line sequence with entry at the beginning and exit at the end.

COMP28 directly defines this sequence as a basic block. Maximality means it is not arbitrarily shortened while retaining the same entry/exit structure. Heap allocation, whole functions and related declarations describe different entities; a function may contain many basic blocks separated by branch targets and control transfers.

Why each choice is right or wrong

A - Incorrect: A heap memory region is storage, not a straight-line control-flow unit.

B - Correct: This matches the maximal straight-line single-entry, end-exit definition in COMP28.

C - Incorrect: A function may contain branches and multiple basic blocks rather than one straight-line block.

D - Incorrect: Related declarations are not the instruction sequence defined by control-flow boundaries.

Primary note proof

Study-note section COMP28

> A basic block is a maximal straight-line instruction sequence entered at its beginning and exited at its end. Leaders are the first instruction, every jump target, and each instruction after a branch. Start a block at each leader and continue until the next leader.

Study-note section COMP28

> A control-flow graph has blocks as vertices and possible next-block transfers as edges, including fall-through. A node D dominates N when every entry-to-N path passes through D. For an edge N→H where H dominates N, H is a loop header of a natural loop. This structure supports loop analysis. An expression DAG records value dependencies, not arbitrary control flow.

Question sources

Compiler Design review questions · Question 32

Question 180 | NS0260

What is 'alias analysis' and why is it important for optimization?

A. Determining which variables have the same name in different scopes; important for scope resolution |

B. Determining whether two pointer expressions can refer to the same memory location; important because aliasing restricts reordering and CSE

C. Detecting variables with the same type; important for type coercion |

D. Finding duplicate function names; important for linking

Hint

Trace whether computation is evaluated, moved, shared or removed. Preserve observable effects and use the stated arithmetic and target assumptions.

Answer B: Determine whether references may denote the same memory, constraining transformations.

COMP33 asks whether references can designate the same memory. A write through p can invalidate a value loaded through q unless nonaliasing or another proof permits reuse. Therefore alias facts constrain CSE and reordering. Identical spellings, types or function names concern scope, typing or linkage rather than memory-location overlap.

Why each choice is right or wrong

A - Incorrect: Equal spelling in different scopes concerns declaration identity rather than whether references share memory.

B - Correct: Potential shared locations determine whether writes can invalidate reused loads or reordered memory operations.

C - Incorrect: Equal types do not prove shared addresses and are not the alias-analysis question.

D - Incorrect: Duplicate linker names concern symbol resolution rather than potential overlap of referenced memory.

Primary note proof

Study-note section COMP33

> Optimization preserves defined observable behavior, including required side effects and exceptions. Alias analysis asks whether references can denote the same memory. After *p=5, a previous load through q cannot be reused unless p and q are known not to alias or an equivalent proof applies. Function calls can also invalidate memory facts.

Study-note section COMP33

> Do not move a potentially trapping division outside a loop that might execute zero times. Floating-point reassociation can change rounding and NaN behavior. Signed C/C++ overflow and shift rules differ from unsigned modular arithmetic; a mathematical identity is not automatically a legal transformation. Dependence analysis must show that fusion or scheduling preserves the required order of memory accesses.

Question sources

Compiler Design review questions · Question 33

Question 181 | NS0261

Which statement about recursive-descent parsers is TRUE?

A. They cannot handle left-recursive grammars without modification |

B. They inherently support all context-free grammars

C. They require a parsing table to function |

D. They build the parse tree bottom-up

Hint

Use construction direction, lookahead and grammar restrictions. Distinguish algorithm families, implementations and coverage before comparing them.

Answer A: Ordinary recursive descent needs modification to handle left recursion.

COMP12 explains that ordinary unmodified recursive descent can recurse forever on left recursion before consuming a token. Removing left recursion or changing the algorithm is therefore necessary for that direct implementation. Recursive descent is top-down and normally procedural, so it does not inherently require an explicit table or support every CFG unchanged.

Why each choice is right or wrong

A - Correct: Without transformation or algorithmic modification, left recursion can cause infinite recursive calls before input consumption.

B - Incorrect: Ordinary recursive descent is not an unrestricted parser for every context-free grammar.

C - Incorrect: Procedures can encode production choices directly; an explicit parsing table is not required.

D - Incorrect: Recursive descent expands productions top-down rather than constructing a reverse-rightmost bottom-up parse.

Primary note proof

Study-note section COMP12

> Immediate left recursion has $A \to A\alpha$. For $A \to A\alpha \mid \beta$, where β does not start with A, introduce a new nonterminal A' and use:
> $A \to \beta A'$
> $A' \to \alpha A' \mid \varepsilon$
> This preserves the generated language; tree shape changes, so semantic actions must preserve intended associativity. Indirect left recursion follows a cycle through other nonterminals and also needs removal for ordinary predictive descent.

Study-note section COMP12

Left factoring rewrites A→αβ|αγ using:
A→αA′
A′→β|γ
It postpones a choice until after the common prefix. It does not by itself remove ambiguity or guarantee LL(1). LR parsers can handle suitable left-recursive grammars; ordinary unmodified recursive descent can recurse forever before consuming input.

Question sources

Compiler Design review questions · Question 34

Question 182 | NS0262

In attribute grammar terminology, which of the following is an 'inherited' attribute?

A. The value of an expression node computed from its children |

B. The type environment passed from a function declaration down to its body

C. The size of an array determined from its element type and length |

D. The result type of an arithmetic operation

Hint

Track where each computed value comes from and when each production action runs. Distinguish the representation from its attached information.

Answer B: A type environment passed from a declaration into its body is inherited.

COMP24 explicitly gives the declaration’s type environment passed into its body as an inherited attribute. This carries context inward rather than computing a parent from child values. Expression values, array sizes computed from components and arithmetic result types are ordinarily synthesized examples when obtained from the node’s own child information.

Why each choice is right or wrong

A - Incorrect: Computing an expression from its children is synthesized upward flow.

B - Correct: The surrounding declaration supplies type context to the nested body, matching the explicit inherited example.

C - Incorrect: Computing size from element information and length is a synthesized result, not supplied surrounding context.

D - Incorrect: An operation’s result type derived from operands is normally synthesized from its child information.

Primary note proof

Study-note section COMP24

A syntax-directed definition is a CFG with attributes on grammar symbols and semantic rules on productions. An annotated parse tree displays computed attribute values; it is not itself an

inherited or synthesized attribute. Synthesized attributes flow from children to a parent; inherited attributes carry context from parent or siblings.

Study-note section COMP24

For E→E1+T, E.val=E1.val+T.val synthesizes an expression value. A declaration’s type environment passed into its body is inherited. S-attributed definitions use only synthesized attributes and fit LR reduction-time evaluation naturally; suitable LL parsers can also compute them. L-attributed definitions restrict dependencies so a left-to-right traversal can evaluate inherited context. Attribute dependency cycles can prevent evaluation.

Question sources

Compiler Design review questions · Question 35

Question 183 | NS0263

A compiler emits the error 'variable used before initialization'. This is detected during:

A. Lexical analysis |

B. Syntax analysis

C. Semantic analysis / data flow analysis |

D. Code generation

Hint

Track which facts can hold along one path and which must hold along every path. Apply the specified direction, transfer rule and join operation.

Answer C: Semantic/data-flow analysis.

COMP29 distinguishes definite assignment, which asks whether initialization occurs on every incoming path, from reaching definitions alone. Such control/data-flow facts go beyond recognizing legal tokens or grammar. The error therefore belongs to semantic/data-flow analysis before target emission, even though exact acceptance and diagnostic rules depend on the language.

Why each choice is right or wrong

A - Incorrect: Scanning recognizes identifier tokens but does not prove initialization along every control-flow path.

B - Incorrect: A grammatically valid variable use can still occur before initialization.

C - Correct: Semantic data-flow analysis checks that required initialization precedes each use on every relevant path.

D - Incorrect: Target generation ordinarily consumes checked input rather than supplying the primary definite-assignment analysis.

Primary note proof

Study-note section COMP29

> Liveness is backward may-analysis: a value might be read before redefinition on some future path. OUT[B]=union of IN over successors; IN[B]=USE[B]∪(OUT[B]−DEF[B]). Iterate to a fixed point. Liveness supports register allocation and dead-value removal. Definite-assignment analysis asks whether initialization occurs on every path before use; reaching definitions alone does not prove this.

Question sources

Compiler Design review questions · Question 36

Question 184 | NS0264

In graph-coloring register allocation, what is an 'interference graph'?

A. A graph where nodes represent machine instructions and edges represent data dependencies |

B. A graph where nodes represent variables and edges connect pairs of variables that are simultaneously live

C. A graph where nodes represent registers and edges represent compatibility |

D. A graph representing the control flow of the program

Hint

Match stored information to its lifetime, access path and calling-convention role; distinguish compile-time organization from run-time storage.

Answer B: A graph connecting values that must coexist in distinct registers.

COMP36 models concurrently needed values as vertices joined by interference edges, with physical registers represented by colors. Thus the variable/live-range graph in B is the intended model. Instruction dependencies and control-flow edges have different meanings; a graph of register compatibility reverses the allocation model's vertices and does not express live-value interference.

Why each choice is right or wrong

A - Incorrect: Instruction-dependency edges constrain scheduling rather than describing interference among live values.

B - Correct: Variables or live ranges form vertices; an edge requires distinct registers for simultaneously needed values.

C - Incorrect: Registers are colors in this model, not the vertices whose live ranges interfere.

D - Incorrect: A CFG connects basic blocks by possible transfers, not values by register interference.

Primary note proof

Study-note section COMP36

> A value is live where it can be used before redefinition. In the interference model, values that must coexist in distinct registers are connected by an edge; each register is a color. Nonoverlapping live ranges may share a register. If a valid assignment cannot fit the available registers, spilling places selected values in memory and inserts loads/stores.

Study-note section COMP36

> The general graph k-colorability decision problem is NP-complete for fixed k≥3; optimal register assignment/spill minimization is a hard optimization problem in general, so practical allocators use heuristics.

Question sources

Compiler Design review questions · Question 37

Question 185 | NS0265

What is 'dead code' in the context of compiler optimization?

A. Code that causes a runtime error |

B. Code that is syntactically incorrect

C. Code that is unreachable or whose computed results are never used |

D. Code that depends on uninitialized variables

Hint

Trace whether computation is evaluated, moved, shared or removed. Preserve observable effects and use the stated arithmetic and target assumptions.

Answer C: Unreachable code or unused computations without required effects.

COMP30 permits removing unreachable code and unused computations only when evaluation has no necessary side effects. C states the intended two dead-code categories, with this semantic caveat. Runtime faults, syntax defects and uninitialized uses are different error categories, not definitions of code being safely removable. An unused volatile read or effectful call may still be required.

Why each choice is right or wrong

A - Incorrect: A runtime fault does not make arbitrary reachable code safely removable as dead code.

B - Incorrect: Syntactically invalid code is a compilation error, not the definition of dead computation.

C - Correct: Unreachability or unused results identify candidates, provided necessary observable side effects are preserved.

D - Incorrect: An uninitialized dependency is an analysis or correctness issue, not automatically dead code.

Primary note proof

Study-note section COMP30

> Constant folding evaluates constant expressions during compilation: 3*4→12. Constant propagation substitutes known values: x=3; y=x+2 becomes y=3+2 before folding. Copy propagation substitutes a copied name while its source remains unchanged. Dead-code elimination removes unreachable code or computations whose values are unused and whose evaluation has no necessary side effects.

Question sources

Compiler Design review questions · Question 38

Question 186 | NS0266

What is the precise relationship between the general term compiler and the term transpiler?

A. A transpiler is a source-to-source compiler; compilers can also target assembly, machine code or bytecode.

B. A compiler is faster than a transpiler

C. A transpiler performs more optimizations than a compiler |

D. There is no meaningful distinction

Hint

Identify each activity's input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer A: A transpiler is a source-to-source compiler; compilers can also target assembly, machine code or bytecode.

A compiler translates a source program to an equivalent target representation, which may be machine code, assembly, bytecode or another source language. A transpiler is the source-to-source subtype of compiler. This gives a meaningful target-based distinction while retaining the shared category. Speed and optimization count depend on implementations and workloads; neither defines the relationship between the two terms.

Why each choice is right or wrong

A - Correct: A transpiler is a compiler whose target is another source language.

B - Incorrect: There is no universal speed ordering.

C - Incorrect: Optimization count does not define the subtype.

D - Incorrect: The source-to-source target is a meaningful distinction.

Primary note proof

Study-note section COMP01

> A compiler translates a source program into an equivalent target representation while preserving defined observable behavior. The target may be machine code, assembly, bytecode or another source language. A transpiler is a source-to-source compiler, not a fundamentally separate noncompiler technology. A compiler preserves language semantics, not the programmer's unstated intention.

Study-note section COMP01

> An interpreter executes a program representation; it need not work one source line at a time. Systems can compile to bytecode and then interpret or JIT-compile it. AOT compilation happens before execution; JIT compilation happens during execution and may use runtime profiles. Neither is universally faster; startup cost, optimization and workload matter.

Question sources

Compiler Design review questions · Question 39

Question 187 | NS0267

In the context of lexical analysis, 'lexeme' vs 'token' means:

A. Lexeme is the abstract category; token is the actual text |

B. Lexeme is the actual sequence of characters in the source; token is the abstract category with optional attribute value

C. They are synonymous terms |

D. Lexeme refers to keywords only; token refers to all other units

Hint

Identify each activity's input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer B: Lexeme is the source text; token is its category with optional attributes.

COMP04 directly distinguishes the actual character sequence from its token category and optional attribute. For example, total is a lexeme that may produce an ID token associated with a symbol entry. Neither term is restricted to keywords; the same distinction applies to identifiers, numeric literals, operators and other lexical units.

Why each choice is right or wrong

A - Incorrect: This reverses the roles: the lexeme is concrete text and the token identifies its class.

B - Correct: The concrete source sequence is the lexeme; category and optional information form the token.

C - Incorrect: The note explicitly separates the two abstractions rather than treating them as synonyms.

D - Incorrect: Lexemes include identifiers, literals and operators, not just keywords.

Primary note proof

Study-note section COMP04

> A token is a category with optional attribute, such as (ID, symbol-entry) or (INT_LITERAL,42). A lexeme is the actual character sequence, such as total or 42. A pattern specifies which lexemes belong to a token class. The scanner emits an ordered token stream, not an unordered mathematical set.

Study-note section COMP04

> Keywords, identifiers, literals, operators and punctuation are token classes. Whitespace and comments are usually skipped while line/column positions are retained. In indentation-sensitive or newline-sensitive languages, layout can carry tokens. Parse-tree construction is a parser task; scanning can intern identifier spellings, but declaration scope and types need later analysis.

Question sources

Compiler Design review questions · Question 40

Question 188 | NS0268

Under the general interference-graph model with fixed k≥3, which task is an NP-complete decision problem?

A. Converting an NFA to a DFA |

B. Constructing a LL(1) parsing table

C. Deciding whether an arbitrary interference graph can use k registers without spilling, for fixed k≥3

D. Computing FIRST sets for a CFG

Hint

Match stored information to its lifetime, access path and calling-convention role; distinguish compile-time organization from run-time storage.

Answer C: Deciding whether an arbitrary interference graph can use k registers without spilling, for fixed k≥3

In the general interference model, simultaneously needed values are adjacent and registers are colors. Deciding whether the graph can be colored with k registers without spilling is general graph k-colorability, NP-complete for fixed k≥3. Optimal allocation is instead an optimization task. The other alternatives are construction or fixed-point tasks and do not state this membership-plus-hardness decision problem.

Why each choice is right or wrong

A - Incorrect: NFA determinization is a construction task, even when its output is exponential.

B - Incorrect: LL(1) table construction is not the specified graph-coloring decision task.

C - Correct: No-spill allocation is k-colorability under the stipulated general model.

D - Incorrect: FIRST-set computation is a fixed-point task rather than this NP-complete decision form.

Primary note proof

Study-note section COMP36

> A value is live where it can be used before redefinition. In the interference model, values that must coexist in distinct registers are connected by an edge; each register is a color. Nonoverlapping live ranges may share a register. If a valid assignment cannot fit the available registers, spilling places selected values in memory and inserts loads/stores.

Study-note section COMP36

> The general graph k-colorability decision problem is NP-complete for fixed k≥3; optimal register assignment/spill minimization is a hard optimization problem in general, so practical allocators use heuristics.

Question sources

Compiler Design review questions · Question 41

Question 189 | NS0269

What is the 'reaching definitions' data flow problem used for?

A. Determining which variables are live at each program point |

B. Determining which variable assignments might reach a given program point without being overwritten

C. Determining which expressions are available at each program point |

D. Determining which functions can be called from a given call site

Hint

Track which facts can hold along one path and which must hold along every path. Apply the specified direction, transfer rule and join operation.

Answer B: Assignments that may reach a point without being overwritten.

COMP29 directly defines reaching definitions as assignments that can arrive at a point without a replacement definition on the path. Its join is union because one possible path suffices. Liveness asks about future uses, available expressions asks about previous computations on every path, and possible call targets is a separate analysis question.

Why each choice is right or wrong

A - Incorrect: Future reads before redefinition are the liveness question, not reaching definitions.

B - Correct: This is the exact assignment-and-no-overwrite property defined for reaching definitions.

C - Incorrect: Available expressions concerns prior computations with unchanged operands, not assignment definitions.

D - Incorrect: Possible function targets concern call-graph or points-to analysis rather than reaching assignment definitions.

Primary note proof

Study-note section COMP29

> Reaching definitions is forward may-analysis: which assignments can reach this point without a replacement definition? OUT=GEN∪(IN−KILL), with IN the union of predecessor OUT sets. Available expressions is usually forward must-analysis: an expression has been computed on every relevant path and its operands have not changed. Join with intersection.

Question sources

Compiler Design review questions · Question 42

Question 190 | NS0270

In predictive (LL(1)) parsing, when should the parser use an ε-production A → ε?

A. When the lookahead token is in FIRST(A) |

B. When the lookahead token is in FOLLOW(A) and no other production for A begins with that token

C. When the stack is empty |

D. Whenever the next token is not a keyword

Hint

Use construction direction, lookahead and grammar restrictions. Distinguish algorithm families, implementations and coverage before comparing them.

Answer B: Use ε on an appropriate FOLLOW(A) lookahead with no competing alternative.

COMP14 enters a nullable alternative under the left-hand nonterminal's FOLLOW symbols and requires no conflicting production in that cell. An epsilon reduction consumes no input. FIRST(A) alone can refer to a nonempty alternative, while stack emptiness and token being a keyword do not define nullable-alternative selection. Thus B supplies the correct lookahead rule.

Why each choice is right or wrong

A - Incorrect: A FIRST terminal may require a nonempty alternative; FIRST(A) alone does not select epsilon.

B - Correct: FOLLOW lookahead selects the nullable alternative when its predictive table cell has no competing production.

C - Incorrect: An empty stack is not the rule for selecting a production for a pending nonterminal.

D - Incorrect: Keyword status has no general relation to a nonterminal's nullable-production table entries.

Primary note proof

Study-note section COMP14

> For every A→α, put it in M[A,a] for each terminal a in FIRST(α). If α is nullable, also enter it under every symbol in FOLLOW(A). More than one production in a cell is a conflict. Pairwise SELECT sets must be disjoint; SELECT(α)=FIRST(α)−{ε}, plus FOLLOW(A) when α is nullable. This also detects two nullable alternatives.

Study-note section COMP14

> Initialize stack with $S. Match and pop terminals; for a nonterminal consult its row and lookahead, then push the chosen RHS in reverse. An ε production consumes no input. Accept when stack and input reach $. For A→a|ε with b∈FOLLOW(A), choose a on lookahead a and ε on b.

Question sources

Compiler Design review questions · Question 43

Question 191 | NS0271

Which of the following correctly describes a 'dominator' in a control flow graph?

A. A node that is executed before all other nodes unconditionally |

B. Node D dominates node N if every path from the entry node to N must pass through D

C. The node with the most outgoing edges |

D. The unique successor of every conditional branch

Hint

Identify what the representation stores, what it omits and which later transformations it must support; separate a representation property from an algorithmic task.

Answer B: Every entry-to-N path passes through D.

COMP28 defines domination relative to a particular node N: every path from entry to N must pass D. This is not a claim that D precedes every node in the program, nor is domination measured by out-degree or being a unique successor. The definition concerns unavoidable traversal on paths reaching the specified node.

Why each choice is right or wrong

A - Incorrect: A dominator is defined relative to a node, not necessarily as preceding all program nodes.

B - Correct: This exactly states the all-entry-to-N-paths definition in COMP28.

C - Incorrect: The number of outgoing edges does not establish unavoidable traversal on paths.

D - Incorrect: Branch successor uniqueness is unrelated to the general dominator definition.

Primary note proof

Study-note section COMP28

> A basic block is a maximal straight-line instruction sequence entered at its beginning and exited at its end. Leaders are the first instruction, every jump target, and each instruction after a branch. Start a block at each leader and continue until the next leader.

Study-note section COMP28

> A control-flow graph has blocks as vertices and possible next-block transfers as edges, including fall-through. A node D dominates N when every entry-to-N path passes through D. For an edge N→H where H dominates N, H is a loop header of a natural loop. This structure supports loop analysis. An expression DAG records value dependencies, not arbitrary control flow.

Question sources

Compiler Design review questions · Question 44

Question 192 | NS0272

In SLR(1) parsing, the reduce action for production A → α is triggered when the lookahead is in:

A. FIRST(A) |

B. FOLLOW(A)

C. FIRST(α) |

D. FOLLOW(α)

Hint

Use construction direction, lookahead and grammar restrictions. Distinguish algorithm families, implementations and coverage before comparing them.

Answer B: FOLLOW(A), once the item for A→α is complete.

COMP17 says SLR uses LR(0) states and FOLLOW(A) for reduction by a completed A production. The completed item establishes that the right side has been recognized; FOLLOW restricts which lookaheads permit reducing it. FIRST information predicts beginnings instead, and FOLLOW of an arbitrary right-hand string is not the table rule used here.

Why each choice is right or wrong

A - Incorrect: FIRST(A) concerns beginnings of derived strings rather than lookaheads after a completed A.

B - Correct: SLR places a completed A-production reduction under the lookaheads in FOLLOW(A).

C - Incorrect: FIRST of the right side predicts starting tokens, not permitted post-recognition reduction lookaheads.

D - Incorrect: SLR uses FOLLOW of the left-hand nonterminal A, not this right-side expression.

Primary note proof

Study-note section COMP17

> SLR(1) uses LR(0) states and FOLLOW(A) for reduction by a completed A production. Canonical LR(1) attaches context-specific lookahead to items. LALR(1) merges canonical states with the same LR(0) core, combining lookaheads; merging can introduce reduce/reduce conflicts. The standard grammar-class hierarchy is LR(0)⊆SLR(1)⊆LALR(1)⊆LR(1), with increasing capability and often table size.

Study-note section COMP17

> A shift/reduce conflict offers both consuming a token and reducing; reduce/reduce offers two reductions. An SLR or LALR conflict does not by itself prove the grammar ambiguous. Canonical LR(1) handles LR(1) grammars, not every unambiguous CFG. Precedence and associativity can resolve suitable expression conflicts; changing parser names alone does not repair all ambiguity.

Question sources

Compiler Design review questions · Question 45

Question 193 | NS0273

What is 'escape analysis' and how does it help optimization?

A. Analysis to detect out-of-bounds array accesses; helps prevent security vulnerabilities |

B. Analysis to determine whether an object's reference can 'escape' the function where it is created; enables stack allocation of non-escaping objects

C. Analysis to find unreachable exception handlers; enables dead code elimination |

D. Analysis to track pointer arithmetic; enables bounds checking elimination

Hint

Match stored information to its lifetime, access path and calling-convention role; distinguish compile-time organization from run-time storage.

Answer B: Determine whether references outlive or escape a region, enabling safe allocation changes.

COMP37 asks whether an object/reference can outlive or be accessed outside its allocating region. A proven nonescaping object may use stack storage or be eliminated when lifetime and identity are preserved. Bounds checking, exception reachability and pointer arithmetic are separate analyses and do not define the reference-escape property described.

Why each choice is right or wrong

A - Incorrect: Array bounds concern index validity rather than whether references leave their allocation region.

B - Correct: Reference escape information can justify stack allocation when lifetime and identity remain correct.

C - Incorrect: Unreachable exception handlers concern control-flow reachability, not reference lifetime or external access.

D - Incorrect: Pointer arithmetic tracking does not by itself define escape beyond a function or allocation region.

Primary note proof

Study-note section COMP37

> Static storage lasts throughout execution; stack frames support nested calls and recursion; heap storage supports lifetimes beyond a call. A frame may contain parameters, return address, saved registers, locals and temporaries. Sizes, alignment and offsets are target-dependent; a two-byte int is an example, not a C++ guarantee.

Study-note section COMP37

> A calling convention specifies argument and result locations, caller/callee-saved registers, stack alignment and frame responsibilities. Escape analysis asks whether an object/reference can outlive or be accessed outside a region such as its allocating call. Proven nonescaping allocations may use stack storage or be eliminated by scalar replacement, provided identity and lifetime semantics remain correct.

Question sources

Compiler Design review questions · Question 46

Question 194 | NS0274

Which of the following is a valid reason why LALR(1) parsers may have reduce/reduce conflicts that canonical LR(1) parsers do not?

A. LALR(1) uses a larger parsing table than canonical LR(1) |

B. LALR(1) merges LR(1) states with the same core but different lookaheads, potentially merging incompatible lookahead sets

C. LALR(1) does not support left-recursive grammars |

D. LALR(1) computes FOLLOW sets incorrectly

Hint

Use construction direction, lookahead and grammar restrictions. Distinguish algorithm families, implementations and coverage before comparing them.

Answer B: Merging equal-core LR(1) states can combine incompatible reduction lookaheads.

COMP17 directly explains that LALR merges canonical states with identical LR(0) cores while unioning their lookahead sets. Distinctions that prevented competing reductions in separate states can disappear, creating reduce/reduce conflicts. This is not due to incorrect FOLLOW computation or rejection of left recursion; the loss comes from deliberate state merging.

Why each choice is right or wrong

A - Incorrect: Merging aims to reduce state count, and a larger table is not the reason for new conflicts.

B - Correct: Combining lookaheads of equal-core states can make previously separated reductions compete.

C - Incorrect: LALR can handle suitable left-recursive grammars, as other LR methods can.

D - Incorrect: The conflict can arise from correct merging, without any erroneous FOLLOW-set computation.

Primary note proof

Study-note section COMP17

> SLR(1) uses LR(0) states and FOLLOW(A) for reduction by a completed A production. Canonical LR(1) attaches context-specific lookahead to items. LALR(1) merges canonical states with the same LR(0) core, combining lookaheads; merging can introduce reduce/reduce conflicts. The standard grammar-class hierarchy is LR(0)⊆SLR(1)⊆LALR(1)⊆LR(1), with increasing capability and often table size.

Study-note section COMP17

A shift/reduce conflict offers both consuming a token and reducing; reduce/reduce offers two reductions. An SLR or LALR conflict does not by itself prove the grammar ambiguous. Canonical LR(1) handles LR(1) grammars, not every unambiguous CFG. Precedence and associativity can resolve suitable expression conflicts; changing parser names alone does not repair all ambiguity.

Question sources

Compiler Design review questions · Question 47

Question 195 | NS0275

Which is a common implementation mechanism for runtime virtual dispatch in an object-oriented language, when the receiver's class cannot be resolved statically?

A. Static binding of function calls at compile time |

B. A virtual method table (vtable) per class, with function pointers resolved at runtime

C. Inline expansion of all polymorphic calls |

D. Name mangling to distinguish overloaded functions

Hint

Match stored information to its lifetime, access path and calling-convention role; distinguish compile-time organization from run-time storage.

Answer B: A virtual method table (vtable) per class, with function pointers resolved at runtime

A common implementation stores virtual-method entries in a per-class vtable and lets an object refer to the appropriate table. A virtual call selects the entry using the receiver's runtime class. Static binding alone does not provide that selection for an unknown class. Mandatory inlining is not generally possible, and name mangling distinguishes linker symbols rather than selecting overrides at runtime.

Why each choice is right or wrong

A - Incorrect: Static binding alone does not choose by an unknown runtime class.

B - Correct: A per-class vtable is the common mechanism described in the note.

C - Incorrect: Unknown runtime receivers prevent mandatory inlining of all polymorphic calls.

D - Incorrect: Name mangling identifies symbols rather than selecting overrides.

Primary note proof

Study-note section COMP38

Inlining replaces a call with a suitably renamed copy of its body, preserving argument evaluation, returns and side effects. It can remove call overhead and expose optimization opportunities, but may increase code size and instruction-cache pressure. A recursive function cannot simply be expanded without limit.

Study-note section COMP38

Virtual dispatch chooses an overridden method based on a receiver's runtime class. A common implementation uses a per-class virtual-method table and an object pointer to the table; the call loads the selected entry. This is an implementation strategy, not a universal language requirement. Name mangling distinguishes linker symbols, often for overloads; it is not itself runtime method selection. Proven receiver types may permit devirtualization.

Question sources

Compiler Design review questions · Question 48

Question 196 | NS0276

Which of the following is true about a 'well-formed' grammar for LL(1) parsing?

A. It may contain left recursion |

B. For every non-terminal A with productions A → α1 | α2 | ... | αn, no two alternatives share a common token in their FIRST sets, and if any αi derives ε, then FIRST(αj) and FOLLOW(A) are disjoint for all j ≠ i

C. It must be ambiguous |

D. It must have at least one ε-production

Hint

Use construction direction, lookahead and grammar restrictions. Distinguish algorithm families, implementations and coverage before comparing them.

Answer B: Disjoint predictive selections, including nullable FIRST/FOLLOW constraints.

COMP14 requires that alternatives for a nonterminal select disjoint lookahead sets. B gives the standard FIRST separation and nullable-alternative FOLLOW restriction; shared epsilon alternatives would also violate pairwise FIRST disjointness. Left recursion and useful ambiguity are not acceptable LL(1) properties, and epsilon productions are optional rather than required.

Why each choice is right or wrong

A - Incorrect: Ordinary LL(1) grammars cannot retain left recursion that recurs without input consumption.

B - Correct: Disjoint alternative selections prevent multiple productions from occupying the same predictive table cell.

C - Incorrect: A useful ambiguous grammar cannot give a unique deterministic LL(1) parse.

D - Incorrect: A grammar may be LL(1) without any epsilon production.

Primary note proof

Study-note section COMP14

For every A→α, put it in M[A,a] for each terminal a in FIRST(α). If α is nullable, also enter it under every symbol in FOLLOW(A). More than one production in a cell is a conflict. Pairwise SELECT

sets must be disjoint; SELECT(α)=FIRST(α)−{ε}, plus FOLLOW(A) when α is nullable. This also detects two nullable alternatives.

Study-note section COMP14

Initialize stack with $S. Match and pop terminals; for a nonterminal consult its row and lookahead, then push the chosen RHS in reverse. An ε production consumes no input. Accept when stack and input reach $. For A→a|ε with b∈FOLLOW(A), choose a on lookahead a and ε on b.

Question sources

Compiler Design review questions · Question 49

Question 197 | NS0277

The primary difference between a 'compiler' and a 'just-in-time (JIT) compiler' is:

A. A JIT compiler produces faster code than an ahead-of-time compiler always |

B. A JIT compiler compiles code at runtime (during program execution), allowing it to use runtime profiling information for optimization, while an AOT compiler compiles before execution

C. A JIT compiler does not perform any optimization |

D. A JIT compiler only works for interpreted languages

Hint

Identify each activity’s input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer B: JIT compiles during execution; AOT compiles before execution.

COMP01 defines AOT before execution and JIT during execution, possibly using runtime profiles. Both are compilation, so the heading compiler versus JIT is better understood as AOT versus JIT. The timing contrast in B is correct, while no universal speed guarantee, absence of optimization or restriction to interpreted languages follows.

Why each choice is right or wrong

A - Incorrect: Neither AOT nor JIT is universally faster; startup and workload affect the comparison.

B - Correct: Runtime compilation can use execution profiles, whereas AOT performs compilation before the run.

C - Incorrect: JIT may optimize using runtime information rather than performing no optimization.

D - Incorrect: JIT is an execution-time compilation strategy, not a technique restricted to a separately defined interpreted-language category.

Primary note proof

Study-note section COMP01

A compiler translates a source program into an equivalent target representation while preserving defined observable behavior. The target may be machine code, assembly, bytecode or another source language. A transpiler is a source-to-source compiler, not a fundamentally separate noncompiler technology. A compiler preserves language semantics, not the programmer's unstated intention.

Study-note section COMP01

An interpreter executes a program representation; it need not work one source line at a time. Systems can compile to bytecode and then interpret or JIT-compile it. AOT compilation happens before execution; JIT compilation happens during execution and may use runtime profiles. Neither is universally faster; startup cost, optimization and workload matter.

Question sources

Compiler Design review questions · Question 50

Question 198 | NS0299

What is the main purpose of syntax-directed translation in a compiler?

A. To interleave semantic analysis with syntax analysis using attributes attached to grammar symbols

B. To generate optimized machine code directly

C. To tokenize the source code

D. To replace the parser with a finite automaton

Hint

Track where each computed value comes from and when each production action runs. Distinguish the representation from its attached information.

Answer A: Associate semantic computations with grammatical structure and attributes.

COMP24 attaches attributes and semantic rules to grammar symbols and productions; COMP25 executes translation actions during processing. This permits semantic work to follow parsing structure, as A states. It does not inherently bypass IR to optimized machine code, reduce to tokenization, or replace the parser with a finite automaton.

Why each choice is right or wrong

A - Correct: Attributes and rules connect grammatical structure to semantic computations during translation.

B - Incorrect: Direct optimized machine-code production is not the required or exclusive purpose of syntax-directed translation.

C - Incorrect: Tokenization is lexical analysis rather than grammar-directed semantic computation.

D - Incorrect: Finite automata recognize ordinary token patterns and do not replace general nested-syntax parsing.

Primary note proof

Study-note section COMP24

> A syntax-directed definition is a CFG with attributes on grammar symbols and semantic rules on productions.

Study-note section COMP25

> A syntax-directed translation scheme embeds executable actions in productions; the actions run while translating a source program, not while generating the compiler. Attributes may compute types, values, AST pointers or generated code. The scheme defines an input-to-output translation, not merely an input language.

Question sources

Computer Science Exit Exam · 2018 · Question 16

Question 199 | NS0303

Straight directed translation uses:

A. Purely lexical rules

B. Backtracking algorithms

C. Grammar without attributes

D. Grammar with sematic rule

Hint

Track where each computed value comes from and when each production action runs. Distinguish the representation from its attached information.

Answer D: Grammar with semantic rules, reading the misspelled term as syntax-directed translation.

The stem's Straight directed translation appears to be a damaged rendering of syntax-directed translation. Under that explicit reading, COMP24 defines a CFG with attributes and semantic rules, and COMP25 embeds translation actions in productions. D expresses that structure despite its spelling error. The other choices omit semantics or prescribe unrelated implementation details.

Why each choice is right or wrong

A - Incorrect: Pure lexical rules do not supply grammar-directed semantic attributes and computations.

B - Incorrect: Backtracking is a parsing implementation choice, not the defining translation structure.

C - Incorrect: A grammar without semantic attributes or rules does not describe the syntax-directed definition requested.

D - Correct: Reading sematic as semantic, this is the grammar-plus-semantic-rules structure of syntax-directed translation.

Primary note proof

Study-note section COMP24

> A syntax-directed definition is a CFG with attributes on grammar symbols and semantic rules on productions.

Study-note section COMP25

> A syntax-directed translation scheme embeds executable actions in productions; the actions run while translating a source program, not while generating the compiler. Attributes may compute types, values, AST pointers or generated code. The scheme defines an input-to-output translation, not merely an input language.

Question sources

Computer Science Exit Exam · 2018 · Question 21

Question 200 | NS0331

A compiler has produced checked three-address code for a function. Which description incorrectly places the ensuing target-lowering task within the standard compilation pipeline?

A. Code generation can be considered as the start phase of compilation

B. The target program is the output of the code generator

C. Checked intermediate code is supplied as input to the code generator.

D. It used to produce the target code for three-address statements.

Hint

Identify each activity's input and output. Distinguish character recognition, grammatical structure, semantic checks and target implementation.

Answer A: Code generation can be considered as the start phase of compilation

Code generation uses checked intermediate code to produce target instructions after the frontend has analyzed the source. It can lower each three-address operation into a suitable target sequence. Lexical analysis, not code generation, begins the standard pipeline. The input condition here means checked IR suitable for lowering; it is not a claim that all possible program bugs have been proved absent.

Why each choice is right or wrong

A - Correct: Target lowering follows scanning, parsing, semantic checks and IR construction; it does not start compilation.

B - Incorrect: The generator's output is target code.

C - Incorrect: Checked IR is the stated input to target lowering.

D - Incorrect: Three-address statements can be translated into target instructions.

Primary note proof

Study-note section COMP03

> The conventional sequence is lexical analysis → syntax analysis → semantic analysis → intermediate-code generation → optimization → target-code generation. Scanning turns characters into tokens; parsing builds structure; semantics checks declarations and types; synthesis produces implementation code. A phase is a logical activity; a pass is a traversal that can combine activities.

Study-note section COMP34

> Code generation lowers checked IR to a target form.

Question sources

Computer Science Exit Exam · 2018 · Question 58
