4.2. Project Planning
• Probably the most time-consuming project management activity.
• Continuous activity from initial concept through to system delivery. Plans must be regularly revised as new information becomes available.
• Various different types of plans may be developed to support the main software project plan that is concerned with schedule and budget.
The project plan sets out:
• The resources available to the project;
• The work breakdown;
• A schedule for the work.
Project Plan Structure
• Introduction.
• Project organisation.
• Risk analysis.
• Hardware and software resource requirements.
• Work breakdown.
• Project schedule.
• Monitoring and reporting mechanisms.

Software Engineering module | PDF page 81 | lines 11-21

3.4.2. Negotiating specifications with clients: Joint Application Design
Joint Application Design (JAD) is effectiveness lies in that the requirements elicitation work is done in one single workshop session in which all stakeholders participate. Users, clients, developers, and a trained session leader sit together in one room to present their viewpoint, listen
to other viewpoints, negotiate, and agree on a mutually acceptable solution. The outcome of the workshop, the final JAD document, is a complete system specification document that includes definitions of data elements, work flows, and interface screens. Because the final document is jointly developed by the stakeholders (that is, the participants who not only have an interest in the
success of the project, but also can make substantial decisions) the final JAD document represents

an agreement between users, clients, and developers, and thus minimizes requirements changes later in the development process.

Question sources

Mock exam 4 · Question 53

Question 29 | Q00252

A software development team is setting up a configuration management process. They need to identify the configuration items (CIs) for their project. Which of the following would not typically be considered a configuration item?

A. Internet browsers used by the development team

B. Source code files

C. User manuals

D. Test plans

Hint

Separate artifact history and controlled changes from scheduling, collaboration benefits and automated execution.

Answer A: Ordinary browsers used by the team are usually tools, not product configuration items.

Controlled configuration items include source files, requirements, manuals and test plans. A team's ordinary browser is normally just a tool. A particular browser version can become an environment CI if the project deliberately controls it for reproducible testing, but the word typically makes A the appropriate exception in the stated scenario.

Why each choice is right or wrong

A - Correct: An ordinary team browser is usually a tool; a deliberately controlled test-browser version would be an exception.

B - Incorrect: Source code files are standard controlled product configuration items.

C - Incorrect: User manuals can be versioned and baselined alongside the software product.

D - Incorrect: Test plans are controlled project artifacts whose versions must match the tested configuration.

Primary note proof

Study-note section SE33

Configuration management identifies controlled items, versions/baselines, change procedures, status and audits. Items may include source code, requirements, manuals, test plans, environments and build configurations. A team’s ordinary browser is usually a tool rather than product CI, but a controlled test-browser version may be an environment CI.

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 142 | lines 5-10

> Configuration management avoids faults caused by undisciplined change in the system models. For example, it is a common mistake to a change a subsystem interface without notifying all developers of calling components. Configuration management can make sure that, if analysis models and code are becoming inconsistent with one another, analysts and implementor are notified. The assumption behind configuration management is that the system contains many less
> faults if change is controlled.

Software Engineering module | PDF page 89 | lines 17-24

> Assigning a role to a participant usually translates into assigning the responsibility of a specific work product. A work product is an artifact that is produced during the development, such as an internal document for other project participants or a deliverable to the customer.
> An analyst is responsible for a section of the RAD describing the functionality of the system. A system architect is responsible for the SDD describing the system's high-level architecture. A project manager is responsible for the SPMP describing the development processes. Finally, the system and its accompanying documentation also constitute a set of work products that are delivered to the client.

Question sources

Mock exam 4 · Question 54

Question 30 | Q00253

Which of the following is NOT a characteristic of a well-defined Work Breakdown Structure (WBS)?

A. It can be used to assign ownership and track the progress of project tasks.

B. It clearly defines deliverables for each level of the breakdown.

C. It includes activities that are outside the project scope.

D. It is organized in a hierarchical manner, with the overall project at the top and smaller tasks at the bottom.

Hint

Distinguish the planning or organization goal from the tool or structure used to support it. Apply the stated project conditions.

Answer C: It includes activities that are outside the project scope.

Planning breaks down the work needed to complete this project. Work outside project scope is therefore not part of its WBS; hierarchy and assignable tasks are consistent with decomposition.

Why each choice is right or wrong

A - Incorrect: Task assignment and tracking serve project management. See PDF p. 90, 95.

B - Incorrect: Deliverables constrain and clarify project work. See PDF p. 90, 95.

C - Correct: Outside-scope activities do not belong to the work needed to complete the defined project. See PDF p. 90, 95.

D - Incorrect: Breaking large tasks into smaller activities supports the hierarchy described. See PDF p. 90, 95.

Primary note proof

Study-note section SE28

Planning is continuous: identify scope/deliverables, decompose work, estimate effort/duration/cost, assign resources, sequence dependencies and revise as evidence changes. A WBS is hierarchical and covers project scope without adding unrelated work. Tools help coordinate ownership, dependencies and progress; they do not replace judgment or automatically fix bugs.

4.6. Scheduling, Organization and Team Structures
Project-task scheduling is an important project planning activity. It involves deciding which tasks would
be taken up when. In order to schedule the project activities, a software project manager needs to do

the following:
• Identify all the tasks needed to complete the project and Break down large tasks into small activities.
• Determine the dependency among different activities and Establish the most likely estimates for the time durations necessary to complete the activities and Allocate resources to activities.
• Plan the starting and ending dates for various activities and Determine the critical path. A critical path is the chain of activities that determines the duration of the project.

Question sources

Mock exam 4 · Question 55

Question 31 | Q00254

A project team is working on a software project with multiple developers. They decided to implement a version control system (VCS). Which of the following scenarios best describes the use case for a distributed VCS like Git?

A. The team prefers to avoid merge conflicts by locking files so only one developer can work on a file at a time.

B. The team is large, geographically distributed, and each developer needs to work on features independently and merge changes later.

C. The team is small, and all developers work in the same physical location on a single branch.

D. The project requires strict control over who can make changes, and all changes must be approved by a central authority before being committed.

Hint

Separate artifact history and controlled changes from scheduling, collaboration benefits and automated execution.

Answer B: Independent distributed development followed by merging.

SE33 says a distributed Git clone contains local history and allows independent branches that can later be merged. B matches that working arrangement directly. Git does not require everyone to lock files, use one local branch or obtain central permission before every local commit. Additional review policies can be imposed, but they do not define distributed version control.

Why each choice is right or wrong

A - Incorrect: Exclusive file locking is not the defining distributed Git collaboration model.

B - Correct: Local histories and independent branches support geographically distributed work followed by merging.

C - Incorrect: A colocated team can use Git, but this scenario does not express its independent distributed-work benefit.

D - Incorrect: Central approval policies can exist, but they do not define or require distributed local commits.

Primary note proof

Study-note section SE33

> Change management handles request, impact assessment, decision/prioritization, implementation and validation; configuration management keeps all affected versions consistent. Distributed Git gives each clone local history and supports independent branches followed by merging; it does not eliminate merge conflicts or approvals. Plan test configuration management early and apply it throughout testing, not at just one exclusive phase.

Module passages - related reading

Question sources

Mock exam 4 · Question 56

Question 32 | Q00255

The given statement describes which type of requirement? "A heat sensor detects an intrusion and alerts the system."

A. Known Requirement

B. None of the given options

C. Functional

D. Non-Functional

Hint

Distinguish observable services, measurable qualities and implementation constraints. Check scope, stakeholder meaning and the requested level of specificity.

Answer C: Functional

Detection followed by an alert specifies an externally observable service, not a timing or quality constraint.

Why each choice is right or wrong

A - Incorrect: Known requirement is not the module's classification for this behavior. See PDF p. 65, 66.

B - Incorrect: A functional option is present. See PDF p. 65, 66.

C - Correct: Describes the system's required interaction with the intrusion sensor and alert recipient. See PDF p. 65, 66.

D - Incorrect: No performance or other quality bound is stated. See PDF p. 65, 66.

Primary note proof

Study-note section SE09

> A functional requirement states an observable service or behavior, including reactions to inputs, errors and forbidden actions. “When the sensor detects intrusion, send an alert” is functional. “Only a manager may approve refunds” also specifies permitted/prohibited behavior. A negative statement is not automatically nonfunctional.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 65 | lines 19-23

> 3.2.1. Functional Requirements
> Functional requirements describe the interactions between the system and its environment independent of its implementation. The environment includes the user and any other external system with which the system interacts. For example, the following is an example of functional requirements for SatWatch, a watch that resets itself without user intervention:

Software Engineering module | PDF page 66 | lines 14-18

> 3.2.2. Non-Functional and Pseudo-Requirements
> Nonfunctional requirements describe user-visible aspects of the system that are not directly related with the functional behavior of the system. Nonfunctional requirements include quantitative constraints, such as response time (i.e., how fast the system reacts to user commands)
> or accuracy (i.e., how precise are the system’s numerical answers). The following are the

Question sources

Mock exam 4 · Question 57

Question 33 | Q00256

In the ordinary software lifecycle terminology used here, which document organizes the agreed user and detailed system requirements?

A. Software Design Description

B. Software Requirement Specification

C. Capability Development Document

D. Domain-Driven Design

Hint

Separate responsibilities inside a component from dependencies across boundaries. Evaluate the stated structure, change and reuse goals without assuming guaranteed benefits.

Answer B: Software Requirement Specification

The SRS records the agreed software services and constraints, including user-level and detailed system requirements. A Software Design Description explains how the solution is organized rather than being the requirements agreement. A Capability Development Document is a specialized defense capability-requirements artifact. Domain-driven design is an approach to organizing software models around business concepts. Thus the ordinary software requirements document requested is the SRS.

Why each choice is right or wrong

A - Incorrect: A design description records the solution structure rather than the agreed requirements specification.

B - Correct: The SRS organizes agreed user and system services and constraints.

C - Incorrect: A Capability Development Document belongs to a specialized defense capability-acquisition context.

D - Incorrect: Domain-driven design is a modeling/design approach, not the name of the requirements document.

Primary note proof

Study-note section SE08

> User requirements describe stakeholder needs at a useful high level; system requirements specify detailed services and constraints. The Software Requirements Specification (SRS) organizes the agreed requirements.

Study-note section SE21

> System design turns the analysis model into architecture: design goals, subsystem responsibilities, dependencies, hardware mapping, data management, access control, control flow and startup/shutdown/error policies.

Study-note section SE-S06

> A Software Requirements Specification records agreed software services and constraints. A Capability Development Document is a defense capability-requirements artifact describing needed capability characteristics and performance parameters; its specialized acquisition context differs from the ordinary software SRS. Domain-driven design is an approach that organizes software models around the business domain, not the name of an agreed requirements specification.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 26 | lines 10-17

3. Requirement’s specification: Requirements specification is the activity of translating the information gathered during the analysis activity in to a document that defines a set of requirements. Two types of requirements may be included in this document. User requirements are
abstract statements of the system requirements for the customer and end-user of the system; system
requirements are a more detailed description of the functionality to be provided.
4. Requirement’s validation: This activity checks the requirements for realism, consistency, and completeness. During this process, errors in the requirements document are inevitably discovered.
It must then be modified to correct these problems.

Software Engineering module | PDF page 18 | lines 13-20

System and software design: The systems design process allocates the requirements to either hardware or software systems by establishing an overall system architecture.
Software design involves identifying and describing the fundamental software system abstractions
and their relationships. The goal of the design phase is to transform the requirements specified in
the SRS document into a structure that is suitable for implementation in some programming language. In technical terms, during the design phase the software architecture is derived from the
SRS document. Two distinctly different approaches are available: the traditional design approach
and the object-oriented design approach.

Question sources

Mock exam 4 · Question 58

Question 34 | Q00257

Which listed statements describe supported advantages or uses of incremental delivery? Select all that apply. Interpret easier testing/debugging as a potential benefit of smaller changes, not a guarantee.

A. Easier to test and debug

B. Easier to test and debug & It is used when there is a need to get a product to the market early

C. Customer can respond to each increment

D. It is used when there is a need to get a product to the market early

Hint

Identify whether the scenario prioritizes delivery, learning, adaptation or risk reduction. Several processes can share individual practices, so compare their defining emphasis.

Answer A, B, C, D: Easier to test and debug; Easier to test and debug & It is used when there is a need to get a product to the market early; Customer can respond to each increment; It is used when there is a need to get a product to the market early

Incremental delivery adds usable capability in stages. Smaller changes can be easier to test and debug, users can provide feedback after increments, and prioritized partial capability can reach the market early. Thus A, C and D each describe a supported benefit, and B is also true because it combines two true points. These benefits still require architecture, integration and testing effort.

Why each choice is right or wrong

A - Correct: Smaller increments can be easier to test and debug.

B - Correct: Both the smaller-change and early-delivery points are supported.

C - Correct: Users can respond to each usable increment.

D - Correct: Early delivery of prioritized capability is a supported use.

Primary note proof

Study-note section SE04

> Choose incremental delivery when prioritized partial capability must reach users early. Smaller changes can be easier to debug and permit feedback, though architecture and integration still require planning. Iteration need not rebuild the whole system every time, and increments need not be perfectly independent modules. Broad descriptions of early working software can fit prototypes, iterative or Agile processes; identify the purpose of that early version.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 22 | lines 24-29

> Advantages of Incremental Model:
> • Generates working software quickly and early during the software life cycle. This model is more flexible - less costly to change scope and requirements. It is easier to test and debug during a smaller iteration.
> • In this model customer can respond to each built. Lowers initial delivery cost.
> • Easier to manage risk because risky pieces are identified and handled during its iteration.

Question sources

Mock exam 4 · Question 59

Question 35 | Q00258

Use a process diagram whose named stages are requirements gathering, quick design, prototype construction, prototype refinement and engineering the production product. Which offered activity is not a separately named stage, although it can occur within prototype construction?

A. Coding

B. Prototype Refinement

C. Engineer Product

D. Quick Design

Hint

Identify whether the scenario prioritizes delivery, learning, adaptation or risk reduction. Several processes can share individual practices, so compare their defining emphasis.

Answer A: Coding

Coding can be part of building an executable prototype even if the process diagram labels that work construction. It is therefore the offered activity that is not a separately named stage in the stated convention. Quick design, refinement and production engineering are named stages there. This answer concerns the diagram's labels and does not claim that prototyping excludes coding or always follows one universal phase taxonomy.

Why each choice is right or wrong

A - Correct: Coding can occur inside construction without a separate stage label.

B - Incorrect: Prototype refinement is a named stage.

C - Incorrect: Engineering the production product is a named stage.

D - Incorrect: Quick design is a named stage.

Primary note proof

Study-note section SE07

> A prototype explores requirements, usability or technical feasibility. A throwaway prototype is discarded after learning; an evolutionary prototype is deliberately refined toward production. A quick prototype may omit robustness, security or architecture, so do not deploy it unchanged without evaluation. Coding may occur during prototyping even if a diagram labels that activity construction rather than coding.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 82 | lines 23-29

> • Prototype test. During this type of test, one or more users are presented with a piece of software that practically implements the system. A vertical prototype implements a complete use case through the system, and a horizontal prototype presents an interface for most use cases (without providing much or any functionality). The advantages of prototype

tests are that they provide a realistic view of the system to the user and that prototypes can be instrumented to collect detailed data. The disadvantages of prototypes are that they are expensive to build and to modify.

Question sources

Mock exam 4 · Question 60

Question 36 | Q00259

What is the major drawback of using the RAD Model?

A. Increases reusability of components, Highly specialized & skilled developers/designers are required

B. Increases reusability of components

C. Highly specialized & skilled developers/designers are required

D. Encourages customer/client feedback

Hint

Identify whether the scenario prioritizes delivery, learning, adaptation or risk reduction. Several processes can share individual practices, so compare their defining emphasis.

Answer C: The need for highly skilled developers and designers.

SE07 describes RAD as rapid construction using timeboxes, user participation and often reusable components, but requiring skilled designers and developers. That staffing prerequisite is the listed drawback. Reuse and customer feedback are useful features. A combines the genuine prerequisite with a benefit, so C states the drawback accurately without misclassifying reuse.

Why each choice is right or wrong

A - Incorrect: It bundles a genuine staffing drawback with component reuse, which is generally a benefit.

B - Incorrect: Component reuse helps rapid construction and is not the drawback asked for.

C - Correct: RAD depends on skilled designers and developers, which can constrain staffing and feasibility.

D - Incorrect: Customer feedback supports learning and fit rather than being the stated RAD disadvantage.

Primary note proof

Study-note section SE07

RAD uses rapid construction, timeboxing, user participation and often reusable components; it requires available users and skilled designers/developers. Reuse-oriented development searches components, evaluates fit, may adjust requirements, designs around interfaces and builds

missing parts. Product-line assets may include requirements, architecture, components and tests; all are potentially reusable.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 24 | lines 20-29

Advantages:
1. Reduced cost and risks
2. Faster delivery of the software (Accelerated development)
Disadvantages:
1. Compromising requirements
2. Some control over the system evolution is lost as new versions of the reusable components are not under the control of the organization using them.
3. Increased maintenance costs
4. Not-invented-here syndrome
5. Lack of tool support

Question sources

Mock exam 4 · Question 61

Question 37 | Q00260

Which requirements are the foundation from which quality is measured?

A. None of the mentioned

B. Hardware

C. Software

D. Programmers

Hint

Distinguish process assurance from product evaluation, and compare specified obligations with actual stakeholder needs.

Answer C: Software

Conformance is evaluated against software behavior specifications, making software requirements the foundation for the quality comparison here.

Why each choice is right or wrong

A - Incorrect: A software requirements option is present. See PDF p. 140, 26.

B - Incorrect: Hardware alone does not specify expected software behavior. See PDF p. 140, 26.

C - Correct: Defines the behavior against which reliability and failure are judged. See PDF p. 140, 26.

D - Incorrect: Programmer preferences are not the behavior specification. See PDF p. 140, 26.

Primary note proof

Study-note section SE34

Quality assurance establishes and checks processes/standards; quality control evaluates work products. An SQA plan identifies standards, responsibilities, evaluations, reviews, audits and assurance records. Quality of conformance means following the design/specification; a product can conform to a poor specification. Verification asks whether specified obligations are implemented correctly; validation asks whether the product meets intended stakeholder needs. Both can use reviews, analysis or execution, so “human-only versus computer-only” is false.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 140 | lines 11-18

Reliability is a measure of success with which the observed behavior of a system conforms to the specification of its behavior. Software reliability is the probability that a software system will not cause the failure of the system for a specified time under specified conditions. Failure is any deviation of the observed behavior from the specified behavior. An error means the system is in a state such that further processing by the system will lead to a failure, which causes the system to
deviate from its intended behavior. A fault, also called defect or bug, is the mechanical or algorithmic cause of an error. The goal of testing is to maximize the number of discovered faults, which then allows developers to correct them and increase the reliability of the system.

Software Engineering module | PDF page 26 | lines 10-17

3. Requirement’s specification: Requirements specification is the activity of translating the information gathered during the analysis activity in to a document that defines a set of requirements. Two types of requirements may be included in this document. User requirements are
abstract statements of the system requirements for the customer and end-user of the system; system
requirements are a more detailed description of the functionality to be provided.
4. Requirement’s validation: This activity checks the requirements for realism, consistency, and completeness. During this process, errors in the requirements document are inevitably discovered.
It must then be modified to correct these problems.

Question sources

Mock exam 4 · Question 62

Question 38 | Q00261

Which of the following is not a SQA plan for a project?

A. Documents to be produced by the SQA group

B. Evaluations to be performed

C. Audits and reviews to be performed

D. Amount of technical work

Hint

Distinguish process assurance from product evaluation, and compare specified obligations with actual stakeholder needs.

Answer D: Amount of general technical development work.

SE34 identifies assurance responsibilities, evaluations, reviews, audits and assurance records as SQA-plan contents. The documents produced by SQA are assurance records; evaluations, audits and reviews are assurance activities. The amount of general technical development work belongs primarily to project scope and effort planning rather than defining the SQA activities listed here.

Why each choice is right or wrong

A - Incorrect: Assurance documents and records are legitimate SQA-plan deliverables.

B - Incorrect: Planned evaluations are explicitly part of an SQA plan.

C - Incorrect: Reviews and audits are explicitly listed assurance-plan activities.

D - Correct: General technical-work quantity is a project scope/effort concern rather than the listed assurance-plan content.

Primary note proof

Study-note section SE34

> Quality assurance establishes and checks processes/standards; quality control evaluates work products. An SQA plan identifies standards, responsibilities, evaluations, reviews, audits and assurance records. Quality of conformance means following the design/specification; a product can conform to a poor specification. Verification asks whether specified obligations are implemented correctly; validation asks whether the product meets intended stakeholder needs. Both can use reviews, analysis or execution, so “human-only versus computer-only” is false.

Module passages - related reading

Software Engineering module | PDF page 99 | lines 14-19

> 4.8. Quality Assurance Monitoring Plans
> Quality assurance consists of the auditing and reporting functions of management. The goal of quality assurance is to provide management with the data necessary to be informed about product
> quality, thereby gaining insight and confidence that product quality is meeting its goals. Of

course,
if the data provided through quality assurance identify problems, it is management's responsibility
to address the problems and apply the necessary resources to resolve quality issues.

Question sources

Mock exam 4 · Question 63

Question 39 | Q00262

Which of the below is not a part of the Test Plan?

A. Schedule

B. Incident reports

C. Entry and exit criteria

D. Risk

Hint

Separate testing scope, technique and purpose. Use the stated workload, observable result or coverage target rather than a universal ranking.

Answer B: Incident reports are execution outputs, rather than the test plan itself.

SE39 places objectives, scope, resources, schedule, risks and entry/exit criteria in test planning. Incident reports document observed problems during execution and are normally outputs of that work. They may be referenced by later plans, but that does not make actual incident reports an intrinsic part of the prospective test plan.

Why each choice is right or wrong

A - Incorrect: The test schedule is planned work and belongs in a test plan.

B - Correct: Incident reports normally record execution findings rather than describing the planned testing work.

C - Incorrect: Entry and exit criteria define when testing can start or finish and belong in planning.

D - Incorrect: Testing risks influence scope and priorities and are legitimate test-plan content.

Primary note proof

Study-note section SE39

A test plan describes intended work; incident/defect reports are normally execution outputs. A defect report should identify build/environment, steps, expected versus actual behavior, evidence and severity. Anyone finding a fault should record it; testers often coordinate reporting, but it is not their exclusive permission. Configuration control makes the tested version reproducible.

Module passages - related reading

Software Engineering module | PDF page 90 | lines 7-24

4.2. Project Planning
• Probably the most time-consuming project management activity.
• Continuous activity from initial concept through to system delivery. Plans must be regularly revised as new information becomes available.
• Various different types of plans may be developed to support the main software project plan that is concerned with schedule and budget.
The project plan sets out:
• The resources available to the project;
• The work breakdown;
• A schedule for the work.
Project Plan Structure
• Introduction.
• Project organisation.
• Risk analysis.
• Hardware and software resource requirements.
• Work breakdown.
• Project schedule.
• Monitoring and reporting mechanisms.

Software Engineering module | PDF page 144 | lines 17-32

Figure 6.2 depicts an overview of the testing activities:
• Unit testing tries to find faults in participating objects and/or subsystems with respect to the use cases from the use case model
• Integration testing is the activity of finding faults when testing the individually tested components together, for example, subsystems described in the subsystem decomposition, while executing the use cases and scenarios from the RAD.
o The system structure testing is the culmination of integration testing involving all components of the system. Integration tests and structure tests exploit knowledge from the SDD using an integration strategy described in the Test Plan (TP).
• System testing tests all the components together, seen as a single system to identify errors with respect to the scenarios from the problem statement and the requirements and design goals identified in the analysis and system design, respectively:
o Functional testing tests the requirements from the RAD and, if available, from the user manual.
o Performance testing checks the nonfunctional requirements and additional design goals from the SDD. Note that functional and performance testing are both done by

Software Engineering module | PDF page 19 | lines 20-23

System testing is normally carried out in a planned manner according to the system test plan document. The system test plan identifies all testing-related activities that must be performed, specifies the schedule of testing, and allocates resources. It also lists all the test cases and the expected outputs for each test case.

Question sources

Mock exam 4 · Question 64

Question 40 | Q00263

Exploratory testing is a -----?

A. Experience-based Test Design Technique

B. Black Box Test Design Technique

C. White Box Test Design Technique

D. Grey Box Test Design Technique

Hint

Separate testing scope, technique and purpose. Use the stated workload, observable result or coverage target rather than a universal ranking.

Answer A: Experience-based testing.

SE36 explicitly classifies exploratory testing as experience based because learning, test design and execution occur together. It may use knowledge of specifications or internals, but black-box, white-box and grey-box describe different bases of test derivation. None of them replaces the defining experience-based classification asked for in this question.

Why each choice is right or wrong

A - Correct: Exploratory testing uses experience while learning, designing and executing tests together.

B - Incorrect: It may use external behavior, but black-box alone is not its defining classification.

C - Incorrect: Exploratory testing does not require test cases to be derived from internal code structure.

D - Incorrect: Partial internal knowledge can help exploration, but it does not define the technique.

Primary note proof

Study-note section SE36

> Black-box techniques derive cases from specified behavior; white-box techniques derive them from internal structure; grey-box uses partial internal knowledge. Regression testing checks for unintended effects after change; confirmation testing checks the particular defect repair. Exploratory testing combines learning, design and execution and is experience based. Manual/automated describe execution support, not a compulsory black-/white-box classification.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 149 | lines 6-10

Equivalence testing is a black box testing technique that minimizes the number of test cases. The possible inputs are partitioned into equivalence classes, and a test case is selected for each class. The assumption of equivalence testing is that systems usually behave in similar ways for all members of a class. To test the behavior associated with an equivalence class, we only need to test
one member of the class. Equivalence testing consists of two steps: identification of the

Software Engineering module | PDF page 149 | lines 24-29

Path testing
Path testing is a white box testing technique that identifies faults in the implementation of the component. The assumption behind path testing is that, by exercising all possible paths through the code at least once, most faults will trigger failures. The identification of paths requires knowledge of the source code and data structures.
The starting point for path testing is the flow graph. A flow graph consists of nodes representing

Question sources

Mock exam 4 · Question 65

Question 41 | Q00264

Non-conformance to software requirements is known as

A. Software reliability

B. Software availability

C. None of the mentioned

D. Software failure

Hint

Distinguish process assurance from product evaluation, and compare specified obligations with actual stakeholder needs.

Answer D: Software failure

Failure is the deviation of observed behavior from its specified behavior; reliability measures conformance rather than the non-conformance event.

Why each choice is right or wrong

A - Incorrect: Probability or measure of success, not the deviation itself. See PDF p. 140.

B - Incorrect: Availability is not defined as non-conformance. See PDF p. 140.

C - Incorrect: The failure option supplies the defined term. See PDF p. 140.

D - Correct: Matches deviation from specified behavior. See PDF p. 140.

Primary note proof

Study-note section SE34

A fault/defect is an underlying problem; an error may be an incorrect internal state; a failure is an externally observed departure from required service. Reliability is a product quality attribute; low cost or short development time are project outcomes. Tests increase confidence and reveal defects but cannot generally guarantee correctness over every possible input.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 140 | lines 11-18

Reliability is a measure of success with which the observed behavior of a system conforms to the specification of its behavior. Software reliability is the probability that a software system will not cause the failure of the system for a specified time under specified conditions. Failure is any deviation of the observed behavior from the specified behavior. An error means the system is in a state such that further processing by the system will lead to a failure, which causes the system to
deviate from its intended behavior. A fault, also called defect or bug, is the mechanical or algorithmic cause of an error. The goal of testing is to maximize the number of discovered faults, which then allows developers to correct them and increase the reliability of the system.

Question sources

Mock exam 4 · Question 66

Question 42 | Q00308

When comparing internal subsystem-grouping criteria with an external user perspective, which option names the external perspective rather than an internal structural or responsibility criterion?

A. Coupling

B. System's functionality

C. Cohesion

D. Users thinking

Hint

Separate responsibilities inside a component from dependencies across boundaries. Evaluate the stated structure, change and reuse goals without assuming guaranteed benefits.

Answer D: Users thinking

Coupling measures dependencies across subsystem boundaries, cohesion measures relatedness within a subsystem, and functionality helps assign responsibilities. These are internal structural grouping criteria. A user’s perspective describes externally needed tasks and behavior, so it is the different kind of information requested. User workflows can still inform architecture; the distinction does not claim users have no influence on design or that internal boundaries should ignore their needs.

Why each choice is right or wrong

A - Incorrect: Coupling directly measures inter-subsystem dependency.

B - Incorrect: Functionality guides internal responsibility grouping.

C - Incorrect: Cohesion measures how well elements grouped inside a subsystem serve a related purpose.

D - Correct: This names the external user perspective rather than an internal structural measure or responsibility criterion.

Primary note proof

Study-note section SE21

> Group closely related objects and functionality, minimize associations crossing boundaries, and isolate communication infrastructure where useful. User workflows inform decomposition but do not alone dictate the internal structure. Analysis describes domain needs; subsystem decomposition is principally a design result. Architecture documentation supports communication and records major decisions, not every source-level execution step.

Study-note section SE22

> Cohesion measures how well elements inside a module serve a related purpose; coupling measures dependency between modules. Seek high cohesion and low coupling. Shared mutable data and knowledge of another module's internal representation increase coupling. Information hiding exposes stable operations while concealing changeable decisions.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 116 | lines 16-29

> The analysis model describes the system completely from the actors' point of view and serves as the basis of communication between the client and the developers. The analysis model, however, does not contain information about the internal structure of the system, its hardware configuration,
> or, more generally, how the system should be realized. System design is the first step in this direction. System design results in the following products:
> • List of design goals, describing the qualities of the system that developers should optimize
> • Software architecture, describing the subsystem decomposition in terms of subsystem responsibilities, dependencies among subsystems, subsystem mapping to hardware, and major policy decisions such as control flow, access control, and data storage.
> The design goals are derived from the nonfunctional requirements. Design goals guide the decisions to be made by the developers especially when trade-offs are needed. The subsystem decomposition constitutes the bulk of system design. Developers divide the system into manageable pieces to deal with complexity: Each subsystem is assigned to a team and realized independently. In order for this to be possible, though, developers need to address system-wide

Software Engineering module | PDF page 120 | lines 6-12

> 6.1.3. Coupling and coherence
> Coupling is the strength of dependencies between two subsystems. If two subsystems are loosely

coupled, they are relatively independent, and thus, modifications to one of the subsystems will have little impact on the other. If two subsystems are strongly coupled, modifications to one subsystem is likely to have impact on the other. A desirable property of a subsystem decomposition
is that subsystems are as loosely coupled as possible. This minimizes the impact that errors or future changes have on the correct operation of the system.

Software Engineering module | PDF page 120 | lines 24-27

Coherence is the strength of dependencies within a subsystem. If a subsystem contains many objects that are related to each other and perform similar tasks, its coherence is high. If a subsystem
contains a number of unrelated objects, its coherence is low. A desirable property of a subsystem decomposition is that it leads to subsystems with high coherence.

University of Gondar model exam · Question 39

Question 43 | Q00309

The functional model is represented graphically with --

A. Use case diagram

B. State transition diagram

C. Class diagram

D. Object diagram

Hint

Distinguish observable services, measurable qualities and implementation constraints. Check scope, stakeholder meaning and the requested level of specificity.

Answer A: Use case diagram

Use case diagrams represent the functional model; different diagrams represent the dynamic and object models.

Why each choice is right or wrong

A - Correct: Explicit graphical form of the functional model. See PDF p. 101.

B - Incorrect: Models dynamic state transitions. See PDF p. 101.

C - Incorrect: Models object structure. See PDF p. 101.

D - Incorrect: Models object instances, not the functional model. See PDF p. 101.

Primary note proof

Study-note section SE13

> A scenario is one concrete execution; a use case abstracts the related successful and alternative scenarios. Analysis integrates functional (use cases/scenarios), structural/object (classes) and dynamic (states/interactions) models. Entity objects represent domain information such as Incident; boundary objects mediate interaction, such as ReportForm; control objects coordinate a use case. A UI form is normally boundary, not entity.

Module passages - related reading

Software Engineering module | PDF page 101 | lines 5-6

> In UML, the functional model is represented with use case diagrams, the object model with class diagrams, and the dynamic model with statechart and sequence diagrams.

Question sources

Computer Science model exam · Question 40

University of Gondar model exam · Question 40

Question 44 | Q00310

Under the course’s distinction between problem analysis and solution design, which statement is false?

A. System Analysis Focuses on the user's view of the system

B. Design focuses on the developer point of view.

C. Result of system analysis is a model that includes a subsystem decomposition

D. Requirements elicitation establishes externally visible stakeholder needs and constraints before internal solution design.

Hint

Separate responsibilities inside a component from dependencies across boundaries. Evaluate the stated structure, change and reuse goals without assuming guaranteed benefits.

Answer C: Result of system analysis is a model that includes a subsystem decomposition

Analysis clarifies the domain and externally required behavior; system design chooses the solution architecture and subsystem responsibilities. Attributing subsystem decomposition to the principal analysis result therefore confuses these stages. Requirements elicitation establishes stakeholder needs and constraints before the internal solution is selected. The revised elicitation option avoids the stronger claim that only one user’s viewpoint matters, while retaining the intended external-needs versus internal-design distinction.

Why each choice is right or wrong

A - Incorrect: Analysis clarifies the user/domain view of required behavior.

B - Incorrect: Design develops the solution structure and implementation-facing decisions.

C - Correct: Subsystem decomposition is principally a system-design result, so attributing it to analysis is the false claim.

D - Incorrect: Elicitation establishes externally visible stakeholder needs and constraints before choosing internal design.

Primary note proof

Study-note section SE02

> Analysis clarifies the problem; system design chooses architecture; object/detail design specifies interfaces and algorithms; implementation writes code; testing evaluates behavior; deployment puts it into service.

Study-note section SE21

> User workflows inform decomposition but do not alone dictate the internal structure. Analysis describes domain needs; subsystem decomposition is principally a design result.

Study-note section SE08

> User requirements describe stakeholder needs at a useful high level; system requirements specify detailed services and constraints.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 63 | lines 3-8

> Requirements elicitation and analysis focus only on the user's view of the system. For example, the system functionality, the interaction between the user and the system, the errors that the system
> can detect and handle, and the environmental conditions in which the system functions, are part of
> the requirements. The system structure, the implementation technology selected to build the system, the system design, the development methodology, and other aspects not directly visible to
> the user are not part of the requirements.

Software Engineering module | PDF page 116 | lines 16-29

> The analysis model describes the system completely from the actors' point of view and serves as the basis of communication between the client and the developers. The analysis model, however, does not contain information about the internal structure of the system, its hardware configuration,
> or, more generally, how the system should be realized. System design is the first step in this direction. System design results in the following products:
> • List of design goals, describing the qualities of the system that developers should optimize

University of Gondar model exam · Question 41

Question 45 | Q00311

Which of the following heuristics is not used to identify Entity objects

A. Real-world entities

B. Real-world activities

C. Forms

D. Data sources

Hint

Distinguish observable services, measurable qualities and implementation constraints. Check scope, stakeholder meaning and the requested level of specificity.

Answer C: Forms normally identify boundary objects.

SE13 defines entity objects as domain information and gives ReportForm as a boundary mediating interaction. Thus forms normally suggest boundary objects rather than entity objects. Real-world things, domain activities represented as information and relevant stored data can suggest entity candidates; those are heuristics, not mechanical rules guaranteeing a class for every noun or activity.

Why each choice is right or wrong

A - Incorrect: Real-world domain entities are natural candidates for entity objects.

B - Incorrect: A domain activity represented as persistent domain information can suggest an entity candidate.

C - Correct: A user-interface form normally mediates interaction and is modeled as a boundary object.

D - Incorrect: Relevant domain data sources can suggest information-holding entities, subject to analysis rather than automatic conversion.

Primary note proof

Study-note section SE13

> Use nouns as candidate objects, possessive descriptions as candidate attributes, and verbs such as manages/reports-to as candidate associations. These are heuristics, not automatic parsing rules. CRC means Class, Responsibilities, Collaborators. A control per use case or participating actor can be a useful starting point, not a mandatory UML rule or fixed object lifetime.

Study-note section SE13

> A UI form is normally boundary, not entity.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 105 | lines 9-15

> 5.2.1. Identifying Entity Objects
> Requirements Elicitation, participating objects are found by examining each use case and identifying candidate objects. Natural language analysis is an intuitive set of heuristics for identifying objects, attributes, and associations from a system specification. Abbott’s heuristics maps parts of speech (e.g., nouns, having verbs, being verbs, adjectives) to model components (e.g., objects, operations, inheritance relationships, classes). Table 4-1 provides examples of such mappings by examining the Report Emergency use case.

Software Engineering module | PDF page 101 | lines 9-15

The analysis object model consists of entity, boundary, and control objects. Entity objects represent the persistent information tracked by the system. Boundary objects represent the interactions between the actors and the system. Control objects represent the tasks that a formed by the user and supported by the system. In the 2B watch example, Year, Month, Day are entity objects; Button Boundary and LCD Display Boundary are boundary objects; Change Date Control is
a control object that represents the activity of changing the date by pressing combinations of buttons.

University of Gondar model exam · Question 42

Question 46 | Q00312

"Consider a system where, a heat sensor detects an intrusion and alerts the security company." What kind of a requirement the system is providing?

A. Functional Requirement

B. Non-Functional

C. Constraints

D. Known Requirement

Hint

Distinguish observable services, measurable qualities and implementation constraints. Check scope, stakeholder meaning and the requested level of specificity.

Answer A: Functional Requirement

Detecting an intrusion and notifying the security company is a required interaction/service independent of implementation.

Why each choice is right or wrong

A - Correct: Specifies the system's required behavior. See PDF p. 65.

B - Incorrect: No response-time, reliability or quality limit is stated. See PDF p. 65.

C - Incorrect: No implementation or resource restriction is stated. See PDF p. 65.

D - Incorrect: Known Requirement is not the behavioral category defined here. See PDF p. 65.

Primary note proof

Study-note section SE09

Write one clear obligation with an actor/trigger, action and observable result. “The system shall generate a PDF report” is functional. “The system shall not reveal another customer’s balance” can be a security-related functional rule. Security as a broad quality goal and the functions

implementing it must be distinguished. Words such as must, should and not work do not by themselves determine a requirement’s classification.

University of Gondar model exam · Question 43

Question 47 | Q00313

which one of the following is used to Identifying Actors

A. What kind of dependencies are exist among use cases.

B. What information does the actor access?

C. Which user groups execute the system's main functions?

D. What are the tasks that the actor wants the system to perform?

Hint

Match the information to be represented with each model’s purpose. Read relationship direction, boundary and ownership conditions before classifying it.

Answer C: Which user groups execute the system's main functions?

Identifying user groups that execute the main functions identifies actors; questions about information and tasks identify scenarios.

Why each choice is right or wrong

A - Incorrect: Concerns use-case relationships rather than identifying external entities. See PDF p. 71, 73.

B - Incorrect: Listed as a scenario-identification question. See PDF p. 71, 73.

C - Correct: Exact actor-identification heuristic. See PDF p. 71, 73.

D - Incorrect: Listed as a scenario-identification question. See PDF p. 71, 73.

Primary note proof

Study-note section SE14

An actor is an external role interacting with the system; it can be a person, device or another system. A person may play several roles, and several people may play one role. A primary actor seeks a goal; a supporting actor provides a service. Ask which user groups perform main functions, administer or maintain the system, and which external systems exchange information.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 71 | lines 13-18

When identifying actors, developers can ask the following questions:
Questions for identifying actors
• Which user groups are supported by the system to perform their work?
• Which user groups execute the system's main functions?
• Which user groups perform secondary functions, such as maintenance and administration?
• Will the system interact with any external hardware or software system?

Software Engineering module | PDF page 73 | lines 4-9

Questions for identifying scenarios
• What are the tasks that the actor wants the system to perform?
• What information does the actor access? Who creates that data? Can it be modified or removed?
By whom?
• Which external changes does the actor need to inform the system about? How often? When?
• Which events does the actor need to be informed by the system about? With what latency?

Question sources

Computer Science model exam · Question 44

University of Gondar model exam · Question 44

Question 48 | Q00547

_____is requirement elicitation techniques that is used to gather the requirements using day-to-day working observation and notes made of the actual tasks.

A. Use case

B. Ethnography

C. Scenario

D. Interview

Hint

Distinguish observable services, measurable qualities and implementation constraints. Check scope, stakeholder meaning and the requested level of specificity.

Answer B: Ethnography.

The stem describes observing people's actual daily tasks and recording what they do. SE12 names that observation-based elicitation approach ethnography. Interviews ask stakeholders questions, while scenarios and use cases describe executions or goals; those can complement observation but do not name the day-to-day fieldwork technique itself.

Why each choice is right or wrong

A - Incorrect: A use case describes goal-oriented interactions rather than naming observational fieldwork.

B - Correct: Ethnography gathers understanding by observing actual day-to-day work and recording it.

C - Incorrect: A scenario is one concrete execution, not the observation-based elicitation technique itself.

D - Incorrect: An interview asks people questions rather than primarily observing their daily tasks.

Primary note proof

Study-note section SE12

> Interviews ask stakeholders about needs; document analysis examines manuals, contracts and current records; observation/ethnography studies actual daily work. Prototypes reveal tacit expectations. Workshops/JAD bring users, managers and developers together with a facilitator and recorder to build consensus. Use several sources and check assumptions against observed work.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 80 | lines 5-11

> Task analysis is based on the assumption that it is inefficient to ask users to describe what they do
> and how they do it. Users usually do not think explicitly about the sequence of tasks that are required to accomplish their work as they have often repeated these tasks many times. Users, when
> ask how they accomplish their work, would describe, at best, how they are supposed to accomplish
> it, which may be far from reality. Consequently, task analysis uses observation as an alternative to
> build an initial task model. This initial task model is then refined by asking the users why they accomplish a task a certain way.

Question sources

Computer Science model exam · 2015 · Question 16

Question 49 | Q00549

Which one of the following is more related to effective management of software complexity?

A. Modularity

B. Reusability

C. Extensibility

D. All

Hint

Separate responsibilities inside a component from dependencies across boundaries. Evaluate the stated structure, change and reuse goals without assuming guaranteed benefits.

Answer A: Modularity

Decomposition into simpler, manageable subsystems controls complexity. Reuse and extensibility can benefit designs, but do not substitute for this direct mechanism.

Why each choice is right or wrong

A - Correct: Divides the solution domain into manageable simpler parts. See PDF p. 118, 32.

B - Incorrect: Reusability is an additional benefit of object-oriented modules. See PDF p. 118, 32.

C - Incorrect: Extensibility concerns future additions rather than directly partitioning complexity. See PDF p. 118, 32.

D - Incorrect: The text directly establishes modularity; it does not identify all three as equivalent complexity mechanisms. See PDF p. 118, 32.

Primary note proof

Study-note section SE21

> System design turns the analysis model into architecture: design goals, subsystem responsibilities, dependencies, hardware mapping, data management, access control, control flow and startup/shutdown/error policies. Detail/object design refines APIs, parameter/return types, exceptions, component choices and algorithms. A subsystem is a manageable logical collection with services and an interface; it need not be a physical replaceable artifact.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 118 | lines 11-16

> 6.1.1. Subsystems and classes
> In order to reduce the complexity of the application domain, we identified smaller parts called classes and organized them into packages. Similarly, to reduce the complexity of the solution domain, we decompose a system into simpler parts, called subsystems, which are made of a number of solution domain classes. In the case of complex subsystems, we recursively apply this principle and decompose a subsystem into simpler subsystems (see Figure 6.2).

Software Engineering module | PDF page 32 | lines 12-21

A class in an object-oriented system carefully delineates between its interfaces the routines and attributes within a class are held together tightly. In a properly designed system, the classes will be grouped into subsystems but remain independent; therefore, changing one class has no impact
on other classes, and so, the impact is minimized. However, the object-oriented approach is not a panacea; nothing is magical here that will promote perfect design or perfect code.
Promotion of reusability
Objects are reusable because they are modeled directly out of a real-world problem domain. Each
object stands by itself or within a small circle of peers (other objects). Within this framework, the class does not concern itself with the rest of the system or how it is going to be used within a particular system.

Computer Science model exam · 2015 · Question 18

Question 50 | Q00551

Which one of the following testing required knowledge about internal structure, design and implementation of the system?

A. Black box Testing

B. White box testing

C. Alpha testing

D. Beta testing

Hint

Separate testing scope, technique and purpose. Use the stated workload, observable result or coverage target rather than a universal ranking.

Answer B: White box testing

Path testing requires source code and data-structure knowledge; black-box equivalence testing instead groups observable inputs.

Why each choice is right or wrong

A - Incorrect: Does not require internal paths. See PDF p. 149, 149.

B - Correct: Matches the source-knowledge requirement. See PDF p. 149, 149.

C - Incorrect: Alpha denotes development-team system testing, not an internal-knowledge technique. See PDF p. 149, 149.

D - Incorrect: Beta denotes testing by customers, not an internal-knowledge technique. See PDF p. 149, 149.

Primary note proof

Study-note section SE36

Black-box techniques derive cases from specified behavior; white-box techniques derive them from internal structure; grey-box uses partial internal knowledge. Regression testing checks for unintended effects after change; confirmation testing checks the particular defect repair. Exploratory testing combines learning, design and execution and is experience based. Manual/automated describe execution support, not a compulsory black-/white-box classification.

Module passages - related reading

Question 51 | Q00554

Which team organization shares development decisions among team members rather than centralizing technical coordination in a chief programmer?

A. Functional

B. Project

C. Democratic

D. Chief programmer

Hint

Distinguish the planning or organization goal from the tool or structure used to support it. Apply the stated project conditions.

Answer C: Democratic

Democratic teams share decisions, whereas chief-programmer teams centralize technical coordination. Functional and project organizations classify how people are grouped, not how authority is distributed. Asking about shared decision-making therefore makes democratic the unique answer. It does not require every individual to perform every lifecycle task; a democratic team can still divide work by expertise and responsibilities.

Why each choice is right or wrong

A - Incorrect: Functional organization groups specialists by discipline.

B - Incorrect: Project organization groups people by project rather than defining shared authority.

C - Correct: Democratic teams share decisions.

D - Incorrect: Chief-programmer teams centralize technical coordination.

Primary note proof

Study-note section SE32

> Functional organizations group specialists by discipline; project organizations group people around projects. Functional specialization helps staffing and knowledge continuity but may create handoff barriers. Democratic teams share decisions; chief-programmer teams centralize technical coordination. These are different classification dimensions. Tuckman’s sequence is forming→storming→norming→performing→adjourning: orientation, conflict, norms, effective work and closure.

Question sources

Computer Science model exam · 2015 · Question 23

Question 52 | Q00555

Which capability maturity model level an organization must master the requirements management software quality assurance, and software project planning

A. Repeatable level

B. Initial level

C. Defined level

D. Managed level

Hint

Distinguish the planning or organization goal from the tool or structure used to support it. Apply the stated project conditions.

Answer A: Historical CMM Level 2: Repeatable.

SE32 explicitly assigns requirements management, software project planning, quality assurance and configuration management to historical Software CMM Level 2. Its name is Repeatable, rather than the later CMMI label Managed. The other named choices correspond to levels 1, 3 and 4 in this historical model, so A matches both practices and terminology.

Why each choice is right or wrong

A - Correct: Repeatable is historical Software CMM Level 2, which establishes the listed basic project practices.

B - Incorrect: Initial is historical Level 1, before the repeatable project discipline specified here.

C - Incorrect: Defined is historical Level 3, not the level associated with this basic practice list.

D - Incorrect: Managed is historical Software CMM Level 4; modern CMMI terminology must not be substituted.

Primary note proof

Study-note section SE32

> Historical Software CMM levels are 1 Initial, 2 Repeatable, 3 Defined, 4 Managed, 5 Optimizing. Level2 establishes basic project discipline including requirements management, project planning, quality assurance and configuration management. These historical labels must not be silently replaced by modern CMMI terminology. A maturity model concerns process capability, not a guarantee that every product is defect free.

• Software Metrics can be used to indicate the basic attributes of the software. The indicative metrics, not exhaustive, are
• Size - Line of code ,Function point count
• Quality- Reliability, Accuracy, Dependability, and these are measured through some measures like errors, failures and number of runs between failures ,etc.
• Execution Time -process time of execution of a critical process and many more.

Question sources

Computer Science model exam · 2015 · Question 24

Question 53 | Q00558

All are the advantages of functional format structure, except

A. Ease of staffing

B. Production of good quality documents

C. No need job specialization

D. Efficient handling manpower turnover

Hint

Distinguish the planning or organization goal from the tool or structure used to support it. Apply the stated project conditions.

Answer C: No need for job specialization is false of a functional organization.

SE32 defines functional organizations as grouping specialists by discipline. Claiming that specialization is unnecessary contradicts that organizing principle. Ease of staffing and knowledge continuity are benefits of specialization; continuity can help with turnover. Specialist expertise can also support documentation quality, although no organizational form guarantees good documents. C is the clear exception.

Why each choice is right or wrong

A - Incorrect: Grouping specialists supports staffing within established disciplines, so this is a plausible benefit.

B - Incorrect: Specialist expertise can support good documentation; this is not the direct contradiction of functional grouping.

C - Correct: This contradicts the defining use of specialist disciplines in a functional organization.

D - Incorrect: Knowledge continuity within a functional group can help absorb staff turnover.

Primary note proof

Study-note section SE32

Functional organizations group specialists by discipline; project organizations group people around projects. Functional specialization helps staffing and knowledge continuity but may create handoff barriers. Democratic teams share decisions; chief-programmer teams centralize

technical coordination. These are different classification dimensions. Tuckman's sequence is forming→storming→norming→performing→adjourning: orientation, conflict, norms, effective work and closure.

Computer Science model exam · 2015 · Question 27

Question 54 | Q00568

Which testing should focus on testing the functionality of objects or methods?

A. Integration testing

B. White box testing

C. Black box testing

D. Unit testing

Hint

Separate testing scope, technique and purpose. Use the stated workload, observable result or coverage target rather than a universal ranking.

Answer D: Unit testing

Unit testing isolates the building blocks, including objects; a method is part of such an individual component's behavior.

Why each choice is right or wrong

A - Incorrect: Tests components together. See PDF p. 148, 144.

B - Incorrect: A technique based on internal paths, not the requested component level. See PDF p. 148, 144.

C - Incorrect: A technique based on external behavior, not a component level. See PDF p. 148, 144.

D - Correct: Tests isolated objects or subsystems and their functionality. See PDF p. 148, 144.

Primary note proof

Study-note section SE35

Acceptance testing supports the customer/user's acceptance decision against agreed needs and criteria. Alpha typically happens in a controlled developer setting with selected users; beta uses external users in their environments. None of these levels is universally the longest. Unit is a level, while white-box is a technique; a unit can be tested using black-box cases too.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 148 | lines 19-26

Unit testing focuses on the building blocks of the software system, that is, objects and subsystems.
There are three motivations behind focusing on components. First, unit testing reduces the complexity of the overall test activities, allowing us to focus on smaller units of the system. Second, unit testing makes it easier to pinpoint and correct faults, given that few components are involved in the test. Third, unit testing allows parallelism in the testing activities; that is, each component can be tested independently of one another.
The specific candidates for unit testing are chosen from the object model and the system decomposition of the system. In principle, all the objects developed during the development

Software Engineering module | PDF page 144 | lines 17-32

Figure 6.2 depicts an overview of the testing activities:
• Unit testing tries to find faults in participating objects and/or subsystems with respect to the use cases from the use case model
• Integration testing is the activity of finding faults when testing the individually tested components together, for example, subsystems described in the subsystem decomposition, while executing the use cases and scenarios from the RAD.
o The system structure testing is the culmination of integration testing involving all components of the system. Integration tests and structure tests exploit knowledge from the SDD using an integration strategy described in the Test Plan (TP).
• System testing tests all the components together, seen as a single system to identify errors with respect to the scenarios from the problem statement and the requirements and design goals identified in the analysis and system design, respectively:
o Functional testing tests the requirements from the RAD and, if available, from the user manual.
o Performance testing checks the nonfunctional requirements and additional design goals from the SDD. Note that functional and performance testing are both done by

Computer Science model exam · 2015 · Question 37

Question 55 | Q00572

Which of the following views represents the interaction of the user with the software but tells nothing about the internal working of the software?

A. Use case diagram

B. Activity diagram

C. Class diagram

D. Sequence diagram

Hint

Match the information to be represented with each model's purpose. Read relationship direction, boundary and ownership conditions before classifying it.

Answer A: Use case diagram

A use case describes external behavior from an actor's point of view without prescribing the internal realization.

Why each choice is right or wrong

A - Correct: Directly models actor-visible interaction. See PDF p. 47, 54, 51.

B - Incorrect: Models action/control flow and may include internal work. See PDF p. 47, 54, 51.

C - Incorrect: Describes classes and their structure. See PDF p. 47, 54, 51.

D - Incorrect: Distributes interaction among participating objects, revealing internal collaboration. See PDF p. 47, 54, 51.

Primary note proof

Study-note section SE14

> Draw actors outside the system boundary rectangle and use-case ovals inside. Name a goal with a verb and noun. The diagram shows roles, goals and relationships, not the full detailed algorithm or UI layout. Being an internal component is different from being an external actor; the chosen boundary determines which role applies.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 47 | lines 30-39

> Actors are external entities that interact with the system. Examples of actors include a user role (e.g., a system administrator, a bank customer, a bank teller) or another system (e.g., a central database, a fabrication line). Actors have unique names and descriptions.
> Use cases describe the behavior of the system as seen from an actor's point of view. Behavior described by the use case model is also called external behavior. A use case describes a function provided by the system as a set of events that yields a visible result for the actors. Actors initiate a
> use case to access the system functionality. The use case can then initiate other use cases and

gather
more information from the actors. When actors and use cases exchange information, they are said
to communicate. We will see later that we represent these exchanges with communication relationships.

Software Engineering module | PDF page 54 | lines 26-35

both buttons simultaneously. Figure 2.10 depicts a sequence diagram for an actor setting his 2Bwatch one minute ahead.
Each column represents an object that participates in the interaction. The vertical axis represents
time from top to bottom. Messages are shown by arrows. Labels on arrows represent message names and may contain arguments. Activations (i.e., executing methods) are depicted by vertical rectangles. Actors are shown as the leftmost column.
Sequence diagrams can be used to describe either an abstract sequence (i.e., all possible interactions) or concrete sequences (i.e., one possible interaction, as in Figure 2.10). When describing all possible interactions, sequence diagrams also provide notations for conditionals and
iterators.

Software Engineering module | PDF page 51 | lines 14-24

2.3.2. Class Diagrams
Classes and objects
Class diagrams describe the structure of the system in terms of classes and objects. Classes are abstractions that specify the attributes and behavior of a set of objects. Objects are entities that encapsulate state and behavior. Each object has an identity: It can be referred individually and is distinguishable from other objects.
In UML, classes and objects are depicted by boxes including three compartments. The top compartment displays the name of the class or object. The center compartment displays its attributes, and the bottom compartment displays its operations. The attribute and operation compartment can be omitted for clarity. Object names are underlined to indicate that they are instances. By convention, class names start with an uppercase letter. Objects in object diagrams

Computer Science model exam · 2015 · Question 126

Question 56 | Q00575

Requirements and technical feasibility are unclear. The immediate goal is to build an exploratory version for user feedback and feasibility learning, then discard it rather than deliver it as production software. Which model best names that immediate activity?

A. Incremental model

B. Prototype model

C. Spiral model

D. Waterfall model

Hint

Identify whether the scenario prioritizes delivery, learning, adaptation or risk reduction. Several processes can share individual practices, so compare their defining emphasis.

Answer B: Prototype model

A throwaway prototype explores requirements, usability or technical feasibility and is discarded after learning. That exactly matches the immediate purpose specified. Incremental delivery would provide usable production capability; spiral would organize broader commitments around risk-driven cycles and might use a prototype within them. Classical waterfall favors understood requirements and familiar technology. The specific learning-and-discard goal therefore identifies the prototype model.

Why each choice is right or wrong

A - Incorrect: Incremental delivery targets usable capability rather than a discarded exploratory artifact.

B - Correct: A throwaway prototype explores needs and feasibility before being discarded.

C - Incorrect: Spiral may use a prototype, but names the broader risk-driven process.

D - Incorrect: The stated uncertainty lacks classical waterfall's stable, familiar conditions.

Primary note proof

Study-note section SE07

> A prototype explores requirements, usability or technical feasibility. A throwaway prototype is discarded after learning; an evolutionary prototype is deliberately refined toward production. A quick prototype may omit robustness, security or architecture, so do not deploy it unchanged without evaluation. Coding may occur during prototyping even if a diagram labels that activity construction rather than coding.

Study-note section SE06

> Spiral development is risk driven. Each cycle identifies objectives and alternatives, assesses and reduces important risks, develops/verifies an appropriate next result, and plans further commitment. A prototype may test a risky technology before a large investment. The amount and type of work depend on the risks.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 26 | lines 6-9

> 2. Requirement's elicitation and analysis: This is the process of deriving the system requirements through observation of existing systems, discussions with potential users and procurers, task analysis, and so on. This may involve the development of one or more system models and prototypes. These help you understand the system to be specified.

Software Engineering module | PDF page 82 | lines 23-29

> • Prototype test. During this type of test, one or more users are presented with a piece of software that practically implements the system. A vertical prototype implements a complete use case through the system, and a horizontal prototype presents an interface for most use cases (without providing much or any functionality). The advantages of prototype tests are that they provide a realistic view of the system to the user and that prototypes can be instrumented to collect detailed data. The disadvantages of prototypes are that they are expensive to build and to modify.

Software Engineering module | PDF page 20 | lines 18-22

> the development plan. Its major problem is the inflexible partitioning of the project into distinct stages. Commitments must be made at an early stage in the process, which makes it difficult to respond to changing customer requirements.
> In principle, the waterfall model should only be used when the requirements are well understood
> and unlikely to change radically during system development. However, the waterfall model

Question sources

Computer Science model exam · 2015 · Question 44

Question 57 | Q00580

What is the purpose of a sequence diagram?

A. To show the interactions between actors and a system

B. To show the behavior of objects in a system

C. To show the flow of activities in a system

D. To show the order and timing of interactions between objects

Hint

Match the information to be represented with each model's purpose. Read relationship direction, boundary and ownership conditions before classifying it.

Answer D: To show the order and timing of interactions between objects

The vertical axis is time and arrows are messages among participating objects; this directly supports order and timing.

Why each choice is right or wrong

A - Incorrect: Actor interaction is part of some sequences but is less precise than object-message order. See PDF p. 54.

B - Incorrect: Broadly describes behavior without identifying temporal interaction. See PDF p. 54.

C - Incorrect: Activity flow is represented by activity diagrams. See PDF p. 54.

D - Correct: Matches time-ordered messages and activations. See PDF p. 54.

Primary note proof

Study-note section SE19

> Sequence diagrams show interactions across lifelines, with order/time generally downward. Messages cross between participants; activation rectangles show execution. A creation message starts a lifeline; an X marks modeled destruction, not a guarantee about when a garbage collector runs. Synchronous calls wait for completion; asynchronous messages permit the sender to proceed.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Science model exam · 2015 · Question 49

Question 58 | Q00592

Which of the following diagram types is used to represent the static structure of a system?

A. Use case documentation

B. Sequence diagram

C. Class diagram

D. Activity diagram

Hint

Match the information to be represented with each model's purpose. Read relationship direction, boundary and ownership conditions before classifying it.

Answer C: Class diagram

Class diagrams describe system structure in classes, attributes, operations and relationships; sequence and activity models describe behavior.

Why each choice is right or wrong

A - Incorrect: Documents functions from actors' viewpoints. See PDF p. 51, 101.

B - Incorrect: Represents interactions over time. See PDF p. 51, 101.

C - Correct: Explicit structural description of classes and objects. See PDF p. 51, 101.

D - Incorrect: Models activities and control flow. See PDF p. 51, 101.

Primary note proof

Study-note section SE17

> A class box lists name, attributes and operations; + public, - private, # protected and ~ package indicate visibility. A class diagram shows static types and relationships, while an object diagram shows particular instances/links. UML is maintained and standardized by OMG; it is a modeling language, not a lifecycle process. Structural things describe conceptual or physical structural elements.

Question sources

Computer Science model exam · 2015 · Question 61

Question 59 | Q00597

Which is the following is the most important feature of the spiral model?

A. Efficiency management

B. Time management

C. Quality management

D. Risk management

Hint

Identify whether the scenario prioritizes delivery, learning, adaptation or risk reduction. Several processes can share individual practices, so compare their defining emphasis.

Answer D: Risk management.

SE06 makes risk the organizing principle of spiral development. Each cycle identifies objectives and alternatives, assesses and reduces important risks, develops an appropriate next result and plans further commitment. Time, efficiency and quality still matter, but they do not distinguish spiral from other processes as directly as its explicit risk-driven cycles.

Why each choice is right or wrong

A - Incorrect: Efficiency is useful, but it is not the defining organizing feature of spiral cycles.

B - Incorrect: Time management matters in many processes and does not distinguish spiral.

C - Incorrect: Quality management is important generally, but the defining spiral emphasis is risk.

D - Correct: Each spiral cycle explicitly evaluates and reduces the most important risks.

Primary note proof

Study-note section SE06

> Spiral development is risk driven. Each cycle identifies objectives and alternatives, assesses and reduces important risks, develops/verifies an appropriate next result, and plans further commitment. A prototype may test a risky technology before a large investment. The amount and type of work depend on the risks.

Software Engineering module | PDF page 121 | lines 6-15

6.1.4. Software architecture
As the complexity of systems increases, the specification of the system decomposition is critical. It is difficult to modify or correct a weak decomposition once development has started, as most subsystem interfaces have to change. In recognition of the importance of this problem, the concept
of software architecture has emerged. A software architecture includes the system decomposition, the global control flow, error-handling policies and inter subsystem communication protocols.
In this section, we describe a few sample architectures that can be used for different systems. This
is by no means a systematic or thorough exposition of the subject. Rather, we aim to provide a few
representative examples and refer the reader to the literature for more details.

Question sources

Computer Science model exam · 2015 · Question 66

Question 60 | Q00606

_____ is the process of writing down the user and system requirements in a requirements document.

A. Feasibility study

B. Requirements elicitation and analysis.

C. Requirements specification

D. Requirements validation

Hint

Distinguish observable services, measurable qualities and implementation constraints. Check scope, stakeholder meaning and the requested level of specificity.

Answer C: Requirements specification

Specification translates analyzed information into a document containing user requirements and detailed system requirements.

Why each choice is right or wrong

A - Incorrect: Decides viability before detailed analysis. See PDF p. 26, 25, 26.

B - Incorrect: Derives requirements rather than being the document-writing step. See PDF p. 26, 25, 26.

C - Correct: Directly names translation into the requirements document. See PDF p. 26, 25, 26.

D - Incorrect: Checks realism, consistency and completeness of the document. See PDF p. 26, 25, 26.

Primary note proof

Study-note section SE08

> Business requirements explain why the project exists and its goals. User requirements describe stakeholder needs at a useful high level; system requirements specify detailed services and constraints. The Software Requirements Specification (SRS) organizes the agreed requirements. A natural-language specification communicates with clients while analysis models formalize it for technical discussion; real specifications can also contain diagrams.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 26 | lines 10-17

> 3. Requirement's specification: Requirements specification is the activity of translating the information gathered during the analysis activity in to a document that defines a set of requirements. Two types of requirements may be included in this document. User requirements are
> abstract statements of the system requirements for the customer and end-user of the system; system
> requirements are a more detailed description of the functionality to be provided.
> 4. Requirement's validation: This activity checks the requirements for realism, consistency, and completeness. During this process, errors in the requirements document are inevitably discovered.
> It must then be modified to correct these problems.

Software Engineering module | PDF page 25 | lines 15-18

> There are four main activities in the requirements engineering process:
> 1. Feasibility study: Feasibility shows viability and practicality of a software, project or idea. An estimate is made of whether the identified user needs may be satisfied using current software and hardware technologies. The study considers whether the proposed system will be cost-

> 2. Requirement's elicitation and analysis: This is the process of deriving the system requirements through observation of existing systems, discussions with potential users and procurers, task analysis, and so on. This may involve the development of one or more system models and prototypes. These help you understand the system to be specified.

Question sources

Computer Science model exam · 2015 · Question 75

Question 61 | Q00612

Incremental model of software development is

A. A reasonable mode when requirements are well define

B. Good model when a working core product is required quickly

C. Good model for the projects with large development teams

D. Good model when user requirements are not complete

Hint

Identify whether the scenario prioritizes delivery, learning, adaptation or risk reduction. Several processes can share individual practices, so compare their defining emphasis.

Answer B: Good model when a working core product is required quickly

Early increments are usable stripped-down products; early working capability is the clearest fit among these options.

Why each choice is right or wrong

A - Incorrect: Well-defined requirements can be useful, but are not the distinctive advantage asked. See PDF p. 22, 22.

B - Correct: Directly supported by early working software. See PDF p. 22, 22.

C - Incorrect: The module specifically notes fewer staff can implement early increments. See PDF p. 22, 22.

D - Incorrect: Feedback can refine requirements, but the module also calls for sufficient overall definition to partition them. See PDF p. 22, 22.

Primary note proof

Study-note section SE04

> Choose incremental delivery when prioritized partial capability must reach users early. Smaller changes can be easier to debug and permit feedback, though architecture and integration still require planning. Iteration need not rebuild the whole system every time, and increments need not be perfectly independent modules. Broad descriptions of early working software can fit prototypes, iterative or Agile processes; identify the purpose of that early version.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 22 | lines 8-12

> This model delivers software in small but usable pieces, called —increments. In general, each increment builds on those that have already been delivered. The model is iterative in nature and focuses on the delivery of an operational product with each increment. Early increments are stripped down versions of the final product, but they do provide capability that serves the user and
> also provide a platform for evaluation by the user.

Software Engineering module | PDF page 22 | lines 24-29

Advantages of Incremental Model:
• Generates working software quickly and early during the software life cycle. This model is more flexible - less costly to change scope and requirements. It is easier to test and debug during a smaller iteration.
• In this model customer can respond to each built. Lowers initial delivery cost.
• Easier to manage risk because risky pieces are identified and handled during its iteration.

Question sources

Computer Science model exam · 2015 · Question 81

Question 62 | Q00620

Which relationship are used when you have one use case that is similar to another, but does something slightly differently or something more.

A. Generalization

B. Aggregation

C. Composition

D. Association

Hint

Match the information to be represented with each model's purpose. Read relationship direction, boundary and ownership conditions before classifying it.

Answer A: Generalization

Use-case generalization specializes a general use case by adding detail or varying its realization, as in password versus smart-card authentication.

Why each choice is right or wrong

A - Correct: Direct specialization mechanism described by the module. See PDF p. 51.

B - Incorrect: Whole-part relationship, not use-case specialization. See PDF p. 51.

C - Incorrect: Whole-part lifecycle ownership, not use-case specialization. See PDF p. 51.

D - Incorrect: Communication/linkage alone does not express the stated specialized behavior. See PDF p. 51.

Primary note proof

Study-note section SE16

Generalization relates a specialized actor/use case to a more general one, with a hollow triangle toward the general element. An abstract use case specifies behavior for specialization and is not directly instantiated as a complete use case. It is not defined merely by reuse or lack of a direct actor line. Included behavior is incorporated where the inclusion is reached; do not infer every conditional branch in the base always executes.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 51 | lines 4-13

> Generalization relationships
> Generalization/specialization relationships are a third mechanism for reducing the complexity of a model. A use case can specialize a more general one by adding more detail. For example, FieldOfficers are required to authenticate before they can use FRIEND. During early stages of requirements elicitation, authentication is modeled as a high-level Authenticate use case. Later, developers describe the Authenticate use case in more detail and allow for several different hardware platforms. This refinement activity results in two more use cases, AuthenticateWithPasswordwhich enables FieldOfficers to login without any specific hardware, and AuthenticateWithCard, which enables FieldOfficers to login using a smart card. The two new use cases are represented as specializations of the Authenticate use case.

Question sources

Computer Science model exam · 2015 · Question 89

Question 63 | Q00649

_____a software product is necessary to rectify the bugs observed while the system is in use.

A. Adaptive maintenance

B. Corrective maintenance

C. Perfective maintenance

D. Preventive maintenance

Hint

Classify the motive for the change before its implementation: repair, environment, useful capability or reduced future risk.

Answer B: Corrective maintenance

The purpose of the change determines the maintenance category. Corrective maintenance repairs faults observed during use. Adaptive maintenance handles environmental changes, perfective maintenance improves useful capability or performance, and preventive maintenance reduces future risk before a corresponding failure occurs. Because the scenario starts with observed bugs that need repair, corrective maintenance is the direct category rather than one of the other three motives.

Why each choice is right or wrong

A - Incorrect: Adaptive maintenance responds to a changed environment.

B - Correct: Corrective maintenance repairs observed defects.

C - Incorrect: Perfective maintenance improves useful capability or performance.

D - Incorrect: Preventive maintenance reduces future risk rather than primarily fixing the stated observed bugs.

Primary note proof

Study-note section SE40

> Corrective maintenance fixes faults; adaptive maintenance responds to environment changes; perfective maintenance improves useful capability/performance; preventive maintenance reduces future risk, such as restructuring fragile code. Motive determines category; refactoring can support preventive or perfective work. Maintenance often lasts years and includes understanding legacy code and regression effort, so it may dominate lifecycle cost.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 19 | lines 24-29

> 5. Operation and maintenance: Normally (although not necessarily), this is the longest life cycle phase. Maintenance of a typical software product requires much more than the effort necessary to
> develop the product itself. The system is installed and put into practical use. Maintenance involves
> correcting errors which were not discovered in earlier stages of the life cycle, improving the implementation of system units and enhancing the system ‘s services as new requirements are discovered.

Question sources

Computer Science model exam · 2015 · Question 118

Question 64 | Q00677

Criteria that should not be considered when evaluating or assessing requirement analysis?

A. Correctness

B. Need assessment

C. Consistency

D. Speed

Hint

Distinguish observable services, measurable qualities and implementation constraints. Check scope, stakeholder meaning and the requested level of specificity.

Answer D: Speed

Validation checks correctness, consistency and realism against stakeholder needs. Speed is a property of the future system's performance, not a general criterion for whether the analysis is valid.

Why each choice is right or wrong

A - Incorrect: Explicit requirements-validation property. See PDF p. 68, 79.

B - Incorrect: Assessing actual needs supports faithful requirements. See PDF p. 68, 79.

C - Incorrect: Explicit absence-of-contradiction property. See PDF p. 68, 79.

D - Correct: System response speed is a nonfunctional requirement, not an analysis quality criterion itself. See PDF p. 68, 79.

Primary note proof

Study-note section SE11

> Correct requirements reflect actual stakeholder needs. Complete requirements address the agreed scope, normal and exceptional behavior. Consistency excludes contradictions. Clarity/unambiguity gives one intended interpretation; feasibility/realism means achievable within constraints. Verifiability means objective evidence can check fulfillment. Replace “fast for most users” with a defined metric, workload and threshold.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 68 | lines 18-26

> system specification. Requirement validation involves checking if the specification is correct, complete, consistent, unambiguous, and realistic. A specification is correct if it represents the client’s view of the system (i.e., everything in the requirements model accurately represents an aspect of the system). It is complete if all possible scenarios through the system are described, including exceptional behavior (i.e., all aspects of the system are represented in the requirements
> model). The system specification is consistent if it does not contradict itself. The system specification is unambiguous if exactly one system is defined (i.e., it is not possible to interpret the specification two or more different ways). Finally, it is realistic if the system can be implemented within constraints. These properties are illustrated with UML instance diagrams in

Software Engineering module | PDF page 79 | lines 3-9

> • Performance characteristics. How responsive should the system be? How many concurrent users should it support? What is a typical or extreme load?
> • Error handling and extreme conditions. How should the system handle exceptions? Which exceptions should the system handle? What is the worse environment in which the system is expected to perform? Are there safety requirements on the system?
> • Quality issues. How reliable/available/robust should the system be? What is the client’s involvement in assessing the quality of the system or the development process?

Question sources

Computer Science model exam 2 · Question 18

Question 65 | Q00739

A measurement that defines the level of inter-dependability among modules of a programis__.

A. Cohesive

B. Coupling

C. Design

D. Testing

Hint

Separate responsibilities inside a component from dependencies across boundaries. Evaluate the stated structure, change and reuse goals without assuming guaranteed benefits.

Answer B: Coupling

Coupling measures dependency between subsystems; coherence/cohesion concerns dependency within one subsystem.

Why each choice is right or wrong

A - Incorrect: Internal relatedness, not inter-module dependency. See PDF p. 120, 120.

B - Correct: Exact strength-of-dependencies measure between subsystems. See PDF p. 120, 120.

C - Incorrect: An activity that chooses structures, not this measurement. See PDF p. 120, 120.

D - Incorrect: An error-detection activity, not this measurement. See PDF p. 120, 120.

Primary note proof

Study-note section SE22

> Cohesion measures how well elements inside a module serve a related purpose; coupling measures dependency between modules. Seek high cohesion and low coupling. Shared mutable data and knowledge of another module's internal representation increase coupling. Information hiding exposes stable operations while concealing changeable decisions.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 120 | lines 6-12

> 6.1.3. Coupling and coherence
> Coupling is the strength of dependencies between two subsystems. If two subsystems are loosely coupled, they are relatively independent, and thus, modifications to one of the subsystems will have little impact on the other. If two subsystems are strongly coupled, modifications to one subsystem is likely to have impact on the other. A desirable property of a subsystem decomposition
> is that subsystems are as loosely coupled as possible. This minimizes the impact that errors or future changes have on the correct operation of the system.

Software Engineering module | PDF page 120 | lines 24-27

Coherence is the strength of dependencies within a subsystem. If a subsystem contains many objects that are related to each other and perform similar tasks, its coherence is high. If a subsystem
contains a number of unrelated objects, its coherence is low. A desirable property of a subsystem decomposition is that it leads to subsystems with high coherence.

Question sources

Computer Science model exam 2 · Question 80

Question 66 | Q00740

Which are supported modularization benefits? Select all that apply. Read D as a claim that modularization alone guarantees security.

A. Smaller components are difficult to maintain

B. Components with high cohesion can be re-used again

C. Program can be divided based on functional aspects

D. Modularization alone guarantees security.

Hint

Separate responsibilities inside a component from dependencies across boundaries. Evaluate the stated structure, change and reuse goals without assuming guaranteed benefits.

Answer B, C: Components with high cohesion can be re-used again; Program can be divided based on functional aspects

Cohesive components with clear interfaces can be reused, and functional decomposition divides responsibilities into manageable modules. Smaller modules can also improve understanding and maintenance, so A reverses the ordinary benefit. Security requires appropriate protection and boundary enforcement; simply dividing code into modules does not guarantee it. Thus B and C are supported structural benefits without the unconditional security promise.

Why each choice is right or wrong

A - Incorrect: This reverses the ordinary maintenance benefit of manageable cohesive modules.

B - Correct: Cohesive components can be reused in suitable contexts.

C - Correct: Functional decomposition separates related responsibilities into modules.

D - Incorrect: Module boundaries alone do not guarantee security.

Primary note proof

Study-note section SE22

Logical cohesion groups similar-category operations, often selected by a flag; temporal cohesion groups operations done at the same time; functional cohesion focuses on one task. Splitting an unrelated three-purpose component improves modularity. If behavior is preserved, the restructuring is refactoring; the words are not mutually exclusive answers. Smaller modules can

aid understanding, independent work, reuse and maintenance, but too many interfaces also create complexity.

Software Engineering module | PDF page 118 | lines 11-16

6.1.1. Subsystems and classes
In order to reduce the complexity of the application domain, we identified smaller parts called classes and organized them into packages. Similarly, to reduce the complexity of the solution domain, we decompose a system into simpler parts, called subsystems, which are made of a number of solution domain classes. In the case of complex subsystems, we recursively apply this principle and decompose a subsystem into simpler subsystems (see Figure 6.2).

Software Engineering module | PDF page 120 | lines 24-27

Coherence is the strength of dependencies within a subsystem. If a subsystem contains many objects that are related to each other and perform similar tasks, its coherence is high. If a subsystem
contains a number of unrelated objects, its coherence is low. A desirable property of a subsystem decomposition is that it leads to subsystems with high coherence.

Software Engineering module | PDF page 32 | lines 12-21

A class in an object-oriented system carefully delineates between its interfaces the routines and attributes within a class are held together tightly. In a properly designed system, the classes will be grouped into subsystems but remain independent; therefore, changing one class has no impact
on other classes, and so, the impact is minimized. However, the object-oriented approach is not a panacea; nothing is magical here that will promote perfect design or perfect code.
Promotion of reusability
Objects are reusable because they are modeled directly out of a real-world problem domain. Each
object stands by itself or within a small circle of peers (other objects). Within this framework, the class does not concern itself with the rest of the system or how it is going to be used within a particular system.

Computer Science model exam 2 · Question 81

Question 67 | Q00741

Which of the following is not element of Requirement Engineering Process?

A. Software Requirement Specification

B. Feasibility Steady

C. Software Requirement Design

D. Requirement Gathering

Hint

Distinguish observable services, measurable qualities and implementation constraints. Check scope, stakeholder meaning and the requested level of specificity.

Answer C: Software Requirement Design

The four listed requirements-engineering activities are feasibility, elicitation/analysis, specification and validation. Software requirement design is not one of them.

Why each choice is right or wrong

A - Incorrect: Specification is explicitly included. See PDF p. 25, 26, 26.

B - Incorrect: Feasibility study is explicitly included, despite the typo Steady. See PDF p. 25, 26, 26.

C - Correct: Designing the solution is separate from the listed requirements-engineering activities. See PDF p. 25, 26, 26.

D - Incorrect: Gathering is part of elicitation/analysis. See PDF p. 25, 26, 26.

Primary note proof

Study-note section SE08

> Business requirements explain why the project exists and its goals. User requirements describe stakeholder needs at a useful high level; system requirements specify detailed services and constraints. The Software Requirements Specification (SRS) organizes the agreed requirements. A natural-language specification communicates with clients while analysis models formalize it for technical discussion; real specifications can also contain diagrams.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 25 | lines 15-18

> There are four main activities in the requirements engineering process:
> 1. Feasibility study: Feasibility shows viability and practicality of a software, project or idea. An estimate is made of whether the identified user needs may be satisfied using current software and hardware technologies. The study considers whether the proposed system will be cost-

Software Engineering module | PDF page 26 | lines 10-17

> 3. Requirement’s specification: Requirements specification is the activity of translating the information gathered during the analysis activity in to a document that defines a set of requirements. Two types of requirements may be included in this document. User requirements are
> abstract statements of the system requirements for the customer and end-user of the system; system
> requirements are a more detailed description of the functionality to be provided.
> 4. Requirement’s validation: This activity checks the requirements for realism, consistency, and completeness. During this process, errors in the requirements document are inevitably discovered.
> It must then be modified to correct these problems.

Software Engineering module | PDF page 26 | lines 6-9

> 2. Requirement’s elicitation and analysis: This is the process of deriving the system requirements through observation of existing systems, discussions with potential users and procurers, task analysis, and so on. This may involve the development of one or more system models and prototypes. These help you understand the system to be specified.

Question sources

Computer Science model exam 2 · Question 82

Question 68 | Q00742

Which type of test determine if the system meets the entire requirements (functional and nonfunctional)

A. Unit Test

B. Integration test

C. System test

D. Acceptance test

Hint

Separate testing scope, technique and purpose. Use the stated workload, observable result or coverage target rather than a universal ranking.

Answer C: System test

System testing examines the complete system's functional and nonfunctional requirements. Acceptance is a client decision against the agreement, which may also cover requirements but is a more specific acceptance purpose.

Why each choice is right or wrong

A - Incorrect: Isolates objects/components. See PDF p. 144, 147, 145.

B - Incorrect: Finds faults among combined components. See PDF p. 144, 147, 145.

C - Correct: Explicit complete-system functional/nonfunctional scope. See PDF p. 144, 147, 145.

D - Incorrect: Client agreement testing, rather than the general full-system test scope asked. See PDF p. 144, 147, 145.

Primary note proof

Study-note section SE35

> Acceptance testing supports the customer/user’s acceptance decision against agreed needs and criteria. Alpha typically happens in a controlled developer setting with selected users; beta uses external users in their environments. None of these levels is universally the longest. Unit is a level, while white-box is a technique; a unit can be tested using black-box cases too.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 144 | lines 17-32

Figure 6.2 depicts an overview of the testing activities:
• Unit testing tries to find faults in participating objects and/or subsystems with respect to the use cases from the use case model
• Integration testing is the activity of finding faults when testing the individually tested components together, for example, subsystems described in the subsystem decomposition, while executing the use cases and scenarios from the RAD.
o The system structure testing is the culmination of integration testing involving all components of the system. Integration tests and structure tests exploit knowledge from the SDD using an integration strategy described in the Test Plan (TP).
• System testing tests all the components together, seen as a single system to identify errors with respect to the scenarios from the problem statement and the requirements and design goals identified in the analysis and system design, respectively:
o Functional testing tests the requirements from the RAD and, if available, from the user manual.
o Performance testing checks the nonfunctional requirements and additional design goals from the SDD. Note that functional and performance testing are both done by

Software Engineering module | PDF page 147 | lines 14-18

• Unit testing, which finds faults by isolating an individual component using test stubs and drivers and by exercising the component using a test case
• Integration testing, which finds faults by integrating several components together
• System testing, which focuses on the complete system, its functional and nonfunctional requirements, and its target environment

Software Engineering module | PDF page 145 | lines 3-5

o Acceptance testing and installation testing check the requirements against the project agreement and should be done by the client, if necessary with support by the developers.

Question sources

Computer Science model exam 2 · Question 83

Question 69 | Q00744

All of the following are required to develop an effective test except:

A. Detailed understanding of the system

B. Application and solution domain knowledge

C. Knowledge of the testing techniques

D. Skill to specific programming language

Hint

Separate testing scope, technique and purpose. Use the stated workload, observable result or coverage target rather than a universal ranking.

Answer D: Skill to specific programming language

Black-box equivalence tests can be derived from inputs and expected behavior without writing in a particular implementation language. Domain/system knowledge and testing methods remain relevant.

Why each choice is right or wrong

A - Incorrect: Needed to choose meaningful cases and expected results. See PDF p. 149, 149.

B - Incorrect: Needed to interpret required behavior. See PDF p. 149, 149.

C - Incorrect: Needed to partition inputs or choose boundaries/paths appropriately. See PDF p. 149, 149.

D - Correct: Not universally necessary for behavior-based test design; source-language knowledge applies particularly to white-box work. See PDF p. 149, 149.

Primary note proof

Study-note section SE36

> Functional tests check required behavior against the SRS and acceptance criteria. Performance tests assess speed, throughput and resources under a specified workload; load uses expected demands and stress exceeds normal limits. Usability, security, compatibility and reliability tests target their respective qualities. “Normal operating conditions” alone does not distinguish functional from performance testing.

Module passages - related reading

Question 70 | Q00745

Use case description commonly contain:

A. Trigger, associations, guarantee.

B. Precondition, generalizations, main scenario.

C. Precondition, main scenario, alternative scenarios

D. None of the above

Hint

Match the information to be represented with each model's purpose. Read relationship direction, boundary and ownership conditions before classifying it.

Answer C: Precondition, main scenario, alternative scenarios

A use-case description includes entry conditions, the numbered normal flow and exceptional cases.

Why each choice is right or wrong

A - Incorrect: Trigger/associations/guarantee are not its stated three-part summary. See PDF p. 48.

B - Incorrect: Generalization is a relationship, not one of these template fields. See PDF p. 48.

C - Correct: Matches preconditions and normal/exceptional flow content. See PDF p. 48.

D - Incorrect: A supported summary is offered. See PDF p. 48.

Primary note proof

Study-note section SE15

> Example: Submit Incident. Precondition: officer authenticated. 1 Officer supplies location and description. 2 System validates details. 3 System records the incident. 4 System returns its ID. Alternative 2a: location missing → report the problem and request correction; save nothing. Success postcondition: incident and ID persist; failure guarantee: no partial record. An alternate flow is a conditional variation; an exception flow handles a failure. Preconditions hold before entry, while a trigger starts the use case.

Module passages - related reading

Computer Science model exam 2 · Question 86

Question 71 | Q00746

Aggregation, composition, generalization. Which document is created by a system analyst after the requirements are collected from different stakeholders?

A. Requirement gathering

B. Software Requirement specification

C. Software Requirement testing

D. Software Requirement validation

Hint

Distinguish observable services, measurable qualities and implementation constraints. Check scope, stakeholder meaning and the requested level of specificity.

Answer B: Software Requirement specification

After collection, requirements are organized into the SRS. The opening aggregation/composition/generalization fragment does not alter the requested document.

Why each choice is right or wrong

A - Incorrect: A gathering activity, not the resulting specification document. See PDF p. 26, 83.

B - Correct: The defined organized requirements document. See PDF p. 26, 83.

C - Incorrect: Testing is an activity rather than this document. See PDF p. 26, 83.

D - Incorrect: Validation checks a specification rather than naming its document. See PDF p. 26, 83.

Primary note proof

Study-note section SE08

Business requirements explain why the project exists and its goals. User requirements describe stakeholder needs at a useful high level; system requirements specify detailed services and constraints. The Software Requirements Specification (SRS) organizes the agreed requirements. A natural-language specification communicates with clients while analysis models formalize it for technical discussion; real specifications can also contain diagrams.

Software Engineering module | PDF page 26 | lines 10-17

3. Requirement's specification: Requirements specification is the activity of translating the information gathered during the analysis activity in to a document that defines a set of requirements. Two types of requirements may be included in this document. User requirements are
abstract statements of the system requirements for the customer and end-user of the system; system
requirements are a more detailed description of the functionality to be provided.
4. Requirement's validation: This activity checks the requirements for realism, consistency, and completeness. During this process, errors in the requirements document are inevitably discovered.
It must then be modified to correct these problems.

Software Engineering module | PDF page 83 | lines 12-25

3.4.4. Documenting Requirements Elicitation
The results of the requirements elicitation activity and the analysis activity are documented in the
Requirements Analysis Document (RAD). This document completely describes the system in terms of functional and nonfunctional requirements and serves as a contractual basis between the
client and the developers. The audience for the RAD includes the client, the users, the project management, the system analysts (i.e., the developers who participate in the requirements), and the system designers (i.e., the developers who participate in the system design). The first part of the document, including use cases and nonfunctional requirements, is written during requirements
elicitation. The formalization of the specification in terms of object models is written during analysis.
The first section of the RAD is an Introduction. Its purpose is to provide a brief overview of the function of the system and the reasons for its development, its scope, and references to the development context (e.g., related problem statement, references to existing systems, feasibility studies). The introduction also includes the objectives and success criteria of the project.

Question sources

Computer Science model exam 2 · Question 87

Question 72 | Q00749

_____is a process which translate system specification into a formal or semi formal model.

A. Implementation

B. Elicitation

C. Analysis

D. Design

Hint

Distinguish observable services, measurable qualities and implementation constraints. Check scope, stakeholder meaning and the requested level of specificity.

Answer C: Analysis

Analysis structures and formalizes the natural-language system specification into a formal or semiformal analysis model.

Why each choice is right or wrong

A - Incorrect: Converts design to executable code. See PDF p. 100, 62.

B - Incorrect: Produces the initial specification with stakeholders. See PDF p. 100, 62.

C - Correct: Exact formalization activity described. See PDF p. 100, 62.

D - Incorrect: Derives internal solution structure after analysis. See PDF p. 100, 62.

Primary note proof

Study-note section SE13

> A scenario is one concrete execution; a use case abstracts the related successful and alternative scenarios. Analysis integrates functional (use cases/scenarios), structural/object (classes) and dynamic (states/interactions) models. Entity objects represent domain information such as Incident; boundary objects mediate interaction, such as ReportForm; control objects coordinate a use case. A UI form is normally boundary, not entity.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 100 | lines 11-24

> Analysis focuses on producing a model of the system, called the analysis model, which is correct, complete, consistent, and verifiable. Analysis is different from requirements elicitation in that developers focus on structuring and formalizing the requirements elicited from users
> Figure 4.1 Products of requirements elicitation and analysis (UML activity diagram).
> Althoughtheanalysismodelmaynotbeunderstandabletotheusersandtheclient, it helps developers verify the system specification produced during requirements elicitation. There is a natural tendency for users and developers to postpone difficult decisions until later in the project. A decision may be difficult because of lack of domain knowledge, lack of technological knowledge,

or simply because of disagreements among users and developers. Postponing decisions enables the
project to move on smoothly and avoid confrontation with reality or peers. Unfortunately, difficult
decisions will eventually need to be made, often at higher cost when intrinsic problems are discovered during testing, or worse, during user evaluation. Translating a system specification in to a formal or semi-formal model forces developers to identify and resolve difficult issues early in
the development.

Software Engineering module | PDF page 62 | lines 9-16

Requirement's elicitation focuses on describing the purpose of the system. The client, the developers, and the users identify a problem area and define a system that addresses the problem.
Such a definition is called a system specification and serves as a contract between the client and the developers. The system specification is structured and formalized during analysis to produce an analysis model (see Figure 3.1). Both system specification and analysis model represent the same information. They differ only in the language and notation they use. The system specification
is written in natural language, whereas the analysis model is usually expressed in a formal or semiformal notation.

Question sources

Computer Science model exam 2 · Question 90

Question 73 | Q00750

Which maintenance risk can arise from poorly designed objects with complex or poorly separated responsibilities?

A. Easier maintenance

B. Objects may be understood as stand-alone entities

C. Objects are potentially reusable components

D. Poorly designed objects can be difficult to maintain.

Hint

Separate responsibilities inside a component from dependencies across boundaries. Evaluate the stated structure, change and reuse goals without assuming guaranteed benefits.

Answer D: Poorly designed objects can be difficult to maintain.

Encapsulation and reuse can ease maintenance when objects have clear responsibilities and interfaces. Poor object design can still be complex, so its objects may become difficult to maintain. That conditional risk is D. The other choices describe potential advantages of well-designed objects rather than disadvantages arising from the stated poor design. Object orientation alone does not guarantee either maintenance outcome.

Why each choice is right or wrong

A - Incorrect: Easier maintenance is a potential benefit, not this risk.

B - Incorrect: Understanding encapsulated objects through their interfaces is a potential benefit.

C - Incorrect: Potential reuse is an advantage of suitable design.

D - Correct: Poorly designed complex objects can be difficult to maintain.

Primary note proof

Study-note section SE22

> Cohesion measures how well elements inside a module serve a related purpose; coupling measures dependency between modules. Seek high cohesion and low coupling. Shared mutable data and knowledge of another module's internal representation increase coupling. Information hiding exposes stable operations while concealing changeable decisions.

Study-note section SE01

> Procedural decomposition organizes functions; object oriented decomposition organizes objects with state and behavior. Either can use iterative or sequential development. OOP does not automatically shorten every project. Reuse, encapsulation and consistent models can reduce duplication and ease change; poor object design can still be complex. Functional programming emphasizes function evaluation and controlled side effects; event-driven programs react to events.

Study-note section SE22

> Splitting an unrelated three-purpose component improves modularity. If behavior is preserved, the restructuring is refactoring; the words are not mutually exclusive answers.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 31 | lines 19-31

> 1.3.1. Why an object oriented
> • Object oriented systems are
> o Easier to adapt to changes
> o More robust
> o Easier to maintain
> o Promote greater design and code reuse
> o Creates modules of functionality
> • REASONS FOR WORKING OF OBJECT ORIENTED SYSTEMS:

Higher level of abstraction
The object-oriented approach supports abstraction at the object level. Since objects encapsulate both data (attributes) and functions (methods), they work at a higher level of abstraction. The development can proceed at the object level and ignore the rest of the system for as long as necessary. This makes designing, coding, testing, and maintaining the system much simpler.

Question sources

Computer Science model exam 2 · Question 91

Question 74 | Q00897

In a class diagram, a filled diamond is at Car's end of its Engine association. In this model an Engine remains owned by its Car for its entire lifetime, with no detachment or transfer. What does the relationship imply?

A. Car uses Engine temporarily

B. Engine can exist independently of the Car

C. Engine is part of Car and cannot exist independently under the stated lifetime policy.

D. Car inherits from Engine

Hint

Match the information to be represented with each model's purpose. Read relationship direction, boundary and ownership conditions before classifying it.

Answer C: Engine is part of Car and cannot exist independently under the stated lifetime policy.

The filled diamond at Car denotes composition: Car is the whole and Engine is its strongly owned part. Composition destroys parts that remain owned when the whole is destroyed. Because this model forbids detachment or transfer, the Engine's lifetime cannot continue independently of its Car. Temporary use would be a dependency, and inheritance would use a hollow generalization triangle instead.

Why each choice is right or wrong

A - Incorrect: Temporary use is a dependency, not composition.

B - Incorrect: The stipulated permanent ownership excludes an independent Engine lifetime.

C - Correct: Engine is the owned part and cannot outlive Car under the stated policy.

D - Incorrect: Inheritance uses a hollow triangle rather than a filled diamond.

Primary note proof

Study-note section SE18

Composition uses a filled diamond at the whole end and strong ownership: a part is in at most one composite at a time, and parts still owned are destroyed with that composite. Parts may be

detached/transferred under a defined model. Thus “cannot ever exist independently” is an oversimplification. For Car composing Engine, the diamond belongs beside Car; saying it points to Engine is imprecise. The Car-Engine example describes composition.

Software Engineering module | PDF page 51 | lines 14-24

2.3.2. Class Diagrams
Classes and objects
Class diagrams describe the structure of the system in terms of classes and objects. Classes are abstractions that specify the attributes and behavior of a set of objects. Objects are entities that encapsulate state and behavior. Each object has an identity: It can be referred individually and is distinguishable from other objects.
In UML, classes and objects are depicted by boxes including three compartments. The top compartment displays the name of the class or object. The center compartment displays its attributes, and the bottom compartment displays its operations. The attribute and operation compartment can be omitted for clarity. Object names are underlined to indicate that they are instances. By convention, class names start with an uppercase letter. Objects in object diagrams

Software Engineering module | PDF page 53 | lines 19-28

Aggregation
Associations are used to represent a wide range of connections among a set of objects. In practice,
a special case of association occurs frequently: composition. For example, a State contains many Counties, which in turn contains many Townships. A PoliceStation is composed of PoliceOfficers. Another example is a Directory that contains a number of Files. Such relationships could be modeled using a one-to-many association. Instead, UML provides the concept of an aggregation to denote composition. An aggregation is denoted by a simple line with a diamond at the container
end of the association. Although one-to-many associations and aggregations can be used alternatively, aggregations are preferable because they emphasize the hierarchical aspects of the relationship.

Computer Science Exit Exam · 2018 · Question 10

Question 75 | Q00942

From the following statement which one is disadvantage of waterfall model?

A. model is simple and easy to understand and use

B. It is easy manage due to the rigidity of the model

C. .
Not suitable for projects where requirements are at a moderate to high risk of changing

D. In this model phases are processed and completed one at a time

Hint

Identify whether the scenario prioritizes delivery, learning, adaptation or risk reduction. Several processes can share individual practices, so compare their defining emphasis.

Answer C: .
Not suitable for projects where requirements are at a moderate to high risk of changing

Waterfall requires early stable requirements and has difficulty responding to change, so moderate-to-high change risk is its documented disadvantage.

Why each choice is right or wrong

A - Incorrect: Listed as an advantage. See PDF p. 20.

B - Incorrect: Listed as an advantage from distinct deliverables/reviews. See PDF p. 20.

C - Correct: Directly matches the disadvantage on PDF p.21. See PDF p. 20.

D - Incorrect: Sequential non-overlap is a structural feature, not the stated change-risk disadvantage. See PDF p. 20.

Primary note proof

Study-note section SE03

> Classical waterfall separates planned phases with reviewed deliverables. It fits well-understood, stable requirements and familiar technology; late feedback makes changes costly. It does not make change physically impossible: real projects revisit work under control, and modified waterfall explicitly includes feedback. Rigidity offers milestone visibility but can freeze incorrect assumptions.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 20 | lines 18-22

> the development plan. Its major problem is the inflexible partitioning of the project into distinct stages. Commitments must be made at an early stage in the process, which makes it difficult to respond to changing customer requirements.
> In principle, the waterfall model should only be used when the requirements are well

understood
and unlikely to change radically during system development. However, the waterfall model

Question sources

Computer Science Exit Exam · 2018 · Question 55

Question 76 | Q00948

Which statement specifically constrains response-time performance under a stated workload?

A. The system allow user to generate PDF report.

B. The system respond to user's request within 2 second under normal load

C. .
The system allow user to store data on relational database

D. The system allow user to submit emergency report

Hint

Distinguish observable services, measurable qualities and implementation constraints. Check scope, stakeholder meaning and the requested level of specificity.

Answer B: The system respond to user's request within 2 second under normal load

The two-second response obligation bounds the speed of a service under the stated load, so it is a performance requirement. Generating a PDF and submitting an emergency report describe services the system provides. The database clause describes storage behavior together with an implementation choice; it does not impose a response-time threshold. The explicit performance scope removes the broader taxonomy overlap between nonfunctional requirements and technology constraints.

Why each choice is right or wrong

A - Incorrect: Report generation specifies a service, not its response-time limit.

B - Correct: A two-second response bound under normal load is a quantitative speed target.

C - Incorrect: This specifies storage behavior and a database technology, without a timing bound.

D - Incorrect: Submitting an emergency report specifies a function rather than its speed.

Primary note proof

Study-note section SE10

Nonfunctional requirements include quality attributes and constraints. Performance concerns response time, throughput and resource use; reliability concerns failure-free service; availability concerns being ready for use; usability concerns task success and ease of learning. Security concerns protection; compatibility concerns cooperating environments; portability concerns moving environments; maintainability/supportability concern change, diagnosis and evolution.

Study-note section SE10

"Search responds within two seconds under 100 concurrent users" is measurable performance. "New users finish checkout within one minute without help" is usability. "Use Java" is a technology/pseudo-requirement, often separately classified as a system constraint. Dependability includes reliability, safety and robustness; portability is not its usual central category. Performance degradation at peak load primarily concerns performance, not automatically reliability.

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 65 | lines 19-23

3.2.1. Functional Requirements
Functional requirements describe the interactions between the system and its environment independent of its implementation. The environment includes the user and any other external system with which the system interacts. For example, the following is an example of functional requirements for SatWatch, a watch that resets itself without user intervention:

Software Engineering module | PDF page 66 | lines 14-18

3.2.2. Non-Functional and Pseudo-Requirements
Nonfunctional requirements describe user-visible aspects of the system that are not directly related with the functional behavior of the system. Nonfunctional requirements include quantitative constraints, such as response time (i.e., how fast the system reacts to user commands)
or accuracy (i.e., how precise are the system's numerical answers). The following are the

Software Engineering module | PDF page 67 | lines 3-8

Pseudo-requirements are requirements imposed by the client that restrict the implementation of the system. Typical pseudo-requirements are the implementation language and the platform on which the system is to be implemented. For life-critical developments, pseudo-requirements often
include process and documentation requirements (e.g., the use of a formal specification method, the complete release of all work products). Pseudo-requirements have usually no direct effect on the users' view of the system. The following are the pseudo functional requirements for SatWatch:

Question sources

Computer Science Exit Exam · 2018 · Question 61

Question 77 | Q00949

In object design, what does the contract typically includes?

A. The class diagram and sequence diagram

B. Project budget and timeline

C. Invariants, preconditions, post conditions

D. The use case names and actors role

Hint

Separate responsibilities inside a component from dependencies across boundaries. Evaluate the stated structure, change and reuse goals without assuming guaranteed benefits.

Answer C: Invariants, preconditions, post conditions

Contracts establish class-wide invariants and caller/callee obligations before and after an operation.

Why each choice is right or wrong

A - Incorrect: Diagrams can document a design but are not the contract constraint categories. See PDF p. 136.

B - Incorrect: Project planning terms, not class contracts. See PDF p. 136.

C - Correct: Exactly the three contract constraint types. See PDF p. 136.

D - Incorrect: Use-case identifiers and roles do not specify class invariants and operation obligations. See PDF p. 136.

Primary note proof

Study-note section SE25

> A contract states preconditions, postconditions and invariants. For withdraw(amount): require amount>0 and amount<=balance; ensure balance=oldBalance-amount; preserve balance>=0. Validation checks inputs; implementation enforces the transition. A complete feature needs both UI/API and persisted behavior, not only a diagram.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 136 | lines 3-11

> • An invariant is a predicate that is always true for all instances of a class. Invariants are constraints associated with classes or interfaces. Invariants are used to specify consistency constraints among class attributes.
> • A precondition is a predicate that must be true before an operation is invoked. Preconditions are associated with a specific operation. Preconditions are used to specify constraints that a caller must meet before calling an operation.
> • A post-condition is a predicate that must be true after an operation is invoked. Post-conditions are associated with a specific operation. Post-conditions are used to specify constraints that the object must ensure after the invocation of the operation.

Computer Science Exit Exam · 2018 · Question 62

Question 78 | Q00967

Which one of the following UML building block that defines the static part of the model and represents physical and conceptual elements?

A. Structural things

B. Behavioral things

C. ¢.
An notational things

D. Grouping things

Hint

Match the information to be represented with each model's purpose. Read relationship direction, boundary and ownership conditions before classifying it.

Answer A: Structural things

Structural things explicitly define the static model and physical/conceptual elements.

Why each choice is right or wrong

A - Correct: Matches the module verbatim. See PDF p. 45, 45, 46.

B - Incorrect: Behavioral things are dynamic. See PDF p. 45, 45, 46.

C - Incorrect: Annotational things capture notes and remarks. See PDF p. 45, 45, 46.

D - Incorrect: Grouping things organize elements into packages. See PDF p. 45, 45, 46.

Primary note proof

Study-note section SE17

> A class box lists name, attributes and operations; + public, - private, # protected and ~ package indicate visibility. A class diagram shows static types and relationships, while an object diagram shows particular instances/links. UML is maintained and standardized by OMG; it is a modeling language, not a lifecycle process. Structural things describe conceptual or physical structural elements.

Study-note section SE-S03

> In the course's UML building-block terminology, structural things describe static conceptual or physical elements. Behavioral things describe dynamic interactions and state behavior. Grouping things organize model elements into packages. Annotational things attach explanatory remarks or constraints, usually as notes.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 45 | lines 3-17

> Structural things:
> The Structural things define the static part of the model. They represent physical and conceptual

elements. Following are the brief descriptions of the structural things.
Class:
Class represents set of objects having similar responsibilities.
Interface:
Interface defines a set of operations which specify the responsibility of a class.
Collaboration:
Collaboration defines interaction between elements.
Use case:
Use case represents a set of actions performed by a system for a specific goal.
Component:
Component describes physical part of a system.
Node:
A node can be defined as a physical element that exists at run time.

Software Engineering module | PDF page 45 | lines 18-23

Behavioral things:
A behavioral thing consists of the dynamic parts of UML models. Following are the behavioral things:
Interaction:
Interaction is defined as a behavior that consists of a group of messages exchanged among elements to accomplish a specific task.

Software Engineering module | PDF page 46 | lines 7-16

Grouping things:
Grouping things can be defined as a mechanism to group elements of a UML model together. There is only one grouping thing available:
Package:
Package is the only one grouping thing available for gathering structural and behavioral things.
An notational things:
An notational things can be defined as a mechanism to capture remarks, descriptions, and comments of UML model elements. Note is the only one An notational thing available.
Note:
A note is used to render comments, constraints etc. of an UML element.

Computer Science Exit Exam · 2018 · Question 80

Question 79 | Q00971

After deploying a new software system, users reports that the system slows during peak hour. Which software quality attribute primarily affected?

A. Maintainability

B. Performance

C. Reliability

D. Usability

Hint

Distinguish observable services, measurable qualities and implementation constraints. Check scope, stakeholder meaning and the requested level of specificity.

Answer B: Performance

Slow response at peak load concerns responsiveness and concurrency/load constraints, hence performance.

Why each choice is right or wrong

A - Incorrect: Concerns cost/ease of modifying the system. See PDF p. 79, 66.

B - Correct: Directly affected response-speed/load quality. See PDF p. 79, 66.

C - Incorrect: Reliability concerns conformance/failures; slow service could violate requirements, but performance is the specific attribute. See PDF p. 79, 66.

D - Incorrect: Usability concerns ease of learning/using rather than primarily load-dependent response speed. See PDF p. 79, 66.

Primary note proof

Study-note section SE10

> “Search responds within two seconds under 100 concurrent users” is measurable performance. “New users finish checkout within one minute without help” is usability. “Use Java” is a technology/pseudo-requirement, often separately classified as a system constraint. Dependability includes reliability, safety and robustness; portability is not its usual central category. Performance degradation at peak load primarily concerns performance, not automatically reliability.

Module passages - related reading

Software Engineering module | PDF page 79 | lines 3-9

> • Performance characteristics. How responsive should the system be? How many concurrent users should it support? What is a typical or extreme load?
> • Error handling and extreme conditions. How should the system handle exceptions? Which exceptions should the system handle? What is the worse environment in which the system is expected to perform? Are there safety requirements on the system?

• Quality issues. How reliable/available/robust should the system be? What is the client's involvement in assessing the quality of the system or the development process?

Software Engineering module | PDF page 66 | lines 14-18

3.2.2. Non-Functional and Pseudo-Requirements
Nonfunctional requirements describe user-visible aspects of the system that are not directly related with the functional behavior of the system. Nonfunctional requirements include quantitative constraints, such as response time (i.e., how fast the system reacts to user commands)
or accuracy (i.e., how precise are the system's numerical answers). The following are the

Question sources

Computer Science Exit Exam · 2018 · Question 84

Question 80 | Q01197

Which choice most completely lists candidate heuristics for grouping objects into subsystems? Treat them as starting guidance, not mandatory boundaries.

A. Assign objects identified in one use case into the same subsystem.

B. Create a dedicated subsystem for objects used for moving data among subsystems.

C. Minimize the number of associations crossing subsystem boundaries.

D. All of the above

Hint

Separate responsibilities inside a component from dependencies across boundaries. Evaluate the stated structure, change and reuse goals without assuming guaranteed benefits.

Answer D: All of the above

SE21 recommends grouping related functionality, minimizing cross-subsystem associations and isolating communication infrastructure where useful. Grouping objects serving one use case can be a starting heuristic, though workflows do not dictate every boundary. B and C directly support isolation and low coupling. Since the question asks what can be a heuristic, the inclusive option is appropriate.

Why each choice is right or wrong

A - Incorrect: True as one component, but incomplete as the requested full selection. Objects collaborating on one use case can be grouped as a starting heuristic, subject to other design constraints.

B - Incorrect: True as one component, but incomplete as the requested full selection. Communication infrastructure can be isolated in a dedicated subsystem when useful.

C - Incorrect: True as one component, but incomplete as the requested full selection. Reducing cross-boundary associations reduces coupling between subsystems.

D - Correct: All three can guide decomposition, provided use-case grouping is not treated as an absolute rule.

Primary note proof

Study-note section SE21

> System design turns the analysis model into architecture: design goals, subsystem responsibilities, dependencies, hardware mapping, data management, access control, control flow and startup/shutdown/error policies. Detail/object design refines APIs, parameter/return types, exceptions, component choices and algorithms. A subsystem is a manageable logical collection with services and an interface; it need not be a physical replaceable artifact.

Study-note section SE21

> Group closely related objects and functionality, minimize associations crossing boundaries, and isolate communication infrastructure where useful.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 118 | lines 11-16

> 6.1.1. Subsystems and classes
> In order to reduce the complexity of the application domain, we identified smaller parts called classes and organized them into packages. Similarly, to reduce the complexity of the solution domain, we decompose a system into simpler parts, called subsystems, which are made of a number of solution domain classes. In the case of complex subsystems, we recursively apply this principle and decompose a subsystem into simpler subsystems (see Figure 6.2).

Software Engineering module | PDF page 116 | lines 16-29

> The analysis model describes the system completely from the actors' point of view and serves as the basis of communication between the client and the developers. The analysis model, however, does not contain information about the internal structure of the system, its hardware configuration,
> or, more generally, how the system should be realized. System design is the first step in this direction. System design results in the following products:
> • List of design goals, describing the qualities of the system that developers should optimize
> • Software architecture, describing the subsystem decomposition in terms of subsystem responsibilities, dependencies among subsystems, subsystem mapping to hardware, and major policy decisions such as control flow, access control, and data storage.
> The design goals are derived from the nonfunctional requirements. Design goals guide the decisions to be made by the developers especially when trade-offs are needed. The subsystem decomposition constitutes the bulk of system design. Developers divide the system into manageable pieces to deal with complexity: Each subsystem is assigned to a team and realized independently. In order for this to be possible, though, developers need to address system-wide

Software Engineering module | PDF page 120 | lines 6-12

6.1.3. Coupling and coherence
Coupling is the strength of dependencies between two subsystems. If two subsystems are loosely coupled, they are relatively independent, and thus, modifications to one of the subsystems will have little impact on the other. If two subsystems are strongly coupled, modifications to one subsystem is likely to have impact on the other. A desirable property of a subsystem decomposition
is that subsystems are as loosely coupled as possible. This minimizes the impact that errors or future changes have on the correct operation of the system.

Question sources

Computer Science model exam 2 · Question 18

Question 81 | Q01205

Which statement is false about a logical software subsystem? Interpret complexity reduction as managing solution-design complexity, not changing the inherent application domain.

A. A physical and replaceable part of the system.

B. It helps manage the complexity of the solution design.

C. Decompose a system into simpler parts.

D. Well-defined interfaces that encapsulate the state and behavior of its contained classes.

Hint

Separate responsibilities inside a component from dependencies across boundaries. Evaluate the stated structure, change and reuse goals without assuming guaranteed benefits.

Answer A: A physical and replaceable part of the system.

A subsystem is a manageable logical collection of responsibilities with services and an interface. It need not be a physical replaceable artifact, so A is false as a definition. Decomposing the designed solution into simpler groups helps manage complexity, and defined interfaces can encapsulate implementation state and behavior. These design benefits concern the solution organization rather than reducing the inherent complexity of its problem domain.

Why each choice is right or wrong

A - Correct: A logical subsystem need not be physical or independently replaceable.

B - Incorrect: Managing solution-design complexity is a supported decomposition benefit.

C - Incorrect: Decomposition groups the system into simpler responsibilities.

D - Incorrect: Defined interfaces encapsulate contained implementation details.

Primary note proof

Study-note section SE21

Group closely related objects and functionality, minimize associations crossing boundaries, and isolate communication infrastructure where useful. User workflows inform decomposition but do not alone dictate the internal structure. Analysis describes domain needs; subsystem decomposition is principally a design result. Architecture documentation supports communication and records major decisions, not every source-level execution step.

Study-note section SE21

A subsystem is a manageable logical collection with services and an interface; it need not be a physical replaceable artifact.

6.1.1. Subsystems and classes
In order to reduce the complexity of the application domain, we identified smaller parts called classes and organized them into packages. Similarly, to reduce the complexity of the solution domain, we decompose a system into simpler parts, called subsystems, which are made of a number of solution domain classes. In the case of complex subsystems, we recursively apply this principle and decompose a subsystem into simpler subsystems (see Figure 6.2).

Software Engineering module | PDF page 119 | lines 13-25

6.1.2. Services and subsystem interfaces
A subsystem is characterized by the services it provides to other subsystems. A service is a set of related operations that share a common purpose. A subsystem providing a notification service, for
example, defines operations to send notices, look up notification channels, and subscribe and unsubscribe to a channel.
The set of operations of a subsystem that are available to other subsystems form the subsystem interface. The subsystem interface, also referred to as the application programmer interface (API),
includes the name of the operations, their parameters, their types, and their return values. System
design focuses on defining the services provided by each subsystem that is, enumerating the operations, their parameters, and their high-level behavior. Object design will focus on defining the subsystem interfaces, that is, the type of the parameters and the return value of each operation.
The definition of a subsystem in terms of the services it provides helps us focus on its interface as opposed to its implementation. A good subsystem interface should provide as little information

Question sources

Computer Science model exam 2 · Question 26

Question 82 | Q01208

Which of the following
is an example of Usability requirements?

A. A new user shall complete the main interface task within one minute without help.

B. Robustness

C. Mean time to failure

D. Adaptability

Hint

Distinguish observable services, measurable qualities and implementation constraints. Check scope, stakeholder meaning and the requested level of specificity.

Answer A: A new user shall complete the main interface task within one minute without help.

A usability requirement states an observable target for successful and learnable use. Requiring a new user to finish a main interface task without help within one minute gives a task, user context, success condition and threshold. Robustness concerns dependable behavior under adverse conditions, mean time to failure is a reliability measure, and adaptability concerns change. Merely naming a user interface would not itself specify an obligation, so the option supplies a genuine requirement.

Why each choice is right or wrong

A - Correct: The task-success and unaided-learning target is a measurable usability obligation.

B - Incorrect: Robustness concerns dependable behavior under adverse conditions rather than ease of learning a task.

C - Incorrect: Mean time to failure measures reliability rather than user task ease.

D - Incorrect: Adaptability concerns accommodating change rather than the stated user task target.

Primary note proof

Study-note section SE10

> Performance concerns response time, throughput and resource use; reliability concerns failure-free service; availability concerns being ready for use; usability concerns task success and ease of learning.

Study-note section SE10

> “New users finish checkout within one minute without help” is usability.

Study-note section SE-S07

> Robustness concerns reliable operation across varied or difficult operating conditions and controlled failure outside the supported range. It is different from usability, which concerns

people successfully learning and carrying out tasks. Improving an interface's task success does not by itself establish robustness under adverse conditions.

Software Engineering module | PDF page 78 | lines 12-30

3.3.7. Identifying Non-Functional Requirements
Nonfunctional requirements describe user-visible aspects of the system that are not directly related
to the functional behavior of the system. Nonfunctional requirements span a number of issues, from user interface look and feel to response time requirements to security issues.
Nonfunctional
requirements are defined at the same time as functional requirements are, because they have as much impact on the development and cost of the system.
For example, consider a mosaic display that an air traffic controller uses to track planes. A mosaic
display system complies data from a series of radar and databases (hence the term "mosaic") into
a summary display indicating all aircraft in a certain area, including their identification, speed, and
altitude. The number of aircraft such a system can display constrains the performance of the air traffic controller and the cost of the system. If the system can only handle a few aircraft simultaneously, the system cannot be used at busy airports. On the other hand, a system able to handle a large number of aircraft is more costly and more complex to build.
Nonfunctional requirements can be elicited by investigating the following issues.
• User interface and human factors. What kind of interface should the system provide? What is the level of expertise of the users?
• Documentation. What level of document is required? Should only user documentation be provided? Should there be technical documentation for maintainers? Should the development process be documented?

Software Engineering module | PDF page 82 | lines 3-12

though this type of approach could be used for any parameter, usability tests focus on usability parameters, such as the ease to learn the system, the time to accomplish a task, or the rate of errors
a user makes when accomplishing a task.
There are two important differences between classical experiments and usability tests. Whereas the classical experimental method is designed to confirm or refute a hypothesis, the goal of usability tests is to obtain qualitative information on how to fix usability problems and how to improve the system. Another difference is the rigor with which the experiments need to be performed. It has been shown that even a series of quick focused tests starting as early as requirements elicitation is extremely helpful. Nielsen uses the term "discount usability engineering" to indicate that a few usability tests are better than none at all.

Computer Science model exam 2 · Question 29

Question 83 | Q01260

Which one of the following is a Nonfunctional requirement?

A. Admin can upload photos

B. Admin can search book

C. Librarian can delete student

D. The system delivers the search items within 2 seconds

Hint

Distinguish observable services, measurable qualities and implementation constraints. Check scope, stakeholder meaning and the requested level of specificity.

Answer D: The system delivers the search items within 2 seconds

The two-second limit constrains how quickly the search service responds; the others specify permitted operations.

Why each choice is right or wrong

A - Incorrect: Uploading is a service. See PDF p. 65, 66.

B - Incorrect: Searching is a service. See PDF p. 65, 66.

C - Incorrect: Deletion is a service. See PDF p. 65, 66.

D - Correct: Quantitative response-time requirement. See PDF p. 65, 66.

Primary note proof

Study-note section SE10

> Nonfunctional requirements include quality attributes and constraints. Performance concerns response time, throughput and resource use; reliability concerns failure-free service; availability concerns being ready for use; usability concerns task success and ease of learning. Security concerns protection; compatibility concerns cooperating environments; portability concerns moving environments; maintainability/supportability concern change, diagnosis and evolution.

Software Engineering module | PDF page 65 | lines 19-23

> 3.2.1. Functional Requirements
> Functional requirements describe the interactions between the system and its environment independent of its implementation. The environment includes the user and any other external system with which the system interacts. For example, the following is an example of functional requirements for SatWatch, a watch that resets itself without user intervention:

Software Engineering module | PDF page 66 | lines 14-18

3.2.2. Non-Functional and Pseudo-Requirements
Nonfunctional requirements describe user-visible aspects of the system that are not directly related with the functional behavior of the system. Nonfunctional requirements include quantitative constraints, such as response time (i.e., how fast the system reacts to user commands)
or accuracy (i.e., how precise are the system's numerical answers). The following are the

Question sources

Computer Science model exam 2 · Question 81

Question 84 | Q01261

Which of the following is false about functional requirement?

A. Requirements should complete

B. Requirement should be accurate as possible.

C. Each requirement should state a clear, independently verifiable obligation.

D. A requirement can be interpreted in many exclusive ways.

Hint

Distinguish observable services, measurable qualities and implementation constraints. Check scope, stakeholder meaning and the requested level of specificity.

Answer D: A requirement can be interpreted in many exclusive ways.

Requirements should accurately reflect stakeholder needs, cover the agreed scope and express clear, verifiable obligations. Unambiguity requires one intended interpretation; mutually exclusive readings violate that property. The revised third option states the useful single-obligation writing rule without claiming that duplicate requirements can never be consolidated. Thus the multiple-interpretation option is the single false quality claim, while completeness, accuracy and clarity remain valid goals.

Why each choice is right or wrong

A - Incorrect: Completeness requires coverage of the agreed behavior and exceptional cases.

B - Incorrect: Accuracy requires requirements to reflect the actual stakeholder needs.

C - Incorrect: A clear independently verifiable obligation supports precise specification.

D - Correct: Mutually exclusive readings violate the unambiguity requirement.

Primary note proof

Study-note section SE11

Correct requirements reflect actual stakeholder needs. Complete requirements address the agreed scope, normal and exceptional behavior. Consistency excludes contradictions. Clarity/unambiguity gives one intended interpretation; feasibility/realism means achievable

within constraints. Verifiability means objective evidence can check fulfillment. Replace “fast for most users” with a defined metric, workload and threshold.

Study-note section SE09

Write one clear obligation with an actor/trigger, action and observable result.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 68 | lines 18-26

system specification. Requirement validation involves checking if the specification is correct, complete, consistent, unambiguous, and realistic. A specification is correct if it represents the client’s view of the system (i.e., everything in the requirements model accurately represents an aspect of the system). It is complete if all possible scenarios through the system are described, including exceptional behavior (i.e., all aspects of the system are represented in the requirements
model). The system specification is consistent if it does not contradict itself. The system specification is unambiguous if exactly one system is defined (i.e., it is not possible to interpret the specification two or more different ways). Finally, it is realistic if the system can be implemented within constraints. These properties are illustrated with UML instance diagrams in

Question sources

Computer Science model exam 2 · Question 82

Question 85 | Q01272

Which of the following is not true about requirement elicitation?

A. Errors introduced during requirements elicitation are expensive to correct.

B. Define the purpose of the system by collaboration of the client and developers.

C. Requirements elicitation is less challenging than Analysis.

D. Requirements specification is the result of requirement elicitation.

Hint

Distinguish observable services, measurable qualities and implementation constraints. Check scope, stakeholder meaning and the requested level of specificity.

Answer C: Requirements elicitation is less challenging than Analysis.

Elicitation requires stakeholder agreement and accurate problem understanding; analysis formalizes it. Elicitation is not inherently less challenging, and postponed decisions can be costly.

Why each choice is right or wrong

A - Incorrect: Late correction raises cost, consistent with identifying issues early. See PDF p. 62, 100.

B - Incorrect: Matches collaborative purpose definition. See PDF p. 62, 100.

C - Correct: The claimed easier-than-analysis ranking is unsupported and contrary to the described difficulty. See PDF p. 62, 100.

D - Incorrect: The system specification is its explicit output. See PDF p. 62, 100.

Primary note proof

Study-note section SE11

Correct requirements reflect actual stakeholder needs. Complete requirements address the agreed scope, normal and exceptional behavior. Consistency excludes contradictions. Clarity/unambiguity gives one intended interpretation; feasibility/realism means achievable within constraints. Verifiability means objective evidence can check fulfillment. Replace “fast for most users” with a defined metric, workload and threshold.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 62 | lines 9-16

Requirement’s elicitation focuses on describing the purpose of the system. The client, the developers, and the users identify a problem area and define a system that addresses the problem.
Such a definition is called a system specification and serves as a contract between the client and the developers. The system specification is structured and formalized during analysis to produce an analysis model (see Figure 3.1). Both system specification and analysis model represent the same information. They differ only in the language and notation they use. The system specification
is written in natural language, whereas the analysis model is usually expressed in a formal or semiformal notation.

Software Engineering module | PDF page 100 | lines 11-24

Analysis focuses on producing a model of the system, called the analysis model, which is correct, complete, consistent, and verifiable. Analysis is different from requirements elicitation in that developers focus on structuring and formalizing the requirements elicited from users
Figure 4.1 Products of requirements elicitation and analysis (UML activity diagram).
Althoughtheanalysismodelmaynotbeunderstandabletotheusersandtheclient, it helps developers verify the system specification produced during requirements elicitation. There is a natural tendency for users and developers to postpone difficult decisions until later in the project. A decision may be difficult because of lack of domain knowledge, lack of technological knowledge, or simply because of disagreements among users and developers. Postponing decisions enables the
project to move on smoothly and avoid confrontation with reality or peers. Unfortunately, difficult
decisions will eventually need to be made, often at higher cost when intrinsic problems are discovered during testing, or worse, during user evaluation. Translating a system specification in to a formal or semi-formal model forces developers to identify and resolve difficult issues early in
the development.

Question sources

Computer Science model exam 2 · Question 93

Question 86 | Q01512

Which named approach develops an experimental version specifically to explore unclear requirements or feasibility, and can therefore serve both as a development approach and an elicitation technique?

A. Spiral process model

B. Waterfall process model

C. Prototype process model

D. Agile process model

Hint

Identify whether the scenario prioritizes delivery, learning, adaptation or risk reduction. Several processes can share individual practices, so compare their defining emphasis.

Answer C: Prototype process model

Prototyping uses an early experimental representation or working version to discover requirements, usability needs or technical feasibility. It can be organized as a development approach and also used within elicitation. Spiral may contain a prototype to reduce risk, but risk-driven cycles define spiral itself. Waterfall names phased development, while Agile names a broader adaptive approach. The question asks the named experimentation technique that directly serves both purposes.

Why each choice is right or wrong

A - Incorrect: Spiral may employ prototypes but is itself defined by risk-driven cycles.

B - Incorrect: Waterfall is a phased lifecycle rather than the experimentation technique described.

C - Correct: Prototyping directly explores requirements or feasibility using an experimental version.

D - Incorrect: Agile is a broad adaptive approach and can use several elicitation techniques.

Primary note proof

Study-note section SE07

> A prototype explores requirements, usability or technical feasibility. A throwaway prototype is discarded after learning; an evolutionary prototype is deliberately refined toward production. A quick prototype may omit robustness, security or architecture, so do not deploy it unchanged without evaluation. Coding may occur during prototyping even if a diagram labels that activity construction rather than coding.

Study-note section SE06

Spiral development is risk driven. Each cycle identifies objectives and alternatives, assesses and reduces important risks, develops/verifies an appropriate next result, and plans further commitment. A prototype may test a risky technology before a large investment. The amount and type of work depend on the risks.

2. Requirement's elicitation and analysis: This is the process of deriving the system requirements through observation of existing systems, discussions with potential users and procurers, task analysis, and so on. This may involve the development of one or more system models and prototypes. These help you understand the system to be specified.

Software Engineering module | PDF page 82 | lines 23-29

• Prototype test. During this type of test, one or more users are presented with a piece of software that practically implements the system. A vertical prototype implements a complete use case through the system, and a horizontal prototype presents an interface for most use cases (without providing much or any functionality). The advantages of prototype tests are that they provide a realistic view of the system to the user and that prototypes can be instrumented to collect detailed data. The disadvantages of prototypes are that they are expensive to build and to modify.

Question sources

Mock exam 1 · Question 28

Question 87 | Q01513

What is the base for functional testing?

A. We have to refer to the system design document

B. We have to refer to the system requirement specification document

C. We have to refer to user manual if any exists

D. A and B

Hint

Separate testing scope, technique and purpose. Use the stated workload, observable result or coverage target rather than a universal ranking.

Answer B: We have to refer to the system requirement specification document

Functional testing tests requirements from the RAD and, if available, the user manual. Of the options, the requirements specification is the primary basis; the user manual is supplementary.

Why each choice is right or wrong

A - Incorrect: Design goals support performance tests and architecture supports integration, rather than being the primary functional oracle. See PDF p. 144, 83, 130.

B - Correct: The requirement document defines what behavior to test. See PDF p. 144, 83, 130.

C - Incorrect: A manual can supplement functional requirements, but is not the primary complete basis. See PDF p. 144, 83, 130.

D - Incorrect: Adding design as an equal required functional basis overstates the cited rule. See PDF p. 144, 83, 130.

Primary note proof

Study-note section SE36

Black-box techniques derive cases from specified behavior; white-box techniques derive them from internal structure; grey-box uses partial internal knowledge. Regression testing checks for unintended effects after change; confirmation testing checks the particular defect repair. Exploratory testing combines learning, design and execution and is experience based. Manual/automated describe execution support, not a compulsory black-/white-box classification.

Module passages - related reading

Software Engineering module | PDF page 144 | lines 17-32

Figure 6.2 depicts an overview of the testing activities:
• Unit testing tries to find faults in participating objects and/or subsystems with respect to the use cases from the use case model
• Integration testing is the activity of finding faults when testing the individually tested components together, for example, subsystems described in the subsystem decomposition, while executing the use cases and scenarios from the RAD.
o The system structure testing is the culmination of integration testing involving all components of the system. Integration tests and structure tests exploit knowledge from the SDD using an integration strategy described in the Test Plan (TP).
• System testing tests all the components together, seen as a single system to identify errors with respect to the scenarios from the problem statement and the requirements and design goals identified in the analysis and system design, respectively:
o Functional testing tests the requirements from the RAD and, if available, from the user manual.
o Performance testing checks the nonfunctional requirements and additional design goals from the SDD. Note that functional and performance testing are both done by

Software Engineering module | PDF page 83 | lines 12-25

3.4.4. Documenting Requirements Elicitation
The results of the requirements elicitation activity and the analysis activity are documented in the
Requirements Analysis Document (RAD). This document completely describes the system in terms of functional and nonfunctional requirements and serves as a contractual basis between the

client and the developers. The audience for the RAD includes the client, the users, the project management, the system analysts (i.e., the developers who participate in the requirements), and the system designers (i.e., the developers who participate in the system design). The first part of the document, including use cases and nonfunctional requirements, is written during requirements
elicitation. The formalization of the specification in terms of object models is written during analysis.
The first section of the RAD is an Introduction. Its purpose is to provide a brief overview of the function of the system and the reasons for its development, its scope, and references to the development context (e.g., related problem statement, references to existing systems, feasibility studies). The introduction also includes the objectives and success criteria of the project.

Software Engineering module | PDF page 130 | lines 3-11

6.3. DOCUMENTING SYSTEM DESIGN
System design is documented in the System Design Document (SDD). It describes design goals set by the project, the subsystem decomposition (with UML class diagrams), the hardware/software mapping (with UML deployment diagrams), the data management, the access control, control flow mechanisms, and boundary conditions. The SDD is used to define interfaces between teams of developers and as reference when architecture-level decisions need to be revisited. The audience for the SDD includes the project management, the system architects (i.e., the developers who participate in the system design), and the developers who design and implement each subsystem. The following is an example template for a SDD:

Question sources

Mock exam 1 · Question 29

Question 88 | Q01514

Evaluate statements A-C about subsystem decomposition. Which is false? Select D if none is false.

A. In designing the desirable effect is low coupling and high cohesion in sub system decomposition

B. Cohesion refers to the dependency of classes with in subsystem

C. Coupling refers to the dependency between sub systems

D. None of statements A-C is false.

Hint

Separate responsibilities inside a component from dependencies across boundaries. Evaluate the stated structure, change and reuse goals without assuming guaranteed benefits.

Answer D: None of statements A-C is false.

Low coupling limits dependencies between subsystems, while high cohesion keeps related responsibilities together inside each subsystem. The first statement recommends this combination, the second identifies cohesion within the subsystem, and the third identifies coupling across subsystems. All three substantive statements are therefore true. The final alternative is explicitly the response for finding no false statement among those three, rather than a self-referential assertion about all choices.

Why each choice is right or wrong

A - Incorrect: Low coupling and high cohesion are the stated decomposition goals.

B - Incorrect: Cohesion concerns relatedness and dependencies among elements within a subsystem.

C - Incorrect: Coupling concerns dependencies between subsystems.

D - Correct: None of the substantive statements A-C is false, so this is the required response.

Primary note proof

Study-note section SE22

> Cohesion measures how well elements inside a module serve a related purpose; coupling measures dependency between modules. Seek high cohesion and low coupling. Shared mutable data and knowledge of another module’s internal representation increase coupling. Information hiding exposes stable operations while concealing changeable decisions.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 120 | lines 6-12

> 6.1.3. Coupling and coherence
> Coupling is the strength of dependencies between two subsystems. If two subsystems are loosely coupled, they are relatively independent, and thus, modifications to one of the subsystems will have little impact on the other. If two subsystems are strongly coupled, modifications to one subsystem is likely to have impact on the other. A desirable property of a subsystem decomposition
> is that subsystems are as loosely coupled as possible. This minimizes the impact that errors or future changes have on the correct operation of the system.

Software Engineering module | PDF page 120 | lines 24-27

> Coherence is the strength of dependencies within a subsystem. If a subsystem contains many objects that are related to each other and perform similar tasks, its coherence is high. If a subsystem
> contains a number of unrelated objects, its coherence is low. A desirable property of a subsystem decomposition is that it leads to subsystems with high coherence.

Question sources

Mock exam 1 · Question 30

Question 89 | Q01593

Which offered asset is inherently excluded from reuse in a software product line?

A. Test cases

B. Requirement

C. Architecture

D. None of A-C; all three can be reusable product-line assets.

Hint

Identify whether the scenario prioritizes delivery, learning, adaptation or risk reduction. Several processes can share individual practices, so compare their defining emphasis.

Answer D: None of A-C; all three can be reusable product-line assets.

Product-line assets can include requirements, architecture, components and tests. Consequently test cases, requirements and architecture are all potentially reusable, although each must be evaluated for fit in a particular product. None of A-C is inherently excluded by its asset type. Option D expresses this conclusion directly rather than contradicting the negative stem with an undefined all-choices assertion.

Why each choice is right or wrong

A - Incorrect: Test cases can be reusable product-line assets.

B - Incorrect: Requirements can be shared across related products.

C - Incorrect: Architecture can be a reusable product-line asset.

D - Correct: None of A-C is inherently excluded; all can be reused.

Primary note proof

Study-note section SE07

> RAD uses rapid construction, timeboxing, user participation and often reusable components; it requires available users and skilled designers/developers. Reuse-oriented development searches components, evaluates fit, may adjust requirements, designs around interfaces and builds missing parts. Product-line assets may include requirements, architecture, components and tests; all are potentially reusable.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 24 | lines 20-29

> Advantages:
> 1. Reduced cost and risks
> 2. Faster delivery of the software (Accelerated development)
> Disadvantages:
> 1. Compromising requirements

2. Some control over the system evolution is lost as new versions of the reusable components are not under the control of the organization using them.
3. Increased maintenance costs
4. Not-invented-here syndrome
5. Lack of tool support

Question sources

Mock exam 3 · Question 25

Question 90 | Q01594

A software design model states exact withdraw preconditions and balance equations but omits physical implementation detail. Compare it with an informal mathematical sketch that leaves those constraints unspecified and a fully detailed engine drawing. Which statement is FALSE for these particular models?

A. This software model is less precise than the specified mathematical sketch.

B. This software model is more abstract than the fully detailed engine drawing.

C. A main role of this model is to represent the software designer’s ideas.

D. None of A-C is false.

Hint

Separate responsibilities inside a component from dependencies across boundaries. Evaluate the stated structure, change and reuse goals without assuming guaranteed benefits.

Answer A: This software model is less precise than the specified mathematical sketch.

The software model states exact preconditions and balance equations, whereas the informal mathematical sketch omits those constraints. It is therefore not less precise in the stated comparison, making A false. Omitting implementation detail makes it more abstract than the specified detailed engine drawing, and representing design ideas remains a legitimate purpose. These are scenario-specific judgments rather than universal rankings of all software and mathematical models.

Why each choice is right or wrong

A - Correct: Its exact constraints make the stated less-precise comparison false.

B - Incorrect: The software model omits implementation detail retained in the detailed drawing.

C - Incorrect: A design model can represent the designer’s ideas and decisions.

D - Incorrect: A is false, so the no-false-statements alternative is wrong.

Primary note proof

Study-note section SE43

Choose designs by their effect on stated goals. Fine-grained self-contained components, separation of producers/consumers and limited shared mutable data often improve maintainability. Trade-offs remain: interfaces can add latency, isolation can complicate transactions, and global state can simplify one operation while coupling many others. Prefer measurable quality scenarios to counting components alone.

Study-note section SE25

A contract states preconditions, postconditions and invariants. For withdraw(amount): require amount>0 and amount<=balance; ensure balance=oldBalance-amount; preserve balance>=0. Validation checks inputs; implementation enforces the transition. A complete feature needs both UI/API and persisted behavior, not only a diagram.

Study-note section SE23

A layer is a logical abstraction level; a tier is a deployment separation. A closed layered architecture permits calls only to the immediately lower layer; an open one permits approved skipping. For top-to-bottom A,B,C,D, A→B obeys closed layering, A→C skips, and lower-to-upper calls violate the simple dependency rule unless explicitly mediated by a defined mechanism.

Study-note section SE23

A structure is the elements/relations themselves; a view represents selected aspects.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 100 | lines 11-24

Analysis focuses on producing a model of the system, called the analysis model, which is correct, complete, consistent, and verifiable. Analysis is different from requirements elicitation in that developers focus on structuring and formalizing the requirements elicited from users
Figure 4.1 Products of requirements elicitation and analysis (UML activity diagram).
Althoughtheanalysismodelmaynotbeunderstandabletotheusersandtheclient, it helps developers verify the system specification produced during requirements elicitation. There is a natural tendency for users and developers to postpone difficult decisions until later in the project. A decision may be difficult because of lack of domain knowledge, lack of technological knowledge, or simply because of disagreements among users and developers. Postponing decisions enables the
project to move on smoothly and avoid confrontation with reality or peers. Unfortunately, difficult
decisions will eventually need to be made, often at higher cost when intrinsic problems are discovered during testing, or worse, during user evaluation. Translating a system specification in to a formal or semi-formal model forces developers to identify and resolve difficult issues early in
the development.

Software Engineering module | PDF page 18 | lines 13-20

System and software design: The systems design process allocates the requirements to either hardware or software systems by establishing an overall system architecture.
Software design involves identifying and describing the fundamental software system

abstractions
and their relationships. The goal of the design phase is to transform the requirements specified in
the SRS document into a structure that is suitable for implementation in some programming language. In technical terms, during the design phase the software architecture is derived from the
SRS document. Two distinctly different approaches are available: the traditional design approach
and the object-oriented design approach.

Question sources

Mock exam 3 · Question 26

Question 91 | Q01595

Which among the following designing models show sequence functional transformation done on inputs into outputs?

A. ER diagrams

B. DFD diagrams

C. Component diagrams

D. None of the choices are correct

Hint

Match the information to be represented with each model's purpose. Read relationship direction, boundary and ownership conditions before classifying it.

Answer B: Data-flow diagrams.

SE20 defines a DFD through data flows, stores and transformations from inputs to outputs. That matches the functional-transformation focus in the stem. An ER diagram focuses on domain data relationships, while a component diagram describes software components and dependencies. A DFD need not show detailed control timing merely because it depicts connected transformations.

Why each choice is right or wrong

A - Incorrect: ER diagrams describe entities and relationships rather than transformations of input data into outputs.

B - Correct: DFDs depict data flows and the processes that transform inputs into outputs.

C - Incorrect: Component diagrams describe component interfaces and dependencies rather than this data-transformation view.

D - Incorrect: DFD is listed and directly matches the functional-transformation description.

Primary note proof

Study-note section SE20

Choose a sequence diagram for message order between participants, a state machine for event-dependent state changes, and activity for workflow. Both sequence and state diagrams describe behavior over time. State machines are useful for objects with significant states, whether entity or control. A DFD shows data stores/flows and transformations from inputs to outputs; it is not a UML diagram.

Study-note section SE-S03

An entity-relationship diagram models entity types, their attributes and the relationships between them, commonly for data design. Its focus differs from a use-case diagram of external roles and goals, a class diagram of classes and their features, or a deployment diagram mapping artifacts to execution nodes.

Software Engineering module | PDF page 126 | lines 7-16

Pipe and filter architecture
In the pipe and filter architecture (see Figure 6.13), subsystems process data received from a set of
inputs and send results to other subsystems via a set of outputs. The subsystems are called filters, and the associations between the subsystems are called pipes. Each filter only knows the content and the format of the data received on the input pipes, not the filters that produced them. Each filter is executed concurrently and synchronization is done via the pipes. The pipe and filter architecture is modifiable: Filters can be substituted for others or reconfigured to achieve a different purpose.
Figure 6.13 Pipe and filter architecture (UML class diagram). A Filter can have many inputs and outputs. A Pipe connects one of the outputs of a Filter to one of the inputs of another Filter.

Software Engineering module | PDF page 101 | lines 5-6

In UML, the functional model is represented with use case diagrams, the object model with class diagrams, and the dynamic model with statechart and sequence diagrams.

Question sources

Mock exam 3 · Question 27

Question 92 | Q01596

Which of the following is step in software development life cycle that tell us if developing a software makes sense for the current company situation or not.

A. Requirement analysis

B. Feasibility analysis

C. Designing phase

D. Requirement elicitation

Hint

Distinguish observable services, measurable qualities and implementation constraints. Check scope, stakeholder meaning and the requested level of specificity.

Answer B: Feasibility analysis

Feasibility assesses technological practicality, budget and business cost-effectiveness before deciding to proceed with detailed analysis.

Why each choice is right or wrong

A - Incorrect: Further analysis follows a feasibility decision. See PDF p. 25, 26.

B - Correct: Direct viability/go-ahead decision. See PDF p. 25, 26.

C - Incorrect: Derives a solution after requirements are understood. See PDF p. 25, 26.

D - Incorrect: Collects stakeholder needs rather than deciding whether the investment is viable. See PDF p. 25, 26.

Primary note proof

Study-note section SE08

> Feasibility asks whether a proposal is worth doing and can be delivered within technical, economic, operational and schedule constraints. Examine existing limitations, organizational impacts, benefits, cost, available skills and integration risk. System analysis studies the problem and needed behavior in more detail; the activities inform each other.

Module passages - related reading

Software Engineering module | PDF page 25 | lines 15-18

> There are four main activities in the requirements engineering process:
> 1. Feasibility study: Feasibility shows viability and practicality of a software, project or idea. An estimate is made of whether the identified user needs may be satisfied using current software and hardware technologies. The study considers whether the proposed system will be cost-

Software Engineering module | PDF page 26 | lines 3-5

> effective from a business point of view and if it can be developed within existing budgetary constraints. A feasibility study should be relatively cheap and quick. The result should inform the decision of whether or not to go ahead with a more detailed analysis.

Question sources

Mock exam 3 · Question 28

Question 93 | Q01597

Which choice gives the most complete supported comparison of object-oriented model continuity and transitions between different development models?

A. Object-oriented development can use a consistent vocabulary of objects and classes across analysis and design.

B. Reuse and consistent models in object-oriented development can reduce development effort and duration on suitable projects.

C. Moving between different representations in a traditional phased approach can add translation complexity and errors.

D. All statements A-C are correct.

Hint

Separate responsibilities inside a component from dependencies across boundaries. Evaluate the stated structure, change and reuse goals without assuming guaranteed benefits.

Answer D: All statements A-C are correct.

A consistent object vocabulary across development stages can reduce errors from translating between unrelated models. Reuse and continuity can also reduce effort on suitable projects, while transitions between different representations can add complexity. These are potential benefits and risks, not guarantees that every OO project is shorter or every traditional project is worse. With those qualifications, all three substantive statements are supported, making their aggregate the most complete answer.

Why each choice is right or wrong

A - Incorrect: True but incomplete alone: a consistent object/class vocabulary can connect analysis and design.

B - Incorrect: True but incomplete alone: reuse and model continuity can reduce effort, without guaranteeing it.

C - Incorrect: True but incomplete alone: translation between different representations can add complexity or errors.

D - Correct: All three qualified statements hold, so the aggregate is the complete selection.

Primary note proof

Study-note section SE01

> Software engineering applies systematic methods to development, operation and maintenance. A software product includes executable code and relevant requirements, designs, test assets, configuration and user documentation. A process defines activities, ordering, roles, products and entry/exit conditions. Its four broad activities are specification, design/implementation, validation and evolution.

Study-note section SE01

Procedural decomposition organizes functions; object oriented decomposition organizes objects with state and behavior. Either can use iterative or sequential development. OOP does not automatically shorten every project. Reuse, encapsulation and consistent models can reduce duplication and ease change; poor object design can still be complex. Functional programming emphasizes function evaluation and controlled side effects; event-driven programs react to events.

Study-note section SE-S02

An object-oriented approach can use a consistent vocabulary of objects, classes and relationships across analysis, design and implementation. Models are refined for different purposes rather than being identical artifacts. This continuity can reduce translation errors and effort; reusable classes can shorten suitable projects, but neither shorter duration nor good design is guaranteed.

Software Engineering module | PDF page 31 | lines 19-31

1.3.1. Why an object oriented
• Object oriented systems are
o Easier to adapt to changes
o More robust
o Easier to maintain
o Promote greater design and code reuse
o Creates modules of functionality
• REASONS FOR WORKING OF OBJECT ORIENTED SYSTEMS:
Higher level of abstraction
The object-oriented approach supports abstraction at the object level. Since objects encapsulate both data (attributes) and functions (methods), they work at a higher level of abstraction. The development can proceed at the object level and ignore the rest of the system for as long as necessary. This makes designing, coding, testing, and maintaining the system much simpler.

Software Engineering module | PDF page 32 | lines 22-27

1.3.2. Overview of the unified approach.
The unified modeling language (UML) is a set of notations and conventions used to describe and model an application. But, the UML does not specify a methodology or what steps to follow to develop an application; that would be the task of the UA. Figure 1.2 depicts the essence of the unified approach. The heart of the UA is Jacobson's use case. The use case represents a typical interaction between a user and a computer system to capture the users' goals and needs. The main

Software Engineering module | PDF page 32 | lines 3-10

The traditional approach to software development requires different styles and methodologies for
each step of the process. Moving from one phase to another requires a complex transition of perspective between models that almost can be in different worlds. This transition not only can slow the development process but also increases the size of the project and the chance for errors introduced in moving from one language to another. The object-oriented approach, on the other hand, essentially uses the same language to talk about analysis, design, programming, and database
design. This seamless approach reduces the level of complexity and redundancy and makes for clearer, more robust system development.

Question sources

Mock exam 3 · Question 29

Question 94 | Q01598

Which of the following process model is concerned with how changes are incorporated in software?

A. Configuration management process

B. Change management process

C. Inspection management process

D. Project management process

Hint

Separate artifact history and controlled changes from scheduling, collaboration benefits and automated execution.

Answer B: Change management process.

SE33 assigns handling change requests, impact assessment, decisions, implementation and validation to change management. Configuration management coordinates versions and baselines of affected artifacts, which supports that work but is a different focus. Inspection and general project management also contribute, yet B specifically names how proposed software changes are evaluated and incorporated.

Why each choice is right or wrong

A - Incorrect: Configuration management maintains controlled versions and baselines rather than primarily deciding and incorporating requested changes.

B - Correct: Change management evaluates, approves/prioritizes, implements and validates proposed changes.

C - Incorrect: Inspection evaluates artifacts rather than defining the complete change-handling process.

D - Incorrect: Project management is broader than the specific process for handling software change requests.

Primary note proof

Study-note section SE33

> Change management handles request, impact assessment, decision/prioritization, implementation and validation; configuration management keeps all affected versions consistent. Distributed Git gives each clone local history and supports independent branches followed by merging; it does not eliminate merge conflicts or approvals. Plan test configuration management early and apply it throughout testing, not at just one exclusive phase.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 142 | lines 5-10

> Configuration management avoids faults caused by undisciplined change in the system models. For example, it is a common mistake to a change a subsystem interface without notifying all developers of calling components. Configuration management can make sure that, if analysis models and code are becoming inconsistent with one another, analysts and implementor are notified. The assumption behind configuration management is that the system contains many less
> faults if change is controlled.

Question sources

Mock exam 3 · Question 30

Question 95 | Q01599

After a maintenance change request has been received, which is the earliest listed technical activity before release planning and implementation?

A. Release planning

B. Change management

C. Impact analysis

D. Testing

Hint

Classify the motive for the change before its implementation: repair, environment, useful capability or reduced future risk.

Answer C: Impact analysis

A typical evolution sequence is change request, impact analysis, release planning, implementation/testing and release. Once the request has arrived, impact analysis is the earliest listed technical step, assessing consequences before scheduling and implementation. Change management names the broader handling process rather than that next step. Release planning and testing occur later, so neither starts the specified post-request technical sequence.

Why each choice is right or wrong

A - Incorrect: Release planning follows impact analysis.

B - Incorrect: Change management is the overarching process.

C - Correct: Impact analysis is the first listed technical activity after the request.

D - Incorrect: Testing follows analysis, planning and implementation.

Primary note proof

Study-note section SE40

> A typical evolution sequence is change request→impact analysis→release planning→implementation/testing→release. Among a list lacking the request step, impact analysis may be the earliest listed technical activity. Major restructuring is reengineering; if the architecture itself changes, architectural transformation is the more specific description. Markets, technology, stakeholders and funding can all change scope or priorities.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 19 | lines 24-29

> 5. Operation and maintenance: Normally (although not necessarily), this is the longest life cycle phase. Maintenance of a typical software product requires much more than the effort necessary to
> develop the product itself. The system is installed and put into practical use. Maintenance involves

correcting errors which were not discovered in earlier stages of the life cycle, improving the implementation of system units and enhancing the system ‘s services as new requirements are discovered.

Software Engineering module | PDF page 41 | lines 16-17

✓ Software evolution takes place when you change existing software systems to meet new requirements. Changes are continuous and the software must evolve to remain useful.

Question sources

Mock exam 3 · Question 31

Question 96 | Q01600

A takes 5 days. B takes 3 days and C takes 4 days; both depend only on A and may run in parallel with sufficient resources. The project finishes when all three complete. What is its earliest duration?

A. 3 days

B. 4 days

C. 5 days

D. 9 days

Hint

Write out the supplied quantities and dependency constraints. Compute and compare values under the stated metric, finish condition and assumptions.

Answer D: 9 days

A completes at day five. B and C then start together, finishing at days eight and nine respectively. The project must wait for both required tasks, so its earliest finish is 5+max(3,4)=9 days. Adding all durations would ignore the permitted parallelism, while using eight days would count only the shorter A-B path and leave C incomplete.

Why each choice is right or wrong

A - Incorrect: Three counts B alone and omits its predecessor.

B - Incorrect: Four counts C alone and omits A.

C - Incorrect: Five stops after A, before both successors.

D - Correct: A followed by the longer parallel branch takes nine days.

Primary note proof

Study-note section SE29

If A takes 5 days and B=3,C=4 both follow A, project duration is 5+max(3,4)=9 days. B finishes at 8, but the project waits for C at 9. If paths B5+C6 and D8+E3 share a zero-duration start/end, both total 11; there are two critical paths, not one.

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 95 | lines 3-12

4.6. Scheduling, Organization and Team Structures
Project-task scheduling is an important project planning activity. It involves deciding which tasks would
be taken up when. In order to schedule the project activities, a software project manager needs to do
the following:
• Identify all the tasks needed to complete the project and Break down large tasks into small activities.
• Determine the dependency among different activities and Establish the most likely estimates for the time durations necessary to complete the activities and Allocate resources to activities.
• Plan the starting and ending dates for various activities and Determine the critical path. A critical path is the chain of activities that determines the duration of the project.

Question sources

Mock exam 3 · Question 32

Question 97 | Q01601

A project starts at day 0 and must finish at day 9. It consists of exactly two parallel paths, A → B and C → D. A and C have no predecessors, B depends only on A, D depends only on C, and the project finishes when both B and D are complete. Activity durations and early times are: A: duration 4 days, ES=0, EF=4; B: duration 5 days, ES=4, EF=9; C: duration 3 days, ES=0, EF=3; D: duration 6 days, ES=3, EF=9. What is the total slack (float) of Activity C?

A. 0 days

B. 1 day

C. 3 days

D. 6 days

Hint

Write out the supplied quantities and dependency constraints. Compute and compare values under the stated metric, finish condition and assumptions.

Answer A: 0 days.

Each complete path takes 9 days: A→B is 4+5 and C→D is 3+6. Working backward from day 9, D must start by day 3. Therefore C must finish by day 3 and start by day 0. C has LS=0 and ES=0, so total slack = LS−ES = 0 days (equivalently LF−EF = 3−3). A is correct. Delaying C would delay its successor D and the required project finish.

Why each choice is right or wrong

A - Correct: C has latest start 0 and earliest start 0, giving zero total slack.

B - Incorrect: A one-day delay would make the C→D path finish on day 10, beyond the day-9 finish.

C - Incorrect: C's three-day duration is not its slack; a three-day delay would finish this path on day 12.

D - Incorrect: D's six-day duration is not C's slack; a six-day delay to C would finish the path on day 15.

Primary note proof

Study-note section SE30

> Early start/finish values alone do not determine slack without successor relationships and the project completion constraint. If C3→D6 is a complete path parallel to A4→B5 and both finish at day9, C has zero float. That network cannot be silently inferred from four unrelated ES/EF rows.

Study-note section SE30

> Traditional CPM uses point durations; PERT models uncertainty with optimistic a, most-likely m and pessimistic b. The classic estimate is TE=(a+4m+b)/6 and variance=((b-a)/6)^2. For 3,6,15 days, TE=42/6=7 days and variance=4 days². Do not replace the weighted estimate by a simple average. These formulas are approximations, not guaranteed actual completion times.

Question sources

Mock exam 3 · Question 33

Question 98 | Q01602

PERT considers which of the following time estimates for each activity?

A. Ideal time only

B. Worst-case time only

C. Three-point estimates (optimistic, most likely, pessimistic)

D. Average of historical data (if available) statement.

Hint

Write out the supplied quantities and dependency constraints. Compute and compare values under the stated metric, finish condition and assumptions.

Answer C: Optimistic, most likely and pessimistic estimates.

SE30 defines the classic PERT inputs as optimistic a, most-likely m and pessimistic b. These feed the weighted expected time (a+4m+b)/6 and an uncertainty estimate. Neither a single ideal or worst-case time nor an unqualified historical average supplies the three-point representation of uncertainty described by PERT.

Why each choice is right or wrong

A - Incorrect: An ideal estimate alone omits the most-likely and pessimistic values needed by classic PERT.

B - Incorrect: A worst-case estimate alone omits the optimistic and most-likely possibilities.

C - Correct: Classic PERT uses optimistic, most-likely and pessimistic duration estimates.

D - Incorrect: Historical data may inform estimates, but an average alone is not the PERT three-point input model.

Primary note proof

Study-note section SE30

> Traditional CPM uses point durations; PERT models uncertainty with optimistic a, most-likely m and pessimistic b. The classic estimate is TE=(a+4m+b)/6 and variance=((b-a)/6)^2. For 3,6,15 days, TE=42/6=7 days and variance=4 days^2. Do not replace the weighted estimate by a simple average. These formulas are approximations, not guaranteed actual completion times.

Mock exam 3 · Question 34

Question 99 | Q01603

_____diagram is not supported by UML considering Data-driven modeling.

A. Activity

B. Data Flow Diagram (DFD)

C. State Chart

D. Component

Hint

Match the information to be represented with each model’s purpose. Read relationship direction, boundary and ownership conditions before classifying it.

Answer B: Data Flow Diagram (DFD)

The traditional nine UML diagram types include activity, statechart and component diagrams; DFD is not a UML diagram type. Thus DFD is the offered non-UML notation.

Why each choice is right or wrong

A - Incorrect: Listed UML activity diagram. See PDF p. 101, 56, 55.

B - Correct: Not included among the module's nine UML diagrams on PDF p.47. See PDF p. 101, 56, 55.

C - Incorrect: Listed UML statechart diagram. See PDF p. 101, 56, 55.

D - Incorrect: Listed UML component diagram on PDF p.47. See PDF p. 101, 56, 55.

Primary note proof

Study-note section SE20

Choose a sequence diagram for message order between participants, a state machine for event-dependent state changes, and activity for workflow. Both sequence and state diagrams describe behavior over time. State machines are useful for objects with significant states,

whether entity or control. A DFD shows data stores/flows and transformations from inputs to outputs; it is not a UML diagram.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 101 | lines 5-6

In UML, the functional model is represented with use case diagrams, the object model with class diagrams, and the dynamic model with statechart and sequence diagrams.

Software Engineering module | PDF page 56 | lines 18-24

2.3.4. Activity diagrams
The outgoing transitions are triggered by the completion of an action associated with the state. This is called an action state. By convention, the name of a state denotes a condition, whereas the name of an action state denotes an action. Activity diagrams are statechart diagrams whose states
are action states. is an activity diagram corresponding to the state diagram. An alternate and equivalent view of activity diagrams is to interpret action states as control flow between activities
and transitions; that is, the arrows are interpreted as sequential constraints between activities.

Software Engineering module | PDF page 55 | lines 4-9

2.3.3. State chart Diagram
A UML statechart is a notation for describing the sequence of states an object goes through in response to external events. Statecharts are extensions of the finite state machine model. On the one hand, statecharts provide notation for nesting states and state machines (i.e., a state can be described by a state machine). On the other hand, statecharts provide notation for binding transitions with message sends and conditions on objects.

Question sources

Mock exam 3 · Question 35

Question 100 | Q01604

What defining intention distinguishes a throwaway prototype from an evolutionary prototype?

A. It involves successive steps

B. It involves just one task

C. The prototype is built with the idea that it will eventually be converted into final system

D. It is intended to be discarded after learning, rather than refined into the production system.

Hint

Identify whether the scenario prioritizes delivery, learning, adaptation or risk reduction. Several processes can share individual practices, so compare their defining emphasis.

Answer D: It is intended to be discarded after learning, rather than refined into the production system.

A throwaway prototype is built to learn about requirements, usability or feasibility and is discarded after serving that purpose. An evolutionary prototype is deliberately refined toward production. Either may involve successive steps, multiple tasks and varying development time, so those features do not define the difference. The artifact's intended future, rather than how quickly it was built, distinguishes the approaches.

Why each choice is right or wrong

A - Incorrect: Either kind may involve successive steps.

B - Incorrect: Either kind can explore more than one task.

C - Incorrect: Intended refinement into the final system describes evolutionary prototyping.

D - Correct: Discard after learning is the defining throwaway intention.

Primary note proof

Study-note section SE07

> A prototype explores requirements, usability or technical feasibility. A throwaway prototype is discarded after learning; an evolutionary prototype is deliberately refined toward production. A quick prototype may omit robustness, security or architecture, so do not deploy it unchanged without evaluation. Coding may occur during prototyping even if a diagram labels that activity construction rather than coding.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 82 | lines 23-29

> • Prototype test. During this type of test, one or more users are presented with a piece of software that practically implements the system. A vertical prototype implements a complete use case through the system, and a horizontal prototype presents an interface for most use cases (without providing much or any functionality). The advantages of prototype

tests are that they provide a realistic view of the system to the user and that prototypes can be instrumented to collect detailed data. The disadvantages of prototypes are that they are expensive to build and to modify.

Software Engineering module | PDF page 26 | lines 6-9

2. Requirement's elicitation and analysis: This is the process of deriving the system requirements through observation of existing systems, discussions with potential users and procurers, task analysis, and so on. This may involve the development of one or more system models and prototypes. These help you understand the system to be specified.

Question sources

Mock exam 3 · Question 36

Question 101 | Q01605

Which factors can cause requirements, scope or priorities to evolve during a project? Select all that apply.

A. Changing needs of stakeholders

B. Advances in technology

C. Market dynamics

D. Lack of project funding

Hint

Classify the motive for the change before its implementation: repair, environment, useful capability or reduced future risk.

Answer A, B, C, D: Changing needs of stakeholders; Advances in technology; Market dynamics; Lack of project funding

Stakeholder needs can change the services required, technology can introduce new constraints or opportunities, and market dynamics can alter business priorities. A funding shortfall can also reduce scope or force reprioritization. The note explicitly includes all four sources of change. Their effects depend on the project, but each can cause evolution, so none is an unconditional exception.

Why each choice is right or wrong

A - Correct: Changed stakeholder needs can revise required behavior.

B - Correct: Technology changes can alter constraints or opportunities.

C - Correct: Market changes can alter goals and priorities.

D - Correct: Funding limits can reduce scope or reorder requirements.

Primary note proof

Study-note section SE11

Trace each requirement backward to its source/rationale and forward to design, code and tests. Record dependencies among requirements. A traceability matrix links these artifacts and helps impact analysis; it is not just a cost/schedule ledger. Stakeholders must negotiate conflicting requirements rather than independently approving incompatible demands. Scope, understanding and volatility are distinct elicitation difficulties.

Study-note section SE40

Corrective maintenance fixes faults; adaptive maintenance responds to environment changes; perfective maintenance improves useful capability/performance; preventive maintenance reduces future risk, such as restructuring fragile code. Motive determines category; refactoring can support preventive or perfective work. Maintenance often lasts years and includes understanding legacy code and regression effort, so it may dominate lifecycle cost.

Study-note section SE40

Markets, technology, stakeholders and funding can all change scope or priorities.

Module passages - related reading

4.7. Risk Management
• Risk management is concerned with identifying risks and drawing up plans to minimise their effect on a project.
• A risk is a probability that some adverse circumstance will occur
- Project risks affect schedule or resources;
- Product risks affect the quality or performance of the software being developed;
- Business risks affect the organisation developing or procuring the software.
Risk Management Process
- Risk identification- Identify project, product and business risks;
- Risk analysis -Assess the likelihood and consequences of these risks;

Question sources

Mock exam 3 · Question 37

Question 102 | Q01606

Used when a large amount of testing is needed and the changes, while small, can affect many parts of the system

A. Preventive testing

B. Unit Testing

C. Regression Testing

D. Acceptance Testing

Hint

Separate testing scope, technique and purpose. Use the stated workload, observable result or coverage target rather than a universal ranking.

Answer C: Regression testing.

The concern is that small changes may disturb other previously working parts of the software. Regression testing means checking unintended effects after change, rather than only confirming the defect. Such testing can span multiple levels and a large scope; the question describes its purpose, not the size of a unit or an acceptance decision.

Why each choice is right or wrong

A - Incorrect: Preventive testing is not the defined technique for detecting unintended effects of a specific software change.

B - Incorrect: Unit testing isolates a small component and does not by itself define the cross-system change-impact purpose.

C - Correct: Regression tests check whether changes unintentionally damage previously working behavior elsewhere.

D - Incorrect: Acceptance testing supports a user acceptance decision rather than specifically checking unintended change effects.

Primary note proof

Study-note section SE36

> Black-box techniques derive cases from specified behavior; white-box techniques derive them from internal structure; grey-box uses partial internal knowledge. Regression testing checks for unintended effects after change; confirmation testing checks the particular defect repair. Exploratory testing combines learning, design and execution and is experience based. Manual/automated describe execution support, not a compulsory black-/white-box classification.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 142 | lines 5-10

> Configuration management avoids faults caused by undisciplined change in the system models. For example, it is a common mistake to a change a subsystem interface without notifying all

developers of calling components. Configuration management can make sure that, if analysis models and code are becoming inconsistent with one another, analysts and implementor are notified. The assumption behind configuration management is that the system contains many less
faults if change is controlled.

Software Engineering module | PDF page 147 | lines 14-18

• Unit testing, which finds faults by isolating an individual component using test stubs and drivers and by exercising the component using a test case
• Integration testing, which finds faults by integrating several components together
• System testing, which focuses on the complete system, its functional and nonfunctional requirements, and its target environment

Software Engineering module | PDF page 147 | lines 3-8

• A test stub is a partial implementation of components on which the tested component depends. A test driver is a partial implementation of a component that depends on the tested component. Test stubs and drivers enable components to be isolated from the rest of the system for testing.
• A correction is a change to a component. The purpose of a correction is to repair a fault. Note that a correction can introduce new faults.

Question sources

Mock exam 3 · Question 38

Question 103 | Q01607

The Decision table testing is a ----------?

A. White box Test Design Technique

B. Black Box Test Design Technique

C. Experience-based Test Design Technique

D. Grey Box Test Design Technique

Hint

Separate testing scope, technique and purpose. Use the stated workload, observable result or coverage target rather than a universal ranking.

Answer B: Black-box, specification-based testing.

SE37 derives decision-table cases from combinations of specified conditions and resulting actions. This is specification-based rather than code-structure-based testing. It therefore belongs to black-box techniques. Experience or partial internal knowledge may help a tester, but they do not define the decision-table method or change its condition/action test basis.

Why each choice is right or wrong

A - Incorrect: White-box techniques derive tests from internal implementation structure rather than specified condition/action rules.

B - Correct: Decision tables derive cases from specified conditions and expected actions, making them black-box.

C - Incorrect: The technique has an explicit specification-based structure rather than being defined by tester experience.

D - Incorrect: Partial knowledge of internals is not required to derive decision-table test cases.

Primary note proof

Study-note section SE37

> A decision table lists condition combinations and resulting actions. For validCard and enoughFunds, enumerate TT,TF,FT,FF; specify dispense only for TT and the proper rejection for others. Cover feasible rules rather than blindly using every impossible combination. These are specification-based techniques. Test requirements can also define state-transition cases, such as rejecting dispatch from an already closed incident.

Mock exam 3 · Question 39

Question 104 | Q01608

Which of the following testing is related to the boundary value analysis?

A. White & black box testing

B. White-box testing

C. Black box testing

D. None of the above

Hint

Separate testing scope, technique and purpose. Use the stated workload, observable result or coverage target rather than a universal ranking.

Answer C: Black box testing

Boundary testing is a special case of equivalence testing, a black-box testing technique.

Why each choice is right or wrong

A - Incorrect: The cited classification does not require both white and black knowledge. See PDF p. 149, 149.

B - Incorrect: Internal path knowledge is not required by input-class edges. See PDF p. 149, 149.

C - Correct: Follows by boundary being a special case of black-box equivalence testing. See PDF p. 149, 149.

D - Incorrect: The black-box option is supported. See PDF p. 149, 149.

Primary note proof

Study-note section SE37

> Equivalence partitioning groups inputs expected to behave alike, then samples valid and invalid groups. For allowed age18..60, useful partitions are below18,18..60,above60. Boundary tests target edges and neighbors, such as 17,18,19,59,60,61, with the exact set chosen under the stated coverage scheme.

one member of the class. Equivalence testing consists of two steps: identification of the

Question sources

Mock exam 3 · Question 40

Question 105 | Q01636

During initial design, a component with three unrelated responsibilities is split into three cohesive components. Which concept most specifically names the resulting decomposition into responsibility-based modules, rather than a general restructuring activity?

A. Refactoring

B. Modularization

C. Information hiding

D. Refinement

Hint

Separate responsibilities inside a component from dependencies across boundaries. Evaluate the stated structure, change and reuse goals without assuming guaranteed benefits.

Answer B: Modularization

Separating unrelated responsibilities into cohesive components is modularization: the design is divided into modules with focused purposes. Refactoring can describe behavior-preserving restructuring of an existing solution, but that broader activity is not the specific decomposition concept requested. Information hiding concerns concealed decisions behind interfaces, while refinement is a general elaboration concept. The stated split primarily establishes better module responsibility boundaries.

Why each choice is right or wrong

A - Incorrect: Refactoring names behavior-preserving restructuring rather than the specific module decomposition principle.

B - Correct: Modularization separates responsibilities into cohesive components.

C - Incorrect: No particular hidden implementation decision defines the stated split.

D - Incorrect: Refinement is broader than the specified module-boundary decomposition.

Primary note proof

Study-note section SE22

Logical cohesion groups similar-category operations, often selected by a flag; temporal cohesion groups operations done at the same time; functional cohesion focuses on one task. Splitting an unrelated three-purpose component improves modularity. If behavior is preserved, the restructuring is refactoring; the words are not mutually exclusive answers. Smaller modules can aid understanding, independent work, reuse and maintenance, but too many interfaces also create complexity.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 120 | lines 24-27

Coherence is the strength of dependencies within a subsystem. If a subsystem contains many objects that are related to each other and perform similar tasks, its coherence is high. If a subsystem
contains a number of unrelated objects, its coherence is low. A desirable property of a subsystem decomposition is that it leads to subsystems with high coherence.

Software Engineering module | PDF page 133 | lines 3-15

transformation on subsets of a particular model. Typical activities include transforming n-ary associations into binary associations, implementing binary associations as references, merging two similar classes from two different subsystems into a single class, collapsing classes with no significant behavior into attributes, splitting complex classes into simpler ones, rearranging classes and operations to increase the inheritance and packaging. During restructuring, we address design goals such as maintainability, readability, and understandability of the system model.
• Optimization. Optimization activities address performance requirements of the system model. This includes changing algorithms to respond to speed or memory requirements, reducing multiplicities in associations to speed up queries, adding redundant associations for efficiency, rearranging execution orders, adding derived attributes to improve the access time to objects and opening up the architecture, that is, adding access to lower layers because of performance requirements.

Question sources

Mock exam 2 · Question 25

Question 106 | Q01637

Which design approach characteristically starts with available reusable components and assembles them into a larger system, rather than starting from high-level decomposition?

A. Both can be used

B. Top down

C. Bottom up

D. None of the choices are correct

Hint

Separate responsibilities inside a component from dependencies across boundaries. Evaluate the stated structure, change and reuse goals without assuming guaranteed benefits.

Answer C: Bottom up

Bottom-up design begins with existing components and assembles them into a larger solution. Top-down design instead starts with high-level structure and refines it, although it can still reuse components later. A hybrid combines the two directions, but the question asks which approach characteristically begins with the parts. Reuse by itself would not distinguish them; the explicit starting direction does.

Why each choice is right or wrong

A - Incorrect: A hybrid may use both directions but does not name the specifically described starting approach.

B - Incorrect: Top-down begins with high-level structure.

C - Correct: Bottom-up assembles existing components into the larger system.

D - Incorrect: Bottom-up directly matches, so none is false.

Primary note proof

Study-note section SE25

> Use abstraction and decomposition to manage complexity; preserve consistency, traceability and clear responsibilities. Top-down design refines high-level structure; bottom-up design assembles existing components. A hybrid combines both. SOLID includes Single Responsibility, Open-Closed, Liskov substitution, Interface Segregation and Dependency Inversion. Depend on abstractions; add compatible extensions; avoid forcing unused operations. DRY limits duplicated knowledge, KISS avoids unnecessary complexity, and YAGNI avoids speculative work.

Software Engineering module | PDF page 24 | lines 20-29

> Advantages:
> 1. Reduced cost and risks
> 2. Faster delivery of the software (Accelerated development)
> Disadvantages:
> 1. Compromising requirements
> 2. Some control over the system evolution is lost as new versions of the reusable components are not under the control of the organization using them.
> 3. Increased maintenance costs
> 4. Not-invented-here syndrome
> 5. Lack of tool support

Software Engineering module | PDF page 18 | lines 13-20

System and software design: The systems design process allocates the requirements to either hardware or software systems by establishing an overall system architecture.
Software design involves identifying and describing the fundamental software system abstractions
and their relationships. The goal of the design phase is to transform the requirements specified in
the SRS document into a structure that is suitable for implementation in some programming language. In technical terms, during the design phase the software architecture is derived from the
SRS document. Two distinctly different approaches are available: the traditional design approach
and the object-oriented design approach.

Question sources

Mock exam 2 · Question 26

Question 107 | Q01638

Processes and threads are element types we find in _____ software structure.

A. Service software structure

B. Use software structure

C. Layer software structure

D. Concurrent software structure

Hint

Separate responsibilities inside a component from dependencies across boundaries. Evaluate the stated structure, change and reuse goals without assuming guaranteed benefits.

Answer D: Concurrent software structure.

SE23 explicitly puts processes and threads in concurrency views because they represent independently scheduled execution. Layer structure instead describes logical abstraction levels, while uses and service relations describe different dependencies or interfaces. Thus the concurrent structure is the offered category that directly matches these runtime execution elements.

Why each choice is right or wrong

A - Incorrect: Service structure emphasizes provided behavior or interfaces rather than processes and threads as execution elements.

B - Incorrect: Uses structure emphasizes dependencies rather than the concurrency entities named in the stem.

C - Incorrect: Layers organize logical abstraction levels rather than identifying independently scheduled execution units.

D - Correct: Concurrent structure models execution elements such as processes and threads.

Primary note proof

Study-note section SE23

A structure is the elements/relations themselves; a view represents selected aspects. Module structures show code organization, component-and-connector structures runtime interaction, and allocation structures map software to hardware, teams or environment. Processes/threads belong in concurrency views. Evaluate architectures against quality attributes and scenarios; processor allocation, decomposition and style selection can all be architectural concerns.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 121 | lines 6-15

6.1.4. Software architecture
As the complexity of systems increases, the specification of the system decomposition is critical. It is difficult to modify or correct a weak decomposition once development has started, as most subsystem interfaces have to change. In recognition of the importance of this problem, the concept
of software architecture has emerged. A software architecture includes the system decomposition, the global control flow, error-handling policies and inter subsystem communication protocols.
In this section, we describe a few sample architectures that can be used for different systems. This
is by no means a systematic or thorough exposition of the subject. Rather, we aim to provide a few
representative examples and refer the reader to the literature for more details.

Question sources

Mock exam 2 · Question 27

Question 108 | Q01639

Which statements correctly describe verification and validation? Select all that apply.

A. Verification consists of checking of documents/files and is performed by human where as validation consists of execution of program and is performed by computer.

B. All choices are correct

C. Validation assesses whether the built software meets intended stakeholder needs.

D. Verification refers to the set of activities that ensure software correctly implements the specific function.

Hint

Distinguish process assurance from product evaluation, and compare specified obligations with actual stakeholder needs.

Answer C, D: Validation assesses whether the built software meets intended stakeholder needs.; Verification refers to the set of activities that ensure software correctly implements the specific function.

Verification checks whether specified functions and obligations have been implemented correctly. Validation checks whether the built product meets intended stakeholder needs. Both can use reviews, analysis and execution, so the claimed human-only versus computer-only split is false. Traceability can support these activities but does not alone establish satisfaction. If C states that validation checks whether software meets intended stakeholder needs, C and D are correct.

Why each choice is right or wrong

A - Incorrect: Both activities can use human reviews and execution; the exclusive split is false.

B - Incorrect: A is false, so all choices are not correct.

C - Correct: Validation assesses whether the product meets intended stakeholder needs.

D - Correct: Verification assesses correct implementation of specified obligations.

Primary note proof

Study-note section SE34

> Quality assurance establishes and checks processes/standards; quality control evaluates work products. An SQA plan identifies standards, responsibilities, evaluations, reviews, audits and assurance records. Quality of conformance means following the design/specification; a product can conform to a poor specification. Verification asks whether specified obligations are implemented correctly; validation asks whether the product meets intended stakeholder needs. Both can use reviews, analysis or execution, so “human-only versus computer-only” is false.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 142 | lines 11-23

> Verification attempts to find faults before any execution of the system. Verification is possible in specific cases, such as the verification of a small operating system kernel. Verification, however, has limits. It is not in a mature enough state that it can be applied to assure the quality of large complex systems. Moreover, it assumes that the requirements are correct, which is seldom the case: Assume we need to verify an operation and we know the pre- and postconditions for the operation. If we can verify that the operation provides a transformation such that, before the execution of the operation the precondition is true, and after the execution the postcondition holds,
> then the operation is correctly implemented; that is, it is verified. However, sometimes we forget important parts of the pre- or postcondition. For example, the postconditions might not state that the train should stay on the ground while moving from track 1 to track 2. Finally, verification addresses only algorithmic faults: It cannot deal with mechanical faults in the virtual machine. For
> verification, we must assume that the virtual machine on which the system is executing is correct
> and does not change during the proof.

Mock exam 2 · Question 28

Question 109 | Q01640

Which architectural style is more suitable for if a system has to have successive transformation of streams of data?

A. Pipe and filter

B. Layered architecture

C. Client server architecture

D. All choices are correct

Hint

Separate responsibilities inside a component from dependencies across boundaries. Evaluate the stated structure, change and reuse goals without assuming guaranteed benefits.

Answer A: Pipe and filter

Pipe-and-filter architecture explicitly applies transformations to streams without user intervention.

Why each choice is right or wrong

A - Correct: Direct match to successive stream transformations. See PDF p. 126, 127, 124.

B - Incorrect: Layers organize levels, but the module does not identify them as the stream transformation style. See PDF p. 126, 127, 124.

C - Incorrect: Client/server organizes requests/services, not the requested transformation pipeline. See PDF p. 126, 127, 124.

D - Incorrect: Client/server is not equally established for the specific stream criterion. See PDF p. 126, 127, 124.

Primary note proof

Study-note section SE24

> Repository style shares central data, simplifying common access but creating bottleneck/schema dependencies. MVC separates domain model, display view and interaction controller. Client-server separates requesters from service providers; peer-to-peer permits both roles. Pipe-and-filter applies successive transformations to data streams. Three-tier separates presentation, application logic and storage; some four-tier variants split presentation client/server.

Software Engineering module | PDF page 126 | lines 7-16

Pipe and filter architecture
In the pipe and filter architecture (see Figure 6.13), subsystems process data received from a set of
inputs and send results to other subsystems via a set of outputs. The subsystems are called filters, and the associations between the subsystems are called pipes. Each filter only knows the content and the format of the data received on the input pipes, not the filters that produced them. Each filter is executed concurrently and synchronization is done via the pipes. The pipe and filter architecture is modifiable: Filters can be substituted for others or reconfigured to achieve a different purpose.
Figure 6.13 Pipe and filter architecture (UML class diagram). A Filter can have many inputs and outputs. A Pipe connects one of the outputs of a Filter to one of the inputs of another Filter.

Software Engineering module | PDF page 127 | lines 5-8

Pipe and filter architectures are suited for systems that apply transformations to streams of data without intervention by users. They are not suited for systems that require more-complex interactions between components, such as an information management system or an interactive system.

Software Engineering module | PDF page 124 | lines 8-16

Client/server architecture
In the client/server architecture (Figure 6.9), a subsystem, the server, provides servicesto instances
of other subsystems called the clients, which are responsible for interacting with theuser. The request for a service is usually done via a remote procedure call mechanism or acommon object broker (e.g., CORBA or Java RMI). Control flow in the clients and the servers isindependent except for synchronization to manage requests or to receive results.
Figure 6.9 Client/server architecture (UML class diagram).
Clients request services from one or more servers. The server has no knowledge of the client. The client/server architecture is a generalization of the repository architecture.

Question sources

Mock exam 2 · Question 29

Question 110 | Q01641

Which of the following is quality measure for software?

A. Reliability

B. Low cost

C. Productivity

D. Low development time

Hint

Distinguish process assurance from product evaluation, and compare specified obligations with actual stakeholder needs.

Answer A: Reliability

Reliability is a software quality attribute characterized by behavior conformance and failure probability.

Why each choice is right or wrong

A - Correct: Explicit quality metric. See PDF p. 91, 140.

B - Incorrect: A project cost consideration rather than the offered software-behavior quality metric. See PDF p. 91, 140.

C - Incorrect: An output/effort process measure, not the specific product quality attribute. See PDF p. 91, 140.

D - Incorrect: A schedule measure rather than product reliability. See PDF p. 91, 140.

Primary note proof

Study-note section SE34

> A fault/defect is an underlying problem; an error may be an incorrect internal state; a failure is an externally observed departure from required service. Reliability is a product quality attribute; low cost or short development time are project outcomes. Tests increase confidence and reveal defects but cannot generally guarantee correctness over every possible input.

Mock exam 2 · Question 30

Question 111 | Q01642

A project manager is using PERT to estimate the duration of a project activity. The optimistic time (a) is 3 days, the most likely time (m) is 6 days, and the pessimistic time (b) is 15 days. What is the expected time (TE) for the activity?

A. 8 days

B. 10 days

C. 7 days

D. 9 days

Hint

Write out the supplied quantities and dependency constraints. Compute and compare values under the stated metric, finish condition and assumptions.

Answer C: 7 days.

Use TE=(a+4m+b)/6 from SE30 with a=3, m=6 and b=15. The numerator is 3+24+15=42, so TE=42/6=7 days. A simple average would give 8, but that discards the fourfold weighting of the most-likely estimate. The expected duration is an estimate, not a guaranteed actual completion time.

Why each choice is right or wrong

A - Incorrect: Eight is the simple mean of 3, 6 and 15, not the weighted PERT estimate.

B - Incorrect: Ten does not result from substituting the three given values into the PERT formula.

C - Correct: The weighted sum is 42 and dividing by six gives 7 days.

D - Incorrect: Nine does not equal the PERT weighted expected time for these estimates.

Primary note proof

Study-note section SE30

> Traditional CPM uses point durations; PERT models uncertainty with optimistic a, most-likely m and pessimistic b. The classic estimate is TE=(a+4m+b)/6 and variance=((b-a)/6)^2. For 3,6,15 days, TE=42/6=7 days and variance=4 days². Do not replace the weighted estimate by a simple average. These formulas are approximations, not guaranteed actual completion times.

> the following:

• Identify all the tasks needed to complete the project and Break down large tasks into small activities.
• Determine the dependency among different activities and Establish the most likely estimates for the time durations necessary to complete the activities and Allocate resources to activities.
• Plan the starting and ending dates for various activities and Determine the critical path. A critical path is the chain of activities that determines the duration of the project.

Question sources

Mock exam 2 · Question 31

Question 112 | Q01643

Which of the following is NOT a characteristic of a critical path in a CPM network diagram for software development?

A. Any delay in tasks on this path delays the entire project.

B. It identifies tasks with strict dependencies.

C. It represents the longest sequence of tasks.

D. It has the most slack (buffer time) compared to other paths.

Hint

Write out the supplied quantities and dependency constraints. Compute and compare values under the stated metric, finish condition and assumptions.

Answer D: It has the most slack (buffer time) compared to other paths.

The critical path is the chain determining project duration. The maximum-slack claim contradicts this: freely postponable tasks would not determine the earliest completion under a fixed network.

Why each choice is right or wrong

A - Incorrect: Delaying a controlling chain delays completion. See PDF p. 95.

B - Incorrect: Dependency order constrains the chain, though noncritical tasks can also have strict dependencies. See PDF p. 95.

C - Incorrect: The duration-determining chain is the longest required chain in the fixed-duration network. See PDF p. 95.

D - Correct: Maximum slack is inconsistent with a path that controls completion; no resource constraints are assumed. See PDF p. 95.

Primary note proof

Study-note section SE29

In a dependency network, ES=max predecessor EF and EF=ES+duration; start tasks have ES=0 unless another constraint applies. Project earliest finish is the maximum terminal EF. Backward, LF=min successor LS and LS=LF-duration, starting from the required finish. Total

float/slack=LS-ES=LF-EF. A critical path has the longest total duration and normally zero float in an unconstrained schedule.

Software Engineering module | PDF page 95 | lines 3-12

4.6. Scheduling, Organization and Team Structures
Project-task scheduling is an important project planning activity. It involves deciding which tasks would
be taken up when. In order to schedule the project activities, a software project manager needs to do
the following:
• Identify all the tasks needed to complete the project and Break down large tasks into small activities.
• Determine the dependency among different activities and Establish the most likely estimates for the time durations necessary to complete the activities and Allocate resources to activities.
• Plan the starting and ending dates for various activities and Determine the critical path. A critical path is the chain of activities that determines the duration of the project.

Question sources

Mock exam 2 · Question 32

Question 113 | Q01644

A zero-duration start A leads to parallel paths B(5)→C(6) and D(8)→E(3), both ending at a zero-duration finish. Which critical-path statements are true? Select all that apply. Multiple critical paths are allowed.

A. A→B→C is a critical path with total duration 11 days.

B. A→D→E is a critical path with total duration 11 days.

C. A→D→E is a critical path with total duration 14 days.

D. A→B→C is a critical path with total duration 14 days.

Hint

Write out the supplied quantities and dependency constraints. Compute and compare values under the stated metric, finish condition and assumptions.

Answer A, B: A→B→C is a critical path with total duration 11 days.; A→D→E is a critical path with total duration 11 days.

The B-C branch totals 5+6=11 days and the D-E branch totals 8+3=11 days. With zero-duration start and finish, both are equally longest complete paths, so both are critical and the project duration is eleven days. There is no rule requiring a unique critical path. The alternatives using fourteen days miscalculate the corresponding branch totals.

Why each choice is right or wrong

A - Correct: The B-C branch totals eleven and is critical.

B - Correct: The D-E branch also totals eleven and is critical.

C - Incorrect: Eight plus three is eleven, not fourteen.

D - Incorrect: Five plus six is eleven, not fourteen.

Primary note proof

Study-note section SE29

> In a dependency network, ES=max predecessor EF and EF=ES+duration; start tasks have ES=0 unless another constraint applies. Project earliest finish is the maximum terminal EF. Backward, LF=min successor LS and LS=LF-duration, starting from the required finish. Total float/slack=LS-ES=LF-EF. A critical path has the longest total duration and normally zero float in an unconstrained schedule.

Study-note section SE29

> If A takes 5 days and B=3,C=4 both follow A, project duration is 5+max(3,4)=9 days. B finishes at 8, but the project waits for C at 9. If paths B5+C6 and D8+E3 share a zero-duration start/end, both total 11; there are two critical paths, not one.

Question 114 | Q01645

How can market dynamics influence the evolution of requirements?

A. By introducing new competitors with innovative products

B. By stabilizing existing market conditions

C. By reducing the need for frequent updates

D. By minimizing consumer demands

Hint

Distinguish observable services, measurable qualities and implementation constraints. Check scope, stakeholder meaning and the requested level of specificity.

Answer A: By introducing new competitors with innovative products

Product competition is a business risk. A competitor introducing a product can alter customer needs and thus motivate evolution.

Why each choice is right or wrong

A - Correct: Direct concrete competitive stimulus consistent with the risk table on PDF p.97. See PDF p. 96, 41.

B - Incorrect: Stabilization does not supply the change stimulus described. See PDF p. 96, 41.

C - Incorrect: Reduced updates does not explain new competitive requirements. See PDF p. 96, 41.

D - Incorrect: Minimizing demands is not the described competitive pressure. See PDF p. 96, 41.

Primary note proof

Study-note section SE11

> Correct requirements reflect actual stakeholder needs. Complete requirements address the agreed scope, normal and exceptional behavior. Consistency excludes contradictions. Clarity/unambiguity gives one intended interpretation; feasibility/realism means achievable within constraints. Verifiability means objective evidence can check fulfillment. Replace “fast for most users” with a defined metric, workload and threshold.

Mock exam 2 · Question 34

Question 115 | Q01646

The static nature of the system is represented by which model?

A. Context Model

B. Data Model

C. Structural Model

D. Behavioral Model

Hint

Match the information to be represented with each model's purpose. Read relationship direction, boundary and ownership conditions before classifying it.

Answer C: Structural Model

The class/object model describes structure rather than temporal behavior; structural model is the offered general category.

Why each choice is right or wrong

A - Incorrect: Context concerns system boundaries, not all internal static structure. See PDF p. 51, 101.

B - Incorrect: Data is one aspect of structure but narrower than the overall static model. See PDF p. 51, 101.

C - Correct: Best matches the system's static classes/relationships. See PDF p. 51, 101.

D - Incorrect: Behavioral models describe interactions and changes over time. See PDF p. 51, 101.

Primary note proof

Study-note section SE17

A class box lists name, attributes and operations; + public, - private, # protected and ~ package indicate visibility. A class diagram shows static types and relationships, while an object diagram shows particular instances/links. UML is maintained and standardized by OMG; it is a modeling language, not a lifecycle process. Structural things describe conceptual or physical structural elements.

Software Engineering module | PDF page 51 | lines 14-24

2.3.2. Class Diagrams
Classes and objects
Class diagrams describe the structure of the system in terms of classes and objects. Classes are abstractions that specify the attributes and behavior of a set of objects. Objects are entities that encapsulate state and behavior. Each object has an identity: It can be referred individually and is distinguishable from other objects.
In UML, classes and objects are depicted by boxes including three compartments. The top compartment displays the name of the class or object. The center compartment displays its attributes, and the bottom compartment displays its operations. The attribute and operation compartment can be omitted for clarity. Object names are underlined to indicate that they are instances. By convention, class names start with an uppercase letter. Objects in object diagrams

Software Engineering module | PDF page 101 | lines 5-6

In UML, the functional model is represented with use case diagrams, the object model with class diagrams, and the dynamic model with statechart and sequence diagrams.

Mock exam 2 · Question 35

Question 116 | Q01647

How does backward traceability help in requirements management?

A. By identifying redundant requirements

B. By mapping requirements to design documents

C. By ensuring that each requirement can be traced back to its source

D. By linking requirements to future project phases

Hint

Distinguish observable services, measurable qualities and implementation constraints. Check scope, stakeholder meaning and the requested level of specificity.

Answer C: Trace each requirement back to its source and rationale.

SE11 directs requirements backward to their source or rationale and forward to design, code and tests. Backward traceability therefore establishes why a requirement exists and where it came from. It can assist reviews, but redundancy detection is not its definition. Design mappings and future phases primarily describe the forward direction.

Why each choice is right or wrong

A - Incorrect: Redundancy detection can benefit from traceability, but it is not the definition of backward tracing.

B - Incorrect: Mapping toward design documents is forward traceability from the requirement.

C - Correct: Backward tracing establishes the source or rationale from which each requirement originated.

D - Incorrect: Links toward later project artifacts describe forward rather than backward traceability.

Primary note proof

Study-note section SE11

> Trace each requirement backward to its source/rationale and forward to design, code and tests. Record dependencies among requirements. A traceability matrix links these artifacts and helps impact analysis; it is not just a cost/schedule ledger. Stakeholders must negotiate conflicting requirements rather than independently approving incompatible demands. Scope, understanding and volatility are distinct elicitation difficulties.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 70 | lines 3-16

> 3.2.5. Verifiability and Traceability
> Two more desirable properties of a system specification are that it be verifiable and traceable. The
> specification is verifiable if, once the system is built; a repeatable test can be designed to demonstrate that the system fulfills the requirement. For example, a mean time to failure of a hundred years for SatWatch would be difficult to achieve (assuming it is realistic in the first place).
> The following requirements are additional examples of non-verifiable requirements:
> • The product shall have a good user interface (good is not defined).
> • The product shall be error free (requires large amount of resources to establish).
> • The product shall respond to the user with 1 second for most cases (“most cases” is not defined).
> A system specification is traceable if each system function can be traced to its corresponding set of requirements. Traceability is not a constraint on the content of the specification, but rather, on its organization. Traceability facilitates the development of tests and the systematic validation of the design against the requirements.

Question sources

Mock exam 2 · Question 36

Question 117 | Q01648

Which artifact primarily serves project budgeting rather than specifying, planning or tracing tests?

A. Test strategy

B. Test Case

C. Project-wide cost estimate

D. Requirements Traceability Matrix [RTM]

Hint

Separate testing scope, technique and purpose. Use the stated workload, observable result or coverage target rather than a universal ranking.

Answer C: Project-wide cost estimate

A test strategy describes how testing will be approached, a test case supplies actions or inputs with expected results, and an RTM links requirements to tests to support coverage and impact analysis. A project-wide cost estimate instead budgets the broader project. It may include testing costs and inform a test plan, but its primary purpose is project planning rather than specifying or tracing tests. The distractor uses that explicit distinction.

Why each choice is right or wrong

A - Incorrect: A test strategy defines the intended testing approach.

B - Incorrect: A test case specifies inputs or actions and expected results.

C - Correct: A project-wide cost estimate is a budgeting artifact, not primarily a testing specification or trace.

D - Incorrect: An RTM links requirements to tests and supports test coverage.

Primary note proof

Study-note section SE39

> Plan objectives, scope, resources, schedule, risks and entry/exit criteria. Analyze the test basis for testable features and defects; design cases/expected results; implement data, scripts and environment; execute and compare; report defects; evaluate completion.

Study-note section SE11

> Trace each requirement backward to its source/rationale and forward to design, code and tests. Record dependencies among requirements. A traceability matrix links these artifacts and helps impact analysis; it is not just a cost/schedule ledger.

Study-note section SE28

Planning is continuous: identify scope/deliverables, decompose work, estimate effort/duration/cost, assign resources, sequence dependencies and revise as evidence changes.

Figure 6.2 depicts an overview of the testing activities:
• Unit testing tries to find faults in participating objects and/or subsystems with respect to the use cases from the use case model
• Integration testing is the activity of finding faults when testing the individually tested components together, for example, subsystems described in the subsystem decomposition, while executing the use cases and scenarios from the RAD.
o The system structure testing is the culmination of integration testing involving all components of the system. Integration tests and structure tests exploit knowledge from the SDD using an integration strategy described in the Test Plan (TP).
• System testing tests all the components together, seen as a single system to identify errors with respect to the scenarios from the problem statement and the requirements and design goals identified in the analysis and system design, respectively:
o Functional testing tests the requirements from the RAD and, if available, from the user manual.
o Performance testing checks the nonfunctional requirements and additional design goals from the SDD. Note that functional and performance testing are both done by

Software Engineering module | PDF page 90 | lines 7-24

4.2. Project Planning
• Probably the most time-consuming project management activity.
• Continuous activity from initial concept through to system delivery. Plans must be regularly revised as new information becomes available.
• Various different types of plans may be developed to support the main software project plan that is concerned with schedule and budget.
The project plan sets out:
• The resources available to the project;
• The work breakdown;
• A schedule for the work.
Project Plan Structure
• Introduction.
• Project organisation.
• Risk analysis.
• Hardware and software resource requirements.
• Work breakdown.
• Project schedule.
• Monitoring and reporting mechanisms.

Question sources

Mock exam 2 · Question 37

Question 118 | Q01649

Degree to which design specifications are followed in manufacturing the product is called

A. Quality Control

B. None of the mentioned

C. Quality of conformance

D. Quality Assurance

Hint

Distinguish process assurance from product evaluation, and compare specified obligations with actual stakeholder needs.

Answer C: Quality of conformance.

SE34 defines quality of conformance as following the design or specification. That is exactly the degree asked for in the stem. Quality control evaluates work products and quality assurance establishes and checks processes, but neither is the name of this conformance property. A conforming product may still follow an inadequate specification.

Why each choice is right or wrong

A - Incorrect: Quality control evaluates products rather than naming their degree of adherence to the design.

B - Incorrect: The exact property is offered as quality of conformance.

C - Correct: Conformance measures how faithfully the product follows its design or specification.

D - Incorrect: Quality assurance concerns processes and standards rather than the named degree of product conformance.

Primary note proof

Study-note section SE34

> Quality assurance establishes and checks processes/standards; quality control evaluates work products. An SQA plan identifies standards, responsibilities, evaluations, reviews, audits and assurance records. Quality of conformance means following the design/specification; a product can conform to a poor specification. Verification asks whether specified obligations are implemented correctly; validation asks whether the product meets intended stakeholder needs. Both can use reviews, analysis or execution, so “human-only versus computer-only” is false.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 99 | lines 14-19

> 4.8. Quality Assurance Monitoring Plans
> Quality assurance consists of the auditing and reporting functions of management. The goal of quality assurance is to provide management with the data necessary to be informed about product

quality, thereby gaining insight and confidence that product quality is meeting its goals. Of course,
if the data provided through quality assurance identify problems, it is management's responsibility
to address the problems and apply the necessary resources to resolve quality issues.

Software Engineering module | PDF page 140 | lines 11-18

Reliability is a measure of success with which the observed behavior of a system conforms to the specification of its behavior. Software reliability is the probability that a software system will not cause the failure of the system for a specified time under specified conditions. Failure is any deviation of the observed behavior from the specified behavior. An error means the system is in a state such that further processing by the system will lead to a failure, which causes the system to
deviate from its intended behavior. A fault, also called defect or bug, is the mechanical or algorithmic cause of an error. The goal of testing is to maximize the number of discovered faults, which then allows developers to correct them and increase the reliability of the system.

Question sources

Mock exam 2 · Question 38

Question 119 | Q01650

Which of the below testing is related to Non-functional testing?

A. Performance Testing

B. Unit Testing

C. Black-box Testing

D. None of the choices are correct

Hint

Separate testing scope, technique and purpose. Use the stated workload, observable result or coverage target rather than a universal ranking.

Answer A: Performance Testing

Performance testing explicitly checks nonfunctional requirements and additional design goals.

Why each choice is right or wrong

A - Correct: Directly tests nonfunctional qualities. See PDF p. 144.

B - Incorrect: A test level that can use several techniques and requirement types. See PDF p. 144.

C - Incorrect: A knowledge-based technique category, not specifically nonfunctional scope. See PDF p. 144.

D - Incorrect: The performance option is supported. See PDF p. 144.

Primary note proof

Study-note section SE36

Black-box techniques derive cases from specified behavior; white-box techniques derive them from internal structure; grey-box uses partial internal knowledge. Regression testing checks for unintended effects after change; confirmation testing checks the particular defect repair. Exploratory testing combines learning, design and execution and is experience based. Manual/automated describe execution support, not a compulsory black-/white-box classification.

Mock exam 2 · Question 39

Question 120 | Q00034B

First design the very high level structure of the system. Then gradually work down to detailed decisions about low-level constructs. Which design approach follows the given strategy?

A. Bottom-up

B. System design

C. Top-down

D. Hybrid

Hint

Separate responsibilities inside a component from dependencies across boundaries. Evaluate the stated structure, change and reuse goals without assuming guaranteed benefits.

Answer C: Top-down design.

The described direction starts with high-level structure and refines it into lower-level decisions. SE25 explicitly calls that top-down design. Bottom-up starts from existing components and assembles them; a hybrid combines directions. System design names a design activity or level, not the specific refinement direction requested by the question.

Why each choice is right or wrong

A - Incorrect: Bottom-up proceeds from components toward a larger structure, reversing the described direction.

B - Incorrect: System design names an architectural activity rather than the specific high-to-low refinement approach.

C - Correct: Top-down begins with high-level structure and progressively refines implementation details.

D - Incorrect: A hybrid combines both directions; the stem describes only top-down refinement.

Primary note proof

Study-note section SE25

> Use abstraction and decomposition to manage complexity; preserve consistency, traceability and clear responsibilities. Top-down design refines high-level structure; bottom-up design assembles existing components. A hybrid combines both. SOLID includes Single Responsibility, Open-Closed, Liskov substitution, Interface Segregation and Dependency Inversion. Depend on abstractions; add compatible extensions; avoid forcing unused operations. DRY limits duplicated knowledge, KISS avoids unnecessary complexity, and YAGNI avoids speculative work.

MOE Computer Science Exit Exam · 2016 · Question 34

Question 121 | SM0006

If you plan a software test to be done by clients to demonstrate that the system satisfies their requirements, which phase of software testing is appropriate?

A. Acceptance testing

B. Integration testing

C. System testing

D. Unit testing

Hint

Separate testing scope, technique and purpose. Use the stated workload, observable result or coverage target rather than a universal ranking.

Answer A: Acceptance testing

Acceptance testing checks requirements against the project agreement and is performed by the client, matching both actor and purpose in the stem.

Why each choice is right or wrong

A - Correct: Direct client agreement/acceptance check. See PDF p. 145, 144.

B - Incorrect: Combines individually tested components. See PDF p. 145, 144.

C - Incorrect: Tests the complete system, but the specified client acceptance purpose identifies the narrower level. See PDF p. 145, 144.

D - Incorrect: Isolates building blocks, not client acceptance. See PDF p. 145, 144.

Primary note proof

Study-note section SE35

Acceptance testing supports the customer/user's acceptance decision against agreed needs and criteria. Alpha typically happens in a controlled developer setting with selected users; beta uses external users in their environments. None of these levels is universally the longest. Unit is a level, while white-box is a technique; a unit can be tested using black-box cases too.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 145 | lines 3-5

o Acceptance testing and installation testing check the requirements against the project agreement and should be done by the client, if necessary with support by the developers.

Question 122 | SM0027

Assume you make modification to your software. Then you want to make sure that the modification
has not introduced new errors. Which software testing level is required?

A. Regression testing

B. Static testing

C. Beta testing

D. Dynamic testing

Hint

Separate testing scope, technique and purpose. Use the stated workload, observable result or coverage target rather than a universal ranking.

Answer A: Regression testing.

Regression testing means checking for unintended effects after a software change. That matches the stated goal of finding newly introduced errors. Static and dynamic describe execution-related approaches rather than this change-focused purpose; beta describes an external-user test setting. Although the stem says level, regression is more accurately a testing purpose/type.

Why each choice is right or wrong

A - Correct: Regression testing checks whether a modification damages behavior that previously worked.

B - Incorrect: Static testing examines artifacts without execution and does not specifically define the change-impact purpose.

C - Incorrect: Beta testing involves external users in their environments rather than specifically checking every change's unintended effects.

D - Incorrect: Dynamic testing means executing software; it is broader than the regression purpose described.

Primary note proof

Study-note section SE36

> Black-box techniques derive cases from specified behavior; white-box techniques derive them from internal structure; grey-box uses partial internal knowledge. Regression testing checks for unintended effects after change; confirmation testing checks the particular defect repair. Exploratory testing combines learning, design and execution and is experience based. Manual/automated describe execution support, not a compulsory black-/white-box classification.

Question 123 | SM0066

After deep analysis if your software requires major change to the architecture of the system, which
strategy of software change should be applied?

A. Preventative maintenance

B. Architectural transformation

C. Software reengineering

D. Software maintenance

Hint

Classify the motive for the change before its implementation: repair, environment, useful capability or reduced future risk.

Answer B: Architectural transformation.

SE40 names major restructuring reengineering and identifies architectural transformation as the more specific term when the architecture itself changes. The stem expressly requires major architecture change, making B the best match. Maintenance and reengineering are broader categories, while preventive maintenance describes a motive and need not involve architectural restructuring.

Why each choice is right or wrong

A - Incorrect: Preventive maintenance reduces future risk but does not specifically denote a major architectural change.

B - Correct: Architectural transformation directly names the major architecture change required by the scenario.

C - Incorrect: Reengineering is a broader restructuring category; architectural transformation is more specific here.

D - Incorrect: Maintenance is the broad activity family rather than the particular architecture-change strategy.

Primary note proof

Study-note section SE40

A typical evolution sequence is change request→impact analysis→release planning→implementation/testing→release. Among a list lacking the request step, impact analysis may be the earliest listed technical activity. Major restructuring is reengineering; if the architecture itself changes, architectural transformation is the more specific description. Markets, technology, stakeholders and funding can all change scope or priorities.

Software Engineering module | PDF page 121 | lines 6-15

6.1.4. Software architecture
As the complexity of systems increases, the specification of the system decomposition is critical. It is difficult to modify or correct a weak decomposition once development has started, as most subsystem interfaces have to change. In recognition of the importance of this problem, the concept
of software architecture has emerged. A software architecture includes the system decomposition, the global control flow, error-handling policies and inter subsystem communication protocols.
In this section, we describe a few sample architectures that can be used for different systems. This
is by no means a systematic or thorough exposition of the subject. Rather, we aim to provide a few
representative examples and refer the reader to the literature for more details.

Software Engineering module | PDF page 19 | lines 24-29

5. Operation and maintenance: Normally (although not necessarily), this is the longest life cycle phase. Maintenance of a typical software product requires much more than the effort necessary to
develop the product itself. The system is installed and put into practical use. Maintenance involves
correcting errors which were not discovered in earlier stages of the life cycle, improving the implementation of system units and enhancing the system ‘s services as new requirements are discovered.

Question 124 | SM0078

Which one of the following does NOT show a non-functional requirement of software systems?

A. Response time

B. Memory requirement

C. Reliability

D. Displaying information

Hint

Distinguish observable services, measurable qualities and implementation constraints. Check scope, stakeholder meaning and the requested level of specificity.

Answer D: Displaying information

Response time, memory constraints and reliability are nonfunctional qualities. Displaying information specifies a service rather than a quality bound.

Why each choice is right or wrong

A - Incorrect: Quantitative speed constraint. See PDF p. 65, 66, 127.

B - Incorrect: Space/resource constraint. See PDF p. 65, 66, 127.

C - Incorrect: Dependability quality. See PDF p. 65, 66, 127.

D - Correct: Observable function of presenting information. See PDF p. 65, 66, 127.

Primary note proof

Study-note section SE09

> A functional requirement states an observable service or behavior, including reactions to inputs, errors and forbidden actions. “When the sensor detects intrusion, send an alert” is functional. “Only a manager may approve refunds” also specifies permitted/prohibited behavior. A negative statement is not automatically nonfunctional.

Software Engineering module | PDF page 65 | lines 19-23

> 3.2.1. Functional Requirements
> Functional requirements describe the interactions between the system and its environment independent of its implementation. The environment includes the user and any other external system with which the system interacts. For example, the following is an example of functional requirements for SatWatch, a watch that resets itself without user intervention:

Software Engineering module | PDF page 66 | lines 14-18

> 3.2.2. Non-Functional and Pseudo-Requirements
> Nonfunctional requirements describe user-visible aspects of the system that are not directly related with the functional behavior of the system. Nonfunctional requirements include

quantitative constraints, such as response time (i.e., how fast the system reacts to user commands)
or accuracy (i.e., how precise are the system's numerical answers). The following are the

Software Engineering module | PDF page 127 | lines 10-28

6.2.1. Identifying design goals
The definition of design goals is the first step of system design. It identifies the qualities that our system should focus on. Many design goals can be inferred from the nonfunctional requirements or from the application domain. Others will have to be elicited from the client. It is, however, necessary to state them explicitly such that every important design decision can be made consistently following the same set of criteria.
For example, in the light of the nonfunctional requirements for MyTrip, we identify reliability and
fault tolerance to connectivity loss as design goals. We then identify security as a design goal, as numerous drivers will have access to the same trip planning server. We add modifiability as a design goal, as we want to provide the ability for drivers to select a trip planning service of their choice. The following box summarizes the design goals we identified.
In general, we can select design goals from a long list of highly desirable qualities. Tables 5-1-5-5 list a number of possible design criteria. These criteria are organized into five groups: performance, dependability, cost, maintenance, and end user criteria. Performance, dependability,
and end user criteria are usually specified in the requirements or inferred from the application domain. Cost and maintenance criteria are dictated by the customer and the supplier.
Performance criteria (Table 5-1) include the speed and space requirements imposed on the system. Should the system be responsive or should it accomplish a maximum number of tasks? Is memory space available for speed optimizations or should memory be used sparingly?

Question 125 | SM0079

Which one of the following is false about project planning stage?

A. Risk analysis is done during project planning

B. Preparing time schedule is done during project planning

C. Cost estimation is done during project planning

D. Project planning is a one-time task in software development life cycle

Hint

Distinguish the planning or organization goal from the tool or structure used to support it. Apply the stated project conditions.

Answer D: Project planning is a one-time task in software development life cycle

Planning is explicitly continuous from initial concept through delivery and revised as information changes. Therefore the one-time statement is false.

Why each choice is right or wrong

A - Incorrect: Risk analysis is in the plan structure. See PDF p. 90.

B - Incorrect: Schedule is in the project plan. See PDF p. 90.

C - Incorrect: Plans concern schedule and budget, so cost estimation belongs in planning. See PDF p. 90.

D - Correct: Direct contradiction of continuous revision. See PDF p. 90.

Primary note proof

Study-note section SE28

> Planning is continuous: identify scope/deliverables, decompose work, estimate effort/duration/cost, assign resources, sequence dependencies and revise as evidence changes. A WBS is hierarchical and covers project scope without adding unrelated work. Tools help coordinate ownership, dependencies and progress; they do not replace judgment or automatically fix bugs.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 90 | lines 7-24

> 4.2. Project Planning
> • Probably the most time-consuming project management activity.
> • Continuous activity from initial concept through to system delivery. Plans must be regularly revised as new information becomes available.
> • Various different types of plans may be developed to support the main software project plan that is concerned with schedule and budget.
> The project plan sets out:
> • The resources available to the project;
> • The work breakdown;
> • A schedule for the work.
> Project Plan Structure
> • Introduction.
> • Project organisation.
> • Risk analysis.
> • Hardware and software resource requirements.

Question 126 | SM0090

Which phase of software development process refers to modification of software to reflect changing customer and market requirements?

A. Validation

B. Evolution

C. Development

D. Specification

Hint

Identify whether the scenario prioritizes delivery, learning, adaptation or risk reduction. Several processes can share individual practices, so compare their defining emphasis.

Answer B: Evolution

Changing existing software to meet new requirements is software evolution.

Why each choice is right or wrong

A - Incorrect: Checks conformance and customer expectations. See PDF p. 41.

B - Correct: Exact ongoing change activity. See PDF p. 41.

C - Incorrect: Produces a software implementation. See PDF p. 41.

D - Incorrect: Defines required services and constraints. See PDF p. 41.

Primary note proof

Study-note section SE01

Software engineering applies systematic methods to development, operation and maintenance. A software product includes executable code and relevant requirements, designs, test assets, configuration and user documentation. A process defines activities, ordering, roles, products and entry/exit conditions. Its four broad activities are specification, design/implementation, validation and evolution.

Module passages - related reading

Question 127 | SM0203

When is it appropriate to use the Spiral model?

A. Where business modeling is clearly understood and in use

B. When it is too risky to develop the overall system as one block

C. When requirements are understood early but can change during the project's life cycle

D. When requirements are unstable and constantly changing

Hint

Identify whether the scenario prioritizes delivery, learning, adaptation or risk reduction. Several processes can share individual practices, so compare their defining emphasis.

Answer B: When major risks make one-block development unsafe.

SE06 uses explicit risk assessment and reduction to distinguish spiral development from other iterative approaches. B directly states that risk makes a single overall commitment inappropriate. Changing or unstable requirements can occur in several processes and do not alone identify spiral; clear business modeling likewise does not supply the distinctive risk-based reason.

Why each choice is right or wrong

A - Incorrect: Understanding business modeling alone does not identify the need for risk-driven spiral cycles.

B - Correct: Important risks justify staged investigation and commitment rather than building the entire system in one block.

C - Incorrect: Possible requirement changes fit multiple processes and omit spiral's distinguishing explicit risk emphasis.

D - Incorrect: Unstable requirements alone do not uniquely select spiral over other adaptive approaches.

Primary note proof

Study-note section SE06

> Spiral development is risk driven. Each cycle identifies objectives and alternatives, assesses and reduces important risks, develops/verifies an appropriate next result, and plans further commitment. A prototype may test a risky technology before a large investment. The amount and type of work depend on the risks.

Study-note section SE06

> Use risk emphasis to distinguish spiral from a generic changing-requirements scenario.

Computer Science Exit Exam practice collection · Question 14

Question 128 | SM0235

A module is said to have logical cohesion if:

A. All the functions of the module are executed within the same time span

B. All elements of the module depend on their interface complexity

C. It performs a set of tasks that relate to each other very loosely

D. All elements of the module perform similar operations

Hint

Separate responsibilities inside a component from dependencies across boundaries. Evaluate the stated structure, change and reuse goals without assuming guaranteed benefits.

Answer D: The module groups similar-category operations.

SE22 defines logical cohesion as grouping operations in a similar category, often selected through a flag. D matches that shared logical category. A instead describes temporal cohesion, where operations occur at the same time. Interface complexity concerns dependencies, and a loose collection of unrelated tasks does not state the defining category-based relationship.

Why each choice is right or wrong

A - Incorrect: Grouping operations because they occur at the same time is temporal cohesion.

B - Incorrect: Interface complexity concerns dependencies and does not define logical cohesion inside a module.

C - Incorrect: Loose task relatedness alone does not establish the shared operation category defining logical cohesion.

D - Correct: Grouping similar-category operations is the defining feature of logical cohesion.

Primary note proof

Study-note section SE22

> Logical cohesion groups similar-category operations, often selected by a flag; temporal cohesion groups operations done at the same time; functional cohesion focuses on one task. Splitting an unrelated three-purpose component improves modularity. If behavior is preserved, the restructuring is refactoring; the words are not mutually exclusive answers. Smaller modules can aid understanding, independent work, reuse and maintenance, but too many interfaces also create complexity.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 120 | lines 24-27

> Coherence is the strength of dependencies within a subsystem. If a subsystem contains many objects that are related to each other and perform similar tasks, its coherence is high. If a subsystem

contains a number of unrelated objects, its coherence is low. A desirable property of a subsystem decomposition is that it leads to subsystems with high coherence.

Computer Science Exit Exam · Sene 2016 · Question 11-3

Computer Science Exit Exam practice collection · Question 17

Question 129 | SM0244

Which software engineering principles are used to help reduce programming complexity?

A. Structured and unstructured

B. Object Oriented Design

C. Abstraction and Decomposition

D. Functional and Non-functional

Hint

Separate responsibilities inside a component from dependencies across boundaries. Evaluate the stated structure, change and reuse goals without assuming guaranteed benefits.

Answer C: Abstraction and Decomposition

Abstraction lets developers reason about objects at a higher level while decomposition divides a complex system into simpler subsystems; both directly control complexity.

Why each choice is right or wrong

A - Incorrect: Structured/unstructured names do not identify the paired techniques. See PDF p. 31, 118.

B - Incorrect: OO design employs these mechanisms but is the broader methodology. See PDF p. 31, 118.

C - Correct: Combines the two explicit complexity-management mechanisms. See PDF p. 31, 118.

D - Incorrect: These classify requirements, not techniques for decomposing a program. See PDF p. 31, 118.

Primary note proof

Study-note section SE22

Cohesion measures how well elements inside a module serve a related purpose; coupling measures dependency between modules. Seek high cohesion and low coupling. Shared mutable data and knowledge of another module's internal representation increase coupling. Information hiding exposes stable operations while concealing changeable decisions.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 31 | lines 19-31

1.3.1. Why an object oriented
• Object oriented systems are
o Easier to adapt to changes
o More robust
o Easier to maintain
o Promote greater design and code reuse
o Creates modules of functionality
• REASONS FOR WORKING OF OBJECT ORIENTED SYSTEMS:
Higher level of abstraction
The object-oriented approach supports abstraction at the object level. Since objects encapsulate both data (attributes) and functions (methods), they work at a higher level of abstraction. The development can proceed at the object level and ignore the rest of the system for as long as necessary. This makes designing, coding, testing, and maintaining the system much simpler.

Software Engineering module | PDF page 118 | lines 11-16

6.1.1. Subsystems and classes
In order to reduce the complexity of the application domain, we identified smaller parts called classes and organized them into packages. Similarly, to reduce the complexity of the solution domain, we decompose a system into simpler parts, called subsystems, which are made of a number of solution domain classes. In the case of complex subsystems, we recursively apply this principle and decompose a subsystem into simpler subsystems (see Figure 6.2).

Computer Science Exit Exam · Sene 2016 · Question 14-3

Computer Science Exit Exam practice collection · Question 15

Question 130 | SM0271

Which listed model organizes repeated cycles around risk assessment and can select prototyping, incremental or sequential activities as appropriate within those cycles?

A. Spiral model

B. Prototyping model

C. Classical Waterfall model

D. Iterative Waterfall model

Hint

Identify whether the scenario prioritizes delivery, learning, adaptation or risk reduction. Several processes can share individual practices, so compare their defining emphasis.

Answer A: Spiral model

Spiral development repeatedly identifies objectives, assesses and reduces risks, develops an appropriate result and plans further commitment. Its cycles can incorporate prototyping, incremental work or sequential activities according to the risks. The other listed models name particular exploratory or staged organizations rather than this risk-driven choice framework. This explains the conventional general-model reading without claiming that every process is formally a specialization of spiral.

Why each choice is right or wrong

A - Correct: Spiral selects cycle work through risk assessment.

B - Incorrect: Prototyping is one learning activity that a spiral cycle may use.

C - Incorrect: Classical waterfall is a planned sequential organization.

D - Incorrect: Iterative waterfall adds feedback without defining the risk-driven cycle.

Primary note proof

Study-note section SE03

> Classical waterfall separates planned phases with reviewed deliverables. It fits well-understood, stable requirements and familiar technology; late feedback makes changes costly. It does not make change physically impossible: real projects revisit work under control, and modified waterfall explicitly includes feedback. Rigidity offers milestone visibility but can freeze incorrect assumptions.

Study-note section SE06

> Spiral development is risk driven. Each cycle identifies objectives and alternatives, assesses and reduces important risks, develops/verifies an appropriate next result, and plans further commitment. A prototype may test a risky technology before a large investment. The amount and type of work depend on the risks.

Question 131 | SM0293

Which system requirement specification includes human-computer interface issues from the system?

A. Functional requirements of the system

B. Non-functional requirements of the system

C. Goals of implementation

D. System Testing

Hint

Distinguish observable services, measurable qualities and implementation constraints. Check scope, stakeholder meaning and the requested level of specificity.

Answer B: Non-functional requirements of the system

User-interface look/feel and user expertise are explicitly nonfunctional concerns, under user interface and human factors. Particular interaction services can still be functional; the question is read as interface quality issues.

Why each choice is right or wrong

A - Incorrect: Specific interface functions can be functional, but this is not the broad human-factor quality category. See PDF p. 78, 66.

B - Correct: Explicitly includes user interface and human factors. See PDF p. 78, 66.

C - Incorrect: Implementation goals are not the stated requirement category. See PDF p. 78, 66.

D - Incorrect: Testing is an activity, not a requirement category. See PDF p. 78, 66.

Primary note proof

Study-note section SE10

Nonfunctional requirements include quality attributes and constraints. Performance concerns response time, throughput and resource use; reliability concerns failure-free service; availability concerns being ready for use; usability concerns task success and ease of learning. Security concerns protection; compatibility concerns cooperating environments; portability concerns moving environments; maintainability/supportability concern change, diagnosis and evolution.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 78 | lines 12-30

3.3.7. Identifying Non-Functional Requirements
Nonfunctional requirements describe user-visible aspects of the system that are not directly related
to the functional behavior of the system. Nonfunctional requirements span a number of issues, from user interface look and feel to response time requirements to security issues. Nonfunctional
requirements are defined at the same time as functional requirements are, because they have as much impact on the development and cost of the system.
For example, consider a mosaic display that an air traffic controller uses to track planes. A mosaic
display system complies data from a series of radar and databases (hence the term “mosaic”) into
a summary display indicating all aircraft in a certain area, including their identification, speed, and
altitude. The number of aircraft such a system can display constrains the performance of the air traffic controller and the cost of the system. If the system can only handle a few aircraft simultaneously, the system cannot be used at busy airports. On the other hand, a system able to handle a large number of aircraft is more costly and more complex to build.
Nonfunctional requirements can be elicited by investigating the following issues.
• User interface and human factors. What kind of interface should the system provide? What is the level of expertise of the users?
• Documentation. What level of document is required? Should only user documentation be provided? Should there be technical documentation for maintainers? Should the development process be documented?

Software Engineering module | PDF page 66 | lines 14-18

3.2.2. Non-Functional and Pseudo-Requirements
Nonfunctional requirements describe user-visible aspects of the system that are not directly related with the functional behavior of the system. Nonfunctional requirements include quantitative constraints, such as response time (i.e., how fast the system reacts to user commands)
or accuracy (i.e., how precise are the system’s numerical answers). The following are the

Question 132 | SM0294

In a classical waterfall model, which phase precedes the design phase?

A. Requirements analysis and specification

B. Maintenance

C. Feasibility study

D. Coding and unit testing

Hint

Identify whether the scenario prioritizes delivery, learning, adaptation or risk reduction. Several processes can share individual practices, so compare their defining emphasis.

Answer A: Requirements analysis and specification

The sequential waterfall establishes the requirements specification before deriving the software design from the SRS.

Why each choice is right or wrong

A - Correct: The immediate input and preceding phase. See PDF p. 15, 18, 26.

B - Incorrect: Occurs after delivery and operation. See PDF p. 15, 18, 26.

C - Incorrect: A prior viability activity, not the immediate specification input to design. See PDF p. 15, 18, 26.

D - Incorrect: Implements a design after it has been produced. See PDF p. 15, 18, 26.

Primary note proof

Study-note section SE03

> Classical waterfall separates planned phases with reviewed deliverables. It fits well-understood, stable requirements and familiar technology; late feedback makes changes costly. It does not make change physically impossible: real projects revisit work under control, and modified waterfall explicitly includes feedback. Rigidity offers milestone visibility but can freeze incorrect assumptions.

Software Engineering module | PDF page 15 | lines 16-20

> non-iterative (or sequential) process in which progress is seen as flowing steadily downwards (like
> a waterfall) through the development phases. Thus the waterfall model maintains that one should
> move to a phase only when its preceding phase is reviewed and verified. That is, each phase must
> be completed before the next phase can begin. In waterfall model phases do not overlap. But

there
are various modified waterfall models, and hence, may include slight or major modifications.

Software Engineering module | PDF page 18 | lines 13-20

System and software design: The systems design process allocates the requirements to either hardware or software systems by establishing an overall system architecture.
Software design involves identifying and describing the fundamental software system abstractions
and their relationships. The goal of the design phase is to transform the requirements specified in
the SRS document into a structure that is suitable for implementation in some programming language. In technical terms, during the design phase the software architecture is derived from the
SRS document. Two distinctly different approaches are available: the traditional design approach
and the object-oriented design approach.

Software Engineering module | PDF page 26 | lines 10-17

3. Requirement's specification: Requirements specification is the activity of translating the information gathered during the analysis activity in to a document that defines a set of requirements. Two types of requirements may be included in this document. User requirements are
abstract statements of the system requirements for the customer and end-user of the system; system
requirements are a more detailed description of the functionality to be provided.
4. Requirement's validation: This activity checks the requirements for realism, consistency, and completeness. During this process, errors in the requirements document are inevitably discovered.
It must then be modified to correct these problems.

Question sources

Computer Science Exit Exam · Sene 2016 · Question 31-1

Computer Science Exit Exam practice collection · Question 19

Question 133 | SM0300

When to use the Spiral Model?

A. Where business modeling is clearly understood and in use.

B. When it is too risky to develop the overall system as one block.

C. When requirements are understood in the early stages but can change during the project's life cycle.

D. When requirements are unstable and constantly changing.

Hint

Identify whether the scenario prioritizes delivery, learning, adaptation or risk reduction. Several processes can share individual practices, so compare their defining emphasis.

Answer B: When major risks make whole-system development in one block unsafe.

A spiral cycle identifies objectives, assesses and reduces important risks, develops an appropriate result and plans further commitment. B directly supplies the risk-based reason for choosing that process. Clear business understanding, potentially changing requirements and continuously unstable requirements do not alone distinguish spiral from other staged or adaptive models. The explicit risk is the decisive feature.

Why each choice is right or wrong

A - Incorrect: Clear business modeling does not by itself create a reason for risk-driven spiral development.

B - Correct: Risk makes staged assessment and commitment preferable to building the whole system in one block.

C - Incorrect: Requirements that may change fit several processes and do not specifically identify spiral.

D - Incorrect: Unstable requirements alone do not distinguish spiral without its explicit risk-analysis need.

Primary note proof

Study-note section SE06

> Spiral development is risk driven. Each cycle identifies objectives and alternatives, assesses and reduces important risks, develops/verifies an appropriate next result, and plans further commitment. A prototype may test a risky technology before a large investment. The amount and type of work depend on the risks.

Computer Science Exit Exam · Sene 2016 · Question 32-3

Question 134 | SS096

The process that generates activities such as project schedule, cost estimations and work breakdown structures is described as:

A. Project Executing

B. Project Initiating

C. Project Closing

D. Project Planning

Hint

Distinguish the planning or organization goal from the tool or structure used to support it. Apply the stated project conditions.

Answer D: Project Planning

The project plan explicitly sets out resources, work breakdown and schedule and concerns budget; these are outputs of project planning.

Why each choice is right or wrong

A - Incorrect: Execution carries out planned tasks. See PDF p. 90, 95.

B - Incorrect: Initiation frames a project but does not best identify this full planning output set. See PDF p. 90, 95.

C - Incorrect: Closing concerns completion/acceptance, not scheduling future work. See PDF p. 90, 95.

D - Correct: Directly corresponds to the listed plan contents. See PDF p. 90, 95.

Primary note proof

Study-note section SE28

Planning is continuous: identify scope/deliverables, decompose work, estimate effort/duration/cost, assign resources, sequence dependencies and revise as evidence changes. A WBS is hierarchical and covers project scope without adding unrelated work. Tools help coordinate ownership, dependencies and progress; they do not replace judgment or automatically fix bugs.

Module passages - related reading

Software Engineering module | PDF page 90 | lines 7-24

4.2. Project Planning
• Probably the most time-consuming project management activity.
• Continuous activity from initial concept through to system delivery. Plans must be regularly revised as new information becomes available.
• Various different types of plans may be developed to support the main software project plan that is concerned with schedule and budget.
The project plan sets out:
• The resources available to the project;
• The work breakdown;
• A schedule for the work.
Project Plan Structure
• Introduction.
• Project organisation.
• Risk analysis.
• Hardware and software resource requirements.
• Work breakdown.
• Project schedule.
• Monitoring and reporting mechanisms.

Software Engineering module | PDF page 95 | lines 3-12

4.6. Scheduling, Organization and Team Structures
Project-task scheduling is an important project planning activity. It involves deciding which tasks would
be taken up when. In order to schedule the project activities, a software project manager needs to do
the following:
• Identify all the tasks needed to complete the project and Break down large tasks into small activities.
• Determine the dependency among different activities and Establish the most likely estimates for the time durations necessary to complete the activities and Allocate resources to activities.
• Plan the starting and ending dates for various activities and Determine the critical path. A critical path is the chain of activities that determines the duration of the project.

Question sources

Computer Science model exam collection · Question 3

Question 135 | SS103

Which slogan is against the agile method philosophy?

A. Working software over comprehensive documentation

B. Following a plan over responding to changes

C. Individuals and interactions over processes and tools

D. Customer collaboration over contract negotiation

Hint

Identify whether the scenario prioritizes delivery, learning, adaptation or risk reduction. Several processes can share individual practices, so compare their defining emphasis.

Answer B: Following a plan over responding to changes

Agile values working software, people interacting, customer collaboration and responsiveness to change over the respective items on the other side of each comparison. It still recognizes value in documentation, tools, contracts and plans. The reversed preference for following a plan over responding to changes conflicts with this ordering. The other three alternatives retain the Agile ordering and therefore are not slogans against its philosophy.

Why each choice is right or wrong

A - Incorrect: This preserves the Agile preference for working software while still valuing documentation.

B - Correct: This reverses Agile’s preference for responding to change over following a plan.

C - Incorrect: This preserves the preference for individuals and interactions.

D - Incorrect: This preserves the preference for customer collaboration.

Primary note proof

Study-note section SE05

> Agile favors people collaborating, useful working results, customer participation and adaptation over rigid adherence to procedures, exhaustive documents, contracts or fixed plans. The latter still have value. Agile does not mean no planning or no documentation. A user story states a small user need and value, supported by acceptance criteria; an epic groups broader work.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 13 | lines 22-27

> Sometimes, software processes are categorized as either plan-driven or agile processes. Plan-driven processes are processes where all of the process activities are planned in advance and progress is measured against this plan. In agile processes planning is incremental and it is easier to change the process to reflect changing customer requirements. There is no hard and fast rules to

follow but each approach is suitable for different types of software. Generally, you need to find a balance between plan-driven and agile processes.

Question sources

Computer Science model exam collection · Question 10

Question 136 | SS105

What would be the most likely consequence if every software stakeholder were rushing to be approved for their requirements without discussing with
other stakeholders?

A. Results in excess requirement

B. Attains the project schedule

C. Requirements become unambiguous

D. Leads to conflicting requirement

Hint

Distinguish observable services, measurable qualities and implementation constraints. Check scope, stakeholder meaning and the requested level of specificity.

Answer D: Leads to conflicting requirement

JAD brings stakeholders together to negotiate a mutually acceptable specification; without discussion, incompatible local demands can remain unresolved.

Why each choice is right or wrong

A - Incorrect: Excess scope is possible but not the most direct consequence of unnegotiated differences. See PDF p. 81, 68.

B - Incorrect: Rushing approvals does not prove the schedule is met. See PDF p. 81, 68.

C - Incorrect: Clarity is not obtained automatically by separate approvals. See PDF p. 81, 68.

D - Correct: Competing viewpoints can yield contradictions, precisely what consensus and consistency checks address. See PDF p. 81, 68.

Primary note proof

Study-note section SE11

Correct requirements reflect actual stakeholder needs. Complete requirements address the agreed scope, normal and exceptional behavior. Consistency excludes contradictions. Clarity/unambiguity gives one intended interpretation; feasibility/realism means achievable within constraints. Verifiability means objective evidence can check fulfillment. Replace “fast for most users” with a defined metric, workload and threshold.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 81 | lines 11-21

3.4.2. Negotiating specifications with clients: Joint Application Design
Joint Application Design (JAD) is effectiveness lies in that the requirements elicitation work is done in one single workshop session in which all stakeholders participate. Users, clients, developers, and a trained session leader sit together in one room to present their viewpoint, listen
to other viewpoints, negotiate, and agree on a mutually acceptable solution. The outcome of the workshop, the final JAD document, is a complete system specification document that includes definitions of data elements, work flows, and interface screens. Because the final document is jointly developed by the stakeholders (that is, the participants who not only have an interest in the
success of the project, but also can make substantial decisions) the final JAD document represents
an agreement between users, clients, and developers, and thus minimizes requirements changes later in the development process.

Software Engineering module | PDF page 68 | lines 18-26

system specification. Requirement validation involves checking if the specification is correct, complete, consistent, unambiguous, and realistic. A specification is correct if it represents the client's view of the system (i.e., everything in the requirements model accurately represents an aspect of the system). It is complete if all possible scenarios through the system are described, including exceptional behavior (i.e., all aspects of the system are represented in the requirements
model). The system specification is consistent if it does not contradict itself. The system specification is unambiguous if exactly one system is defined (i.e., it is not possible to interpret the specification two or more different ways). Finally, it is realistic if the system can be implemented within constraints. These properties are illustrated with UML instance diagrams in

Computer Science model exam collection · Question 12

Question 137 | SS113

If the estimate for total discounted benefits for a project is Birr 120,000 and total discounted cost is Birr 100,000, what is the estimated return on
investment (ROI) percentage?

A. 30%

B. 12%

C. 10%

D. 20%

Hint

Write out the supplied quantities and dependency constraints. Compute and compare values under the stated metric, finish condition and assumptions.

Answer D: 20%.

The benefits and costs are already discounted to a common date, so use SE31 directly: ROI=(120000−100000)/100000×100%. Net benefit is Birr 20000, and dividing by Birr 100000 gives 0.20, or 20%. Dividing total benefits by costs would report a benefit-cost ratio, not the net return percentage requested.

Why each choice is right or wrong

A - Incorrect: Thirty percent does not follow from the given net benefit and cost.

B - Incorrect: Twelve percent is not 20000 divided by 100000 as a percentage.

C - Incorrect: Ten percent understates the calculated net return of twenty percent.

D - Correct: Net benefit is Birr 20000, which is 20% of the Birr 100000 cost.

Primary note proof

Study-note section SE31

> With benefits and costs already discounted to a common date, ROI=(benefits-costs)/costs*100%. Birr120000 benefits and Birr100000 costs give 20%, not 120%. Identify project risks to resources/schedule, product risks to quality, and business risks to the organization. Analyze likelihood and impact, plan responses and monitor.

Question sources

Computer Science model exam collection · Question 20

Question 138 | SS114

In a closed layered architecture with A,B,C,D from top to bottom, a pair (X,Y) means X directly calls Y. Calls may go only to the immediately lower layer. Which pair obeys this policy?

A. (A,C)

B. (D,A)

C. (A,B)

D. (C,B)

Hint

Separate responsibilities inside a component from dependencies across boundaries. Evaluate the stated structure, change and reuse goals without assuming guaranteed benefits.

Answer C: (A,B)

Closed layering permits a layer to call only the immediately lower layer. A→B follows that adjacency and direction, so C is valid. A→C skips B and violates the closed policy even though it would be possible in a suitably open architecture. D→A and C→B point upward, which the stipulated dependency policy also forbids. The ordered pair is interpreted as caller then callee.

Why each choice is right or wrong

A - Incorrect: A→C skips B.

B - Incorrect: D→A points upward.

C - Correct: A→B calls the immediately lower layer.

D - Incorrect: C→B points upward.

Primary note proof

Study-note section SE23

A layer is a logical abstraction level; a tier is a deployment separation. A closed layered architecture permits calls only to the immediately lower layer; an open one permits approved skipping. For top-to-bottom A,B,C,D, A→B obeys closed layering, A→C skips, and lower-to-upper calls violate the simple dependency rule unless explicitly mediated by a defined mechanism.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 121 | lines 6-15

6.1.4. Software architecture
As the complexity of systems increases, the specification of the system decomposition is critical. It is difficult to modify or correct a weak decomposition once development has started, as most subsystem interfaces have to change. In recognition of the importance of this problem, the concept
of software architecture has emerged. A software architecture includes the system decomposition, the global control flow, error-handling policies and inter subsystem communication protocols.
In this section, we describe a few sample architectures that can be used for different systems. This
is by no means a systematic or thorough exposition of the subject. Rather, we aim to provide a few
representative examples and refer the reader to the literature for more details.

Question sources

Computer Science model exam collection · Question 21

Question 139 | SS124

Which listed roles should document a fault if they discover it during development? Select all that apply.

A. Tester

B. Requirement engineer

C. Developer

D. Scrum master

Hint

Separate testing scope, technique and purpose. Use the stated workload, observable result or coverage target rather than a universal ranking.

Answer A, B, C, D: Tester; Requirement engineer; Developer; Scrum master

Anyone discovering a fault should record it with enough evidence to reproduce and assess it. Testers often coordinate reporting, but requirements engineers, developers and Scrum masters should also document faults they discover. The report should identify the relevant environment, steps and expected versus actual behavior. Therefore all four roles meet the stated discoverer-based responsibility rather than only the dedicated tester.

Why each choice is right or wrong

A - Correct: A tester discovering a fault should record it.

B - Correct: A requirements engineer discovering a fault should record it.

C - Correct: A developer discovering a fault should record it.

D - Correct: A Scrum master discovering a fault should record it.

Primary note proof

Study-note section SE39

> Plan objectives, scope, resources, schedule, risks and entry/exit criteria. Analyze the test basis for testable features and defects; design cases/expected results; implement data, scripts and environment; execute and compare; report defects; evaluate completion. Analysis asks what to test and assesses testability; design asks how. Monitoring/control run across these activities.

Study-note section SE39

> Anyone finding a fault should record it; testers often coordinate reporting, but it is not their exclusive permission.

Module passages - related reading

Software Engineering module | PDF page 142 | lines 24-33

> A review is the manual inspection of parts or all aspects of the system without actually executing the system. There are two types of reviews: walkthrough and inspection. In a code walkthrough, the developer informally presents the API, the code, and associated documentation of the component to the review team. The review team makes comments on the mapping of the analysis
> and object design to the code using use cases and scenarios from the analysis phase. An inspection
> is similar to a walkthrough, but the presentation of the unit is formal. In fact, in a code inspection,
> the developer is not allowed to present the artifacts (models, code, and documentation). This is done by the review team, which is responsible for checking the interface and code of the component against the requirements. It also checks the algorithms for efficiency with respect to the nonfunctional requirements. Finally, it checks comments about the code and compares them

Software Engineering module | PDF page 140 | lines 27-32

7.1 OVERVIEW OF SOFTWARE QUALITY ASSURANCE
We define testing as the systematic attempt to find errors in a planned way in the implemented software. Contrast this definition with another commonly used definition that says that “testing is
the process of demonstrating that errors are not present.” The distinction between these two definitions is important. Our definition does not mean we simply demonstrate that the program does what it is intended to do. The explicit goal of testing is to demonstrate the presence of faults.

Question sources

Computer Science model exam collection · Question 31

Question 140 | SS127

Select the one that is not correct related to generalization in system modeling.

A. Ingeneralization, the attributes and operations associated with higher-level classes are also associated with the lower-level classes

B. Facilitate easy modification of data

C. The higher-level classes are more specific than the lower-level classes by adding specific attributes and operations

D. Common information will be maintained in one place

Hint

Match the information to be represented with each model’s purpose. Read relationship direction, boundary and ownership conditions before classifying it.

Answer C: The higher-level classes are more specific than the lower-level classes by adding specific attributes and operations

Generalization puts common features in more general superclasses; subclasses add or override details and are more specialized. C reverses the direction.

Why each choice is right or wrong

A - Incorrect: Inherited attributes and methods are available on subclasses. See PDF p. 104.

B - Incorrect: Common definitions can reduce duplicated modification; the wording is broad. See PDF p. 104.

C - Correct: Higher-level classes are more general, not more specific. See PDF p. 104.

D - Incorrect: Consolidating common features in a superclass removes redundancy. See PDF p. 104.

Primary note proof

Study-note section SE18

Association connects related instances. A dashed dependency arrow means a client uses a supplier. Generalization uses a solid line and hollow triangle pointing to the superclass/general

element. Shared aggregation uses a hollow diamond at the whole end and weak whole-part meaning; it does not by itself define a detailed lifecycle policy.

Study-note section SE-S02

Generalization places common concepts in a more general superclass and specialized concepts in subclasses. Available inherited attributes and operations are shared by subclasses, which may extend or override behavior. Defining common features once can reduce duplicated maintenance. The top of the hierarchy is more general, not more specialized.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 104 | lines 6-17

5.1.4. Generalization
Generalization enables us to organize concepts in to hierarchies. There may be any number of intermediate levels in between, covering more-or-less generalized concepts (e.g., Low Priority Incident, Emergency, Disaster). Such hierarchies allow us to refer to many concepts precisely. When
we use the term Incident, we mean all instances of all types of Incidents. When we use the term Emergency, we only refer to an Incident that requires an immediate response. This view of generalization stems from modeling.
In an object-oriented programming language, inheritance is a reusability technique. If a class Child
inherits from a class Parent, all the attributes and methods available on Parent are automatically available on Child. The class Child may add additional methods or override inherited methods, thus refining the class Parent. As in the case of generalization, the class at the top of the hierarchy
tends to be the most general one, whereas the leaves tend to be the most specialized.

Question sources

Computer Science model exam collection · Question 34

Question 141 | SS135

Which statement accurately describes the main evidential goal of software testing within quality assurance?

A. To achieve project timelines and deadlines.

B. To monitor the entire SDLC.

C. To generate software requirement and design documentation.

D. To assess conformance to specified requirements, reveal defects and increase confidence through evidence.

Hint

Distinguish process assurance from product evaluation, and compare specified obligations with actual stakeholder needs.

Answer D: To assess conformance to specified requirements, reveal defects and increase confidence through evidence.

Testing evaluates behavior against required results, revealing failures and increasing confidence in conformance. It does not generally guarantee correctness over every possible input or environment. Meeting schedules and monitoring the whole lifecycle are broader management or assurance activities, while requirements and design documentation usually form part of the test basis. Option D states the supported evidential purpose without promising certainty.

Why each choice is right or wrong

A - Incorrect: Timelines are a project-management goal rather than the test evidence goal.

B - Incorrect: Whole-lifecycle monitoring is broader assurance/control work.

C - Incorrect: Requirements and design documents are typically inputs to testing.

D - Correct: Tests assess conformance, reveal defects and increase confidence.

Primary note proof

Study-note section SE34

> Quality assurance establishes and checks processes/standards; quality control evaluates work products. An SQA plan identifies standards, responsibilities, evaluations, reviews, audits and assurance records. Quality of conformance means following the design/specification; a product can conform to a poor specification. Verification asks whether specified obligations are implemented correctly; validation asks whether the product meets intended stakeholder needs. Both can use reviews, analysis or execution, so “human-only versus computer-only” is false.

Study-note section SE34

> Tests increase confidence and reveal defects but cannot generally guarantee correctness over every possible input.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 140 | lines 27-32

> 7.1 OVERVIEW OF SOFTWARE QUALITY ASSURANCE
> We define testing as the systematic attempt to find errors in a planned way in the implemented software. Contrast this definition with another commonly used definition that says that “testing is
> the process of demonstrating that errors are not present.” The distinction between these two definitions is important. Our definition does not mean we simply demonstrate that the program does what it is intended to do. The explicit goal of testing is to demonstrate the presence of faults.

Software Engineering module | PDF page 140 | lines 11-18

Reliability is a measure of success with which the observed behavior of a system conforms to the specification of its behavior. Software reliability is the probability that a software system will not cause the failure of the system for a specified time under specified conditions. Failure is any deviation of the observed behavior from the specified behavior. An error means the system is in a state such that further processing by the system will lead to a failure, which causes the system to
deviate from its intended behavior. A fault, also called defect or bug, is the mechanical or algorithmic cause of an error. The goal of testing is to maximize the number of discovered faults, which then allows developers to correct them and increase the reliability of the system.

Question sources

Computer Science model exam collection · Question 42

Question 142 | SS137

What component hides the distinction or boundaries between various microservices from end-client application?

A. Alayered system

B. API gateway

C. API logging

D. API proxy

Hint

Separate responsibilities inside a component from dependencies across boundaries. Evaluate the stated structure, change and reuse goals without assuming guaranteed benefits.

Answer B: API gateway.

SE24 defines an API gateway as one entry point that routes or combines service calls and hides service boundaries from clients. That directly matches the stated role. Logging records activity and a layered system describes broader organization; a generic proxy label alone does not establish the multi-service routing and composition role given in the note.

Why each choice is right or wrong

A - Incorrect: Layering organizes abstraction levels rather than naming this single microservice-facing entry component.

B - Correct: An API gateway hides service boundaries behind a unified entry point and routes or combines requests.

C - Incorrect: API logging records activity rather than routing clients across hidden service boundaries.

D - Incorrect: A generic proxy forwards requests; the note names the broader multi-service entry-point role an API gateway.

Primary note proof

Study-note section SE24

An API gateway presents one entry point and routes/combines calls to services, hiding service boundaries from clients. It can centralize policies but also become a bottleneck. A component diagram shows components/interfaces/dependencies; a deployment diagram places software artifacts on nodes. Choose the style for the required interactions and qualities rather than selecting a universally best architecture.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 119 | lines 13-25

6.1.2. Services and subsystem interfaces
A subsystem is characterized by the services it provides to other subsystems. A service is a set of related operations that share a common purpose. A subsystem providing a notification service, for
example, defines operations to send notices, look up notification channels, and subscribe and unsubscribe to a channel.
The set of operations of a subsystem that are available to other subsystems form the subsystem interface. The subsystem interface, also referred to as the application programmer interface (API),
includes the name of the operations, their parameters, their types, and their return values. System
design focuses on defining the services provided by each subsystem that is, enumerating the operations, their parameters, and their high-level behavior. Object design will focus on defining the subsystem interfaces, that is, the type of the parameters and the return value of each operation.
The definition of a subsystem in terms of the services it provides helps us focus on its interface as opposed to its implementation. A good subsystem interface should provide as little information

Software Engineering module | PDF page 124 | lines 8-16

Client/server architecture
In the client/server architecture (Figure 6.9), a subsystem, the server, provides servicesto instances
of other subsystems called the clients, which are responsible for interacting with theuser. The request for a service is usually done via a remote procedure call mechanism or acommon object broker (e.g., CORBA or Java RMI). Control flow in the clients and the servers isindependent except for synchronization to manage requests or to receive results.
Figure 6.9 Client/server architecture (UML class diagram).
Clients request services from one or more servers. The server has no knowledge of the client. The client/server architecture is a generalization of the repository architecture.

Question sources

Computer Science model exam collection · Question 44

Question 143 | SS139

Which question is outside the architectural abstraction level and instead asks for every source-level execution detail?

A. Which architectural organization is best for delivering the functional requirements?

B. How the system will be distributed across a number of cores or processors

C. Which variable is assigned at every individual source-code execution step?

D. Which architectural patterns or styles to use

Hint

Separate responsibilities inside a component from dependencies across boundaries. Evaluate the stated structure, change and reuse goals without assuming guaranteed benefits.

Answer C: Which variable is assigned at every individual source-code execution step?

Architecture addresses major organization, responsibilities, allocation and style decisions. Selecting an arrangement for required behavior, mapping work to processors and choosing patterns are therefore valid architectural concerns. Enumerating every source-level assignment on every execution step is implementation-level tracing, beyond the abstraction of architecture documentation. Option C supplies that genuine exception while preserving the question's comparison of architectural and detailed concerns.

Why each choice is right or wrong

A - Incorrect: Organization supporting required behavior is architectural.

B - Incorrect: Processor allocation is an architectural concern.

C - Correct: Every source-level execution step exceeds the architectural abstraction.

D - Incorrect: Style and pattern selection is architectural.

Primary note proof

Study-note section SE23

> A structure is the elements/relations themselves; a view represents selected aspects. Module structures show code organization, component-and-connector structures runtime interaction, and allocation structures map software to hardware, teams or environment. Processes/threads belong in concurrency views. Evaluate architectures against quality attributes and scenarios; processor allocation, decomposition and style selection can all be architectural concerns.

Study-note section SE21

> System design turns the analysis model into architecture: design goals, subsystem responsibilities, dependencies, hardware mapping, data management, access control, control flow and startup/shutdown/error policies. Detail/object design refines APIs, parameter/return types, exceptions, component choices and algorithms. A subsystem is a manageable logical collection with services and an interface; it need not be a physical replaceable artifact.

Study-note section SE21

Architecture documentation supports communication and records major decisions, not every source-level execution step.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 116 | lines 16-29

The analysis model describes the system completely from the actors' point of view and serves as the basis of communication between the client and the developers. The analysis model, however, does not contain information about the internal structure of the system, its hardware configuration,
or, more generally, how the system should be realized. System design is the first step in this direction. System design results in the following products:
• List of design goals, describing the qualities of the system that developers should optimize
• Software architecture, describing the subsystem decomposition in terms of subsystem responsibilities, dependencies among subsystems, subsystem mapping to hardware, and major policy decisions such as control flow, access control, and data storage.
The design goals are derived from the nonfunctional requirements. Design goals guide the decisions to be made by the developers especially when trade-offs are needed. The subsystem decomposition constitutes the bulk of system design. Developers divide the system into manageable pieces to deal with complexity: Each subsystem is assigned to a team and realized independently. In order for this to be possible, though, developers need to address system-wide

Software Engineering module | PDF page 121 | lines 6-15

6.1.4. Software architecture
As the complexity of systems increases, the specification of the system decomposition is critical. It is difficult to modify or correct a weak decomposition once development has started, as most subsystem interfaces have to change. In recognition of the importance of this problem, the concept
of software architecture has emerged. A software architecture includes the system decomposition, the global control flow, error-handling policies and inter subsystem communication protocols.
In this section, we describe a few sample architectures that can be used for different systems. This
is by no means a systematic or thorough exposition of the subject. Rather, we aim to provide a few
representative examples and refer the reader to the literature for more details.

Question sources

Computer Science model exam collection · Question 46

Question 144 | SS144

Select the one that is not related with the purpose of properly documenting software architectures

A. to Know how the system is organized and interoperate

B. For Stakeholder communication

C. For critical system design decisions

D. To easily figure out the source code flow

Hint

Separate responsibilities inside a component from dependencies across boundaries. Evaluate the stated structure, change and reuse goals without assuming guaranteed benefits.

Answer D: To easily figure out the source code flow

The SDD documents goals, subsystem organization, mapping and interfaces to support teams and architecture decisions. Detailed source-code control flow is a lower-level implementation concern than the document's architectural control-flow mechanisms.

Why each choice is right or wrong

A - Incorrect: Subsystem decomposition and interfaces expose organization/interoperation. See PDF p. 130.

B - Incorrect: Defines interfaces between development teams and supports communication. See PDF p. 130.

C - Incorrect: Serves as reference when architecture-level decisions are revisited. See PDF p. 130.

D - Correct: Detailed source-level flow is not the purpose of an architecture description; global control mechanisms may still be documented. See PDF p. 130.

Primary note proof

Study-note section SE21

> System design turns the analysis model into architecture: design goals, subsystem responsibilities, dependencies, hardware mapping, data management, access control, control flow and startup/shutdown/error policies. Detail/object design refines APIs, parameter/return types, exceptions, component choices and algorithms. A subsystem is a manageable logical collection with services and an interface; it need not be a physical replaceable artifact.

Software Engineering module | PDF page 130 | lines 3-11

> 6.3. DOCUMENTING SYSTEM DESIGN
> System design is documented in the System Design Document (SDD). It describes design goals set by the project, the subsystem decomposition (with UML class diagrams), the hardware/software mapping (with UML deployment diagrams), the data management, the access

control, control flow mechanisms, and boundary conditions. The SDD is used to define interfaces between teams of developers and as reference when architecture-level decisions need to be revisited. The audience for the SDD includes the project management, the system architects (i.e., the developers who participate in the system design), and the developers who design and implement each subsystem. The following is an example template for a SDD:

Question sources

Computer Science model exam collection · Question 51

Question 145 | SS147

Given the following fragment of code, how many tests are required for 100% decision coverage?
if width > length
then biggest_dimension = width
if height > width
then biggest_dimension = height
end_if
else biggest_dimension = length
if height > length
then biggest_dimension = height
end_if
end_if

A. ona. 4

B. 6

C. Ole 2

D. 3

Hint

Separate testing scope, technique and purpose. Use the stated workload, observable result or coverage target rather than a universal ranking.

Answer A: Four tests for 100% decision coverage.

There are three decisions: width>length and one separate height comparison inside each outer branch. Covering both inner outcomes requires two tests with outer true and two with outer false. For example (w,l,h)=(3,2,4),(3,2,1),(2,3,4),(2,3,1) covers all outcomes. One execution cannot visit both outer branches, so two or three tests cannot suffice; six are unnecessary.

Why each choice is right or wrong

A - Correct: Four tests cover true/false of the inner decision on each of the two outer branches.

B - Incorrect: Six can cover the decisions, but four suffice; it is not the required minimum.

C - Incorrect: Two cover the outer decision but cannot cover both outcomes of both separate inner decisions.

D - Incorrect: Three leave at least one inner decision outcome uncovered because each outer branch needs two tests.

Primary note proof

Study-note section SE38

> Statement coverage is the number of distinct executable statements exercised divided by the total executable statements in the declared test scope. Unreachable statements can prevent100%; any justified exclusions must be documented with the adjusted scope. Decision coverage counts decision outcomes; branch coverage counts control-flow edges, including unconditional edges under the stated convention. Testing both true and false of each decision may need more than two overall test cases when branches nest. Coverage is evidence of exercised structure, not proof of all behavior.

Study-note section SE38

> In the width/length/height program, the outer if has separate inner decisions in each branch. Need outer true with inner true and false, and outer false with its inner true and false: four tests, for example (w,l,h)=(3,2,4),(3,2,1),(2,3,4),(2,3,1). One run cannot exercise both outer branches. All paths may be infeasible or infinite with loops; specify the chosen coverage target.

Software Engineering module | PDF page 149 | lines 24-29

> Path testing
> Path testing is a white box testing technique that identifies faults in the implementation of the component. The assumption behind path testing is that, by exercising all possible paths through the code at least once, most faults will trigger failures. The identification of paths requires knowledge of the source code and data structures.
> The starting point for path testing is the flow graph. A flow graph consists of nodes representing

Software Engineering module | PDF page 147 | lines 3-8

> • A test stub is a partial implementation of components on which the tested component depends. A test driver is a partial implementation of a component that depends on the tested component. Test stubs and drivers enable components to be isolated from the rest of the system for testing.
> • A correction is a change to a component. The purpose of a correction is to repair a fault. Note that a correction can introduce new faults.

Question sources

Computer Science model exam collection · Question 54

Question 146 | SS148

Using classical up-front waterfall planning, usable incremental additions and timeboxed adaptive Agile, which lifecycle statements are NOT true? Select all that apply.

A. Ina waterfall life cycle, the project scope, time, and cost are determined in the early phases of the life cycle

B. Inagile life cycle the project scope is generally determined early in the project life cycle, but time and cost estimates are routinely modified

C. Inanincremental life cycle, the deliverable is produced through a series of iterations that successively add functionality within a predetermined time frame

D. Inagile life cycles, the project scope cannot be outlined and agreed before the start of iteration.

Hint

Identify whether the scenario prioritizes delivery, learning, adaptation or risk reduction. Several processes can share individual practices, so compare their defining emphasis.

Answer B, D: Inagile life cycle the project scope is generally determined early in the project life cycle, but time and cost estimates are routinely modified; Inagile life cycles, the project scope cannot be outlined and agreed before the start of iteration.

Classical waterfall establishes planned baselines early, and incremental work adds functionality in successive deliveries. Agile instead adapts content while its timeboxes tend to remain fixed, so B misstates the general organizing pattern. D is also false because Agile permits outlining and agreeing scope before an iteration; planning continues as evidence changes. Adaptation does not mean that scope discussion or early agreement is prohibited.

Why each choice is right or wrong

A - Incorrect: Early planned baselines fit classical waterfall.

B - Correct: The claim reverses the timeboxed/adaptive-content characterization.

C - Incorrect: Successive additions of usable functionality fit incremental delivery.

D - Correct: Agile permits scope discussion and agreement before an iteration.

Primary note proof

Study-note section SE05

> Scrum uses timeboxed Sprints of at most one month, with a Sprint Goal, selected work and a usable Increment meeting a Definition of Done. Scope is discussed before and during planning; it is not forbidden to agree scope. Timeboxes tend to stay fixed while content is adapted without endangering the goal. Agile can be combined with required assurance/documentation; safety-critical context alone cannot prove it is unsuitable.

Software Engineering module | PDF page 13 | lines 22-27

> Sometimes, software processes are categorized as either plan-driven or agile processes. Plan-driven processes are processes where all of the process activities are planned in advance and progress is measured against this plan. In agile processes planning is incremental and it is easier to change the process to reflect changing customer requirements. There is no hard and fast rules to
> follow but each approach is suitable for different types of software. Generally, you need to find a balance between plan-driven and agile processes.

Software Engineering module | PDF page 22 | lines 8-12

> This model delivers software in small but usable pieces, called —increments. In general, each increment builds on those that have already been delivered. The model is iterative in nature and focuses on the delivery of an operational product with each increment. Early increments are stripped down versions of the final product, but they do provide capability that serves the user and
> also provide a platform for evaluation by the user.

Software Engineering module | PDF page 20 | lines 18-22

> the development plan. Its major problem is the inflexible partitioning of the project into distinct stages. Commitments must be made at an early stage in the process, which makes it difficult to respond to changing customer requirements.
> In principle, the waterfall model should only be used when the requirements are well understood
> and unlikely to change radically during system development. However, the waterfall model

Question sources

Computer Science model exam collection · Question 55

Question 147 | SS151

Which design pattern is used to restore the state of an object to its previous state?

A. Iterator pattern

B. Observer pattern

C. Momento pattern

D. Visitor pattern

Hint

Separate responsibilities inside a component from dependencies across boundaries. Evaluate the stated structure, change and reuse goals without assuming guaranteed benefits.

Answer C: Memento, printed as Momento.

SE27 explicitly identifies Memento as storing and restoring state while hiding representation, and notes that Momento in this question bank is a spelling error for Memento. That makes C the intended pattern name. Iterator traverses a collection and Observer notifies subscribers; neither supplies the state-snapshot restoration responsibility asked for here.

Why each choice is right or wrong

A - Incorrect: Iterator traverses elements rather than storing a restorable snapshot of object state.

B - Incorrect: Observer notifies subscribers about changes rather than restoring an earlier object state.

C - Correct: Momento refers here to Memento, the state capture-and-restoration pattern.

D - Incorrect: Visitor is not the state-snapshot restoration pattern; the note assigns that role to Memento.

Primary note proof

Study-note section SE27

> Factory Method lets subclasses choose a concrete product through a creation operation, reducing coupling to concrete constructors. A simple factory centralizes creation but is not identical to Factory Method. Singleton controls access to one instance; Observer notifies subscribers; Memento stores/restores state while hiding representation; Iterator traverses; Decorator adds behavior through wrapping. The pattern name is Memento, not Momento.

Study-note section SE27

> Variability can use selectable features, omission/inclusion and extension points; overloading supplies alternate signatures in code but is not every variability mechanism. Testability improves with controllable inputs, observable outputs, replaceable dependencies and limited structural complexity. A sandbox can isolate execution. Assess each design claim independently before evaluating a combined statement.

Software Engineering module | PDF page 104 | lines 6-17

> 5.1.4. Generalization
> Generalization enables us to organize concepts in to hierarchies. There may be any number of intermediate levels in between, covering more-or-less generalized concepts (e.g., Low Priority Incident, Emergency, Disaster). Such hierarchies allow us to refer to many concepts precisely. When
> we use the term Incident, we mean all instances of all types of Incidents. When we use the term Emergency, we only refer to an Incident that requires an immediate response. This view of generalization stems from modeling.
> In an object-oriented programming language, inheritance is a reusability technique. If a class Child
> inherits from a class Parent, all the attributes and methods available on Parent are automatically available on Child. The class Child may add additional methods or override inherited methods, thus refining the class Parent. As in the case of generalization, the class at the top of the hierarchy
> tends to be the most general one, whereas the leaves tend to be the most specialized.

Software Engineering module | PDF page 121 | lines 6-15

6.1.4. Software architecture
As the complexity of systems increases, the specification of the system decomposition is critical. It is difficult to modify or correct a weak decomposition once development has started, as most subsystem interfaces have to change. In recognition of the importance of this problem, the concept
of software architecture has emerged. A software architecture includes the system decomposition, the global control flow, error-handling policies and inter subsystem communication protocols.
In this section, we describe a few sample architectures that can be used for different systems. This
is by no means a systematic or thorough exposition of the subject. Rather, we aim to provide a few
representative examples and refer the reader to the literature for more details.

Question sources

Computer Science model exam collection · Question 58

Question 148 | SS153

Which of the following shows the five stages in Tuckman's model of team development, in sequential order?

A. forming, storming, performing, norming, and adjourning

B. norming, forming, storming, performing, and adjourning

C. storming, forming, norming, performing, and adjourning

D. forming, storming, norming, performing, and adjourning

Hint

Distinguish the planning or organization goal from the tool or structure used to support it. Apply the stated project conditions.

Answer D: Forming → storming → norming → performing → adjourning.

SE32 lists orientation first, then conflict, development of norms, effective performance and closure. Their stage names are forming, storming, norming, performing and adjourning. D preserves that order. The other alternatives either put performance before norms or move orientation after later stages, contradicting the taught sequence.

Why each choice is right or wrong

A - Incorrect: It places performing before norming, reversing the stated development sequence.

B - Incorrect: It starts with norming before the initial forming and storming stages.

C - Incorrect: It places storming before the initial forming stage.

D - Correct: It matches the taught progression from orientation through conflict, norms, performance and closure.

Primary note proof

Study-note section SE32

Functional organizations group specialists by discipline; project organizations group people around projects. Functional specialization helps staffing and knowledge continuity but may create handoff barriers. Democratic teams share decisions; chief-programmer teams centralize technical coordination. These are different classification dimensions. Tuckman's sequence is forming→storming→norming→performing→adjourning: orientation, conflict, norms, effective work and closure.

Team Structure
• Team structure addresses the issue of organization of the individual project teams. There are some possible ways in which the individual project teams can be organized.
• Problems of different complexities and sizes often require different team structures for chief solution.
• The most common types of team structure are:
· Chief Programmer Team
· Democratic Team
· Mixed Control Team Organization

Question sources

Computer Science model exam collection · Question 60

Question 149 | SS154

Which one of the following is not among the purposes of software testing?

A. Requesting more design and implementation time

B. Identifying shortcomings

C. Improving product acceptance

D. Enhancing reliability

Hint

Distinguish process assurance from product evaluation, and compare specified obligations with actual stakeholder needs.

Answer A: Requesting more design and implementation time

Testing detects faults, supports client acceptance and enables corrections that improve reliability. Requesting more implementation time is a possible project consequence, not a testing purpose.

Why each choice is right or wrong

A - Correct: A request for time is not the fault-detection or confidence purpose. See PDF p. 140, 140, 145.

B - Incorrect: Identifying faults/shortcomings is the explicit goal. See PDF p. 140, 140, 145.

C - Incorrect: Client acceptance is checked through acceptance tests. See PDF p. 140, 140, 145.

D - Incorrect: Fault discovery permits corrections and increased reliability. See PDF p. 140, 140, 145.

Primary note proof

Study-note section SE34

> A fault/defect is an underlying problem; an error may be an incorrect internal state; a failure is an externally observed departure from required service. Reliability is a product quality attribute; low cost or short development time are project outcomes. Tests increase confidence and reveal defects but cannot generally guarantee correctness over every possible input.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 140 | lines 27-32

> 7.1 OVERVIEW OF SOFTWARE QUALITY ASSURANCE
> We define testing as the systematic attempt to find errors in a planned way in the implemented software. Contrast this definition with another commonly used definition that says that “testing is
> the process of demonstrating that errors are not present.” The distinction between these two definitions is important. Our definition does not mean we simply demonstrate that the program does what it is intended to do. The explicit goal of testing is to demonstrate the presence of faults.

Software Engineering module | PDF page 140 | lines 11-18

> Reliability is a measure of success with which the observed behavior of a system conforms to the specification of its behavior. Software reliability is the probability that a software system will not cause the failure of the system for a specified time under specified conditions. Failure is any deviation of the observed behavior from the specified behavior. An error means the system is in a state such that further processing by the system will lead to a failure, which causes the system to
> deviate from its intended behavior. A fault, also called defect or bug, is the mechanical or algorithmic cause of an error. The goal of testing is to maximize the number of discovered faults, which then allows developers to correct them and increase the reliability of the system.

Software Engineering module | PDF page 145 | lines 3-5

> o Acceptance testing and installation testing check the requirements against the
> project agreement and should be done by the client, if necessary with support by
> the developers.

Question sources

Computer Science model exam collection · Question 61

Question 150 | SS155

During which listed activity should the test plan define configuration-management procedures alongside objectives, resources and schedule, before those procedures are applied during execution?

A. During test execution

B. During test planning

C. During test closing

D. During test initiation

Hint

Separate testing scope, technique and purpose. Use the stated workload, observable result or coverage target rather than a universal ranking.

Answer B: During test planning

Test planning specifies intended work, objectives, resources and schedule; configuration-management procedures should be defined early as part of that preparation. They then apply throughout testing to preserve reproducible builds, data and environments. Execution and closing use those procedures rather than being their exclusive establishment point. Initiation may set context, but the question specifically asks for the activity that defines them in the test plan.

Why each choice is right or wrong

A - Incorrect: Execution applies the planned procedures to tested versions.

B - Correct: Test planning defines procedures with the other planned work.

C - Incorrect: Closing preserves final artifacts under established control.

D - Incorrect: Initiation sets context rather than the specified test-plan definition activity.

Primary note proof

Study-note section SE33

> Configuration management identifies controlled items, versions/baselines, change procedures, status and audits. Items may include source code, requirements, manuals, test plans, environments and build configurations. A team’s ordinary browser is usually a tool rather than product CI, but a controlled test-browser version may be an environment CI.

Study-note section SE39

> A test plan describes intended work; incident/defect reports are normally execution outputs. A defect report should identify build/environment, steps, expected versus actual behavior, evidence and severity. Anyone finding a fault should record it; testers often coordinate

reporting, but it is not their exclusive permission. Configuration control makes the tested version reproducible.

Study-note section SE33

Plan test configuration management early and apply it throughout testing, not at just one exclusive phase.

Study-note section SE39

Analysis asks what to test and assesses testability; design asks how.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 142 | lines 5-10

Configuration management avoids faults caused by undisciplined change in the system models. For example, it is a common mistake to a change a subsystem interface without notifying all developers of calling components. Configuration management can make sure that, if analysis models and code are becoming inconsistent with one another, analysts and implementor are notified. The assumption behind configuration management is that the system contains many less
faults if change is controlled.

Software Engineering module | PDF page 90 | lines 7-24

4.2. Project Planning
• Probably the most time-consuming project management activity.
• Continuous activity from initial concept through to system delivery. Plans must be regularly revised as new information becomes available.
• Various different types of plans may be developed to support the main software project plan that is concerned with schedule and budget.
The project plan sets out:
• The resources available to the project;
• The work breakdown;
• A schedule for the work.
Project Plan Structure
• Introduction.
• Project organisation.
• Risk analysis.
• Hardware and software resource requirements.
• Work breakdown.
• Project schedule.
• Monitoring and reporting mechanisms.

Question sources

Computer Science model exam collection · Question 62

Question 151 | SS156

"The system architecture should be designed using fine-grain, self-contained components. Producers of data should be separated from consumers
and shared data structures should be avoided". For which requirement this architecture description applies?

A. Performance

B. Availability

C. Maintainability

D. Security

Hint

Separate responsibilities inside a component from dependencies across boundaries. Evaluate the stated structure, change and reuse goals without assuming guaranteed benefits.

Answer C: Maintainability

Independent self-contained subsystems and avoiding shared attribute data reduce coupling, limiting the impact of future changes. That directly serves maintainability.

Why each choice is right or wrong

A - Incorrect: Fine-grained separation can carry overhead and is not primarily the stated speed optimization. See PDF p. 120, 118.

B - Incorrect: Availability requires continuity/failure treatment beyond component separation alone. See PDF p. 120, 118.

C - Correct: Matches minimizing change impact through low coupling. See PDF p. 120, 118.

D - Incorrect: Security needs explicit access-control policy; independence alone does not establish it. See PDF p. 120, 118.

Primary note proof

Study-note section SE43

> Choose designs by their effect on stated goals. Fine-grained self-contained components, separation of producers/consumers and limited shared mutable data often improve maintainability. Trade-offs remain: interfaces can add latency, isolation can complicate transactions, and global state can simplify one operation while coupling many others. Prefer measurable quality scenarios to counting components alone.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 120 | lines 6-12

> 6.1.3. Coupling and coherence
> Coupling is the strength of dependencies between two subsystems. If two subsystems are loosely coupled, they are relatively independent, and thus, modifications to one of the subsystems will

have little impact on the other. If two subsystems are strongly coupled, modifications to one subsystem is likely to have impact on the other. A desirable property of a subsystem decomposition
is that subsystems are as loosely coupled as possible. This minimizes the impact that errors or future changes have on the correct operation of the system.

Software Engineering module | PDF page 118 | lines 11-16

6.1.1. Subsystems and classes
In order to reduce the complexity of the application domain, we identified smaller parts called classes and organized them into packages. Similarly, to reduce the complexity of the solution domain, we decompose a system into simpler parts, called subsystems, which are made of a number of solution domain classes. In the case of complex subsystems, we recursively apply this principle and decompose a subsystem into simpler subsystems (see Figure 6.2).

Question sources

Computer Science model exam collection · Question 63

Question 152 | SS159

Which of the following is a process of selecting program paths in such a manner that certain branches (i.e., outgoing edges of nodes) of a control flow
graph are covered by the execution of those paths?

A. Branch boundary

B. Branch coverage

C. Branch control

D. Branch expansion

Hint

Separate testing scope, technique and purpose. Use the stated workload, observable result or coverage target rather than a universal ranking.

Answer B: Branch coverage.

The stem explicitly defines branches as outgoing control-flow edges. SE38 identifies branch coverage as counting exercised control-flow edges under the declared convention. This differs from merely counting executed statements or evaluating decision outcomes. Branch boundary, branch control and branch expansion are not the coverage criterion described by selecting paths that exercise graph edges.

Why each choice is right or wrong

A - Incorrect: Branch boundary is not the defined edge-coverage criterion in the note.

B - Correct: Branch coverage measures whether control-flow edges are exercised by the selected test paths.

C - Incorrect: Branch control is not the name of the specified structural coverage measure.

D - Incorrect: Branch expansion does not name the outgoing-edge coverage criterion described.

Primary note proof

Study-note section SE38

> Statement coverage is the number of distinct executable statements exercised divided by the total executable statements in the declared test scope. Unreachable statements can prevent100%; any justified exclusions must be documented with the adjusted scope. Decision coverage counts decision outcomes; branch coverage counts control-flow edges, including unconditional edges under the stated convention. Testing both true and false of each decision may need more than two overall test cases when branches nest. Coverage is evidence of exercised structure, not proof of all behavior.

Question 153 | SS161

Which of the following is the correct sequence that will be followed during software evolution process?

A. Change request, release planning, change implementation, impact analysis, system release

B. Change request, impact analysis, release planning, change implementation, system release

C. Impact analysis, Change request, change implementation, release planning, system release

D. Change request, impact analysis, change implementation, release planning, system release

Hint

Classify the motive for the change before its implementation: repair, environment, useful capability or reduced future risk.

Answer B: Change request → impact analysis → release planning → implementation → release.

SE40 gives the sequence directly. A requested change is analyzed before commitment to a release, then planned, implemented and tested, and finally released. B preserves those dependencies. The alternatives analyze consequences too late, begin analysis before a request exists, or implement before release planning. Implementation here includes the testing work omitted from the abbreviated options.

Why each choice is right or wrong

A - Incorrect: It postpones impact analysis until after implementation, too late to guide planning and commitment.

B - Correct: It preserves request, analysis, planning, implementation/testing and release in the taught order.

C - Incorrect: It begins impact analysis before identifying a change request and implements before release planning.

D - Incorrect: It places implementation before release planning instead of planning the analyzed change first.

Primary note proof

Study-note section SE40

> A typical evolution sequence is change request→impact analysis→release planning→implementation/testing→release. Among a list lacking the request step, impact analysis may be the earliest listed technical activity. Major restructuring is reengineering; if the architecture itself changes, architectural transformation is the more specific description. Markets, technology, stakeholders and funding can all change scope or priorities.

Computer Science model exam collection · Question 68

Question 154 | SS162

Which of the following UML element is wrongly applied?

A. Use case diagram represents an interaction with the system

B. Sequence diagram shows the sequence of interactions required to complete some operation

C. An activity diagram primarily specifies the persistent lifecycle states of one object and the event-triggered transitions between those states.

D. Class diagram shows the object classes in a system and their relation

Hint

Match the information to be represented with each model's purpose. Read relationship direction, boundary and ownership conditions before classifying it.

Answer C: An activity diagram primarily specifies the persistent lifecycle states of one object and the event-triggered transitions between those states.

Use-case diagrams summarize actor goals, sequence diagrams order interactions across participants, and class diagrams describe static types and relationships. An activity diagram models workflow and action/control flow. Persistent lifecycle states and event-triggered transitions of a particular object instead call for a state machine. The revised third statement makes that mismatch explicit; the original generic event wording was too broad because activities can also respond to events.

Why each choice is right or wrong

A - Incorrect: Use-case diagrams summarize external roles and system goals/interactions.

B - Incorrect: Sequence diagrams show ordered participant interactions.

C - Correct: The specified lifecycle-state behavior belongs to a state machine rather than an activity workflow.

D - Incorrect: Class diagrams describe static classes and their relationships.

Primary note proof

Study-note section SE20

> An activity diagram models workflow: filled circle start, rounded actions, guarded decision diamond, thick fork/join bars and partitions/swimlanes for responsibility. A diamond can also merge alternative flows; a join synchronizes concurrent flows. A state machine models states and transitions triggered by events, often with guards/actions, for one object's lifecycle.

Study-note section SE19

> Sequence diagrams show interactions across lifelines, with order/time generally downward. Messages cross between participants; activation rectangles show execution. A creation message starts a lifeline; an X marks modeled destruction, not a guarantee about when a garbage

collector runs. Synchronous calls wait for completion; asynchronous messages permit the sender to proceed.

Study-note section SE17

A class box lists name, attributes and operations; + public, - private, # protected and ~ package indicate visibility. A class diagram shows static types and relationships, while an object diagram shows particular instances/links.

Module passages - related reading

Software Engineering module | PDF page 47 | lines 30-39

Actors are external entities that interact with the system. Examples of actors include a user role (e.g., a system administrator, a bank customer, a bank teller) or another system (e.g., a central database, a fabrication line). Actors have unique names and descriptions.
Use cases describe the behavior of the system as seen from an actor's point of view. Behavior described by the use case model is also called external behavior. A use case describes a function provided by the system as a set of events that yields a visible result for the actors. Actors initiate a
use case to access the system functionality. The use case can then initiate other use cases and gather
more information from the actors. When actors and use cases exchange information, they are said
to communicate. We will see later that we represent these exchanges with communication relationships.

Software Engineering module | PDF page 54 | lines 26-35

both buttons simultaneously. Figure 2.10 depicts a sequence diagram for an actor setting his 2Bwatch one minute ahead.
Each column represents an object that participates in the interaction. The vertical axis represents
time from top to bottom. Messages are shown by arrows. Labels on arrows represent message names and may contain arguments. Activations (i.e., executing methods) are depicted by vertical rectangles. Actors are shown as the leftmost column.
Sequence diagrams can be used to describe either an abstract sequence (i.e., all possible interactions) or concrete sequences (i.e., one possible interaction, as in Figure 2.10). When describing all possible interactions, sequence diagrams also provide notations for conditionals and
iterators.

Software Engineering module | PDF page 56 | lines 18-24

2.3.4. Activity diagrams
The outgoing transitions are triggered by the completion of an action associated with the state. This is called an action state. By convention, the name of a state denotes a condition, whereas the name of an action state denotes an action. Activity diagrams are statechart diagrams whose states
are action states. is an activity diagram corresponding to the state diagram. An alternate and

equivalent view of activity diagrams is to interpret action states as control flow between activities
and transitions; that is, the arrows are interpreted as sequential constraints between activities.

Software Engineering module | PDF page 55 | lines 4-9

2.3.3. State chart Diagram
A UML statechart is a notation for describing the sequence of states an object goes through in response to external events. Statecharts are extensions of the finite state machine model. On the one hand, statecharts provide notation for nesting states and state machines (i.e., a state can be described by a state machine). On the other hand, statecharts provide notation for binding transitions with message sends and conditions on objects.

Software Engineering module | PDF page 51 | lines 14-24

2.3.2. Class Diagrams
Classes and objects
Class diagrams describe the structure of the system in terms of classes and objects. Classes are abstractions that specify the attributes and behavior of a set of objects. Objects are entities that encapsulate state and behavior. Each object has an identity: It can be referred individually and is distinguishable from other objects.
In UML, classes and objects are depicted by boxes including three compartments. The top compartment displays the name of the class or object. The center compartment displays its attributes, and the bottom compartment displays its operations. The attribute and operation compartment can be omitted for clarity. Object names are underlined to indicate that they are instances. By convention, class names start with an uppercase letter. Objects in object diagrams

Question sources

Computer Science model exam collection · Question 69

Question 155 | SS163

Select the wrong statement regarding traceability in software development projects.

A. Traceability shows the dependency among two or more requirements if any

B. Requirements should be linked to the respective stakeholder who generated them

D. Every design element(component) should be linked back to the requirement

G. Traceability traces the overall cost and schedule of every activity in the requirement

Hint

Distinguish observable services, measurable qualities and implementation constraints. Check scope, stakeholder meaning and the requested level of specificity.

Answer G: Traceability traces the overall cost and schedule of every activity in the requirement

Traceability records where requirements came from, how requirements depend on one another, and how each requirement is realized and checked in design, code and tests. Source links support rationale, and forward or backward links support change-impact analysis. A cost-and-schedule ledger instead belongs to project planning and control. It can reference requirements, but recording every activity's cost and schedule is not the definition of requirements traceability.

Why each choice is right or wrong

A - Incorrect: Dependency links among requirements are a valid traceability relation.

B - Incorrect: Source or stakeholder links record a requirement's provenance.

D - Incorrect: Design-to-requirement links support realization and impact analysis.

G - Correct: An overall activity cost-and-schedule ledger is project control, not the defining traceability relation.

Primary note proof

Study-note section SE11

> Trace each requirement backward to its source/rationale and forward to design, code and tests. Record dependencies among requirements. A traceability matrix links these artifacts and helps impact analysis; it is not just a cost/schedule ledger. Stakeholders must negotiate conflicting requirements rather than independently approving incompatible demands. Scope, understanding and volatility are distinct elicitation difficulties.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 70 | lines 3-16

> 3.2.5. Verifiability and Traceability
> Two more desirable properties of a system specification are that it be verifiable and traceable. The
> specification is verifiable if, once the system is built; a repeatable test can be designed to demonstrate that the system fulfills the requirement. For example, a mean time to failure of a hundred years for SatWatch would be difficult to achieve (assuming it is realistic in the first place).
> The following requirements are additional examples of non-verifiable requirements:
> • The product shall have a good user interface (good is not defined).
> • The product shall be error free (requires large amount of resources to establish).
> • The product shall respond to the user with 1 second for most cases ("most cases" is not defined).
> A system specification is traceable if each system function can be traced to its corresponding set of requirements. Traceability is not a constraint on the content of the specification, but rather, on its organization. Traceability facilitates the development of tests and the systematic validation of the design against the requirements.

Software Engineering module | PDF page 90 | lines 7-24

4.2. Project Planning
• Probably the most time-consuming project management activity.
• Continuous activity from initial concept through to system delivery. Plans must be regularly revised as new information becomes available.
• Various different types of plans may be developed to support the main software project plan that is concerned with schedule and budget.
The project plan sets out:
• The resources available to the project;
• The work breakdown;
• A schedule for the work.
Project Plan Structure
• Introduction.
• Project organisation.
• Risk analysis.
• Hardware and software resource requirements.
• Work breakdown.
• Project schedule.
• Monitoring and reporting mechanisms.

Question sources

Computer Science model exam collection · Question 70

Question 156 | SS164

Which named prioritization heuristic suggests that a small subset of causes may account for much of the observed impact, often summarized as 80/20?

A. Pareto principle

B. Pairwise principle

C. Partition principle

D. Parametric principle

Hint

Separate responsibilities inside a component from dependencies across boundaries. Evaluate the stated structure, change and reuse goals without assuming guaranteed benefits.

Answer A: Pareto principle

Pareto's 80/20 idea is a prioritization heuristic: a relatively small set of causes may account for a large share of observed impact. It encourages examining evidence to focus improvement effort. It does not promise that exactly one fifth of the effort fixes exactly four fifths of all defects. The revised question asks for this named heuristic, so the other principle names do not identify the rule described.

Why each choice is right or wrong

A - Correct: Pareto names the small-subset/large-impact heuristic often expressed as 80/20.

B - Incorrect: This is not the name of the described 80/20 prioritization heuristic.

C - Incorrect: Partitioning does not name the described concentration-of-impact heuristic.

D - Incorrect: Parametric reasoning does not name the described concentration-of-impact heuristic.

Primary note proof

Study-note section SE43

> Pareto’s 80/20 rule is a prioritization heuristic: a small subset of causes may account for much of the observed impact. It does not guarantee 80% of defects can be fixed with exactly 20% effort. Refactor to preserve behavior while improving structure; optimize only against measured needs; record rationale and update traceability and regression evidence after change.

Software Engineering module | PDF page 91 | lines 37-42

> • Software Metrics can be used to indicate the basic attributes of the software. The indicative metrics, not exhaustive, are
> • Size - Line of code ,Function point count
> • Quality- Reliability, Accuracy, Dependability, and these are measured through some measures like errors, failures and number of runs between failures ,etc.
> • Execution Time -process time of execution of a critical process and many more.

Question sources

Computer Science model exam collection · Question 71

Question 157 | SS166

A business expects changing requirements and organizes development around repeated customer collaboration and incremental replanning; risk-analysis cycles are not its organizing priority. Which offered approach most directly matches these priorities?

A. Code and run

B. Spiral model

C. Agile development method

D. Water fall model

Hint

Identify whether the scenario prioritizes delivery, learning, adaptation or risk reduction. Several processes can share individual practices, so compare their defining emphasis.

Answer C: Agile development method

The scenario's organizing emphasis is repeated customer collaboration and adaptive planning as needs change, which identifies Agile. Spiral can also accommodate change, but organizes its cycles around explicit risk assessment and reduction. Classical waterfall relies more heavily on stable requirements and planned phase commitments. Code-and-run lacks the described disciplined planning and feedback organization. Changing requirements alone would not uniquely determine a process, so the added priorities matter.

Why each choice is right or wrong

A - Incorrect: Code-and-run does not supply the disciplined adaptive planning and feedback organization stated.

B - Incorrect: Spiral is specifically organized around risk assessment and reduction rather than the stated primary emphasis.

C - Correct: Agile makes customer collaboration and adaptation central to planning.

D - Incorrect: Classical waterfall is a poorer fit for repeated replanning of evolving needs.

Primary note proof

Study-note section SE05

> Agile favors people collaborating, useful working results, customer participation and adaptation over rigid adherence to procedures, exhaustive documents, contracts or fixed plans. The latter still have value. Agile does not mean no planning or no documentation. A user story states a small user need and value, supported by acceptance criteria; an epic groups broader work.

Study-note section SE06

> Spiral development is risk driven. Each cycle identifies objectives and alternatives, assesses and reduces important risks, develops/verifies an appropriate next result, and plans further commitment. A prototype may test a risky technology before a large investment. The amount and type of work depend on the risks.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 13 | lines 22-27

> Sometimes, software processes are categorized as either plan-driven or agile processes. Plan-driven processes are processes where all of the process activities are planned in advance and progress is measured against this plan. In agile processes planning is incremental and it is easier to change the process to reflect changing customer requirements. There is no hard and fast rules to
> follow but each approach is suitable for different types of software. Generally, you need to find a balance between plan-driven and agile processes.

Software Engineering module | PDF page 20 | lines 18-22

> the development plan. Its major problem is the inflexible partitioning of the project into distinct stages. Commitments must be made at an early stage in the process, which makes it difficult to

respond to changing customer requirements.
In principle, the waterfall model should only be used when the requirements are well understood
and unlikely to change radically during system development. However, the waterfall model

Question sources

Computer Science model exam collection · Question 73

Question 158 | SS168

Which statement is correct about the differences between functional and non-functional requirements?

A. Functional requirements are the services the system provide while non-functional requirements are constraints on the services or functions offered by the system

B. Functional requirements are decided by the customer while non-functional requirements are decided by developers

C. Both are the same most of the time and only vary under certain contexts

D. Unlike functional requirement, nonfunctional requirements are stable

Hint

Distinguish observable services, measurable qualities and implementation constraints. Check scope, stakeholder meaning and the requested level of specificity.

Answer A: Functional requirements are the services the system provide while non-functional requirements are constraints on the services or functions offered by the system

Required interactions are distinct from user-visible quality constraints such as response time and accuracy; users and clients participate in defining both.

Why each choice is right or wrong

A - Correct: Correct service-versus-constraint distinction. See PDF p. 65, 66, 78.

B - Incorrect: Both types involve users/clients and developers; they are not separated by who decides. See PDF p. 65, 66, 78.

C - Incorrect: The module explicitly distinguishes their subject matter. See PDF p. 65, 66, 78.

D - Incorrect: No immunity to changing stakeholder needs is stated for nonfunctional requirements. See PDF p. 65, 66, 78.

Primary note proof

Study-note section SE10

Nonfunctional requirements include quality attributes and constraints. Performance concerns response time, throughput and resource use; reliability concerns failure-free service; availability concerns being ready for use; usability concerns task success and ease of learning. Security concerns protection; compatibility concerns cooperating environments; portability concerns moving environments; maintainability/supportability concern change, diagnosis and evolution.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 65 | lines 19-23

3.2.1. Functional Requirements
Functional requirements describe the interactions between the system and its environment independent of its implementation. The environment includes the user and any other external system with which the system interacts. For example, the following is an example of functional requirements for SatWatch, a watch that resets itself without user intervention:

Software Engineering module | PDF page 66 | lines 14-18

3.2.2. Non-Functional and Pseudo-Requirements
Nonfunctional requirements describe user-visible aspects of the system that are not directly related with the functional behavior of the system. Nonfunctional requirements include quantitative constraints, such as response time (i.e., how fast the system reacts to user commands)
or accuracy (i.e., how precise are the system's numerical answers). The following are the

Software Engineering module | PDF page 78 | lines 12-30

3.3.7. Identifying Non-Functional Requirements
Nonfunctional requirements describe user-visible aspects of the system that are not directly related
to the functional behavior of the system. Nonfunctional requirements span a number of issues, from user interface look and feel to response time requirements to security issues. Nonfunctional
requirements are defined at the same time as functional requirements are, because they have as much impact on the development and cost of the system.
For example, consider a mosaic display that an air traffic controller uses to track planes. A mosaic
display system complies data from a series of radar and databases (hence the term "mosaic") into
a summary display indicating all aircraft in a certain area, including their identification, speed, and
altitude. The number of aircraft such a system can display constrains the performance of the air traffic controller and the cost of the system. If the system can only handle a few aircraft simultaneously, the system cannot be used at busy airports. On the other hand, a system able to handle a large number of aircraft is more costly and more complex to build.
Nonfunctional requirements can be elicited by investigating the following issues.
• User interface and human factors. What kind of interface should the system provide? What is the level of expertise of the users?
• Documentation. What level of document is required? Should only user documentation be

provided? Should there be technical documentation for maintainers? Should the development process be documented?

Question sources

Computer Science model exam collection · Question 75

Question 159 | SS169

Which paired activity assesses requirements/system testability and then designs test cases and expected results?

A. Test analysis and requirements

B. Test analysis and design

C. Test analysis and planning

D. Test analysis and Implementation

Hint

Separate testing scope, technique and purpose. Use the stated workload, observable result or coverage target rather than a universal ranking.

Answer B: Test analysis and design

Test analysis examines the test basis, identifies what can be tested and evaluates testability. Test design then specifies how to test it through cases and expected results. The analysis-and-design pair therefore covers both responsibilities. Requirements work, planning and implementation are relevant elsewhere, but do not replace case design: planning addresses resources and scope, while implementation prepares data, scripts and the environment.

Why each choice is right or wrong

A - Incorrect: Requirements work does not supply the requested case-design half.

B - Correct: Analysis assesses testability and design specifies cases and expected results.

C - Incorrect: Planning addresses intended work, resources and schedule rather than case design.

D - Incorrect: Implementation prepares scripts, data and environment rather than being the design half.

Primary note proof

Study-note section SE39

A test plan describes intended work; incident/defect reports are normally execution outputs. A defect report should identify build/environment, steps, expected versus actual behavior, evidence and severity. Anyone finding a fault should record it; testers often coordinate reporting, but it is not their exclusive permission. Configuration control makes the tested version reproducible.

Study-note section SE39

> Analysis asks what to test and assesses testability; design asks how.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 147 | lines 14-18

> • Unit testing, which finds faults by isolating an individual component using test stubs and drivers and by exercising the component using a test case
> • Integration testing, which finds faults by integrating several components together
> • System testing, which focuses on the complete system, its functional and nonfunctional requirements, and its target environment

Question sources

Computer Science model exam collection · Question 76

Question 160 | SS174

Which parameter is used to assess and evaluate software architectures?

A. Number of components in the architecture

B. Durability of the architecture

C. Responsiveness of the architectures

D. Architectural quality attributes

Hint

Separate responsibilities inside a component from dependencies across boundaries. Evaluate the stated structure, change and reuse goals without assuming guaranteed benefits.

Answer D: Architectural quality attributes

Design goals are qualities derived from nonfunctional requirements; choices are evaluated consistently against performance, dependability, maintenance, cost and end-user criteria.

Why each choice is right or wrong

A - Incorrect: Component count alone does not establish architecture quality. See PDF p. 127, 116.

B - Incorrect: Durability alone does not span the taught criteria. See PDF p. 127, 116.

C - Incorrect: Responsiveness is only one performance criterion. See PDF p. 127, 116.

D - Correct: Covers the full set of quality criteria used to judge architectural decisions. See PDF p. 127, 116.

Primary note proof

Study-note section SE23

A layer is a logical abstraction level; a tier is a deployment separation. A closed layered architecture permits calls only to the immediately lower layer; an open one permits approved skipping. For top-to-bottom A,B,C,D, A→B obeys closed layering, A→C skips, and lower-to-upper calls violate the simple dependency rule unless explicitly mediated by a defined mechanism.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 127 | lines 10-28

6.2.1. Identifying design goals
The definition of design goals is the first step of system design. It identifies the qualities that our system should focus on. Many design goals can be inferred from the nonfunctional requirements or from the application domain. Others will have to be elicited from the client. It is, however, necessary to state them explicitly such that every important design decision can be made consistently following the same set of criteria.
For example, in the light of the nonfunctional requirements for MyTrip, we identify reliability and
fault tolerance to connectivity loss as design goals. We then identify security as a design goal, as numerous drivers will have access to the same trip planning server. We add modifiability as a design goal, as we want to provide the ability for drivers to select a trip planning service of their choice. The following box summarizes the design goals we identified.
In general, we can select design goals from a long list of highly desirable qualities. Tables 5-1-5-5 list a number of possible design criteria. These criteria are organized into five groups: performance, dependability, cost, maintenance, and end user criteria. Performance, dependability,
and end user criteria are usually specified in the requirements or inferred from the application domain. Cost and maintenance criteria are dictated by the customer and the supplier.
Performance criteria (Table 5-1) include the speed and space requirements imposed on the system. Should the system be responsive or should it accomplish a maximum number of tasks? Is memory space available for speed optimizations or should memory be used sparingly?

Software Engineering module | PDF page 116 | lines 16-29

The analysis model describes the system completely from the actors' point of view and serves as the basis of communication between the client and the developers. The analysis model, however, does not contain information about the internal structure of the system, its hardware configuration,
or, more generally, how the system should be realized. System design is the first step in this direction. System design results in the following products:
• List of design goals, describing the qualities of the system that developers should optimize
• Software architecture, describing the subsystem decomposition in terms of subsystem responsibilities, dependencies among subsystems, subsystem mapping to hardware, and major policy decisions such as control flow, access control, and data storage.
The design goals are derived from the nonfunctional requirements. Design goals guide the decisions to be made by the developers especially when trade-offs are needed. The subsystem decomposition constitutes the bulk of system design. Developers divide the system into manageable pieces to deal with complexity: Each subsystem is assigned to a team and realized independently. In order for this to be possible, though, developers need to address system-wide

Question sources

Computer Science model exam collection · Question 81

Question 161 | SS176

In software risk management, accepting risk happening but don not do anything is known as:

A. Risk transfer

B. Risk Retention

C. Risk Reduction

D. Risk avoidance

Hint

Write out the supplied quantities and dependency constraints. Compute and compare values under the stated metric, finish condition and assumptions.

Answer B: Risk retention, specifically passive acceptance.

SE31 distinguishes removing a risk, reducing it, transferring consequences and retaining or accepting it. It explicitly says passive acceptance may take no action. The stem describes recognizing the risk and allowing it to remain without action, so retention matches. The other responses all involve a deliberate change to the risk or its consequences.

Why each choice is right or wrong

A - Incorrect: Transfer assigns consequences contractually rather than simply keeping the risk without action.

B - Correct: Retention or passive acceptance keeps the risk and may involve no immediate action.

C - Incorrect: Reduction actively lowers likelihood or impact instead of merely accepting exposure.

D - Incorrect: Avoidance changes the plan to remove the risk rather than allowing it to remain.

Primary note proof

Study-note section SE31

> Avoidance changes the plan to remove a risk, mitigation reduces likelihood/impact, transfer assigns consequences contractually, and retention/acceptance keeps the risk; passive acceptance may take no action. Resource leveling adjusts dates to respect resource availability and can change project finish; smoothing uses available float within schedule constraints. Neither magically creates extra staff.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 96 | lines 12-21

4.7. Risk Management
• Risk management is concerned with identifying risks and drawing up plans to minimise their effect on a project.
• A risk is a probability that some adverse circumstance will occur
- Project risks affect schedule or resources;
- Product risks affect the quality or performance of the software being developed;
- Business risks affect the organisation developing or procuring the software.
Risk Management Process
- Risk identification- Identify project, product and business risks;
- Risk analysis -Assess the likelihood and consequences of these risks;

Software Engineering module | PDF page 97 | lines 3-4

- Risk planning- Draw up plans to avoid or minimise the effects of the risk;
- Risk monitoring- Monitor the risks throughout the project.

Question sources

Computer Science model exam collection · Question 83

Question 162 | SS182

Which software process model will you use if you want to deliver different functionalities (modules) of the software product that have different priority
at different time?

A. Waterfall model

B. Spiral model

C. Incremental model

D. Linear model

Hint

Identify whether the scenario prioritizes delivery, learning, adaptation or risk reduction. Several processes can share individual practices, so compare their defining emphasis.

Answer C: Incremental model

Incremental development delivers prioritized functionality in usable stages. Earlier increments provide value while later increments add further capability. This is a delivery organization, distinct from a strict single-pass waterfall sequence. Spiral cycles are organized around risks and may use increments, but risk-driven development is not the specific name of the stated delivery strategy. A generic linear sequence also does not describe prioritized usable subsets.

Why each choice is right or wrong

A - Incorrect: Classical waterfall organizes phases before the principal usable delivery.

B - Incorrect: Spiral is defined by risk-driven cycles, even when an increment is produced.

C - Correct: Incremental development names the successive delivery of usable functionality.

D - Incorrect: A linear model does not name prioritized delivery of separate usable subsets.

Primary note proof

Study-note section SE04

> Choose incremental delivery when prioritized partial capability must reach users early. Smaller changes can be easier to debug and permit feedback, though architecture and integration still require planning. Iteration need not rebuild the whole system every time, and increments need not be perfectly independent modules. Broad descriptions of early working software can fit prototypes, iterative or Agile processes; identify the purpose of that early version.

Study-note section SE06

> Spiral development is risk driven. Each cycle identifies objectives and alternatives, assesses and reduces important risks, develops/verifies an appropriate next result, and plans further commitment. A prototype may test a risky technology before a large investment. The amount and type of work depend on the risks.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 22 | lines 8-12

> This model delivers software in small but usable pieces, called —increments. In general, each increment builds on those that have already been delivered. The model is iterative in nature and focuses on the delivery of an operational product with each increment. Early increments are stripped down versions of the final product, but they do provide capability that serves the user and
> also provide a platform for evaluation by the user.

Software Engineering module | PDF page 22 | lines 24-29

> Advantages of Incremental Model:
> • Generates working software quickly and early during the software life cycle. This model is more flexible - less costly to change scope and requirements. It is easier to test and debug during a smaller iteration.
> • In this model customer can respond to each built. Lowers initial delivery cost.
> • Easier to manage risk because risky pieces are identified and handled during its iteration.

Question sources

Computer Science model exam collection · Question 89

Question 163 | SS184

Which of the following is a resource optimization techniques in which start and finish dates are adjusted based on resource constraints with the goal
of balancing the demand for resources with the available supply?

A. Resource smoothing

B. Responsibility assignment matrix

C. Resource leveling

D. Resource grouping

Hint

Write out the supplied quantities and dependency constraints. Compute and compare values under the stated metric, finish condition and assumptions.

Answer C: Resource leveling.

SE31 defines resource leveling as adjusting dates to respect resource availability, potentially changing the project finish. That matches balancing resource demand against supply by moving starts and finishes. Smoothing instead works within available float and schedule constraints. A responsibility matrix assigns ownership, and resource grouping is not the defined date-adjustment technique.

Why each choice is right or wrong

A - Incorrect: Smoothing uses available float while retaining schedule constraints rather than generally leveling against availability.

B - Incorrect: A responsibility assignment matrix maps work to owners rather than adjusting task dates for resource capacity.

C - Correct: Resource leveling changes dates to balance required resources against available supply.

D - Incorrect: Resource grouping is not the defined schedule-adjustment method described by the stem.

Primary note proof

Study-note section SE31

> Avoidance changes the plan to remove a risk, mitigation reduces likelihood/impact, transfer assigns consequences contractually, and retention/acceptance keeps the risk; passive acceptance may take no action. Resource leveling adjusts dates to respect resource availability and can change project finish; smoothing uses available float within schedule constraints. Neither magically creates extra staff.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 95 | lines 3-12

4.6. Scheduling, Organization and Team Structures
Project-task scheduling is an important project planning activity. It involves deciding which tasks would
be taken up when. In order to schedule the project activities, a software project manager needs to do
the following:
• Identify all the tasks needed to complete the project and Break down large tasks into small activities.
• Determine the dependency among different activities and Establish the most likely estimates for the time durations necessary to complete the activities and Allocate resources to activities.
• Plan the starting and ending dates for various activities and Determine the critical path. A critical path is the chain of activities that determines the duration of the project.

Question sources

Computer Science model exam collection · Question 91

Question 164 | SS190

Identify the design principle that does not apply to software systems

A. design should be structured to accommodate change

B. design should exhibit uniformity and integration

C. design should be reinventing the wheel from scratch

D. design should be traceable to the analysis model

Hint

Separate responsibilities inside a component from dependencies across boundaries. Evaluate the stated structure, change and reuse goals without assuming guaranteed benefits.

Answer C: design should be reinventing the wheel from scratch

Reusable classes, controlled change and traceability to requirements support software engineering. Recreating existing solutions from scratch contradicts its reuse rationale.

Why each choice is right or wrong

A - Incorrect: Low coupling explicitly limits future change impact. See PDF p. 32, 120, 70.

B - Incorrect: Consistent interfaces and integrated structures support the system, though this exact slogan is not quoted. See PDF p. 32, 120, 70.

C - Correct: Contradicts the documented promotion of reuse and component selection. See PDF p. 32, 120, 70.

D - Incorrect: Traceability explicitly supports validating design against requirements. See PDF p. 32, 120, 70.

Primary note proof

Study-note section SE25

Use abstraction and decomposition to manage complexity; preserve consistency, traceability and clear responsibilities. Top-down design refines high-level structure; bottom-up design assembles existing components. A hybrid combines both. SOLID includes Single Responsibility, Open-Closed, Liskov substitution, Interface Segregation and Dependency Inversion. Depend on abstractions; add compatible extensions; avoid forcing unused operations. DRY limits duplicated knowledge, KISS avoids unnecessary complexity, and YAGNI avoids speculative work.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 32 | lines 12-21

A class in an object-oriented system carefully delineates between its interfaces the routines and attributes within a class are held together tightly. In a properly designed system, the classes will be grouped into subsystems but remain independent; therefore, changing one class has no impact
on other classes, and so, the impact is minimized. However, the object-oriented approach is not a panacea; nothing is magical here that will promote perfect design or perfect code.
Promotion of reusability
Objects are reusable because they are modeled directly out of a real-world problem domain. Each
object stands by itself or within a small circle of peers (other objects). Within this framework, the class does not concern itself with the rest of the system or how it is going to be used within a particular system.

Software Engineering module | PDF page 120 | lines 6-12

6.1.3. Coupling and coherence
Coupling is the strength of dependencies between two subsystems. If two subsystems are loosely coupled, they are relatively independent, and thus, modifications to one of the subsystems will have little impact on the other. If two subsystems are strongly coupled, modifications to one subsystem is likely to have impact on the other. A desirable property of a subsystem decomposition
is that subsystems are as loosely coupled as possible. This minimizes the impact that errors or future changes have on the correct operation of the system.

Software Engineering module | PDF page 70 | lines 3-16

3.2.5. Verifiability and Traceability
Two more desirable properties of a system specification are that it be verifiable and traceable. The
specification is verifiable if, once the system is built; a repeatable test can be designed to demonstrate that the system fulfills the requirement. For example, a mean time to failure of a hundred years for SatWatch would be difficult to achieve (assuming it is realistic in the first place).
The following requirements are additional examples of non-verifiable requirements:
• The product shall have a good user interface (good is not defined).
• The product shall be error free (requires large amount of resources to establish).
• The product shall respond to the user with 1 second for most cases (“most cases” is not defined).

A system specification is traceable if each system function can be traced to its corresponding set of requirements. Traceability is not a constraint on the content of the specification, but rather, on its organization. Traceability facilitates the development of tests and the systematic validation of the design against the requirements.

Question sources

Computer Science model exam collection · Question 97

Question 165 | AM0001

Which phase of the software development life cycle is responsible for gathering and analyzing user requirements?

A. Analysis

B. Design

C. Development

D. Testing

Hint

Distinguish observable services, measurable qualities and implementation constraints. Check scope, stakeholder meaning and the requested level of specificity.

Answer A: Analysis

Requirements elicitation and analysis establish the system's purpose with users and formalize their needs; design and implementation follow.

Why each choice is right or wrong

A - Correct: The offered phase covering gathering and analysis. See PDF p. 62, 100.

B - Incorrect: Derives internal structure from requirements. See PDF p. 62, 100.

C - Incorrect: Produces executable code. See PDF p. 62, 100.

D - Incorrect: Detects faults in implemented behavior. See PDF p. 62, 100.

Primary note proof

Study-note section SE08

Business requirements explain why the project exists and its goals. User requirements describe stakeholder needs at a useful high level; system requirements specify detailed services and constraints. The Software Requirements Specification (SRS) organizes the agreed requirements. A natural-language specification communicates with clients while analysis models formalize it for technical discussion; real specifications can also contain diagrams.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 62 | lines 9-16

Requirement’s elicitation focuses on describing the purpose of the system. The client, the developers, and the users identify a problem area and define a system that addresses the problem.
Such a definition is called a system specification and serves as a contract between the client and the developers. The system specification is structured and formalized during analysis to produce an analysis model (see Figure 3.1). Both system specification and analysis model represent the same information. They differ only in the language and notation they use. The system specification
is written in natural language, whereas the analysis model is usually expressed in a formal or semiformal notation.

Software Engineering module | PDF page 100 | lines 11-24

Analysis focuses on producing a model of the system, called the analysis model, which is correct, complete, consistent, and verifiable. Analysis is different from requirements elicitation in that developers focus on structuring and formalizing the requirements elicited from users
Figure 4.1 Products of requirements elicitation and analysis (UML activity diagram).
Althoughtheanalysismodelmaynotbeunderstandabletotheusersandtheclient, it helps developers verify the system specification produced during requirements elicitation. There is a natural tendency for users and developers to postpone difficult decisions until later in the project. A decision may be difficult because of lack of domain knowledge, lack of technological knowledge, or simply because of disagreements among users and developers. Postponing decisions enables the
project to move on smoothly and avoid confrontation with reality or peers. Unfortunately, difficult
decisions will eventually need to be made, often at higher cost when intrinsic problems are discovered during testing, or worse, during user evaluation. Translating a system specification in to a formal or semi-formal model forces developers to identify and resolve difficult issues early in
the development.

Question sources

Computer Science MCQ practice collection · Question 1

Question 166 | AM0002

Which design principle suggests that software components should have a single, well-defined responsibility?

A. DRY (Don't Repeat Yourself) principle

B. SOLID principle

C. KISS (Keep It Simple, Stupid) principle

D. YAGNI (You Ain't Gonna Need It) principle

Hint

Separate responsibilities inside a component from dependencies across boundaries. Evaluate the stated structure, change and reuse goals without assuming guaranteed benefits.

Answer B: Single Responsibility, within SOLID.

SE25 includes Single Responsibility among the SOLID principles. That principle assigns a component one well-defined responsibility. DRY limits duplicated knowledge, KISS avoids unnecessary complexity and YAGNI avoids speculative work. Those can complement focused responsibilities, but none is the named principle directly described by the question.

Why each choice is right or wrong

A - Incorrect: DRY limits duplication of knowledge rather than specifically assigning one responsibility per component.

B - Correct: SOLID includes the Single Responsibility principle that the stem describes.

C - Incorrect: KISS favors simplicity, a different design concern from the specific single-responsibility rule.

D - Incorrect: YAGNI avoids speculative work rather than defining responsibility boundaries.

Primary note proof

Study-note section SE25

> Use abstraction and decomposition to manage complexity; preserve consistency, traceability and clear responsibilities. Top-down design refines high-level structure; bottom-up design assembles existing components. A hybrid combines both. SOLID includes Single Responsibility, Open-Closed, Liskov substitution, Interface Segregation and Dependency Inversion. Depend on abstractions; add compatible extensions; avoid forcing unused operations. DRY limits duplicated knowledge, KISS avoids unnecessary complexity, and YAGNI avoids speculative work.

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 120 | lines 24-27

> Coherence is the strength of dependencies within a subsystem. If a subsystem contains many objects that are related to each other and perform similar tasks, its coherence is high. If a subsystem
> contains a number of unrelated objects, its coherence is low. A desirable property of a subsystem decomposition is that it leads to subsystems with high coherence.

Question sources

Computer Science MCQ practice collection · Question 2

Question 167 | AM0003

Which of the following is an agile development methodology?

A. Waterfall model

B. Scrum

C. V-model

D. Spiral model

Hint

Identify whether the scenario prioritizes delivery, learning, adaptation or risk reduction. Several processes can share individual practices, so compare their defining emphasis.

Answer B: Scrum.

SE05 presents Scrum through timeboxed Sprints, a Sprint Goal and a usable Increment, in the Agile context. Waterfall and the V-model organize planned stages and corresponding tests, while spiral is defined by risk-driven cycles. Therefore Scrum is the specifically Agile approach among the listed alternatives; iteration alone does not make every process Scrum.

Why each choice is right or wrong

A - Incorrect: Classical waterfall organizes planned phases rather than the Agile Scrum approach described.

B - Correct: Scrum is the Agile framework using Sprints and usable Increments.

C - Incorrect: The V-model pairs development stages with test levels rather than being the listed Agile framework.

D - Incorrect: Spiral is risk driven and is not the specifically Agile methodology named among these choices.

Primary note proof

Study-note section SE05

> Scrum uses timeboxed Sprints of at most one month, with a Sprint Goal, selected work and a usable Increment meeting a Definition of Done. Scope is discussed before and during planning; it is not forbidden to agree scope. Timeboxes tend to stay fixed while content is adapted without endangering the goal. Agile can be combined with required assurance/documentation; safety-critical context alone cannot prove it is unsuitable.

Software Engineering module | PDF page 13 | lines 22-27

> Sometimes, software processes are categorized as either plan-driven or agile processes. Plan-driven processes are processes where all of the process activities are planned in advance and progress is measured against this plan. In agile processes planning is incremental and it is easier to change the process to reflect changing customer requirements. There is no hard and fast rules

to
follow but each approach is suitable for different types of software. Generally, you need to find a balance between plan-driven and agile processes.

Question sources

Computer Science MCQ practice collection · Question 3

Question 168 | AM0004

A team delivers small usable capabilities, replans the next work with customers and treats adaptation as a central value rather than organizing cycles around risk analysis. Which broad approach best fits?

A. Waterfall model

B. Agile methodology

C. Prototype model

D. Spiral model

Hint

Identify whether the scenario prioritizes delivery, learning, adaptation or risk reduction. Several processes can share individual practices, so compare their defining emphasis.

Answer B: Agile methodology

The team adds small usable capabilities and repeatedly replans with customers. Agile makes this combination of working results, customer participation and adaptation central. A prototype's immediate purpose is learning about requirements or feasibility; a spiral cycle is organized around risk reduction. Classical waterfall instead emphasizes planned phase commitments. Increments by themselves can occur in several processes, so the collaboration and planning priorities establish the intended comparison.

Why each choice is right or wrong

A - Incorrect: Classical waterfall does not make repeated adaptive replanning its organizing emphasis.

B - Correct: Agile combines working increments with ongoing customer collaboration and adaptation.

C - Incorrect: Prototyping primarily explores uncertainty rather than naming this ongoing delivery-and-planning organization.

D - Incorrect: Spiral's defining emphasis is risk analysis and reduction.

Primary note proof

Study-note section SE04

Iteration revisits and improves a solution; an increment adds usable functionality. A process may do both. Delivering registration first, then payments, then reporting is incremental; revising

a registration prototype after feedback is iterative. Each increment still needs design, implementation and testing.

Study-note section SE06

Spiral development is risk driven. Each cycle identifies objectives and alternatives, assesses and reduces important risks, develops/verifies an appropriate next result, and plans further commitment. A prototype may test a risky technology before a large investment. The amount and type of work depend on the risks.

Study-note section SE05

Agile favors people collaborating, useful working results, customer participation and adaptation over rigid adherence to procedures, exhaustive documents, contracts or fixed plans. The latter still have value. Agile does not mean no planning or no documentation. A user story states a small user need and value, supported by acceptance criteria; an epic groups broader work.

Software Engineering module | PDF page 22 | lines 8-12

This model delivers software in small but usable pieces, called —increments. In general, each increment builds on those that have already been delivered. The model is iterative in nature and focuses on the delivery of an operational product with each increment. Early increments are stripped down versions of the final product, but they do provide capability that serves the user and
also provide a platform for evaluation by the user.

Question sources

Computer Science MCQ practice collection · Question 4

Question 169 | AM0005

Which software testing technique focuses on finding defects by executing the software without knowledge of its internal structure?

A. White-box testing

B. Black-box testing

C. Integration testing

D. System testing

Hint

Separate testing scope, technique and purpose. Use the stated workload, observable result or coverage target rather than a universal ranking.

Answer B: Black-box testing

Black-box equivalence testing chooses input classes based on expected behavior without tracing internal paths; white-box paths require source knowledge.

Why each choice is right or wrong

A - Incorrect: Requires code/data-structure knowledge for path selection. See PDF p. 149, 149.

B - Correct: Matches behavior testing without internal-structure knowledge. See PDF p. 149, 149.

C - Incorrect: A test level that can combine techniques. See PDF p. 149, 149.

D - Incorrect: A complete-system scope rather than the knowledge-based distinction. See PDF p. 149, 149.

Primary note proof

Study-note section SE36

> Black-box techniques derive cases from specified behavior; white-box techniques derive them from internal structure; grey-box uses partial internal knowledge. Regression testing checks for unintended effects after change; confirmation testing checks the particular defect repair. Exploratory testing combines learning, design and execution and is experience based. Manual/automated describe execution support, not a compulsory black-/white-box classification.

Computer Science MCQ practice collection · Question 5

Question 170 | AM0006

Which diagrams describe detailed behavioral evolution over time through either ordered participant interactions or event-triggered state changes? Select all that apply.

A. Use case diagrams

B. Class diagrams

C. Sequence diagrams

D. State machine diagrams

Hint

Match the information to be represented with each model's purpose. Read relationship direction, boundary and ownership conditions before classifying it.

Answer C, D: Sequence diagrams; State machine diagrams

Sequence diagrams show ordered messages across participant lifelines, while state machines show event-triggered transitions through an object's lifecycle states. Both therefore describe behavioral evolution over time under the stated scope. A use-case diagram summarizes external roles and goals without that detailed temporal evolution, and a class diagram describes static types and relationships. Neither replaces the two detailed dynamic views requested.

Why each choice is right or wrong

A - Incorrect: Use-case diagrams summarize roles/goals rather than detailed temporal evolution.

B - Incorrect: Class diagrams are static.

C - Correct: Sequence diagrams show ordered participant interactions.

D - Correct: State machines show event-triggered lifecycle changes.

Primary note proof

Study-note section SE20

Choose a sequence diagram for message order between participants, a state machine for event-dependent state changes, and activity for workflow. Both sequence and state diagrams describe behavior over time. State machines are useful for objects with significant states,

whether entity or control. A DFD shows data stores/flows and transformations from inputs to outputs; it is not a UML diagram.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 54 | lines 26-35

both buttons simultaneously. Figure 2.10 depicts a sequence diagram for an actor setting his 2Bwatch one minute ahead.
Each column represents an object that participates in the interaction. The vertical axis represents
time from top to bottom. Messages are shown by arrows. Labels on arrows represent message names and may contain arguments. Activations (i.e., executing methods) are depicted by vertical rectangles. Actors are shown as the leftmost column.
Sequence diagrams can be used to describe either an abstract sequence (i.e., all possible interactions) or concrete sequences (i.e., one possible interaction, as in Figure 2.10). When describing all possible interactions, sequence diagrams also provide notations for conditionals and
iterators.

Software Engineering module | PDF page 55 | lines 4-9

2.3.3. State chart Diagram
A UML statechart is a notation for describing the sequence of states an object goes through in response to external events. Statecharts are extensions of the finite state machine model. On the one hand, statecharts provide notation for nesting states and state machines (i.e., a state can be described by a state machine). On the other hand, statecharts provide notation for binding transitions with message sends and conditions on objects.

Computer Science MCQ practice collection · Question 6

Question 171 | AM0007

Which software development methodology promotes adaptive planning, evolutionary development, and continuous improvement?

A. Waterfall model

B. Agile methodology

C. V-model

D. Spiral model

Hint

Identify whether the scenario prioritizes delivery, learning, adaptation or risk reduction. Several processes can share individual practices, so compare their defining emphasis.

Answer B: Agile methodology

Adaptive planning, evolutionary improvement and responsiveness to customer feedback characterize Agile as a broad development approach. Waterfall emphasizes planned phase progression; the V-model pairs development stages with corresponding test levels. Spiral can evolve a product as well, but its defining organization is repeated risk assessment and reduction. The question asks for the approach whose core emphasis matches the stated planning and collaboration values.

Why each choice is right or wrong

A - Incorrect: Waterfall emphasizes planned phase progression rather than adaptive planning.

B - Correct: Agile places adaptive planning and ongoing improvement at the center.

C - Incorrect: The V-model emphasizes correspondence between development and test stages.

D - Incorrect: Spiral is organized primarily around risk reduction, even when development is evolutionary.

Primary note proof

Study-note section SE05

> Agile favors people collaborating, useful working results, customer participation and adaptation over rigid adherence to procedures, exhaustive documents, contracts or fixed plans. The latter still have value. Agile does not mean no planning or no documentation. A user story states a small user need and value, supported by acceptance criteria; an epic groups broader work.

Study-note section SE03

> Classical waterfall separates planned phases with reviewed deliverables. It fits well-understood, stable requirements and familiar technology; late feedback makes changes costly. It does not make change physically impossible: real projects revisit work under control, and modified waterfall explicitly includes feedback. Rigidity offers milestone visibility but can freeze incorrect assumptions.

Study-note section SE06

> Spiral development is risk driven. Each cycle identifies objectives and alternatives, assesses and reduces important risks, develops/verifies an appropriate next result, and plans further commitment. A prototype may test a risky technology before a large investment. The amount and type of work depend on the risks.

Module passages - related reading

follow but each approach is suitable for different types of software. Generally, you need to find a balance between plan-driven and agile processes.

Software Engineering module | PDF page 22 | lines 8-12

This model delivers software in small but usable pieces, called —increments. In general, each increment builds on those that have already been delivered. The model is iterative in nature and focuses on the delivery of an operational product with each increment. Early increments are stripped down versions of the final product, but they do provide capability that serves the user and
also provide a platform for evaluation by the user.

Question sources

Computer Science MCQ practice collection · Question 7

Question 172 | AM0008

Which technique is used to represent the flow of activities and decisions in a software system?

A. Use case modeling

B. Activity diagrams

C. State machine diagrams

D. Component diagrams

Hint

Match the information to be represented with each model's purpose. Read relationship direction, boundary and ownership conditions before classifying it.

Answer B: Activity diagrams

Activity diagrams interpret actions and transitions as control flow; decision diamonds branch that flow based on conditions.

Why each choice is right or wrong

A - Incorrect: Captures external functions, not detailed action flow. See PDF p. 56, 57.

B - Correct: Explicit action/control-flow notation with decisions. See PDF p. 56, 57.

C - Incorrect: Shows states responding to events rather than primarily the activity sequence. See PDF p. 56, 57.

D - Incorrect: Represents component organization rather than activity decisions. See PDF p. 56, 57.

Primary note proof

Study-note section SE20

An activity diagram models workflow: filled circle start, rounded actions, guarded decision diamond, thick fork/join bars and partitions/swimlanes for responsibility. A diamond can also

merge alternative flows; a join synchronizes concurrent flows. A state machine models states and transitions triggered by events, often with guards/actions, for one object's lifecycle.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 56 | lines 18-24

2.3.4. Activity diagrams
The outgoing transitions are triggered by the completion of an action associated with the state. This is called an action state. By convention, the name of a state denotes a condition, whereas the name of an action state denotes an action. Activity diagrams are statechart diagrams whose states
are action states. is an activity diagram corresponding to the state diagram. An alternate and equivalent view of activity diagrams is to interpret action states as control flow between activities
and transitions; that is, the arrows are interpreted as sequential constraints between activities.

Software Engineering module | PDF page 57 | lines 7-11

Decisions are branches in the control flow. They denote alternative transitions based on a condition
of the state of an object or a set of objects. Decisions are depicted by a diamond with one or more incoming arrows and two or more outgoing arrows. The outgoing arrows are labeled with the conditions that select a branch in the control flow. The set of all outgoing transitions from a decision represents the set of all possible outcomes.

Question sources

Computer Science MCQ practice collection · Question 8

Question 173 | AM0009

Developers build a quick interface version solely to discover how users perform an unfamiliar task; it is not a production release. Which named approach describes the immediate purpose of that version?

A. Waterfall model

B. Agile methodology

C. Prototype model

D. Spiral model

Hint

Identify whether the scenario prioritizes delivery, learning, adaptation or risk reduction. Several processes can share individual practices, so compare their defining emphasis.

Answer C: Prototype model

The early version is built to learn how users understand and carry out a task, not to deliver a production increment. That exploratory purpose identifies a prototype. Agile can use prototypes but its broader definition centers on collaboration and adaptation. Spiral may prototype to reduce a risk, but risk cycles are not the specific technique requested. Classical waterfall does not itself name early experimental versions. The purpose of the artifact distinguishes these overlapping practices.

Why each choice is right or wrong

A - Incorrect: Waterfall is a phased lifecycle rather than the named exploratory artifact technique.

B - Incorrect: Agile may use prototypes but does not specifically name the described usability experiment.

C - Correct: Prototyping uses an experimental version to discover requirements or usability needs.

D - Incorrect: Spiral may employ a prototype, but its defining method is organizing cycles around risk reduction.

Primary note proof

Study-note section SE07

> A prototype explores requirements, usability or technical feasibility. A throwaway prototype is discarded after learning; an evolutionary prototype is deliberately refined toward production. A quick prototype may omit robustness, security or architecture, so do not deploy it unchanged without evaluation. Coding may occur during prototyping even if a diagram labels that activity construction rather than coding.

Study-note section SE06

> Spiral development is risk driven. Each cycle identifies objectives and alternatives, assesses and reduces important risks, develops/verifies an appropriate next result, and plans further commitment. A prototype may test a risky technology before a large investment. The amount and type of work depend on the risks.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 82 | lines 23-29

> • Prototype test. During this type of test, one or more users are presented with a piece of software that practically implements the system. A vertical prototype implements a complete use case through the system, and a horizontal prototype presents an interface for most use cases (without providing much or any functionality). The advantages of prototype tests are that they provide a realistic view of the system to the user and that prototypes can be instrumented to collect detailed data. The disadvantages of prototypes are that they are expensive to build and to modify.

Software Engineering module | PDF page 26 | lines 6-9

2. Requirement’s elicitation and analysis: This is the process of deriving the system requirements through observation of existing systems, discussions with potential users and procurers, task analysis, and so on. This may involve the development of one or more system models and prototypes. These help you understand the system to be specified.

Question sources

Computer Science MCQ practice collection · Question 9

Question 174 | AM0010

Which testing technique focuses on testing the interaction between different components or modules of a software system?

A. Unit testing

B. Integration testing

C. System testing

D. Regression testing

Hint

Separate testing scope, technique and purpose. Use the stated workload, observable result or coverage target rather than a universal ranking.

Answer B: Integration testing

Integration testing targets interfaces and interactions among components that have been combined. Unit testing isolates a smaller function or component, while system testing evaluates the complete integrated product against its requirements. Regression testing is triggered by a change and looks for unintended effects; it can be performed at several levels. The scenario is categorized by its interaction scope, so integration is the specific level requested.

Why each choice is right or wrong

A - Incorrect: Unit testing isolates a function or small component.

B - Correct: Integration testing exercises interactions among combined components.

C - Incorrect: System testing evaluates the complete product rather than specifically the component interfaces.

D - Incorrect: Regression names the after-change purpose, not a particular component-combination level.

Primary note proof

Study-note section SE35

Unit testing isolates a function, class or small component, often replacing dependencies with stubs/mocks; a driver invokes the unit and a stub substitutes a called dependency. Integration testing exercises interfaces and interactions among combined parts. System testing checks the

complete integrated system against functional and nonfunctional requirements in a representative environment.

Study-note section SE36

Functional tests check required behavior against the SRS and acceptance criteria. Performance tests assess speed, throughput and resources under a specified workload; load uses expected demands and stress exceeds normal limits. Usability, security, compatibility and reliability tests target their respective qualities. “Normal operating conditions” alone does not distinguish functional from performance testing.

Module passages - related reading

Software Engineering module | PDF page 144 | lines 17-32

Figure 6.2 depicts an overview of the testing activities:
• Unit testing tries to find faults in participating objects and/or subsystems with respect to the use cases from the use case model
• Integration testing is the activity of finding faults when testing the individually tested components together, for example, subsystems described in the subsystem decomposition, while executing the use cases and scenarios from the RAD.
o The system structure testing is the culmination of integration testing involving all components of the system. Integration tests and structure tests exploit knowledge from the SDD using an integration strategy described in the Test Plan (TP).
• System testing tests all the components together, seen as a single system to identify errors with respect to the scenarios from the problem statement and the requirements and design goals identified in the analysis and system design, respectively:
o Functional testing tests the requirements from the RAD and, if available, from the user manual.
o Performance testing checks the nonfunctional requirements and additional design goals from the SDD. Note that functional and performance testing are both done by

Software Engineering module | PDF page 147 | lines 14-18

• Unit testing, which finds faults by isolating an individual component using test stubs and drivers and by exercising the component using a test case
• Integration testing, which finds faults by integrating several components together
• System testing, which focuses on the complete system, its functional and nonfunctional requirements, and its target environment

Question sources

Computer Science MCQ practice collection · Question 10

Question 175 | AM0011

Which design principle suggests that software entities should depend on abstractions, not on concrete implementations?

A. DRY (Don't Repeat Yourself) principle

B. SOLID principle

C. KISS (Keep It Simple, Stupid) principle

D. YAGNI (You Ain't Gonna Need It) principle

Hint

Separate responsibilities inside a component from dependencies across boundaries. Evaluate the stated structure, change and reuse goals without assuming guaranteed benefits.

Answer B: Dependency Inversion, within SOLID.

SE25 lists Dependency Inversion within SOLID and explicitly directs designs to depend on abstractions. That reduces dependence on concrete implementation details and matches the stem. DRY, KISS and YAGNI address duplication, simplicity and speculative functionality respectively; none is the principle defining the abstraction-based dependency relationship.

Why each choice is right or wrong

A - Incorrect: DRY addresses duplicated knowledge rather than the direction and target of dependencies.

B - Correct: SOLID includes Dependency Inversion, which directs dependencies toward abstractions.

C - Incorrect: KISS addresses unnecessary complexity rather than specifying abstraction-based dependencies.

D - Incorrect: YAGNI limits speculative work rather than defining dependency direction.

Primary note proof

Study-note section SE25

> Use abstraction and decomposition to manage complexity; preserve consistency, traceability and clear responsibilities. Top-down design refines high-level structure; bottom-up design assembles existing components. A hybrid combines both. SOLID includes Single Responsibility, Open-Closed, Liskov substitution, Interface Segregation and Dependency Inversion. Depend on abstractions; add compatible extensions; avoid forcing unused operations. DRY limits duplicated knowledge, KISS avoids unnecessary complexity, and YAGNI avoids speculative work.

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 119 | lines 13-25

> 6.1.2. Services and subsystem interfaces
> A subsystem is characterized by the services it provides to other subsystems. A service is a set of

related operations that share a common purpose. A subsystem providing a notification service, for
example, defines operations to send notices, look up notification channels, and subscribe and unsubscribe to a channel.
The set of operations of a subsystem that are available to other subsystems form the subsystem interface. The subsystem interface, also referred to as the application programmer interface (API),
includes the name of the operations, their parameters, their types, and their return values. System
design focuses on defining the services provided by each subsystem that is, enumerating the operations, their parameters, and their high-level behavior. Object design will focus on defining the subsystem interfaces, that is, the type of the parameters and the return value of each operation.
The definition of a subsystem in terms of the services it provides helps us focus on its interface as opposed to its implementation. A good subsystem interface should provide as little information

Software Engineering module | PDF page 120 | lines 6-12

6.1.3. Coupling and coherence
Coupling is the strength of dependencies between two subsystems. If two subsystems are loosely coupled, they are relatively independent, and thus, modifications to one of the subsystems will have little impact on the other. If two subsystems are strongly coupled, modifications to one subsystem is likely to have impact on the other. A desirable property of a subsystem decomposition
is that subsystems are as loosely coupled as possible. This minimizes the impact that errors or future changes have on the correct operation of the system.

Question sources

Computer Science MCQ practice collection · Question 11

Question 176 | AM0012

Which software development approach follows a linear, sequential flow from requirements gathering to testing and maintenance?

A. Waterfall model

B. Agile methodology

C. Prototype model

D. Spiral model

Hint

Identify whether the scenario prioritizes delivery, learning, adaptation or risk reduction. Several processes can share individual practices, so compare their defining emphasis.

Answer A: Waterfall model

Classical waterfall organizes development as planned sequential phases such as requirements, design, implementation and testing. Agile instead adapts work through feedback, prototyping uses experimental versions to learn, and spiral cycles organize work around risk reduction. Real waterfall projects can revisit work under change control, but the idealized linear organization described by the question is its characteristic model rather than one of the feedback-centered alternatives.

Why each choice is right or wrong

A - Correct: The idealized waterfall model follows the stated planned phase sequence.

B - Incorrect: Agile emphasizes adaptation and incremental planning.

C - Incorrect: Prototyping learns through experimental versions and feedback.

D - Incorrect: Spiral organizes repeated cycles around risk assessment and reduction.

Primary note proof

Study-note section SE03

> Classical waterfall separates planned phases with reviewed deliverables. It fits well-understood, stable requirements and familiar technology; late feedback makes changes costly. It does not make change physically impossible: real projects revisit work under control, and modified waterfall explicitly includes feedback. Rigidity offers milestone visibility but can freeze incorrect assumptions.

Study-note section SE06

> Spiral development is risk driven. Each cycle identifies objectives and alternatives, assesses and reduces important risks, develops/verifies an appropriate next result, and plans further commitment. A prototype may test a risky technology before a large investment. The amount and type of work depend on the risks.

Question sources

Computer Science MCQ practice collection · Question 12

Question 177 | AM0013

Which technique is used to estimate the size and complexity of a software project?

A. Use case modeling

B. Storyboarding

C. Function point analysis

D. Pair programming

Hint

Distinguish the planning or organization goal from the tool or structure used to support it. Apply the stated project conditions.

Answer C: Function point analysis

Function-point analysis counts system externals, assigns complexity weights and aggregates them to estimate software size independent of implementation language.

Why each choice is right or wrong

A - Incorrect: Captures functionality but is not the stated weighted size-estimation method. See PDF p. 93, 91.

B - Incorrect: A user-experience representation, not the module's quantitative size method. See PDF p. 93, 91.

C - Correct: Directly taught size/complexity weighting technique. See PDF p. 93, 91.

D - Incorrect: A development collaboration practice, not this sizing method. See PDF p. 93, 91.

Primary note proof

Study-note section SE28

> Function points estimate functional size using inputs, outputs, inquiries, internal logical files and external interface files, weighted under the chosen method. They are not just lines of code and are not a direct exact measure of complexity. Git tracks versions; issue trackers such as Jira track work/defects; CI tools such as Jenkins automate checks; Docker packages application/runtime dependencies into containers.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 93 | lines 3-21

> • Function points allow the measurement of software size in standard units, independent of the underlying language in which the software is developed.
> • Counting the number of externals (inputs, outputs, inquiries, and interfaces) that make up the system.
> • There are five types of externals to count:
> 1. External inputs - data or control inputs (input files, tables, forms, screens, messages,

etc.) to the system
2. External outputs - data or control outputs from the system
3. External inquiries - I/O queries which require a response (prompts, interrupts, calls, etc.)
4. External interfaces - libraries or programs which are passed into and out of the system (I/O routines, sorting procedures, math libraries, run-time libraries, etc.)
5. Internal data files - groupings of data stored internally in the system (entities, internal control files, directories)
Apply these steps to calculate the size of a project:
1. Count or estimate all the occurrences of each type of external.
2. Assign each occurrence a complexity weight.
3. Multiply each occurrence by its complexity weight, and total the results to obtain a function count. Complexity weights are as listed below.

Software Engineering module | PDF page 91 | lines 37-42

• Software Metrics can be used to indicate the basic attributes of the software. The indicative metrics, not exhaustive, are
• Size - Line of code ,Function point count
• Quality- Reliability, Accuracy, Dependability, and these are measured through some measures like errors, failures and number of runs between failures ,etc.
• Execution Time -process time of execution of a critical process and many more.

Question sources

Computer Science MCQ practice collection · Question 13

Question 178 | AM0014

Which tool is used to track and manage software issues, bugs, and tasks throughout the development process?

A. Git

B. Jira

C. Jenkins

D. Docker

Hint

Distinguish the planning or organization goal from the tool or structure used to support it. Apply the stated project conditions.

Answer B: Jira.

SE28 distinguishes version tracking, issue tracking, automated checks and container packaging. It names Jira as an issue tracker for work and defects, matching bugs and tasks across development. Git records versions, Jenkins automates checks and Docker packages runtime dependencies; those tools may integrate with issue tracking but have different primary roles.

Why each choice is right or wrong

A - Incorrect: Git tracks source versions and history rather than serving as the named issue/task tracker.

B - Correct: Jira tracks work items, defects and tasks through their development workflow.

C - Incorrect: Jenkins automates checks and integration work rather than primarily managing issue records.

D - Incorrect: Docker packages runtime dependencies into containers rather than tracking bugs and tasks.

Primary note proof

Study-note section SE28

> Function points estimate functional size using inputs, outputs, inquiries, internal logical files and external interface files, weighted under the chosen method. They are not just lines of code and are not a direct exact measure of complexity. Git tracks versions; issue trackers such as Jira track work/defects; CI tools such as Jenkins automate checks; Docker packages application/runtime dependencies into containers.

Computer Science MCQ practice collection · Question 14

Question 179 | AM0015

Which design principle suggests that software entities should be open for extension but closed for modification?

A. DRY (Don't Repeat Yourself) principle

B. SOLID principle

C. KISS (Keep It Simple, Stupid) principle

D. YAGNI (You Ain't Gonna Need It) principle

Hint

Separate responsibilities inside a component from dependencies across boundaries. Evaluate the stated structure, change and reuse goals without assuming guaranteed benefits.

Answer B: Open-Closed, within SOLID.

SE25 lists Open-Closed within SOLID and recommends adding compatible extensions. The stem quotes that principle's central idea: support extension while keeping established code stable. DRY, KISS and YAGNI address other concerns. Open-Closed is a design goal achieved through suitable abstractions, rather than a claim that software can never need modification.

Why each choice is right or wrong

A - Incorrect: DRY limits duplicated knowledge rather than defining openness for extension.

B - Correct: SOLID includes the Open-Closed principle explicitly described by the stem.

C - Incorrect: KISS favors simple solutions rather than the specific extension-versus-modification relationship.

D - Incorrect: YAGNI avoids speculative functionality rather than defining the Open-Closed design goal.

Primary note proof

Study-note section SE25

Use abstraction and decomposition to manage complexity; preserve consistency, traceability and clear responsibilities. Top-down design refines high-level structure; bottom-up design assembles existing components. A hybrid combines both. SOLID includes Single Responsibility, Open-Closed, Liskov substitution, Interface Segregation and Dependency Inversion. Depend on

abstractions; add compatible extensions; avoid forcing unused operations. DRY limits duplicated knowledge, KISS avoids unnecessary complexity, and YAGNI avoids speculative work.

Software Engineering module | PDF page 104 | lines 6-17

5.1.4. Generalization
Generalization enables us to organize concepts in to hierarchies. There may be any number of intermediate levels in between, covering more-or-less generalized concepts (e.g., Low Priority Incident, Emergency, Disaster). Such hierarchies allow us to refer to many concepts precisely. When
we use the term Incident, we mean all instances of all types of Incidents. When we use the term Emergency, we only refer to an Incident that requires an immediate response. This view of generalization stems from modeling.
In an object-oriented programming language, inheritance is a reusability technique. If a class Child
inherits from a class Parent, all the attributes and methods available on Parent are automatically available on Child. The class Child may add additional methods or override inherited methods, thus refining the class Parent. As in the case of generalization, the class at the top of the hierarchy
tends to be the most general one, whereas the leaves tend to be the most specialized.

Software Engineering module | PDF page 32 | lines 12-21

A class in an object-oriented system carefully delineates between its interfaces the routines and attributes within a class are held together tightly. In a properly designed system, the classes will be grouped into subsystems but remain independent; therefore, changing one class has no impact
on other classes, and so, the impact is minimized. However, the object-oriented approach is not a panacea; nothing is magical here that will promote perfect design or perfect code.
Promotion of reusability
Objects are reusable because they are modeled directly out of a real-world problem domain. Each
object stands by itself or within a small circle of peers (other objects). Within this framework, the class does not concern itself with the rest of the system or how it is going to be used within a particular system.

Question 180 | AM0016

Which technique is used to represent the static structure of a software system, including classes, relationships, and attributes?

A. Use case diagrams

B. Class diagrams

C. Sequence diagrams

D. State machine diagrams

Hint

Match the information to be represented with each model's purpose. Read relationship direction, boundary and ownership conditions before classifying it.

Answer B: Class diagrams

Class diagrams explicitly depict classes with attributes and operations and their associations/generalizations.

Why each choice is right or wrong

A - Incorrect: External functions and actors. See PDF p. 51.

B - Correct: Exact structural modeling notation. See PDF p. 51.

C - Incorrect: Time-ordered messages among objects. See PDF p. 51.

D - Incorrect: State evolution rather than static attributes/relationships. See PDF p. 51.

Primary note proof

Study-note section SE17

> A class box lists name, attributes and operations; + public, - private, # protected and ~ package indicate visibility. A class diagram shows static types and relationships, while an object diagram shows particular instances/links. UML is maintained and standardized by OMG; it is a modeling language, not a lifecycle process. Structural things describe conceptual or physical structural elements.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 51 | lines 14-24

> 2.3.2. Class Diagrams
> Classes and objects
> Class diagrams describe the structure of the system in terms of classes and objects. Classes are abstractions that specify the attributes and behavior of a set of objects. Objects are entities that encapsulate state and behavior. Each object has an identity: It can be referred individually and is distinguishable from other objects.
> In UML, classes and objects are depicted by boxes including three compartments. The top compartment displays the name of the class or object. The center compartment displays its

attributes, and the bottom compartment displays its operations. The attribute and operation compartment can be omitted for clarity. Object names are underlined to indicate that they are instances. By convention, class names start with an uppercase letter. Objects in object diagrams

Question sources

Computer Science MCQ practice collection · Question 16

Question 181 | AM0017

Customer representatives stay in close contact with developers and use feedback to reshape the next timeboxed work. Which methodology makes this collaboration and adaptation a foundational priority?

A. Waterfall model

B. Agile methodology

C. V-model

D. Spiral model

Hint

Identify whether the scenario prioritizes delivery, learning, adaptation or risk reduction. Several processes can share individual practices, so compare their defining emphasis.

Answer B: Agile methodology

Frequent stakeholder communication alone is possible in several lifecycles. The scenario additionally gives customer representatives ongoing access to the team and lets feedback reshape the next timeboxed body of work, matching Agile's collaboration and adaptation values. Waterfall and the V-model primarily organize planned stages, while spiral organizes commitments around risk reduction. The combination of priorities, rather than communication frequency by itself, identifies the intended methodology.

Why each choice is right or wrong

A - Incorrect: Waterfall is defined by planned phase progression, not the stated adaptive collaboration priority.

B - Correct: Agile explicitly prioritizes customer collaboration and responding to change.

C - Incorrect: The V-model is defined by linked development and testing stages.

D - Incorrect: Spiral's organizing priority is risk assessment and reduction, though stakeholders can participate.

Primary note proof

Study-note section SE05

Agile favors people collaborating, useful working results, customer participation and adaptation over rigid adherence to procedures, exhaustive documents, contracts or fixed plans. The latter

still have value. Agile does not mean no planning or no documentation. A user story states a small user need and value, supported by acceptance criteria; an epic groups broader work.

Study-note section SE03

Classical waterfall separates planned phases with reviewed deliverables. It fits well-understood, stable requirements and familiar technology; late feedback makes changes costly. It does not make change physically impossible: real projects revisit work under control, and modified waterfall explicitly includes feedback. Rigidity offers milestone visibility but can freeze incorrect assumptions.

Study-note section SE06

Spiral development is risk driven. Each cycle identifies objectives and alternatives, assesses and reduces important risks, develops/verifies an appropriate next result, and plans further commitment. A prototype may test a risky technology before a large investment. The amount and type of work depend on the risks.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 13 | lines 22-27

Sometimes, software processes are categorized as either plan-driven or agile processes. Plan-driven processes are processes where all of the process activities are planned in advance and progress is measured against this plan. In agile processes planning is incremental and it is easier to change the process to reflect changing customer requirements. There is no hard and fast rules to
follow but each approach is suitable for different types of software. Generally, you need to find a balance between plan-driven and agile processes.

Software Engineering module | PDF page 22 | lines 8-12

This model delivers software in small but usable pieces, called —increments. In general, each increment builds on those that have already been delivered. The model is iterative in nature and focuses on the delivery of an operational product with each increment. Early increments are stripped down versions of the final product, but they do provide capability that serves the user and
also provide a platform for evaluation by the user.

Software Engineering module | PDF page 81 | lines 11-21

3.4.2. Negotiating specifications with clients: Joint Application Design
Joint Application Design (JAD) is effectiveness lies in that the requirements elicitation work is done in one single workshop session in which all stakeholders participate. Users, clients, developers, and a trained session leader sit together in one room to present their viewpoint, listen
to other viewpoints, negotiate, and agree on a mutually acceptable solution. The outcome of the workshop, the final JAD document, is a complete system specification document that includes definitions of data elements, work flows, and interface screens. Because the final document is jointly developed by the stakeholders (that is, the participants who not only have an interest in the

success of the project, but also can make substantial decisions) the final JAD document represents
an agreement between users, clients, and developers, and thus minimizes requirements changes later in the development process.

Question sources

Computer Science MCQ practice collection · Question 17

Question 182 | AM0018

Which technique documents an actor’s goal with preconditions, a main success flow, alternative flows and postconditions?

A. Use case modeling

B. Storyboarding

C. Wireframing

D. Pair programming

Hint

Match the information to be represented with each model’s purpose. Read relationship direction, boundary and ownership conditions before classifying it.

Answer A: Use case modeling

A use-case description captures an actor’s goal together with preconditions, main flow, alternatives and postconditions. This provides the structured behavioral requirements record in the scenario. Storyboards illustrate moments in an interaction and wireframes sketch interface structure; either can help discovery without supplying that full behavioral contract. Pair programming organizes two people’s implementation work. It is therefore use-case modeling that directly names the requested requirements representation.

Why each choice is right or wrong

A - Correct: Use-case modeling records actors, goals and structured successful and alternative flows.

B - Incorrect: Storyboarding sketches interaction moments rather than necessarily supplying the full goal-and-flow description.

C - Incorrect: Wireframing sketches interface structure and layout.

D - Incorrect: Pair programming is collaborative implementation work.

Primary note proof

Study-note section SE14

An actor is an external role interacting with the system; it can be a person, device or another system. A person may play several roles, and several people may play one role. A primary actor

seeks a goal; a supporting actor provides a service. Ask which user groups perform main functions, administer or maintain the system, and which external systems exchange information.

Study-note section SE-S05

A storyboard sketches a sequence of moments in a proposed interaction, helping people explore how a concept would be used. A wireframe sketches interface structure and the arrangement of content or controls. Both can inform requirements, but neither automatically supplies a complete use-case description with actors, preconditions, flows and postconditions.

Study-note section SE-S05

Pair programming is a way for two programmers to work together on the same implementation task, commonly sharing a workstation with complementary writing and reviewing roles. It is an implementation collaboration practice rather than a replacement for modeling a user goal.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 47 | lines 30-39

Actors are external entities that interact with the system. Examples of actors include a user role (e.g., a system administrator, a bank customer, a bank teller) or another system (e.g., a central database, a fabrication line). Actors have unique names and descriptions.
Use cases describe the behavior of the system as seen from an actor's point of view. Behavior described by the use case model is also called external behavior. A use case describes a function provided by the system as a set of events that yields a visible result for the actors. Actors initiate a
use case to access the system functionality. The use case can then initiate other use cases and gather
more information from the actors. When actors and use cases exchange information, they are said
to communicate. We will see later that we represent these exchanges with communication relationships.

Software Engineering module | PDF page 48 | lines 18-32

To describe a use case, we use a template composed of six fields (see also Figure 2.2):
• The name of the use case is unique across the system so that developers (and project participants) can unambiguously refer to the use case.
• Participating actors are actors interacting with the use case.
• Entry conditions describe the conditions that need to be satisfied before the use case is initiated.
• The flow of events describes the sequence of actions of the use case, which are be numbered for reference. The common case (i.e., cases that occur frequently) and the exceptional cases (i.e., cases that seldom occur, such as errors and unusual conditions) are described separately in different use cases for clarity.
• Exit conditions describe the conditions that are satisfied after the completion of the use case.
• Special requirements are requirements that are not related to the functionality of the

system. These include constraints on the performance of the system, its implementation, the hardware platforms it runs on, and so on.

Question sources

Computer Science MCQ practice collection · Question 18

Question 183 | AM0019

Which testing technique focuses on retesting modified or affected parts of the software to ensure that changes do not introduce new defects?

A. Unit testing

B. Integration testing

C. Regression testing

D. System testing

Hint

Separate testing scope, technique and purpose. Use the stated workload, observable result or coverage target rather than a universal ranking.

Answer C: Regression testing.

SE36 defines regression testing by the purpose of detecting unintended effects after change. That includes retesting changed and affected areas to find newly introduced faults. Unit, integration and system testing describe levels or scope; regression tests can be run at any of them, so the change-driven purpose uniquely identifies C.

Why each choice is right or wrong

A - Incorrect: Unit testing defines a small-component scope rather than the purpose of checking change-induced defects.

B - Incorrect: Integration testing focuses on interfaces and interactions, which may be regression-tested but do not define regression.

C - Correct: Regression testing retests previously working behavior to detect unintended effects of modifications.

D - Incorrect: System testing addresses the complete integrated system rather than specifically the after-change purpose.

Primary note proof

Study-note section SE36

Black-box techniques derive cases from specified behavior; white-box techniques derive them from internal structure; grey-box uses partial internal knowledge. Regression testing checks for unintended effects after change; confirmation testing checks the particular defect repair.

Exploratory testing combines learning, design and execution and is experience based. Manual/automated describe execution support, not a compulsory black-/white-box classification.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 147 | lines 14-18

• Unit testing, which finds faults by isolating an individual component using test stubs and drivers and by exercising the component using a test case
• Integration testing, which finds faults by integrating several components together
• System testing, which focuses on the complete system, its functional and nonfunctional requirements, and its target environment

Software Engineering module | PDF page 142 | lines 5-10

Configuration management avoids faults caused by undisciplined change in the system models. For example, it is a common mistake to a change a subsystem interface without notifying all developers of calling components. Configuration management can make sure that, if analysis models and code are becoming inconsistent with one another, analysts and implementor are notified. The assumption behind configuration management is that the system contains many less
faults if change is controlled.

Software Engineering module | PDF page 147 | lines 3-8

• A test stub is a partial implementation of components on which the tested component depends. A test driver is a partial implementation of a component that depends on the tested component. Test stubs and drivers enable components to be isolated from the rest of the system for testing.
• A correction is a change to a component. The purpose of a correction is to repair a fault. Note that a correction can introduce new faults.

Computer Science MCQ practice collection · Question 19

Question 184 | AM0020

Which tool is used to package an application and its dependencies into a container for easy deployment and scalability?

A. Git

B. Jira

C. Jenkins

D. Docker

Hint

Distinguish the planning or organization goal from the tool or structure used to support it. Apply the stated project conditions.

Answer D: Docker.

SE28 explicitly says Docker packages an application and its runtime dependencies into containers. That matches the deployment packaging task in the question. Git tracks versions, Jira tracks issues and Jenkins automates checks; they can participate in a deployment pipeline, but none replaces Docker's specified container packaging responsibility.

Why each choice is right or wrong

A - Incorrect: Git manages version history rather than packaging the runtime into a container.

B - Incorrect: Jira manages work and defects rather than building application containers.

C - Incorrect: Jenkins automates checks and pipelines but is not the named container-packaging tool.

D - Correct: Docker packages the application and runtime dependencies into a deployable container.

Primary note proof

Study-note section SE28

> Function points estimate functional size using inputs, outputs, inquiries, internal logical files and external interface files, weighted under the chosen method. They are not just lines of code and are not a direct exact measure of complexity. Git tracks versions; issue trackers such as Jira track work/defects; CI tools such as Jenkins automate checks; Docker packages application/runtime dependencies into containers.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 124 | lines 8-16

> Client/server architecture
> In the client/server architecture (Figure 6.9), a subsystem, the server, provides servicesto instances
> of other subsystems called the clients, which are responsible for interacting with theuser. The request for a service is usually done via a remote procedure call mechanism or acommon object broker (e.g., CORBA or Java RMI). Control flow in the clients and the servers isindependent except for synchronization to manage requests or to receive results.
> Figure 6.9 Client/server architecture (UML class diagram).
> Clients request services from one or more servers. The server has no knowledge of the client. The client/server architecture is a generalization of the repository architecture.

Software Engineering module | PDF page 119 | lines 13-25

> 6.1.2. Services and subsystem interfaces
> A subsystem is characterized by the services it provides to other subsystems. A service is a set of

related operations that share a common purpose. A subsystem providing a notification service, for
example, defines operations to send notices, look up notification channels, and subscribe and unsubscribe to a channel.
The set of operations of a subsystem that are available to other subsystems form the subsystem interface. The subsystem interface, also referred to as the application programmer interface (API),
includes the name of the operations, their parameters, their types, and their return values. System
design focuses on defining the services provided by each subsystem that is, enumerating the operations, their parameters, and their high-level behavior. Object design will focus on defining the subsystem interfaces, that is, the type of the parameters and the return value of each operation.
The definition of a subsystem in terms of the services it provides helps us focus on its interface as opposed to its implementation. A good subsystem interface should provide as little information

Question sources

Computer Science MCQ practice collection · Question 20

Question 185 | AM0021

Which phase of the software development life cycle (SDLC) focuses on gathering and understanding user requirements?

A. Analysis

B. Design

C. Implementation

D. Testing

Hint

Distinguish observable services, measurable qualities and implementation constraints. Check scope, stakeholder meaning and the requested level of specificity.

Answer A: Analysis

Elicitation and analysis establish user needs before internal design and implementation.

Why each choice is right or wrong

A - Correct: Corresponds to gathering and structuring requirements. See PDF p. 62, 100.

B - Incorrect: Plans the internal realization. See PDF p. 62, 100.

C - Incorrect: Realizes the software design in code. See PDF p. 62, 100.

D - Incorrect: Tries to expose faults in implemented software. See PDF p. 62, 100.

Primary note proof

Study-note section SE08

Business requirements explain why the project exists and its goals. User requirements describe stakeholder needs at a useful high level; system requirements specify detailed services and constraints. The Software Requirements Specification (SRS) organizes the agreed requirements. A natural-language specification communicates with clients while analysis models formalize it for technical discussion; real specifications can also contain diagrams.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 62 | lines 9-16

Requirement's elicitation focuses on describing the purpose of the system. The client, the developers, and the users identify a problem area and define a system that addresses the problem.
Such a definition is called a system specification and serves as a contract between the client and the developers. The system specification is structured and formalized during analysis to produce an analysis model (see Figure 3.1). Both system specification and analysis model represent the same information. They differ only in the language and notation they use. The system specification
is written in natural language, whereas the analysis model is usually expressed in a formal or semiformal notation.

Software Engineering module | PDF page 100 | lines 11-24

Analysis focuses on producing a model of the system, called the analysis model, which is correct, complete, consistent, and verifiable. Analysis is different from requirements elicitation in that developers focus on structuring and formalizing the requirements elicited from users
Figure 4.1 Products of requirements elicitation and analysis (UML activity diagram).
Althoughtheanalysismodelmaynotbeunderstandabletotheusersandtheclient, it helps developers verify the system specification produced during requirements elicitation. There is a natural tendency for users and developers to postpone difficult decisions until later in the project. A decision may be difficult because of lack of domain knowledge, lack of technological knowledge, or simply because of disagreements among users and developers. Postponing decisions enables the
project to move on smoothly and avoid confrontation with reality or peers. Unfortunately, difficult
decisions will eventually need to be made, often at higher cost when intrinsic problems are discovered during testing, or worse, during user evaluation. Translating a system specification in to a formal or semi-formal model forces developers to identify and resolve difficult issues early in
the development.

Question sources

Computer Science MCQ practice collection · Question 21

Question 186 | AM0022

What is the primary goal of software design?

A. To create a visually appealing user interface

B. To optimize the performance of the software system

C. To translate user requirements into a detailed plan

D. To develop and test individual software components

Hint

Separate responsibilities inside a component from dependencies across boundaries. Evaluate the stated structure, change and reuse goals without assuming guaranteed benefits.

Answer C: To translate user requirements into a detailed plan

Design transforms the SRS into a structure suitable for implementation and identifies internal architecture and responsibilities.

Why each choice is right or wrong

A - Incorrect: UI appearance is one design concern, not the whole goal. See PDF p. 18, 116.

B - Incorrect: Performance optimization is a design goal, not the full transformation purpose. See PDF p. 18, 116.

C - Correct: Matches transforming requirements into an implementable design. See PDF p. 18, 116.

D - Incorrect: Coding/testing occur after or alongside design refinement, not its primary deliverable. See PDF p. 18, 116.

Primary note proof

Study-note section SE21

> System design turns the analysis model into architecture: design goals, subsystem responsibilities, dependencies, hardware mapping, data management, access control, control flow and startup/shutdown/error policies. Detail/object design refines APIs, parameter/return types, exceptions, component choices and algorithms. A subsystem is a manageable logical collection with services and an interface; it need not be a physical replaceable artifact.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 18 | lines 13-20

> System and software design: The systems design process allocates the requirements to either hardware or software systems by establishing an overall system architecture.
> Software design involves identifying and describing the fundamental software system abstractions
> and their relationships. The goal of the design phase is to transform the requirements specified in
> the SRS document into a structure that is suitable for implementation in some programming

language. In technical terms, during the design phase the software architecture is derived from the
SRS document. Two distinctly different approaches are available: the traditional design approach
and the object-oriented design approach.

Software Engineering module | PDF page 116 | lines 16-29

The analysis model describes the system completely from the actors' point of view and serves as the basis of communication between the client and the developers. The analysis model, however, does not contain information about the internal structure of the system, its hardware configuration,
or, more generally, how the system should be realized. System design is the first step in this direction. System design results in the following products:
• List of design goals, describing the qualities of the system that developers should optimize
• Software architecture, describing the subsystem decomposition in terms of subsystem responsibilities, dependencies among subsystems, subsystem mapping to hardware, and major policy decisions such as control flow, access control, and data storage.
The design goals are derived from the nonfunctional requirements. Design goals guide the decisions to be made by the developers especially when trade-offs are needed. The subsystem decomposition constitutes the bulk of system design. Developers divide the system into manageable pieces to deal with complexity: Each subsystem is assigned to a team and realized independently. In order for this to be possible, though, developers need to address system-wide

Computer Science MCQ practice collection · Question 22

Question 187 | AM0023

Which broad approach explicitly centers its values on collaboration, working results and responding to change, using frequent feedback to improve later work?

A. Waterfall model

B. Agile methodology

C. Spiral model

D. V-model

Hint

Identify whether the scenario prioritizes delivery, learning, adaptation or risk reduction. Several processes can share individual practices, so compare their defining emphasis.

Answer B: Agile methodology

The stated priorities combine short feedback cycles, collaboration and adaptation as central development values. Agile names that broad approach. Waterfall and the V-model emphasize planned stages, with the V-model additionally relating stages to test levels. Spiral can also iterate and consult stakeholders, but its defining cycle is risk-driven. Distinguishing the core emphasis avoids incorrectly claiming that only Agile can communicate or revisit work.

Why each choice is right or wrong

A - Incorrect: Classical waterfall emphasizes planned phase commitments.

B - Correct: Agile makes collaboration and responsiveness to change central values.

C - Incorrect: Spiral is defined by explicit risk-reduction cycles rather than this value-based emphasis.

D - Incorrect: The V-model is defined by development-test correspondences.

Primary note proof

Study-note section SE05

> Agile favors people collaborating, useful working results, customer participation and adaptation over rigid adherence to procedures, exhaustive documents, contracts or fixed plans. The latter still have value. Agile does not mean no planning or no documentation. A user story states a small user need and value, supported by acceptance criteria; an epic groups broader work.

Study-note section SE03

> Classical waterfall separates planned phases with reviewed deliverables. It fits well-understood, stable requirements and familiar technology; late feedback makes changes costly. It does not make change physically impossible: real projects revisit work under control, and modified waterfall explicitly includes feedback. Rigidity offers milestone visibility but can freeze incorrect assumptions.

Study-note section SE06

> Spiral development is risk driven. Each cycle identifies objectives and alternatives, assesses and reduces important risks, develops/verifies an appropriate next result, and plans further commitment. A prototype may test a risky technology before a large investment. The amount and type of work depend on the risks.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 13 | lines 22-27

> Sometimes, software processes are categorized as either plan-driven or agile processes. Plan-driven processes are processes where all of the process activities are planned in advance and progress is measured against this plan. In agile processes planning is incremental and it is easier to change the process to reflect changing customer requirements. There is no hard and fast rules to

follow but each approach is suitable for different types of software. Generally, you need to find a balance between plan-driven and agile processes.

Software Engineering module | PDF page 22 | lines 8-12

This model delivers software in small but usable pieces, called —increments. In general, each increment builds on those that have already been delivered. The model is iterative in nature and focuses on the delivery of an operational product with each increment. Early increments are stripped down versions of the final product, but they do provide capability that serves the user and
also provide a platform for evaluation by the user.

Question sources

Computer Science MCQ practice collection · Question 23

Question 188 | AM0024

A team separates a reusable reporting component behind a stable interface so other applications can use it and its implementation can change without rewriting clients. Which benefit most directly captures both goals?

A. To improve the readability of the code

B. To ensure efficient memory management

C. To facilitate code reuse and maintenance

D. To minimize the number of software defects

Hint

Separate responsibilities inside a component from dependencies across boundaries. Evaluate the stated structure, change and reuse goals without assuming guaranteed benefits.

Answer C: To facilitate code reuse and maintenance

A module with a stable interface can be reused in another application, and hiding its implementation allows localized changes without rewriting its clients. Those are reuse and maintenance benefits. Readability may improve as well, but it does not fully describe the two goals stated in the scenario. Modularization does not automatically optimize memory use or eliminate defects; good boundaries and verification still matter.

Why each choice is right or wrong

A - Incorrect: Readability may improve, but it does not fully describe reuse across applications and localized change.

B - Incorrect: Memory efficiency is not guaranteed by separating modules.

C - Correct: Reuse and maintenance directly match the two stated goals.

D - Incorrect: Reducing defects can be a benefit, but it does not name the stated reuse-and-change objective.

Primary note proof

Study-note section SE22

Logical cohesion groups similar-category operations, often selected by a flag; temporal cohesion groups operations done at the same time; functional cohesion focuses on one task. Splitting an unrelated three-purpose component improves modularity. If behavior is preserved, the restructuring is refactoring; the words are not mutually exclusive answers. Smaller modules can aid understanding, independent work, reuse and maintenance, but too many interfaces also create complexity.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 118 | lines 11-16

6.1.1. Subsystems and classes
In order to reduce the complexity of the application domain, we identified smaller parts called classes and organized them into packages. Similarly, to reduce the complexity of the solution domain, we decompose a system into simpler parts, called subsystems, which are made of a number of solution domain classes. In the case of complex subsystems, we recursively apply this principle and decompose a subsystem into simpler subsystems (see Figure 6.2).

Software Engineering module | PDF page 32 | lines 12-21

A class in an object-oriented system carefully delineates between its interfaces the routines and attributes within a class are held together tightly. In a properly designed system, the classes will be grouped into subsystems but remain independent; therefore, changing one class has no impact
on other classes, and so, the impact is minimized. However, the object-oriented approach is not a panacea; nothing is magical here that will promote perfect design or perfect code.
Promotion of reusability
Objects are reusable because they are modeled directly out of a real-world problem domain. Each
object stands by itself or within a small circle of peers (other objects). Within this framework, the class does not concern itself with the rest of the system or how it is going to be used within a particular system.

Software Engineering module | PDF page 120 | lines 6-12

6.1.3. Coupling and coherence
Coupling is the strength of dependencies between two subsystems. If two subsystems are loosely coupled, they are relatively independent, and thus, modifications to one of the subsystems will have little impact on the other. If two subsystems are strongly coupled, modifications to one subsystem is likely to have impact on the other. A desirable property of a subsystem decomposition
is that subsystems are as loosely coupled as possible. This minimizes the impact that errors or future changes have on the correct operation of the system.

Question sources

Computer Science MCQ practice collection · Question 24

Question 189 | AM0025

Which type of testing aims to uncover defects in the interaction between different components of a software system?

A. Unit testing

B. Integration testing

C. System testing

D. Regression testing

Hint

Separate testing scope, technique and purpose. Use the stated workload, observable result or coverage target rather than a universal ranking.

Answer B: Integration testing

The defects sought are in communication or interfaces among combined components, so the applicable level is integration testing. Unit tests concentrate on isolated units and system tests assess the complete product. Regression testing instead describes checking for unintended effects after a change, and can include unit, integration or system tests. The distinction is between the scope of combination and the purpose that triggers a test run.

Why each choice is right or wrong

A - Incorrect: Unit testing concentrates on an isolated function or small component.

B - Correct: Integration testing targets interactions among combined parts.

C - Incorrect: System testing checks the whole integrated system against requirements.

D - Incorrect: Regression is an after-change objective that can occur at several testing levels.

Primary note proof

Study-note section SE35

> Unit testing isolates a function, class or small component, often replacing dependencies with stubs/mocks; a driver invokes the unit and a stub substitutes a called dependency. Integration testing exercises interfaces and interactions among combined parts. System testing checks the complete integrated system against functional and nonfunctional requirements in a representative environment.

Study-note section SE36

> Functional tests check required behavior against the SRS and acceptance criteria. Performance tests assess speed, throughput and resources under a specified workload; load uses expected demands and stress exceeds normal limits. Usability, security, compatibility and reliability tests

target their respective qualities. “Normal operating conditions” alone does not distinguish functional from performance testing.

Question 190 | AM0026

Which programming paradigm is based on the concept of objects and their interactions?

A. Functional programming

B. Procedural programming

C. Object-oriented programming

D. Event-driven programming

Hint

Identify whether the scenario prioritizes delivery, learning, adaptation or risk reduction. Several processes can share individual practices, so compare their defining emphasis.

Answer C: Object-oriented programming

Object-oriented programming organizes a system around objects that combine state and behavior and interact through operations. Procedural programming decomposes work into functions or procedures that manipulate data. Functional programming emphasizes function evaluation and controlled side effects, while event-driven programming organizes reactions to events. An object-oriented program may also use events or functions, but the question asks which paradigm is defined by objects and their interactions.

Why each choice is right or wrong

A - Incorrect: Functional programming emphasizes evaluation of functions and controlled side effects.

B - Incorrect: Procedural programming emphasizes functions or procedures operating on data.

C - Correct: Object-oriented programming centers on objects with state and behavior.

D - Incorrect: Event-driven programming centers on reactions to events, independent of object-based decomposition.

Primary note proof

Study-note section SE01

> Procedural decomposition organizes functions; object oriented decomposition organizes objects with state and behavior. Either can use iterative or sequential development. OOP does not automatically shorten every project. Reuse, encapsulation and consistent models can reduce duplication and ease change; poor object design can still be complex. Functional programming emphasizes function evaluation and controlled side effects; event-driven programs react to events.

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 40 | lines 12-18

> ✓ Object -Oriented paradigm is an approach to the solution of problems in which all computations are performed in the context of objects.
> ✓ Object-oriented programming allows decomposition of a problem into a number of objects and then builds data and functions around these objects.
> ✓ In an object-oriented environment everything is an object and each object is responsible for itself.
> ✓ Object oriented systems are easier to adapt to changes, more robust, and easier to maintain.

Question sources

Computer Science MCQ practice collection · Question 26

Question 191 | AM0027

What is the defining artifact-management function of version control, distinguishing it from collaboration benefits and CI services?

A. To manage project schedules and milestones

B. To facilitate collaboration among team members

C. To track and control changes to source code and files

D. To automate the testing and deployment processes

Hint

Separate artifact history and controlled changes from scheduling, collaboration benefits and automated execution.

Answer C: To track and control changes to source code and files

Version control records artifact versions and their history, making it possible to inspect changes, maintain branches and combine compatible work. Collaboration is an important benefit, but it is broader than the defining version-history function. Scheduling belongs to project planning, while automated testing and deployment belong to CI or delivery tooling that can use version-control events. These roles can be integrated without becoming the same activity.

Why each choice is right or wrong

A - Incorrect: Scheduling and milestones belong to project planning and tracking.

B - Incorrect: Collaboration is a benefit enabled by shared versions and merging, rather than the defining artifact-history function.

C - Correct: Tracking and controlling file changes is the direct version-control function.

D - Incorrect: Testing and deployment automation is CI/delivery work that may integrate with version control.

Primary note proof

Study-note section SE33

> Configuration management identifies controlled items, versions/baselines, change procedures, status and audits. Items may include source code, requirements, manuals, test plans, environments and build configurations. A team’s ordinary browser is usually a tool rather than product CI, but a controlled test-browser version may be an environment CI.

Study-note section SE28

> Git tracks versions; issue trackers such as Jira track work/defects; CI tools such as Jenkins automate checks; Docker packages application/runtime dependencies into containers.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 142 | lines 5-10

Configuration management avoids faults caused by undisciplined change in the system models. For example, it is a common mistake to a change a subsystem interface without notifying all developers of calling components. Configuration management can make sure that, if analysis models and code are becoming inconsistent with one another, analysts and implementor are notified. The assumption behind configuration management is that the system contains many less
faults if change is controlled.

Question sources

Computer Science MCQ practice collection · Question 27

Question 192 | AM0028

Which conventional lifecycle is described by a simple linear requirements→design→implementation→testing sequence with reviewed phase completion, without the V-model's explicit development-to-test pairing?

A. Waterfall model

B. Agile methodology

C. Spiral model

D. V-model

Hint

Identify whether the scenario prioritizes delivery, learning, adaptation or risk reduction. Several processes can share individual practices, so compare their defining emphasis.

Answer A: Waterfall model

Classical waterfall organizes work as separated planned phases with reviewed deliverables, matching the stated linear sequence. The V-model additionally pairs development artifacts with later test levels, which this question excludes. Agile emphasizes adaptation and feedback, while spiral organizes repeated risk-driven cycles. Explicitly distinguishing the test-pairing structure removes the overlap between two staged processes without denying their relationship.

Why each choice is right or wrong

A - Correct: Classical waterfall matches the specified simple linear organization.

B - Incorrect: Agile emphasizes adaptive content and feedback.

C - Incorrect: Spiral uses risk-driven cycles.

D - Incorrect: The V-model adds explicit development-to-test pairing excluded here.

Primary note proof

Study-note section SE03

The V-model pairs specification/design stages with later test levels. Requirements inform acceptance tests; system design informs system tests; component/detail design informs

integration/unit tests. Coding lies at the bottom. Test planning starts early. Stable requirements and strong assurance may favor this organization, but neither a V shape nor waterfall guarantees safety or correctness.

Study-note section SE03

Classical waterfall separates planned phases with reviewed deliverables. It fits well-understood, stable requirements and familiar technology; late feedback makes changes costly.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 15 | lines 16-20

non-iterative (or sequential) process in which progress is seen as flowing steadily downwards (like
a waterfall) through the development phases. Thus the waterfall model maintains that one should
move to a phase only when its preceding phase is reviewed and verified. That is, each phase must
be completed before the next phase can begin. In waterfall model phases do not overlap. But there
are various modified waterfall models, and hence, may include slight or major modifications.

Question sources

Computer Science MCQ practice collection · Question 28

Question 193 | AM0029

What is the primary purpose of software documentation?

A. To serve as a record of code authorship

B. To provide instructions for end-users

C. To assist in software maintenance and understanding

D. To ensure compliance with coding standards

Hint

Distinguish process assurance from product evaluation, and compare specified obligations with actual stakeholder needs.

Answer C: To assist in software maintenance and understanding

Documentation records requirements and architecture so developers can understand decisions, revisit designs and coordinate later change. A user manual is one audience-specific part of this broader purpose.

Why each choice is right or wrong

A - Incorrect: Authorship alone does not capture system decisions or behavior. See PDF p. 130, 83, 32.

B - Incorrect: End-user instructions are a valid subset, not the overall technical purpose. See PDF p. 130, 83, 32.

C - Correct: Matches understanding, revisiting and maintaining documented structures. See PDF p. 130, 83, 32.

D - Incorrect: Coding-standard compliance is narrower than the general understanding purpose. See PDF p. 130, 83, 32.

Primary note proof

Study-note section SE34

Quality assurance establishes and checks processes/standards; quality control evaluates work products. An SQA plan identifies standards, responsibilities, evaluations, reviews, audits and assurance records. Quality of conformance means following the design/specification; a product can conform to a poor specification. Verification asks whether specified obligations are implemented correctly; validation asks whether the product meets intended stakeholder needs. Both can use reviews, analysis or execution, so “human-only versus computer-only” is false.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 130 | lines 3-11

6.3. DOCUMENTING SYSTEM DESIGN
System design is documented in the System Design Document (SDD). It describes design goals set by the project, the subsystem decomposition (with UML class diagrams), the hardware/software mapping (with UML deployment diagrams), the data management, the access control, control flow mechanisms, and boundary conditions. The SDD is used to define interfaces between teams of developers and as reference when architecture-level decisions need to be revisited. The audience for the SDD includes the project management, the system architects (i.e., the developers who participate in the system design), and the developers who design and implement each subsystem. The following is an example template for a SDD:

Software Engineering module | PDF page 83 | lines 12-25

3.4.4. Documenting Requirements Elicitation
The results of the requirements elicitation activity and the analysis activity are documented in the
Requirements Analysis Document (RAD). This document completely describes the system in terms of functional and nonfunctional requirements and serves as a contractual basis between the
client and the developers. The audience for the RAD includes the client, the users, the project management, the system analysts (i.e., the developers who participate in the requirements), and the system designers (i.e., the developers who participate in the system design). The first part of the document, including use cases and nonfunctional requirements, is written during requirements

elicitation. The formalization of the specification in terms of object models is written during analysis.
The first section of the RAD is an Introduction. Its purpose is to provide a brief overview of the function of the system and the reasons for its development, its scope, and references to the development context (e.g., related problem statement, references to existing systems, feasibility studies). The introduction also includes the objectives and success criteria of the project.

Software Engineering module | PDF page 32 | lines 12-21

A class in an object-oriented system carefully delineates between its interfaces the routines and attributes within a class are held together tightly. In a properly designed system, the classes will be grouped into subsystems but remain independent; therefore, changing one class has no impact
on other classes, and so, the impact is minimized. However, the object-oriented approach is not a panacea; nothing is magical here that will promote perfect design or perfect code.
Promotion of reusability
Objects are reusable because they are modeled directly out of a real-world problem domain. Each
object stands by itself or within a small circle of peers (other objects). Within this framework, the class does not concern itself with the rest of the system or how it is going to be used within a particular system.

Question sources

Computer Science MCQ practice collection · Question 29

Question 194 | AM0030

After each short usable release, customers reorder the remaining work and the team adapts the next release’s content while keeping its timebox. Which broad approach most directly fits this planning behavior?

A. Waterfall model

B. Agile methodology

C. Spiral model

D. V-model

Hint

Identify whether the scenario prioritizes delivery, learning, adaptation or risk reduction. Several processes can share individual practices, so compare their defining emphasis.

Answer B: Agile methodology

A fixed short timebox with usable results and customer-driven adaptation of later content fits Agile planning. Classical waterfall and the V-model organize planned development stages, with the latter pairing stages to tests. Spiral cycles organize commitments around risk assessment and reduction. All can incorporate some staged work, so the stated treatment of feedback and later scope is what makes the Agile option the most direct match.

Why each choice is right or wrong

A - Incorrect: Classical waterfall emphasizes planned phases and later delivery feedback.

B - Correct: Agile adapts later work from customer feedback while producing usable increments.

C - Incorrect: Spiral is specifically organized around risk reduction, not the stated timeboxed adaptation rule.

D - Incorrect: The V-model is defined by paired development and test stages.

Primary note proof

Study-note section SE04

> Choose incremental delivery when prioritized partial capability must reach users early. Smaller changes can be easier to debug and permit feedback, though architecture and integration still require planning. Iteration need not rebuild the whole system every time, and increments need not be perfectly independent modules. Broad descriptions of early working software can fit prototypes, iterative or Agile processes; identify the purpose of that early version.

Study-note section SE03

> Classical waterfall separates planned phases with reviewed deliverables. It fits well-understood, stable requirements and familiar technology; late feedback makes changes costly. It does not make change physically impossible: real projects revisit work under control, and modified waterfall explicitly includes feedback. Rigidity offers milestone visibility but can freeze incorrect assumptions.

Study-note section SE06

> Spiral development is risk driven. Each cycle identifies objectives and alternatives, assesses and reduces important risks, develops/verifies an appropriate next result, and plans further commitment. A prototype may test a risky technology before a large investment. The amount and type of work depend on the risks.

Study-note section SE05

> Scrum uses timeboxed Sprints of at most one month, with a Sprint Goal, selected work and a usable Increment meeting a Definition of Done. Scope is discussed before and during planning; it is not forbidden to agree scope. Timeboxes tend to stay fixed while content is adapted without endangering the goal. Agile can be combined with required assurance/documentation; safety-critical context alone cannot prove it is unsuitable.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 22 | lines 8-12

> This model delivers software in small but usable pieces, called —increments. In general, each increment builds on those that have already been delivered. The model is iterative in nature and focuses on the delivery of an operational product with each increment. Early increments are stripped down versions of the final product, but they do provide capability that serves the user and
> also provide a platform for evaluation by the user.

Software Engineering module | PDF page 13 | lines 22-27

> Sometimes, software processes are categorized as either plan-driven or agile processes. Plan-driven processes are processes where all of the process activities are planned in advance and progress is measured against this plan. In agile processes planning is incremental and it is easier to change the process to reflect changing customer requirements. There is no hard and fast rules to
> follow but each approach is suitable for different types of software. Generally, you need to find a balance between plan-driven and agile processes.

Question sources

Computer Science MCQ practice collection · Question 30

Question 195 | AM0031

Which design principle advocates for designing software components that have a single responsibility?

A. Encapsulation

B. Inheritance

C. Polymorphism

D. Single Responsibility Principle

Hint

Separate responsibilities inside a component from dependencies across boundaries. Evaluate the stated structure, change and reuse goals without assuming guaranteed benefits.

Answer D: Single Responsibility Principle.

SE25 identifies Single Responsibility among the core design principles. The question asks directly for one responsibility per component, so D is the exact named rule. Encapsulation protects internal decisions, inheritance creates subtype relations, and polymorphism supports varying implementations through a common interface. Those can help a design but do not themselves define a single responsibility.

Why each choice is right or wrong

A - Incorrect: Encapsulation hides implementation details rather than requiring one responsibility per component.

B - Incorrect: Inheritance establishes superclass/subclass reuse rather than the focused-responsibility rule.

C - Incorrect: Polymorphism supports compatible varying implementations rather than defining responsibility count.

D - Correct: Single Responsibility explicitly calls for one focused responsibility in a software component.

Primary note proof

Study-note section SE25

> SOLID includes Single Responsibility, Open-Closed, Liskov substitution, Interface Segregation and Dependency Inversion.

Study-note section SE-S02

> Generalization places common concepts in a more general superclass and specialized concepts in subclasses. Available inherited attributes and operations are shared by subclasses, which may extend or override behavior.

Study-note section SE-S02

> Encapsulation groups state with operations and hides representation behind an interface. Polymorphism permits different object types to respond differently through a common operation or interface. Abstraction exposes the relevant contract while omitting unnecessary detail. Reusability means using suitable existing classes or components in new contexts rather than writing them again. These ideas support each other but name different properties.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 120 | lines 24-27

> Coherence is the strength of dependencies within a subsystem. If a subsystem contains many objects that are related to each other and perform similar tasks, its coherence is high. If a subsystem
> contains a number of unrelated objects, its coherence is low. A desirable property of a subsystem decomposition is that it leads to subsystems with high coherence.

Software Engineering module | PDF page 101 | lines 9-15

> The analysis object model consists of entity, boundary, and control objects. Entity objects represent the persistent information tracked by the system. Boundary objects represent the interactions between the actors and the system. Control objects represent the tasks that a formed by the user and supported by the system. In the 2B watch example, Year, Month, Day are entity objects; Button Boundary and LCD Display Boundary are boundary objects; Change Date Control is
> a control object that represents the activity of changing the date by pressing combinations of buttons.

Question sources

Computer Science MCQ practice collection · Question 31

Question 196 | AM0032

Which design pattern is used to ensure that only one instance of a class is created throughout the system?

A. Singleton pattern

B. Factory pattern

C. Observer pattern

D. Decorator pattern

Hint

Separate responsibilities inside a component from dependencies across boundaries. Evaluate the stated structure, change and reuse goals without assuming guaranteed benefits.

Answer A: Singleton.

SE27 describes Singleton as controlling access to one instance. That is the pattern requested by the one-instance condition. Factory patterns address how concrete objects are created, Observer notifies subscribers and Decorator adds behavior by wrapping. None of those other pattern responsibilities guarantees a single shared instance by itself.

Why each choice is right or wrong

A - Correct: Singleton controls creation and access so that the intended class has one shared instance.

B - Incorrect: A factory selects or constructs products rather than inherently limiting a class to one instance.

C - Incorrect: Observer distributes notifications to subscribers rather than restricting object instance count.

D - Incorrect: Decorator adds behavior through wrapping rather than enforcing a single instance.

Primary note proof

Study-note section SE27

> Factory Method lets subclasses choose a concrete product through a creation operation, reducing coupling to concrete constructors. A simple factory centralizes creation but is not identical to Factory Method. Singleton controls access to one instance; Observer notifies subscribers; Memento stores/restores state while hiding representation; Iterator traverses; Decorator adds behavior through wrapping. The pattern name is Memento, not Momento.

Software Engineering module | PDF page 121 | lines 6-15

6.1.4. Software architecture
As the complexity of systems increases, the specification of the system decomposition is critical. It is difficult to modify or correct a weak decomposition once development has started, as most subsystem interfaces have to change. In recognition of the importance of this problem, the concept
of software architecture has emerged. A software architecture includes the system decomposition, the global control flow, error-handling policies and inter subsystem communication protocols.
In this section, we describe a few sample architectures that can be used for different systems. This
is by no means a systematic or thorough exposition of the subject. Rather, we aim to provide a few
representative examples and refer the reader to the literature for more details.

Question sources

Computer Science MCQ practice collection · Question 32

Question 197 | AM0033

Which test type checks that specified services produce the required outputs under normal operating conditions, without measuring speed/resources or user task ease?

A. Stress testing

B. Performance testing

C. Functional testing

D. Usability testing

Hint

Separate testing scope, technique and purpose. Use the stated workload, observable result or coverage target rather than a universal ranking.

Answer C: Functional testing

Functional tests compare observable services and outputs with the SRS and acceptance criteria. That is the stated objective, so C applies. Performance testing measures speed, throughput or resources, and usability evaluates user task success or ease; neither is requested here. Stress testing exceeds normal limits. Normal operating conditions alone would not distinguish these types, but the explicit behavioral objective does.

Why each choice is right or wrong

A - Incorrect: Stress testing exceeds normal operating limits.

B - Incorrect: Performance testing measures speed, throughput or resources.

C - Correct: Functional testing checks specified services and outputs.

D - Incorrect: Usability testing evaluates user task ease or success.

Primary note proof

Study-note section SE36

Functional tests check required behavior against the SRS and acceptance criteria. Performance tests assess speed, throughput and resources under a specified workload; load uses expected demands and stress exceeds normal limits. Usability, security, compatibility and reliability tests target their respective qualities. “Normal operating conditions” alone does not distinguish functional from performance testing.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

• Performance characteristics. How responsive should the system be? How many concurrent users should it support? What is a typical or extreme load?
• Error handling and extreme conditions. How should the system handle exceptions? Which exceptions should the system handle? What is the worse environment in which the system is expected to perform? Are there safety requirements on the system?
• Quality issues. How reliable/available/robust should the system be? What is the client’s involvement in assessing the quality of the system or the development process?

Question sources

Computer Science MCQ practice collection · Question 33

Question 198 | AM0034

Which programming paradigm promotes the use of data and avoids side effects?

A. Functional programming

B. Procedural programming

C. Object-oriented programming

D. Event-driven programming

Hint

Identify whether the scenario prioritizes delivery, learning, adaptation or risk reduction. Several processes can share individual practices, so compare their defining emphasis.

Answer A: Functional programming, for the side-effect emphasis.

The phrase promotes the use of data is not distinctive because all these paradigms use data. The discriminating part is avoiding or controlling side effects. SE01 explicitly assigns function evaluation and controlled side effects to functional programming. Procedural, object-oriented and event-driven styles organize behavior differently and do not inherently impose that emphasis.

Why each choice is right or wrong

A - Correct: Functional programming emphasizes evaluating functions and controlling side effects.

B - Incorrect: Procedural decomposition organizes functions or procedures without inherently avoiding state-changing effects.

C - Incorrect: Object-oriented decomposition combines state and behavior and does not inherently exclude side effects.

D - Incorrect: Event-driven programs react to events; that does not itself require avoiding side effects.

Primary note proof

Study-note section SE01

> Procedural decomposition organizes functions; object oriented decomposition organizes objects with state and behavior. Either can use iterative or sequential development. OOP does not automatically shorten every project. Reuse, encapsulation and consistent models can reduce duplication and ease change; poor object design can still be complex. Functional programming emphasizes function evaluation and controlled side effects; event-driven programs react to events.

Software Engineering module | PDF page 40 | lines 12-18

✓ Object -Oriented paradigm is an approach to the solution of problems in which all computations are performed in the context of objects.
✓ Object-oriented programming allows decomposition of a problem into a number of objects and then builds data and functions around these objects.
✓ In an object-oriented environment everything is an object and each object is responsible for itself.
✓ Object oriented systems are easier to adapt to changes, more robust, and easier to maintain.

Question sources

Computer Science MCQ practice collection · Question 34

Question 199 | AM0035

Which type of software maintenance involves making changes to a software system to adapt it to new environments or technologies?

A. Corrective maintenance

B. Adaptive maintenance

C. Perfective maintenance

D. Preventive maintenance

Hint

Classify the motive for the change before its implementation: repair, environment, useful capability or reduced future risk.

Answer B: Adaptive maintenance.

SE40 defines adaptive maintenance as responding to changes in the environment. New platforms or technologies therefore create an adaptive-maintenance need even when the original software is not faulty. Corrective maintenance fixes faults, perfective work improves useful capability or performance, and preventive work reduces future risk. The stated environmental motive makes B the appropriate category.

Why each choice is right or wrong

A - Incorrect: Corrective work fixes faults rather than primarily accommodating changed environments or technology.

B - Correct: Adaptive maintenance changes software so it continues working in a new environment or technology context.

C - Incorrect: Perfective work improves capability or performance rather than specifically responding to an environmental change.

D - Incorrect: Preventive work reduces future maintenance risk rather than defining adaptation to a new environment.

Primary note proof

Study-note section SE40

> Corrective maintenance fixes faults; adaptive maintenance responds to environment changes; perfective maintenance improves useful capability/performance; preventive maintenance reduces future risk, such as restructuring fragile code. Motive determines category; refactoring can support preventive or perfective work. Maintenance often lasts years and includes understanding legacy code and regression effort, so it may dominate lifecycle cost.

Module passages - related reading

Software Engineering module | PDF page 19 | lines 24-29

> 5. Operation and maintenance: Normally (although not necessarily), this is the longest life cycle phase. Maintenance of a typical software product requires much more than the effort necessary to
> develop the product itself. The system is installed and put into practical use. Maintenance involves
> correcting errors which were not discovered in earlier stages of the life cycle, improving the implementation of system units and enhancing the system ‘s services as new requirements are discovered.

Software Engineering module | PDF page 41 | lines 16-17

> ✓ Software evolution takes place when you change existing software systems to meet new requirements. Changes are continuous and the software must evolve to remain useful.

Question sources

Computer Science MCQ practice collection · Question 35

Question 200 | AM0036

What is the purpose of usability testing in software development?

A. To evaluate the performance of the software system under stress conditions

B. To assess the user-friendliness and ease of use of the software system

C. To verify the compliance of the software system with specified requirements

D. To identify and fix defects or issues in the software system

Hint

Separate testing scope, technique and purpose. Use the stated workload, observable result or coverage target rather than a universal ranking.

Answer B: To assess the user-friendliness and ease of use of the software system

Usability testing examines ease of learning, task completion and user errors, with the goal of identifying and improving usability problems.

Why each choice is right or wrong

A - Incorrect: Stress performance is not the ease-of-use focus. See PDF p. 82.

B - Correct: Directly matches ease of use and learning. See PDF p. 82.

C - Incorrect: General requirements conformance is broader than this specific user-focused test. See PDF p. 82.

D - Incorrect: General fault fixing is broader; the test identifies user interaction difficulties rather than implementing all repairs. See PDF p. 82.

Primary note proof

Study-note section SE36

> Functional tests check required behavior against the SRS and acceptance criteria. Performance tests assess speed, throughput and resources under a specified workload; load uses expected demands and stress exceeds normal limits. Usability, security, compatibility and reliability tests target their respective qualities. “Normal operating conditions” alone does not distinguish functional from performance testing.

Module passages - related reading

Software Engineering module | PDF page 82 | lines 3-12

> though this type of approach could be used for any parameter, usability tests focus on usability parameters, such as the ease to learn the system, the time to accomplish a task, or the rate of errors
> a user makes when accomplishing a task.
> There are two important differences between classical experiments and usability tests. Whereas the classical experimental method is designed to confirm or refute a hypothesis, the goal of usability tests is to obtain qualitative information on how to fix usability problems and how to improve the system. Another difference is the rigor with which the experiments need to be performed. It has been shown that even a series of quick focused tests starting as early as requirements elicitation is extremely helpful. Nielsen uses the term “discount usability engineering” to indicate that a few usability tests are better than none at all.

Question sources

Computer Science MCQ practice collection · Question 36

Question 201 | AM0037

Which software development methodology involves iterative development cycles called sprints?

A. Waterfall model

B. Agile methodology

C. Spiral model

D. V-model

Hint

Identify whether the scenario prioritizes delivery, learning, adaptation or risk reduction. Several processes can share individual practices, so compare their defining emphasis.

Answer B: Agile methodology, specifically Scrum.

SE05 places Sprints in Scrum, an Agile framework. B is therefore the available category that contains the specific process described. Agile as a whole does not require every method to call its iterations Sprints. Waterfall, spiral and the V-model have other organizing principles, so none is the named Sprint-based method.

Why each choice is right or wrong

A - Incorrect: Classical waterfall uses planned phases rather than Scrum Sprints.

B - Correct: Scrum is an Agile framework whose iterative delivery cycles are called Sprints.

C - Incorrect: Spiral uses risk-driven cycles rather than specifically the Scrum Sprint mechanism.

D - Incorrect: The V-model pairs development stages with tests rather than organizing work into Sprints.

Primary note proof

Study-note section SE05

> Scrum uses timeboxed Sprints of at most one month, with a Sprint Goal, selected work and a usable Increment meeting a Definition of Done. Scope is discussed before and during planning; it is not forbidden to agree scope. Timeboxes tend to stay fixed while content is adapted without endangering the goal. Agile can be combined with required assurance/documentation; safety-critical context alone cannot prove it is unsuitable.

Computer Science MCQ practice collection · Question 37

Question 202 | AM0038

What is the primary purpose of code refactoring?

A. To add new features to the software system

B. To optimize the performance of the software system

C. To improve the readability and maintainability of the code

D. To fix defects or issues in the software system

Hint

Separate responsibilities inside a component from dependencies across boundaries. Evaluate the stated structure, change and reuse goals without assuming guaranteed benefits.

Answer C: To improve the readability and maintainability of the code

Restructuring explicitly addresses maintainability, readability and understandability, while optimization separately addresses speed and memory. C matches refactoring's purpose of improving internal structure and maintainability.

Why each choice is right or wrong

A - Incorrect: Adds behavior, whereas restructuring reorganizes existing design elements. See PDF p. 133.

B - Incorrect: Optimization is separately classified by performance goals. See PDF p. 133.

C - Correct: Direct match to the documented restructuring goals. See PDF p. 133.

D - Incorrect: Repairing a fault is correction; restructuring need not fix a behavioral defect. See PDF p. 133.

Primary note proof

Study-note section SE43

> Pareto's 80/20 rule is a prioritization heuristic: a small subset of causes may account for much of the observed impact. It does not guarantee 80% of defects can be fixed with exactly 20% effort. Refactor to preserve behavior while improving structure; optimize only against measured needs; record rationale and update traceability and regression evidence after change.

Software Engineering module | PDF page 133 | lines 3-15

> transformation on subsets of a particular model. Typical activities include transforming n-ary associations into binary associations, implementing binary associations as references, merging two similar classes from two different subsystems into a single class, collapsing classes with no significant behavior into attributes, splitting complex classes into simpler ones, rearranging classes and operations to increase the inheritance and packaging. During restructuring, we address design goals such as maintainability, readability, and understandability of the system model.

• Optimization. Optimization activities address performance requirements of the system model. This includes changing algorithms to respond to speed or memory requirements, reducing multiplicities in associations to speed up queries, adding redundant associations for efficiency, rearranging execution orders, adding derived attributes to improve the access time to objects and opening up the architecture, that is, adding access to lower layers because of performance requirements.

Computer Science MCQ practice collection · Question 38

Question 203 | AM0039

Which approach treats customer participation in reviewing working results and reprioritizing future work as a foundational value, rather than merely a practice a project may choose?

A. Waterfall model

B. Agile methodology

C. Spiral model

D. V-model

Hint

Identify whether the scenario prioritizes delivery, learning, adaptation or risk reduction. Several processes can share individual practices, so compare their defining emphasis.

Answer B: Agile methodology

The project treats customer participation in reviewing results and reprioritizing future work as a foundational development value. This directly matches Agile's customer collaboration and responsiveness to change. Waterfall and the V-model primarily define phase and test-stage organization. Spiral also includes stakeholder review, but risk assessment and reduction define its cycle. Participation alone is not exclusive; the explicit priority given to continual adaptive collaboration identifies the answer.

Why each choice is right or wrong

A - Incorrect: Classical waterfall's defining organization is planned phase progression.

B - Correct: Agile explicitly prioritizes customer collaboration and adapting to feedback.

C - Incorrect: Spiral includes review but is defined by risk-driven cycles.

D - Incorrect: The V-model organizes linked development and test stages, rather than naming the stated collaboration values.

Primary note proof

Study-note section SE05

Agile favors people collaborating, useful working results, customer participation and adaptation over rigid adherence to procedures, exhaustive documents, contracts or fixed plans. The latter still have value. Agile does not mean no planning or no documentation. A user story states a small user need and value, supported by acceptance criteria; an epic groups broader work.

Study-note section SE03

Classical waterfall separates planned phases with reviewed deliverables. It fits well-understood, stable requirements and familiar technology; late feedback makes changes costly. It does not make change physically impossible: real projects revisit work under control, and modified waterfall explicitly includes feedback. Rigidity offers milestone visibility but can freeze incorrect assumptions.

Study-note section SE06

Spiral development is risk driven. Each cycle identifies objectives and alternatives, assesses and reduces important risks, develops/verifies an appropriate next result, and plans further commitment. A prototype may test a risky technology before a large investment. The amount and type of work depend on the risks.

follow but each approach is suitable for different types of software. Generally, you need to find a balance between plan-driven and agile processes.

Software Engineering module | PDF page 22 | lines 8-12

This model delivers software in small but usable pieces, called —increments. In general, each increment builds on those that have already been delivered. The model is iterative in nature and focuses on the delivery of an operational product with each increment. Early increments are stripped down versions of the final product, but they do provide capability that serves the user and
also provide a platform for evaluation by the user.

Software Engineering module | PDF page 81 | lines 11-21

3.4.2. Negotiating specifications with clients: Joint Application Design
Joint Application Design (JAD) is effectiveness lies in that the requirements elicitation work is done in one single workshop session in which all stakeholders participate. Users, clients, developers, and a trained session leader sit together in one room to present their viewpoint, listen
to other viewpoints, negotiate, and agree on a mutually acceptable solution. The outcome of the workshop, the final JAD document, is a complete system specification document that includes definitions of data elements, work flows, and interface screens. Because the final document is

jointly developed by the stakeholders (that is, the participants who not only have an interest in the
success of the project, but also can make substantial decisions) the final JAD document represents
an agreement between users, clients, and developers, and thus minimizes requirements changes later in the development process.

Computer Science MCQ practice collection · Question 39

Question 204 | AM0040

Which type of testing involves running the entire software system in an environment that closely resembles the production environment?

A. Unit testing

B. Integration testing

C. System testing

D. Regression testing

Hint

Separate testing scope, technique and purpose. Use the stated workload, observable result or coverage target rather than a universal ranking.

Answer C: System testing

System testing evaluates the complete integrated software against its functional and nonfunctional requirements in a representative environment. Unit testing isolates a smaller element and integration testing concentrates on interfaces among combined parts. Regression testing instead checks for unintended consequences after change and is not restricted to any one level or environment. The question specifies the complete-product scope, making system testing the direct classification.

Why each choice is right or wrong

A - Incorrect: Unit testing isolates a function, class or small component.

B - Incorrect: Integration testing focuses on interfaces and interactions among combined parts.

C - Correct: System testing evaluates the complete integrated product in a representative environment.

D - Incorrect: Regression names an after-change checking purpose and can run at multiple levels.

Primary note proof

Study-note section SE35

Unit testing isolates a function, class or small component, often replacing dependencies with stubs/mocks; a driver invokes the unit and a stub substitutes a called dependency. Integration testing exercises interfaces and interactions among combined parts. System testing checks the complete integrated system against functional and nonfunctional requirements in a representative environment.

Study-note section SE36

Functional tests check required behavior against the SRS and acceptance criteria. Performance tests assess speed, throughput and resources under a specified workload; load uses expected demands and stress exceeds normal limits. Usability, security, compatibility and reliability tests target their respective qualities. “Normal operating conditions” alone does not distinguish functional from performance testing.

Computer Science MCQ practice collection · Question 40

Question 205 | AM0041

What is a use case in use case modeling?

A. A description of a specific user interface design

B. A step-by-step procedure for software installation

C. A sequence of activities performed by a user or system

D. A diagram that represents the relationships between software components

Hint

Match the information to be represented with each model's purpose. Read relationship direction, boundary and ownership conditions before classifying it.

Answer C: A sequence of activities performed by a user or system

A use case describes a system-provided function as a flow of events producing an actor-visible result. C is acceptable when understood as goal-related interactions, not any arbitrary sequence of activities.

Why each choice is right or wrong

A - Incorrect: UI layout is an implementation/interface design artifact. See PDF p. 47, 48.

B - Incorrect: Installation instructions are one possible documented procedure, not the general use-case definition. See PDF p. 47, 48.

C - Correct: Best matches the goal-oriented flow of events involving actors and the system. See PDF p. 47, 48.

D - Incorrect: Component relationships describe internal structure rather than actor-visible behavior. See PDF p. 47, 48.

Primary note proof

Study-note section SE14

> Draw actors outside the system boundary rectangle and use-case ovals inside. Name a goal with a verb and noun. The diagram shows roles, goals and relationships, not the full detailed algorithm or UI layout. Being an internal component is different from being an external actor; the chosen boundary determines which role applies.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 47 | lines 30-39

> Actors are external entities that interact with the system. Examples of actors include a user role (e.g., a system administrator, a bank customer, a bank teller) or another system (e.g., a central database, a fabrication line). Actors have unique names and descriptions.
> Use cases describe the behavior of the system as seen from an actor's point of view. Behavior described by the use case model is also called external behavior. A use case describes a function provided by the system as a set of events that yields a visible result for the actors. Actors initiate

a
use case to access the system functionality. The use case can then initiate other use cases and gather
more information from the actors. When actors and use cases exchange information, they are said
to communicate. We will see later that we represent these exchanges with communication relationships.

Software Engineering module | PDF page 48 | lines 18-32

To describe a use case, we use a template composed of six fields (see also Figure 2.2):
• The name of the use case is unique across the system so that developers (and project participants) can unambiguously refer to the use case.
• Participating actors are actors interacting with the use case.
• Entry conditions describe the conditions that need to be satisfied before the use case is initiated.
• The flow of events describes the sequence of actions of the use case, which are be numbered for reference. The common case (i.e., cases that occur frequently) and the exceptional cases (i.e., cases that seldom occur, such as errors and unusual conditions) are described separately in different use cases for clarity.
• Exit conditions describe the conditions that are satisfied after the completion of the use case.
• Special requirements are requirements that are not related to the functionality of the system. These include constraints on the performance of the system, its implementation, the hardware platforms it runs on, and so on.

Question sources

Computer Science MCQ practice collection · Question 41

Question 206 | AM0042

What is an actor in use-case modeling when the system boundary is fixed?

A. A component that performs specific actions in a software system

B. An external interacting role played by a person, device or another system.

C. A diagram that represents the flow of activities in a use case

D. A particular individual user account rather than a role.

Hint

Match the information to be represented with each model’s purpose. Read relationship direction, boundary and ownership conditions before classifying it.

Answer B: An external interacting role played by a person, device or another system.

An actor is an external role that interacts across the chosen system boundary. A person, device or another system may play that role. It is not an internal component, a diagram, or merely one individual user account. Because actors model roles rather than particular people, one person can play multiple actors and multiple people can fulfill the same actor role.

Why each choice is right or wrong

A - Incorrect: An internal component is not an external actor merely because it acts.

B - Correct: The external interacting role is the actor.

C - Incorrect: An activity-flow diagram is a model artifact rather than an actor.

D - Incorrect: An individual account is not the role abstraction.

Primary note proof

Study-note section SE14

> Draw actors outside the system boundary rectangle and use-case ovals inside. Name a goal with a verb and noun. The diagram shows roles, goals and relationships, not the full detailed algorithm or UI layout. Being an internal component is different from being an external actor; the chosen boundary determines which role applies.

Study-note section SE14

> An actor is an external role interacting with the system; it can be a person, device or another system. A person may play several roles, and several people may play one role.

Question sources

Computer Science MCQ practice collection · Question 42

Question 207 | AM0043

What is the purpose of an include relationship between use cases?

A. To represent the reuse of common steps between use cases

B. To represent optional steps within a use case

C. To represent the extension of a use case with additional steps

D. To represent the relationship between actors and use cases

Hint

Match the information to be represented with each model's purpose. Read relationship direction, boundary and ownership conditions before classifying it.

Answer A: To represent the reuse of common steps between use cases

Factoring common functionality into one included use case eliminates redundant descriptions, as in shared HelpDispatcher behavior.

Why each choice is right or wrong

A - Correct: Direct reuse/commonality mechanism. See PDF p. 50, 50.

B - Incorrect: Optional exceptional behavior is more directly represented by extend. See PDF p. 50, 50.

C - Incorrect: Adds events under conditions through extend rather than reuse via include. See PDF p. 50, 50.

D - Incorrect: Actor/use-case communication uses associations, not include. See PDF p. 50, 50.

Primary note proof

Study-note section SE16

> Include factors required reused behavior: Submit Order includes Validate Order, with the dashed arrow from the including/base use case to the included one. Extend adds conditional behavior at extension points: Apply Discount extends Checkout, with the arrow from the extension to the base. The base is meaningful independently. For an extension, draw the arrow from the extending use case to the base use case.

Module passages - related reading

Software Engineering module | PDF page 50 | lines 3-8

> can be modeled by a use case HelpDispatcher that is included by the use cases OpenIncident and AllocateResources (and any other use cases accessible by the Dispatcher). The resulting model only describes the HelpDispatcher functionality once, thus reducing complexity. Two use cases are related by an include relationship if one of them includes the second one in its flow of events. In UML, include relationships are depicted by a dashed arrow originating from the including use case. Include relationships are labeled with the string <<include>>.

Software Engineering module | PDF page 50 | lines 14-24

Extend relationships
Extend relationships are an alternate means for reducing complexity in the use case model. A use
case can extend another use case by adding events. An extend relationship indicates that an instance of an extended use case may include (under certain conditions) the behavior specified by
the extending use case. A typical application of extend relationships is the specification of exceptional behavior. For example (Figure 2-19), assume that the network connection between the
Dispatcher and the FieldOfficer can be interrupted at any time. (e.g., if the FieldOfficer enters a tunnel). The use case ConnectionDown describes the set of events taken by the system and the actors while the connection is lost. ConnectionDown extends the use cases OpenIncident and AllocateResources. Separating exceptional behavior from common behavior enables us to write shorter and more focused use cases.

Question sources

Computer Science MCQ practice collection · Question 43

Question 208 | AM0044

Which statements describe extend between use cases? Select all that apply. Read optional as conditional behavior at an extension point.

A. To factor required reused steps into an included use case.

B. To represent optional steps within a use case

C. To represent the extension of a use case with additional steps

D. To represent the relationship between actors and use cases

Hint

Match the information to be represented with each model’s purpose. Read relationship direction, boundary and ownership conditions before classifying it.

Answer B, C: To represent optional steps within a use case; To represent the extension of a use case with additional steps

Extend adds conditional behavior at extension points in an independently meaningful base use case. It therefore represents optional additional behavior and extends the base with added steps, making both B and C true. Factoring required reused behavior is the include relationship. Associations between actors and use cases are separate from the extend relationship linking use cases to one another.

Why each choice is right or wrong

A - Incorrect: Required reused behavior is factored with include.

B - Correct: Conditional additional behavior need not occur in every base execution.

C - Correct: Extend adds steps to an independently meaningful base.

D - Incorrect: Actor association is a different relationship.

Primary note proof

Study-note section SE16

> Include factors required reused behavior: Submit Order includes Validate Order, with the dashed arrow from the including/base use case to the included one. Extend adds conditional behavior at extension points: Apply Discount extends Checkout, with the arrow from the extension to the base. The base is meaningful independently. Question 209 | AM0045

Which diagram is commonly used to visualize the relationships between actors and use cases in use case modeling?

A. Class diagram

B. Use case diagram

C. Activity diagram

D. Sequence diagram

Hint

Match the information to be represented with each model's purpose. Read relationship direction, boundary and ownership conditions before classifying it.

Answer B: Use case diagram

Use-case diagrams depict actors and use cases with communication associations; these are the requested external interaction relationships.

Why each choice is right or wrong

A - Incorrect: Describes class structure. See PDF p. 47, 48.

B - Correct: Direct actor/use-case representation. See PDF p. 47, 48.

C - Incorrect: Describes action/control flow. See PDF p. 47, 48.

D - Incorrect: Describes time-ordered object interactions, not the high-level actor/function map. See PDF p. 47, 48.

Primary note proof

Study-note section SE14

> Draw actors outside the system boundary rectangle and use-case ovals inside. Name a goal with a verb and noun. Question sources

Computer Science MCQ practice collection · Question 45

Question 210 | AM0046

What defines an abstract use case, rather than optionality, unfinished documentation or reuse alone?

A. To represent a use case that is not yet fully defined

B. To represent a use case that is optional in the system

C. It specifies behavior for specialization and is not directly instantiated as a complete use case.

D. To represent a use case that is reused by other use cases

Hint

Match the information to be represented with each model’s purpose. Read relationship direction, boundary and ownership conditions before classifying it.

Answer C: It specifies behavior for specialization and is not directly instantiated as a complete use case.

An abstract use case specifies behavior for specialization and is not directly instantiated as a complete use case. That is different from being unfinished, optional or reused. Concrete behavior can be included for reuse, and extend can express conditional additions. Nor does the absence of a direct actor line by itself establish abstraction. Option C states the actual defining criterion.

Why each choice is right or wrong

A - Incorrect: An incomplete description is not the abstraction criterion.

B - Incorrect: Optional behavior is not the abstraction criterion.

C - Correct: Specialization without direct complete instantiation defines this abstraction.

D - Incorrect: Reuse alone can also involve concrete use cases.

Primary note proof

Study-note section SE16

> Generalization relates a specialized actor/use case to a more general one, with a hollow triangle toward the general element. An abstract use case specifies behavior for specialization and is not directly instantiated as a complete use case. It is not defined merely by reuse or lack of a direct actor line. Included behavior is incorporated where the inclusion is reached; do not infer every conditional branch in the base always executes.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 51 | lines 4-13

> Generalization relationships
> Generalization/specialization relationships are a third mechanism for reducing the complexity of a model. A use case can specialize a more general one by adding more detail. For example, FieldOfficers are required to authenticate before they can use FRIEND. During early stages of requirements elicitation, authentication is modeled as a high-level Authenticate use case. Later, developers describe the Authenticate use case in more detail and allow for several different hardware platforms. This refinement activity results in two more use cases, AuthenticateWithPasswordwhich enables FieldOfficers to login without any specific hardware, and AuthenticateWithCard, which enables FieldOfficers to login using a smart card. The two new use cases are represented as specializations of the Authenticate use case.

Software Engineering module | PDF page 50 | lines 3-8

> can be modeled by a use case HelpDispatcher that is included by the use cases OpenIncident and AllocateResources (and any other use cases accessible by the Dispatcher). In UML, include relationships are depicted by a dashed arrow originating from the including use case. Include relationships are labeled with the string <<include>>.

Question sources

Computer Science MCQ practice collection · Question 46

Question 211 | AM0047

Which option states the most specific defining purpose of an exception flow, distinguishing it from a generic alternative flow?

A. To represent an error or exceptional situation in the use case

B. To represent an alternative path within the use case

C. To represent the termination of the use case

D. To represent the relationship between primary and secondary actors

Hint

Match the information to be represented with each model's purpose. Read relationship direction, boundary and ownership conditions before classifying it.

Answer A: To represent an error or exceptional situation in the use case

An exception flow handles an error or failure encountered in the use case. Such a path is also an alternative to the main success flow in a broad sense, but B alone does not distinguish exceptional handling from normal conditional variations. An exception may allow correction and recovery instead of terminating the use case. Actor relationships do not define its failure-handling purpose.

Why each choice is right or wrong

A - Correct: Error or exceptional handling is the specific defining purpose.

B - Incorrect: Alternative path is broader and does not identify the exceptional nature.

C - Incorrect: Exceptions need not terminate the entire use case.

D - Incorrect: Actor relationships do not describe failure handling.

Primary note proof

Study-note section SE15

> Example: Submit Incident. Precondition: officer authenticated. 1 Officer supplies location and description. 2 System validates details. 3 System records the incident. 4 System returns its ID. Alternative 2a: location missing → report the problem and request correction; save nothing. Success postcondition: incident and ID persist; failure guarantee: no partial record. An alternate flow is a conditional variation; an exception flow handles a failure. Preconditions hold before entry, while a trigger starts the use case.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 48 | lines 18-32

To describe a use case, we use a template composed of six fields (see also Figure 2.2):

• Participating actors are actors interacting with the use case.
• Entry conditions describe the conditions that need to be satisfied before the use case is initiated.
• The flow of events describes the sequence of actions of the use case, which are be numbered for reference. The common case (i.e., cases that occur frequently) and the exceptional cases (i.e., cases that seldom occur, such as errors and unusual conditions) are described separately in different use cases for clarity.
• Exit conditions describe the conditions that are satisfied after the completion of the use case.
• Special requirements are requirements that are not related to the functionality of the system. These include constraints on the performance of the system, its implementation, the hardware platforms it runs on, and so on.

Software Engineering module | PDF page 50 | lines 14-24

Extend relationships
Extend relationships are an alternate means for reducing complexity in the use case model. A use
case can extend another use case by adding events. An extend relationship indicates that an instance of an extended use case may include (under certain conditions) the behavior specified by
the extending use case. A typical application of extend relationships is the specification of exceptional behavior. For example (Figure 2-19), assume that the network connection between the
Dispatcher and the FieldOfficer can be interrupted at any time. (e.g., if the FieldOfficer enters a tunnel). The use case ConnectionDown describes the set of events taken by the system and the actors while the connection is lost. ConnectionDown extends the use cases OpenIncident and AllocateResources. Separating exceptional behavior from common behavior enables us to write shorter and more focused use cases.

Question sources

Computer Science MCQ practice collection · Question 47

Question 212 | AM0048

What is the primary goal of use case modeling?

A. To define the software architecture of the system

B. To identify and document user requirements

C. To design the user interface of the system

D. To implement the functionality of the system

Hint

Match the information to be represented with each model's purpose. Read relationship direction, boundary and ownership conditions before classifying it.

Answer B: To identify and document user requirements

Use cases capture externally visible functionality and let developers validate requirements with users, rather than defining internal architecture or implementation.

Why each choice is right or wrong

A - Incorrect: System design defines architecture after the external analysis model. See PDF p. 47, 62.

B - Correct: Directly captures actor-visible functional requirements. See PDF p. 47, 62.

C - Incorrect: UI layout can be explored alongside use cases but is not their primary purpose. See PDF p. 47, 62.

D - Incorrect: Implementation realizes the requirements instead of documenting them. See PDF p. 47, 62.

Primary note proof

Study-note section SE14

> An actor is an external role interacting with the system; it can be a person, device or another system. A person may play several roles, and several people may play one role. A primary actor seeks a goal; a supporting actor provides a service. Ask which user groups perform main functions, administer or maintain the system, and which external systems exchange information.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 47 | lines 30-39

> Actors are external entities that interact with the system. Examples of actors include a user role (e.g., a system administrator, a bank customer, a bank teller) or another system (e.g., a central database, a fabrication line). Actors have unique names and descriptions.
> Use cases describe the behavior of the system as seen from an actor's point of view. Behavior described by the use case model is also called external behavior. A use case describes a function provided by the system as a set of events that yields a visible result for the actors. Actors initiate a
> use case to access the system functionality. The use case can then initiate other use cases and gather
> more information from the actors. When actors and use cases exchange information, they are said
> to communicate. We will see later that we represent these exchanges with communication relationships.

Software Engineering module | PDF page 62 | lines 9-16

Requirement's elicitation focuses on describing the purpose of the system. The client, the developers, and the users identify a problem area and define a system that addresses the problem.
Such a definition is called a system specification and serves as a contract between the client and the developers. The system specification is structured and formalized during analysis to produce an analysis model (see Figure 3.1). Both system specification and analysis model represent the same information. They differ only in the language and notation they use. The system specification
is written in natural language, whereas the analysis model is usually expressed in a formal or semiformal notation.

Question sources

Computer Science MCQ practice collection · Question 48

Question 213 | AM0049

What is an alternative flow in a use case?

A. A flowchart representation of the use case steps

B. A flow of activities that occurs in parallel with the main flow

C. A different sequence of steps based on specific conditions

D. A representation of the relationship between use cases

Hint

Match the information to be represented with each model's purpose. Read relationship direction, boundary and ownership conditions before classifying it.

Answer C: A different sequence of steps based on specific conditions

A flow of events describes interactions; exceptional conditions introduce alternative event sequences. This is a different path under a condition, rather than necessarily concurrency or inter-use-case structure.

Why each choice is right or wrong

A - Incorrect: A flowchart is a representation format, not the alternative sequence itself. See PDF p. 48, 50.

B - Incorrect: Parallel execution is not required by an alternative branch. See PDF p. 48, 50.

C - Correct: Directly describes a condition-dependent event sequence. See PDF p. 48, 50.

D - Incorrect: Include/extend/generalization describe relationships, not the definition of every alternative flow. See PDF p. 48, 50.

Primary note proof

Study-note section SE15

Example: Submit Incident. Precondition: officer authenticated. 1 Officer supplies location and description. 2 System validates details. 3 System records the incident. 4 System returns its ID. Alternative 2a: location missing → report the problem and request correction; save nothing. Success postcondition: incident and ID persist; failure guarantee: no partial record. An alternate flow is a conditional variation; an exception flow handles a failure. Preconditions hold before entry, while a trigger starts the use case.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 48 | lines 18-32

To describe a use case, we use a template composed of six fields (see also Figure 2.2):
• The name of the use case is unique across the system so that developers (and project participants) can unambiguously refer to the use case.
• Participating actors are actors interacting with the use case.
• Entry conditions describe the conditions that need to be satisfied before the use case is initiated.
• The flow of events describes the sequence of actions of the use case, which are be numbered for reference. The common case (i.e., cases that occur frequently) and the exceptional cases (i.e., cases that seldom occur, such as errors and unusual conditions) are described separately in different use cases for clarity.
• Exit conditions describe the conditions that are satisfied after the completion of the use case.
• Special requirements are requirements that are not related to the functionality of the system. These include constraints on the performance of the system, its implementation, the hardware platforms it runs on, and so on.

Software Engineering module | PDF page 50 | lines 14-24

Extend relationships
Extend relationships are an alternate means for reducing complexity in the use case model. A use
case can extend another use case by adding events. An extend relationship indicates that an instance of an extended use case may include (under certain conditions) the behavior specified by
the extending use case. A typical application of extend relationships is the specification of exceptional behavior. For example (Figure 2-19), assume that the network connection between the
Dispatcher and the FieldOfficer can be interrupted at any time. (e.g., if the FieldOfficer enters a tunnel). The use case ConnectionDown describes the set of events taken by the system and the actors while the connection is lost. ConnectionDown extends the use cases OpenIncident and AllocateResources. Separating exceptional behavior from common behavior enables us to write shorter and more focused use cases.

Question sources

Computer Science MCQ practice collection · Question 49

Question 214 | AM0050

What is the purpose of a use case diagram?

A. To describe the behavior of a use case in detail

B. To represent the internal structure of a use case

C. To visualize the relationships between actors and use cases

D. To represent the flow of activities within a use case

Hint

Match the information to be represented with each model's purpose. Read relationship direction, boundary and ownership conditions before classifying it.

Answer C: To visualize the relationships between actors and use cases

The diagram shows actors, functions and communication links; the separate textual template contains detailed event sequences and conditions.

Why each choice is right or wrong

A - Incorrect: Detailed flow belongs in the use-case description/template. See PDF p. 47, 48.

B - Incorrect: Internal structure is modeled with classes/components. See PDF p. 47, 48.

C - Correct: Direct high-level actor/function interaction view. See PDF p. 47, 48.

D - Incorrect: Activity diagrams or textual flows express detailed action sequences. See PDF p. 47, 48.

Primary note proof

Study-note section SE14

> Draw actors outside the system boundary rectangle and use-case ovals inside. Name a goal with a verb and noun. The diagram shows roles, goals and relationships, not the full detailed algorithm or UI layout. Being an internal component is different from being an external actor; the chosen boundary determines which role applies.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

• Special requirements are requirements that are not related to the functionality of the system. These include constraints on the performance of the system, its implementation, the hardware platforms it runs on, and so on.

Question sources

Computer Science MCQ practice collection · Question 50

Question 215 | CS0007

Identifying and describing the fundamental software system abstractions and their relationships. Establishing the overall system architecture - in which phase are these activities done?

A. System design

B. Requirement analysis and definition

C. System testing

D. Implementation

Hint

Separate responsibilities inside a component from dependencies across boundaries. Evaluate the stated structure, change and reuse goals without assuming guaranteed benefits.

Answer A: System design

System and software design establish the overall architecture and identify software abstractions and relationships.

Why each choice is right or wrong

A - Correct: Direct match to the described design tasks. See PDF p. 18, 116.

B - Incorrect: Establishes required services, constraints and goals. See PDF p. 18, 116.

C - Incorrect: Checks complete-system behavior. See PDF p. 18, 116.

D - Incorrect: Translates a design into code. See PDF p. 18, 116.

Primary note proof

Study-note section SE21

System design turns the analysis model into architecture: design goals, subsystem responsibilities, dependencies, hardware mapping, data management, access control, control flow and startup/shutdown/error policies. Detail/object design refines APIs, parameter/return types, exceptions, component choices and algorithms. A subsystem is a manageable logical collection with services and an interface; it need not be a physical replaceable artifact.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 18 | lines 13-20

System and software design: The systems design process allocates the requirements to either hardware or software systems by establishing an overall system architecture.
Software design involves identifying and describing the fundamental software system abstractions
and their relationships. The goal of the design phase is to transform the requirements specified in
the SRS document into a structure that is suitable for implementation in some programming language. In technical terms, during the design phase the software architecture is derived from the
SRS document. Two distinctly different approaches are available: the traditional design approach
and the object-oriented design approach.

Software Engineering module | PDF page 116 | lines 16-29

The analysis model describes the system completely from the actors' point of view and serves as the basis of communication between the client and the developers. The analysis model, however, does not contain information about the internal structure of the system, its hardware configuration,
or, more generally, how the system should be realized. System design is the first step in this direction. System design results in the following products:
• List of design goals, describing the qualities of the system that developers should optimize
• Software architecture, describing the subsystem decomposition in terms of subsystem responsibilities, dependencies among subsystems, subsystem mapping to hardware, and major policy decisions such as control flow, access control, and data storage.
The design goals are derived from the nonfunctional requirements. Design goals guide the decisions to be made by the developers especially when trade-offs are needed. The subsystem decomposition constitutes the bulk of system design. Developers divide the system into

manageable pieces to deal with complexity: Each subsystem is assigned to a team and realized independently. In order for this to be possible, though, developers need to address system-wide

Question sources

Computer Science Exit Exam practice collection · Question 7

Question 216 | CS0008

Instead of delivering the system as a single delivery, development and delivery is broken down into
phases with each phase delivering part of the required functionality. What type of development model is this?

A. Incremental

B. Waterfall

C. Spiral

D. Evolutionary

Hint

Identify whether the scenario prioritizes delivery, learning, adaptation or risk reduction. Several processes can share individual practices, so compare their defining emphasis.

Answer A: Incremental

Successive deliveries that each add part of the required usable functionality define incremental development. The product gains capability across these deliveries rather than waiting for a single completed-system handoff. Waterfall and a generic linear model organize phase sequence. Spiral is organized around risk assessment, and evolutionary development broadly describes refinement. Those can overlap with staged delivery, but incremental is the specific name for the delivery organization stated.

Why each choice is right or wrong

A - Correct: Incremental development adds usable required functionality in successive deliveries.

B - Incorrect: Waterfall names planned phase progression, not this particular staged-capability strategy.

C - Incorrect: Spiral names risk-driven cycles, even when increments are produced.

D - Incorrect: Evolutionary refinement is broader than the specific addition-of-functionality strategy described.

Primary note proof

Study-note section SE04

Choose incremental delivery when prioritized partial capability must reach users early. Smaller changes can be easier to debug and permit feedback, though architecture and integration still

require planning. Iteration need not rebuild the whole system every time, and increments need not be perfectly independent modules. Broad descriptions of early working software can fit prototypes, iterative or Agile processes; identify the purpose of that early version.

Study-note section SE06

Spiral development is risk driven. Each cycle identifies objectives and alternatives, assesses and reduces important risks, develops/verifies an appropriate next result, and plans further commitment. A prototype may test a risky technology before a large investment. The amount and type of work depend on the risks.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 22 | lines 8-12

This model delivers software in small but usable pieces, called —increments. In general, each increment builds on those that have already been delivered. The model is iterative in nature and focuses on the delivery of an operational product with each increment. Early increments are stripped down versions of the final product, but they do provide capability that serves the user and
also provide a platform for evaluation by the user.

Question sources

Computer Science Exit Exam practice collection · Question 8

Question 217 | CS0009

We should NOT use the Waterfall software development process model in situations like:

A. Plenty of resources with required expertise are available freely

B. There are no ambiguous requirements

C. The project is short

D. Software requirements change quickly

Hint

Identify whether the scenario prioritizes delivery, learning, adaptation or risk reduction. Several processes can share individual practices, so compare their defining emphasis.

Answer D: Software requirements change quickly

Waterfall should be used only when requirements are well understood and unlikely to change radically. Rapid requirement change violates this selection condition.

Why each choice is right or wrong

A - Incorrect: Available expertise is not the documented contraindication. See PDF p. 20.

B - Incorrect: Unambiguous stable requirements support, rather than undermine, the model. See PDF p. 20.

C - Incorrect: The module says waterfall works well for smaller projects with well-understood requirements. See PDF p. 20.

D - Correct: Directly violates the stability assumption and creates costly rework. See PDF p. 20.

Primary note proof

Study-note section SE03

> Classical waterfall separates planned phases with reviewed deliverables. It fits well-understood, stable requirements and familiar technology; late feedback makes changes costly. It does not make change physically impossible: real projects revisit work under control, and modified waterfall explicitly includes feedback. Rigidity offers milestone visibility but can freeze incorrect assumptions.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 20 | lines 18-22

> the development plan. Its major problem is the inflexible partitioning of the project into distinct stages. Commitments must be made at an early stage in the process, which makes it difficult to respond to changing customer requirements.
> In principle, the waterfall model should only be used when the requirements are well understood
> and unlikely to change radically during system development. However, the waterfall model

Question sources

Computer Science Exit Exam practice collection · Question 9

Question 218 | CS0010

Which one of the following is false about divide and conquer or modularization process?

A. Separate people can work on each sub-divided part

B. Opportunities arise for making the component reusable

C. Each individual component is smaller, and therefore easier to understand

D. Replacing or changing a component is difficult because it affects other parts extremely

Hint

Separate responsibilities inside a component from dependencies across boundaries. Evaluate the stated structure, change and reuse goals without assuming guaranteed benefits.

Answer D: Replacing or changing a component is difficult because it affects other parts extremely

Subsystems can be assigned to separate teams, reused and changed with reduced impact when coupled loosely. D contradicts the change-isolation goal of good modularization.

Why each choice is right or wrong

A - Incorrect: Independent teams can realize different manageable subsystems. See PDF p. 118, 116, 32, 120.

B - Incorrect: Reusable self-contained modules are an explicit OO benefit. See PDF p. 118, 116, 32, 120.

C - Incorrect: Decomposition produces simpler manageable units. See PDF p. 118, 116, 32, 120.

D - Correct: Strong propagation of every change describes undesirable tight coupling, not good modularization. See PDF p. 118, 116, 32, 120.

Primary note proof

Study-note section SE22

> Logical cohesion groups similar-category operations, often selected by a flag; temporal cohesion groups operations done at the same time; functional cohesion focuses on one task. Splitting an unrelated three-purpose component improves modularity. If behavior is preserved, the restructuring is refactoring; the words are not mutually exclusive answers. Smaller modules can aid understanding, independent work, reuse and maintenance, but too many interfaces also create complexity.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 118 | lines 11-16

> 6.1.1. Subsystems and classes
> In order to reduce the complexity of the application domain, we identified smaller parts called classes and organized them into packages. Similarly, to reduce the complexity of the solution domain, we decompose a system into simpler parts, called subsystems, which are made of a number of solution domain classes. In the case of complex subsystems, we recursively apply this principle and decompose a subsystem into simpler subsystems (see Figure 6.2).

Software Engineering module | PDF page 116 | lines 16-29

> The analysis model describes the system completely from the actors' point of view and serves as the basis of communication between the client and the developers. The analysis model, however, does not contain information about the internal structure of the system, its hardware configuration,
> or, more generally, how the system should be realized. System design is the first step in this direction. System design results in the following products:
> • List of design goals, describing the qualities of the system that developers should optimize
> • Software architecture, describing the subsystem decomposition in terms of subsystem responsibilities, dependencies among subsystems, subsystem mapping to hardware, and major policy decisions such as control flow, access control, and data storage.
> The design goals are derived from the nonfunctional requirements. Design goals guide the decisions to be made by the developers especially when trade-offs are needed. The subsystem decomposition constitutes the bulk of system design. Developers divide the system into manageable pieces to deal with complexity: Each subsystem is assigned to a team and realized independently. In order for this to be possible, though, developers need to address system-wide

Software Engineering module | PDF page 32 | lines 12-21

A class in an object-oriented system carefully delineates between its interfaces the routines and attributes within a class are held together tightly. In a properly designed system, the classes will be grouped into subsystems but remain independent; therefore, changing one class has no impact
on other classes, and so, the impact is minimized. However, the object-oriented approach is not a panacea; nothing is magical here that will promote perfect design or perfect code.
Promotion of reusability
Objects are reusable because they are modeled directly out of a real-world problem domain. Each
object stands by itself or within a small circle of peers (other objects). Within this framework, the class does not concern itself with the rest of the system or how it is going to be used within a particular system.

Software Engineering module | PDF page 120 | lines 6-12

6.1.3. Coupling and coherence
Coupling is the strength of dependencies between two subsystems. If two subsystems are loosely coupled, they are relatively independent, and thus, modifications to one of the subsystems will have little impact on the other. If two subsystems are strongly coupled, modifications to one subsystem is likely to have impact on the other. A desirable property of a subsystem decomposition
is that subsystems are as loosely coupled as possible. This minimizes the impact that errors or future changes have on the correct operation of the system.

Question sources

Computer Science Exit Exam practice collection · Question 10

Question 219 | CS0013

For this project, planned testing effort in hours is setup + (cases × hours per case). The estimates (setup,cases,hours/case) are Unit=(4,80,0.1), Acceptance=(3,10,1), System=(6,20,0.5), Integration=(4,20,0.5). Which level has the greatest planned effort?

A. Unit testing

B. Acceptance testing

C. System testing

D. Integration testing

Hint

Use the effort formula given in the question separately for every level, then compare all computed totals.

Answer C: System testing

The estimates give unit effort 4+80×0.1=12 hours, acceptance 3+10×1=13, system 6+20×0.5=16, and integration 4+20×0.5=14. System testing therefore has the greatest planned effort for this project. The note does not make any test level universally longest; the explicit workload and setup assumptions are what justify this particular ranking.

Why each choice is right or wrong

A - Incorrect: Unit totals twelve hours, below the maximum.

B - Incorrect: Acceptance totals thirteen hours, below the maximum.

C - Correct: System totals sixteen hours, the largest estimate.

D - Incorrect: Integration totals fourteen hours, below system testing.

Primary note proof

Study-note section SE35

> Unit testing isolates a function, class or small component, often replacing dependencies with stubs/mocks; a driver invokes the unit and a stub substitutes a called dependency. Integration testing exercises interfaces and interactions among combined parts. System testing checks the complete integrated system against functional and nonfunctional requirements in a representative environment.

Study-note section SE35

> None of these levels is universally the longest.

Study-note section SE28

> Planning is continuous: identify scope/deliverables, decompose work, estimate effort/duration/cost, assign resources, sequence dependencies and revise as evidence changes.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Software Engineering module | PDF page 148 | lines 19-26

> Unit testing focuses on the building blocks of the software system, that is, objects and subsystems.
> There are three motivations behind focusing on components. First, unit testing reduces the complexity of the overall test activities, allowing us to focus on smaller units of the system. Second, unit testing makes it easier to pinpoint and correct faults, given that few components are involved in the test. Third, unit testing allows parallelism in the testing activities; that is, each component can be tested independently of one another.
> The specific candidates for unit testing are chosen from the object model and the system decomposition of the system. In principle, all the objects developed during the development

Software Engineering module | PDF page 144 | lines 17-32

> Figure 6.2 depicts an overview of the testing activities:
> • Unit testing tries to find faults in participating objects and/or subsystems with respect to

the use cases from the use case model
• Integration testing is the activity of finding faults when testing the individually tested components together, for example, subsystems described in the subsystem decomposition, while executing the use cases and scenarios from the RAD.
o The system structure testing is the culmination of integration testing involving all components of the system. Integration tests and structure tests exploit knowledge from the SDD using an integration strategy described in the Test Plan (TP).
• System testing tests all the components together, seen as a single system to identify errors with respect to the scenarios from the problem statement and the requirements and design goals identified in the analysis and system design, respectively:
o Functional testing tests the requirements from the RAD and, if available, from the user manual.
o Performance testing checks the nonfunctional requirements and additional design goals from the SDD. Note that functional and performance testing are both done by

Computer Science Exit Exam practice collection · Question 13

Question 220 | NS0293

A filled composition diamond is at Car's end of its Engine association. In this model Engine remains owned for its entire lifetime and cannot be detached or transferred. What does this imply?

A. Car uses Engine temporarily

B. Engine can exist independently of the Car

C. Engine is part of Car and cannot exist independently under the stated lifetime policy.

D. Car inherits from Engine

Hint

Match the information to be represented with each model's purpose. Read relationship direction, boundary and ownership conditions before classifying it.

Answer C: Engine is part of Car and cannot exist independently under the stated lifetime policy.

Composition makes Engine a strongly owned part of Car, with the filled diamond beside the whole. Parts still owned are destroyed when their composite is destroyed. Since this model does not permit Engine to detach or transfer, it cannot continue an independent lifetime without Car. Temporary use would be a dependency, and inheritance would be shown by a hollow triangle.

Why each choice is right or wrong

A - Incorrect: Temporary use is a dependency rather than composition.

B - Incorrect: The no-detachment policy excludes an independent Engine lifetime.

C - Correct: Engine is Car's owned part and cannot outlive it under this policy.

D - Incorrect: Inheritance uses a hollow triangle.

Primary note proof

Study-note section SE18

> Composition uses a filled diamond at the whole end and strong ownership: a part is in at most one composite at a time, and parts still owned are destroyed with that composite. Parts may be detached/transferred under a defined model. Thus "cannot ever exist independently" is an oversimplification. For Car composing Engine, the diamond belongs beside Car; saying it points to Engine is imprecise. The Car-Engine example describes composition.

Question sources

Computer Science Exit Exam · 2018 · Question 10

Question 221 | NS0328

From the following statement which one is disadvantage of waterfall model?

A. model is simple and easy to understand and use

B. It is easy manage due to the rigidity of the model

C. Not suitable for projects where requirements are at a moderate to high risk of changing

D. In this model phases are processed and completed one at a time

Hint

Identify whether the scenario prioritizes delivery, learning, adaptation or risk reduction. Several processes can share individual practices, so compare their defining emphasis.

Answer C: Poor suitability when requirements have substantial change risk.

SE03 says waterfall fits stable understood requirements and familiar technology. Late feedback can make changes costly, so moderate-to-high requirement-change risk is a direct disadvantage. Simplicity and milestone visibility are advantages. Sequential phase organization characterizes the classical model; it can contribute to rigidity, but C explicitly identifies the adverse scenario asked for.

Why each choice is right or wrong

A - Incorrect: Simplicity and ease of understanding are presented as advantages rather than the adverse scenario.

B - Incorrect: Manageable milestones can be an advantage of planned rigidity, despite its trade-offs.

C - Correct: Likely requirement changes make late feedback and rigid commitments costly.

D - Incorrect: Sequential phases describe the model; C more directly states the requested disadvantage.

Primary note proof

Study-note section SE03

> Classical waterfall separates planned phases with reviewed deliverables. It fits well-understood, stable requirements and familiar technology; late feedback makes changes costly. It does not make change physically impossible: real projects revisit work under control, and modified waterfall explicitly includes feedback. Rigidity offers milestone visibility but can freeze incorrect assumptions.

Question sources

Computer Science Exit Exam · 2018 · Question 55

Question 222 | NS0333

For a search service whose functions and database technology are already specified, which requirement adds a quantitative service-speed target?

A. The system allow user to generate PDF report.

B. The system respond to user's request within 2 second under normal load

C. The system allow user to store data on relational database

D. The system allow user to submit emergency report

Hint

Distinguish observable services, measurable qualities and implementation constraints. Check scope, stakeholder meaning and the requested level of specificity.

Answer B: The system respond to user's request within 2 second under normal load

The two-second response obligation bounds the speed of a service under the stated load, so it is a performance requirement. Generating a PDF and submitting an emergency report describe services the system provides. The database clause describes storage behavior together with an implementation choice; it does not impose a response-time threshold. The explicit performance scope removes the broader taxonomy overlap between nonfunctional requirements and technology constraints.

Why each choice is right or wrong

A - Incorrect: Report generation specifies a service, not its response-time limit.

B - Correct: A two-second response bound under normal load is a quantitative speed target.

C - Incorrect: This specifies storage behavior and a database technology, without a timing bound.

D - Incorrect: Submitting an emergency report specifies a function rather than its speed.

Primary note proof

Study-note section SE10

> Nonfunctional requirements include quality attributes and constraints. Performance concerns response time, throughput and resource use; reliability concerns failure-free service; availability concerns being ready for use; usability concerns task success and ease of learning. Security concerns protection; compatibility concerns cooperating environments; portability concerns moving environments; maintainability/supportability concern change, diagnosis and evolution.

Study-note section SE10

> "Search responds within two seconds under 100 concurrent users" is measurable performance. "New users finish checkout within one minute without help" is usability. "Use Java" is a technology/pseudo-requirement, often separately classified as a system constraint. Dependability includes reliability, safety and robustness; portability is not its usual central category. Performance degradation at peak load primarily concerns performance, not automatically reliability.

Question sources

Computer Science Exit Exam · 2018 · Question 61

Question 223 | NS0347

Which one of the following UML building block that defines the static part of the model and represents physical and conceptual elements?

A. Structural things

B. Behavioral things

C. An notational things

D. Grouping things

Hint

Match the information to be represented with each model's purpose. Read relationship direction, boundary and ownership conditions before classifying it.

Answer A: Structural things.

SE17 explicitly describes structural things as conceptual or physical structural elements. They make up the static model in contrast with behavior over time. Behavioral things cover dynamic aspects, grouping organizes elements and annotations add explanatory information rather than being the static elements themselves. Thus A directly matches both parts of the definition.

Why each choice is right or wrong

A - Correct: Structural things are the static conceptual or physical building blocks described.

B - Incorrect: Behavioral things concern dynamic behavior rather than the static structural elements.

C - Incorrect: Annotations add explanatory information rather than defining the static structural building blocks.

D - Incorrect: Grouping organizes model elements rather than being the stated conceptual/physical structural category.

Primary note proof

Study-note section SE17

> A class box lists name, attributes and operations; + public, - private, # protected and ~ package indicate visibility. A class diagram shows static types and relationships, while an object diagram shows particular instances/links. UML is maintained and standardized by OMG; it is a modeling language, not a lifecycle process. Structural things describe conceptual or physical structural elements.

Study-note section SE-S03

> In the course's UML building-block terminology, structural things describe static conceptual or physical elements. Behavioral things describe dynamic interactions and state behavior.

Grouping things organize model elements into packages. Annotational things attach explanatory remarks or constraints, usually as notes.

Question sources

Computer Science Exit Exam · 2018 · Question 80

Question 224 | NS0740

What is the difference between functional and non-functional requirements? Give an example of each.

Hint

Distinguish observable services, measurable qualities and implementation constraints. Check scope, stakeholder meaning and the requested level of specificity.

Answer: Functional requirements specify observable behavior; nonfunctional requirements specify qualities or constraints. Example: generate a PDF report versus respond within two seconds under a stated load.

SE09 includes required and prohibited services, so generating a PDF report is functional. SE10 specifies qualities such as performance, usability and availability; a response-time threshold under defined load is nonfunctional. Security mechanisms can implement functional behavior as well as support quality goals, so a negative or security-related statement is not automatically nonfunctional.

Primary note proof

Study-note section SE09

> A functional requirement states an observable service or behavior, including reactions to inputs, errors and forbidden actions. “When the sensor detects intrusion, send an alert” is functional.

Study-note section SE09

> “The system shall generate a PDF report” is functional. “The system shall not reveal another customer’s balance” can be a security-related functional rule. Security as a broad quality goal and the functions implementing it must be distinguished.

Study-note section SE10

> Nonfunctional requirements include quality attributes and constraints. Performance concerns response time, throughput and resource use; reliability concerns failure-free service; availability concerns being ready for use; usability concerns task success and ease of learning.

Study-note section SE10

> “Search responds within two seconds under 100 concurrent users” is measurable performance. “New users finish checkout within one minute without help” is usability.

Question sources

Software Engineering review questions · Question 1

Question 225 | NS0741

Why is low coupling considered good in software design?

Hint

Separate responsibilities inside a component from dependencies across boundaries. Evaluate the stated structure, change and reuse goals without assuming guaranteed benefits.

Answer: Low coupling limits dependencies, so changes remain local and modules are easier to understand, replace, test and maintain.

SE22 measures coupling through dependencies between modules and recommends low coupling with high cohesion. Shared mutable data and knowledge of another module's representation increase the chance that one change affects others. Stable interfaces and information hiding constrain that impact. More interfaces can add complexity, so minimizing harmful dependencies matters more than simply maximizing the number of modules.

Primary note proof

Study-note section SE22

> Cohesion measures how well elements inside a module serve a related purpose; coupling measures dependency between modules. Seek high cohesion and low coupling. Shared mutable data and knowledge of another module's internal representation increase coupling. Information hiding exposes stable operations while concealing changeable decisions.

Question sources

Software Engineering review questions · Question 2

Question 226 | NS0742

What is the difference between Waterfall and Agile methodologies?

Hint

Identify whether the scenario prioritizes delivery, learning, adaptation or risk reduction. Several processes can share individual practices, so compare their defining emphasis.

Answer: Waterfall uses planned, reviewed stages and suits stable requirements; Agile emphasizes collaboration, working results, feedback and adaptation.

SE03 describes planned phases with costly late feedback, useful for stable requirements and familiar technology. SE05 values customer participation and adaptation with useful working increments. Agile still plans and documents; waterfall can revisit work under control. The practical difference is feedback and commitment organization, not a claim that one process forbids change or the other forbids documentation.

Primary note proof

Study-note section SE03

> Classical waterfall separates planned phases with reviewed deliverables. It fits well-understood, stable requirements and familiar technology; late feedback makes changes costly. It does not make change physically impossible: real projects revisit work under control, and modified waterfall explicitly includes feedback. Rigidity offers milestone visibility but can freeze incorrect assumptions.

Study-note section SE05

> Agile favors people collaborating, useful working results, customer participation and adaptation over rigid adherence to procedures, exhaustive documents, contracts or fixed plans. The latter still have value. Agile does not mean no planning or no documentation. A user story states a small user need and value, supported by acceptance criteria; an epic groups broader work.

Question sources

Software Engineering review questions · Question 3

Question 227 | NS0743

What is the difference between <<include>> and <<extend>> in use case diagrams?

Hint

Match the information to be represented with each model's purpose. Read relationship direction, boundary and ownership conditions before classifying it.

Answer: Include factors required reused behavior, with base→included; extend adds conditional behavior, with extension→base.

SE16 uses include for reused required behavior incorporated when the inclusion point is reached. Extend adds behavior at extension points under a condition, and the base remains meaningful independently. The dashed arrows have different directions: including use case toward included, and extending use case toward base. Neither relation should be confused with actor association or specialization generalization.

Primary note proof

Study-note section SE16

> Include factors required reused behavior: Submit Order includes Validate Order, with the dashed arrow from the including/base use case to the included one. Extend adds conditional behavior at extension points: Apply Discount extends Checkout, with the arrow from the extension to the base. The base is meaningful independently. For an extension, draw the arrow from the extending use case to the base use case.

Study-note section SE16

> Generalization relates a specialized actor/use case to a more general one, with a hollow triangle toward the general element. An abstract use case specifies behavior for specialization and is not directly instantiated as a complete use case. It is not defined merely by reuse or lack of a direct actor line. Included behavior is incorporated where the inclusion is reached; do not infer every conditional branch in the base always executes.

Question sources

Software Engineering review questions · Question 4

Question 228 | NS0744

Why is maintenance often the most expensive phase of the SDLC?

Hint

Classify the motive for the change before its implementation: repair, environment, useful capability or reduced future risk.

Answer: Maintenance can dominate cost because it lasts years and repeatedly requires legacy understanding, changes, regression testing and release work.

SE40 says maintenance often spans years and includes understanding existing code plus regression effort. Work is not limited to bug fixes: environments, useful capabilities and future risks also change. Repeated impact analysis, implementation and testing accumulate across the operational lifetime, so maintenance may dominate lifecycle cost. This is a common outcome, not a guarantee for every project.

Primary note proof

Study-note section SE40

> Corrective maintenance fixes faults; adaptive maintenance responds to environment changes; perfective maintenance improves useful capability/performance; preventive maintenance reduces future risk, such as restructuring fragile code. Motive determines category; refactoring can support preventive or perfective work. Maintenance often lasts years and includes understanding legacy code and regression effort, so it may dominate lifecycle cost.

Study-note section SE40

> A typical evolution sequence is change request→impact analysis→release planning→implementation/testing→release. Among a list lacking the request step, impact analysis may be the earliest listed technical activity. Major restructuring is reengineering; if the architecture itself changes, architectural transformation is the more specific description. Markets, technology, stakeholders and funding can all change scope or priorities.

Question sources

Software Engineering review questions · Question 5

Question 229 | NS0745

Which software development approach emphasizes breaking systems into functions or procedures that manipulate isolated data?

A. Object-Oriented Approach

B. Traditional Approach

C. Agile Approach

D. Iterative Approach

Hint

Identify whether the scenario prioritizes delivery, learning, adaptation or risk reduction. Several processes can share individual practices, so compare their defining emphasis.

Answer B: Traditional/procedural decomposition.

SE01 contrasts procedural decomposition organized around functions with object-oriented decomposition organized around objects combining state and behavior. B is the available traditional/procedural label for functions operating on data. Agile and iterative describe lifecycle organization rather than this decomposition paradigm, and either can be used with procedural or object-oriented programming.

Why each choice is right or wrong

A - Incorrect: Object orientation combines state and behavior in objects rather than organizing primarily around separate procedures.

B - Correct: Traditional/procedural decomposition organizes functions and procedures acting on data.

C - Incorrect: Agile concerns process adaptation rather than requiring function-based decomposition.

D - Incorrect: Iteration describes revisiting development work and does not determine procedural versus object decomposition.

Primary note proof

Study-note section SE01

> Procedural decomposition organizes functions; object oriented decomposition organizes objects with state and behavior. Either can use iterative or sequential development. OOP does not automatically shorten every project. Reuse, encapsulation and consistent models can reduce duplication and ease change; poor object design can still be complex. Functional programming emphasizes function evaluation and controlled side effects; event-driven programs react to events.

Question sources

Software Engineering review questions · Question 1

Question 230 | NS0746

In the Object-Oriented Approach, which property allows classes to be used in different parts of the system or other projects without rewriting them?

A. Encapsulation

B. Polymorphism

C. Reusability

D. Abstraction

Hint

Separate responsibilities inside a component from dependencies across boundaries. Evaluate the stated structure, change and reuse goals without assuming guaranteed benefits.

Answer C: Reusability.

The stem explicitly asks about using existing classes elsewhere without rewriting them, which is reuse. SE01 lists reuse alongside encapsulation and consistent models as ways to reduce duplication and ease change. Encapsulation and abstraction can make reuse safer, while polymorphism supports compatible varying implementations, but those are enabling concepts rather than the name of the capability described.

Why each choice is right or wrong

A - Incorrect: Encapsulation hides implementation and can enable reuse, but it is not the capability's name.

B - Incorrect: Polymorphism supports differing implementations through compatible interfaces rather than directly naming reuse.

C - Correct: Reusability means using suitable existing classes or components in other contexts without rewriting them.

D - Incorrect: Abstraction exposes relevant contracts and can assist reuse, but the requested property is reusability.

Primary note proof

Study-note section SE-S02

> Encapsulation groups state with operations and hides representation behind an interface. Polymorphism permits different object types to respond differently through a common operation or interface. Abstraction exposes the relevant contract while omitting unnecessary detail. Reusability means using suitable existing classes or components in new contexts rather than writing them again. These ideas support each other but name different properties.

Question sources

Software Engineering review questions · Question 2

Question 231 | NS0747

Which of the four fundamental software process activities involves making updates to meet changing customer needs after deployment?

A. Software Specification

B. Software Design and Implementation

C. Software Validation

D. Software Evolution

Hint

Classify the motive for the change before its implementation: repair, environment, useful capability or reduced future risk.

Answer D: Software evolution.

SE40 describes maintenance and evolution through change requests, impact analysis, planning, implementation/testing and release. Updating a deployed product to meet changing customer needs belongs to evolution among the four broad process activities. Specification, implementation and validation still occur within that work, but D names the lifecycle-wide change activity asked for rather than one constituent task.

Why each choice is right or wrong

A - Incorrect: Specification captures needs but does not name the overall postdeployment change activity.

B - Incorrect: Design/implementation is part of making a change rather than the broad evolution activity.

C - Incorrect: Validation checks the changed product against needs rather than naming ongoing adaptation itself.

D - Correct: Evolution updates existing software as stakeholder needs and operating conditions change.

Primary note proof

Study-note section SE40

> Corrective maintenance fixes faults; adaptive maintenance responds to environment changes; perfective maintenance improves useful capability/performance; preventive maintenance reduces future risk, such as restructuring fragile code. Motive determines category; refactoring can support preventive or perfective work. Maintenance often lasts years and includes understanding legacy code and regression effort, so it may dominate lifecycle cost.

Study-note section SE40

> A typical evolution sequence is change request→impact analysis→release planning→implementation/testing→release.

Question sources

Software Engineering review questions · Question 3

Question 232 | NS0748

A software process that plans all activities in advance and measures progress against that plan is classified as:

A. Agile Process

B. Plan-Driven Process

C. Incremental Process

D. Evolutionary Process

Hint

Identify whether the scenario prioritizes delivery, learning, adaptation or risk reduction. Several processes can share individual practices, so compare their defining emphasis.

Answer B: Plan-driven process.

The stem defines up-front planning and measurement against that plan. B names the plan-driven organization, illustrated by SE03's planned phases and reviewed deliverables. Incremental delivery and evolution describe how results grow or change and can coexist with planning. Agile also plans, but it emphasizes adaptation rather than defining all activity commitments in advance as stated here.

Why each choice is right or wrong

A - Incorrect: Agile uses planning but adapts content as feedback arrives rather than defining this fixed up-front emphasis.

B - Correct: Plan-driven explicitly organizes activities and progress measurement around an advance plan.

C - Incorrect: Incremental describes staged capability delivery and does not alone specify up-front planning commitments.

D - Incorrect: Evolutionary describes progressive change rather than necessarily advance planning of all activities.

Primary note proof

Study-note section SE-S04

> In a plan-driven process, activities are planned in advance and progress is assessed against that plan. Agile planning is incremental and adapts to changing needs. This distinction concerns planning strategy; a process can combine advance planning with staged deliveries and feedback.

Question sources

Software Engineering review questions · Question 4

Question 233 | NS0749

In requirement elicitation, the document created to describe what the system should do - agreed upon by clients and developers - is called:

A. Analysis Model

B. Use Case Diagram

C. Requirements Specification

D. Design Document

Hint

Distinguish observable services, measurable qualities and implementation constraints. Check scope, stakeholder meaning and the requested level of specificity.

Answer C: Requirements Specification.

SE08 states that the Software Requirements Specification organizes agreed requirements. That is the artifact describing what the system should do for client/developer agreement. Analysis models support technical discussion, a use-case diagram captures only selected goals/relationships and a design document describes solution decisions. None replaces the overall agreed requirements specification.

Why each choice is right or wrong

A - Incorrect: Analysis models formalize selected aspects for discussion rather than replacing the full agreed requirements document.

B - Incorrect: A use-case diagram shows goals and roles but not the complete requirements specification.

C - Correct: The requirements specification organizes the agreed services and constraints the system must satisfy.

D - Incorrect: A design document describes how the solution is organized rather than the complete statement of required behavior.

Primary note proof

Study-note section SE08

> Business requirements explain why the project exists and its goals. User requirements describe stakeholder needs at a useful high level; system requirements specify detailed services and constraints. The Software Requirements Specification (SRS) organizes the agreed requirements. A natural-language specification communicates with clients while analysis models formalize it for technical discussion; real specifications can also contain diagrams.

Question sources

Software Engineering review questions · Question 5

Question 234 | NS0750

What is the key distinction between a Requirements Specification and an Analysis Model?

A. The specification uses diagrams; the model uses natural language

B. The specification uses natural language; the model uses symbols and diagrams

C. Both use the same representation but serve different purposes

D. The analysis model is only for developers; specification is for testing

Hint

Distinguish observable services, measurable qualities and implementation constraints. Check scope, stakeholder meaning and the requested level of specificity.

Answer B: In the taught convention, natural-language client specification versus symbolic/diagrammatic analysis models.

SE08 explicitly describes natural-language specification for clients and analysis models that formalize it for technical discussion. B matches that teaching convention. This is not a universal ban on diagrams in an SRS: the note immediately allows them in real specifications. The other choices reverse the convention or impose unsupported exclusive audiences and purposes.

Why each choice is right or wrong

A - Incorrect: It reverses the natural-language specification versus formalized-model convention taught in the note.

B - Correct: This matches the taught convention, while real requirements specifications can also include diagrams.

C - Incorrect: The taught distinction does use different representation emphases rather than identical forms.

D - Incorrect: Neither artifact has the exclusive audience or testing-only purpose asserted here.

Primary note proof

Study-note section SE08

> Business requirements explain why the project exists and its goals. User requirements describe stakeholder needs at a useful high level; system requirements specify detailed services and constraints. The Software Requirements Specification (SRS) organizes the agreed requirements. A natural-language specification communicates with clients while analysis models formalize it for technical discussion; real specifications can also contain diagrams.

Question sources

Software Engineering review questions · Question 6

Question 235 | NS0751

In use case modeling, actors can be defined as:

A. Only human users who interact with the system

B. People, machines, or external systems that interact with the system

C. Only primary users who need system assistance

D. Software components within the system boundary

Hint

Match the information to be represented with each model's purpose. Read relationship direction, boundary and ownership conditions before classifying it.

Answer B: External interacting roles played by people, devices or other systems.

SE14 explicitly permits a person, device or other system to play an external actor role. B is the only option including those categories. Actors are not restricted to primary users or humans, and internal components are inside the chosen system boundary rather than external roles. One person may play several actors, so actor instances should not be confused with individual people.

Why each choice is right or wrong

A - Incorrect: Actors can be devices or external systems as well as human users.

B - Correct: People, devices and external systems can play roles interacting across the system boundary.

C - Incorrect: Supporting and administrative external roles can be actors, not only primary goal-seeking users.

D - Incorrect: Internal components are not external actor roles under the chosen system boundary.

Primary note proof

Study-note section SE14

> Draw actors outside the system boundary rectangle and use-case ovals inside. Name a goal with a verb and noun. The diagram shows roles, goals and relationships, not the full detailed algorithm or UI layout. Being an internal component is different from being an external actor; the chosen boundary determines which role applies.

Study-note section SE14

> An actor is an external role interacting with the system; it can be a person, device or another system.

Question sources

Software Engineering review questions · Question 7

Question 236 | NS0752

Which type of requirement specifies that 'the system must respond within 1 second'?

A. Functional Requirement

B. System Constraint

C. Non-Functional Requirement

D. Domain Requirement

Hint

Distinguish observable services, measurable qualities and implementation constraints. Check scope, stakeholder meaning and the requested level of specificity.

Answer C: Nonfunctional performance requirement.

SE10 identifies response time as a performance quality. A one-second threshold constrains how well a service responds rather than naming the service itself, so C is the appropriate category. A complete measurable requirement should also define the operation, load and timing conditions. Those omissions affect test precision, not the underlying classification of the stated response-time target.

Why each choice is right or wrong

A - Incorrect: The statement constrains response speed rather than specifying which service is performed.

B - Incorrect: The specific quality is performance; this is not primarily a technology or implementation constraint.

C - Correct: The one-second limit is a nonfunctional response-time/performance target.

D - Incorrect: No domain-specific business rule is stated; the obligation concerns a general performance quality.

Primary note proof

Study-note section SE10

> Nonfunctional requirements include quality attributes and constraints. Performance concerns response time, throughput and resource use; reliability concerns failure-free service; availability concerns being ready for use; usability concerns task success and ease of learning. Security concerns protection; compatibility concerns cooperating environments; portability concerns moving environments; maintainability/supportability concern change, diagnosis and evolution.

Question sources

Software Engineering review questions · Question 8

Question 237 | NS0753

When technology constraints are separated from quality attributes, what is the most specific category for “the system must be built using Java”?

A. Functional Requirement

B. Non-Functional Requirement

C. System/Constraint Requirement

D. Quality Requirement

Hint

Distinguish observable services, measurable qualities and implementation constraints. Check scope, stakeholder meaning and the requested level of specificity.

Answer C: System/Constraint Requirement

The statement prescribes an implementation technology rather than an externally observable service or a measurable product quality. In the course’s explicit separation of quality attributes from technology constraints, the specific category is a system or constraint requirement. A broad requirements taxonomy can place constraints under nonfunctional requirements, but the question asks for the more specific category. No performance, reliability or usability threshold is supplied by merely naming Java.

Why each choice is right or wrong

A - Incorrect: The statement prescribes technology rather than an observable service.

B - Incorrect: This is a broader umbrella in some taxonomies; it is incomplete when the specific constraint category is offered.

C - Correct: A required implementation language is a technology or system constraint.

D - Incorrect: No measurable quality attribute is specified merely by requiring Java.

Primary note proof

Study-note section SE10

> “Search responds within two seconds under 100 concurrent users” is measurable performance. “New users finish checkout within one minute without help” is usability. “Use Java” is a technology/pseudo-requirement, often separately classified as a system constraint. Dependability includes reliability, safety and robustness; portability is not its usual central category. Performance degradation at peak load primarily concerns performance, not automatically reliability.

Question sources

Software Engineering review questions · Question 9

Question 238 | NS0754

Which nonfunctional requirement category addresses the ability of the system to work across different web browsers and devices?

A. Reliability

B. Scalability

C. Usability

D. Compatibility

Hint

Distinguish observable services, measurable qualities and implementation constraints. Check scope, stakeholder meaning and the requested level of specificity.

Answer D: Compatibility.

SE10 distinguishes compatibility, which concerns cooperating environments, from portability, which concerns moving environments. Supporting different browsers and devices in the question is the offered compatibility category. Reliability concerns failure-free service, scalability concerns growth and usability concerns task success/ease of learning. None of those names the stated cross-environment cooperation requirement as directly.

Why each choice is right or wrong

A - Incorrect: Reliability concerns failure-free service rather than which browsers and devices can cooperate with the system.

B - Incorrect: Scalability concerns handling increased workload rather than cross-browser/device compatibility.

C - Incorrect: Usability concerns ease of learning and successful tasks, not the supported environment set itself.

D - Correct: Compatibility addresses operating/cooperating across the specified browsers and device environments.

Primary note proof

Study-note section SE10

> Nonfunctional requirements include quality attributes and constraints. Performance concerns response time, throughput and resource use; reliability concerns failure-free service; availability concerns being ready for use; usability concerns task success and ease of learning. Security concerns protection; compatibility concerns cooperating environments; portability concerns moving environments; maintainability/supportability concern change, diagnosis and evolution.

Study-note section SE-S07

> Scalability is the ability to accommodate additional workload while maintaining the required service, often by increasing available resources. It concerns growth in demand. Compatibility concerns supported cooperating environments, such as browsers and devices; usability concerns successful and learnable user tasks.

Question sources

Software Engineering review questions · Question 10

Question 239 | NS0755

Dependability in software engineering is a broader concept that includes all of the following EXCEPT:

A. Reliability

B. Robustness

C. Safety

D. Portability

Hint

Distinguish observable services, measurable qualities and implementation constraints. Check scope, stakeholder meaning and the requested level of specificity.

Answer D: Portability is the exception to the usual central dependability categories.

SE10 explicitly includes reliability, safety and robustness in dependability and says portability is not its usual central category. Portability instead concerns moving environments. Thus D is the listed exception. The distinction does not imply portability never affects practical service outcomes, only that it is a different quality category from the taught dependability grouping.

Why each choice is right or wrong

A - Incorrect: Reliability is explicitly included in the taught dependability grouping.

B - Incorrect: Robustness is explicitly included in the broader dependability concept.

C - Incorrect: Safety is explicitly included among dependability concerns.

D - Correct: Portability concerns moving environments rather than the usual central dependability categories.

Primary note proof

Study-note section SE10

> Dependability includes reliability, safety and robustness; portability is not its usual central category.

Study-note section SE10

> Security concerns protection; compatibility concerns cooperating environments; portability concerns moving environments; maintainability/supportability concern change, diagnosis and evolution.

Study-note section SE-S07

> Robustness concerns reliable operation across varied or difficult operating conditions and controlled failure outside the supported range.

Question sources

Software Engineering review questions · Question 11

Question 240 | NS0756

In requirements elicitation activities, which step involves formalizing scenarios into structured descriptions of system interactions?

A. Identifying Actors

B. Identifying Use Cases

C. Identifying Scenarios

D. Refining Use Cases

Hint

Distinguish observable services, measurable qualities and implementation constraints. Check scope, stakeholder meaning and the requested level of specificity.

Answer B: Identifying use cases by abstracting concrete scenarios.

SE13 calls a scenario one concrete execution and a use case an abstraction of related success and alternative scenarios. Formalizing those interactions into the more general use-case description therefore identifies use cases. Identifying actors establishes external roles, identifying scenarios captures individual executions and later refinement adds detail to an already identified use case.

Why each choice is right or wrong

A - Incorrect: Actor identification establishes external roles rather than generalizing scenario executions into interaction descriptions.

B - Correct: Use cases abstract related concrete scenarios into structured goal-oriented interaction descriptions.

C - Incorrect: Scenario identification captures concrete executions rather than their use-case abstraction.

D - Incorrect: Refinement elaborates an existing use case; the scenario-to-use-case abstraction is the identification step asked here.

Primary note proof

Study-note section SE13

> A scenario is one concrete execution; a use case abstracts the related successful and alternative scenarios. Analysis integrates functional (use cases/scenarios), structural/object (classes) and dynamic (states/interactions) models. Entity objects represent domain information such as Incident; boundary objects mediate interaction, such as ReportForm; control objects coordinate a use case. A UI form is normally boundary, not entity.

Question sources

Software Engineering review questions · Question 12

Question 241 | NS0757

According to the Simple Use Case Writing Guide, which of the following is CORRECT practice?

A. Use passive voice so responsibility is unclear

B. Describe user interface elements in detail

C. Document exceptions separately from the main flow

D. Combine multiple tasks into one use case for brevity

Hint

Match the information to be represented with each model's purpose. Read relationship direction, boundary and ownership conditions before classifying it.

Answer C: Document exceptions separately from the main success flow.

SE15 instructs writers to use active subject-verb steps and separate errors from normal flow. C follows that rule directly. Passive voice hides responsibility, detailed UI design distracts from goal-level behavior, and combining unrelated tasks does not produce a clear use case. The distinction concerns organizing scenarios rather than omitting exception handling.

Why each choice is right or wrong

A - Incorrect: Passive voice makes responsibility less clear, contrary to the active subject-verb guideline.

B - Incorrect: Detailed UI elements are not the goal-level behavior and flow structure emphasized by the guide.

C - Correct: Separating exception behavior keeps the main success flow clear while still documenting failures.

D - Incorrect: Combining multiple unrelated tasks sacrifices a coherent goal and consistent abstraction level.

Primary note proof

Study-note section SE15

> Example: Submit Incident. Precondition: officer authenticated. 1 Officer supplies location and description. 2 System validates details. 3 System records the incident. 4 System returns its ID. Alternative 2a: location missing → report the problem and request correction; save nothing. Success postcondition: incident and ID persist; failure guarantee: no partial record. An alternate flow is a conditional variation; an exception flow handles a failure. Preconditions hold before entry, while a trigger starts the use case.

Study-note section SE15

> Use active subject-verb steps at one abstraction level; separate errors from the normal flow.

Question sources

Software Engineering review questions · Question 13

Question 242 | NS0758

In the FAST (Facilitated Application Specification Technique), participants are initially asked to individually create lists of three item categories. Which is NOT one of them?

A. Things that are part of the environment surrounding the system

B. Things the system produces or outputs

C. Technical risks and constraints

D. Things the system uses or takes as inputs

Hint

Distinguish observable services, measurable qualities and implementation constraints. Check scope, stakeholder meaning and the requested level of specificity.

Answer C: Technical risks and constraints are not one of the three initial FAST lists.

SE12 explicitly lists environment elements, outputs and inputs as the initial participant categories. A, B and D match them. Technical risks and constraints can matter elsewhere in engineering, but they are not one of those three named initial FAST lists. The negative question asks about that procedure, not whether risk information is ever useful.

Why each choice is right or wrong

A - Incorrect: Environment elements are explicitly one of the initial FAST categories.

B - Incorrect: System outputs are explicitly included in the three initial lists.

C - Correct: Risks and constraints are not one of the specified environment/output/input categories.

D - Incorrect: Inputs and things the system uses are part of the stated initial categories.

Primary note proof

Study-note section SE12

> In the taught FAST technique, participants list environment elements, outputs and inputs, consolidate lists and develop smaller specifications. QFD prioritizes customer value: normal needs are explicitly stated, expected needs are assumed, and exciting needs provide unanticipated benefit. Brainstorm first to generate ideas, then evaluate and prioritize; do not confuse that with letting every idea become a committed requirement.

Question sources

Software Engineering review questions · Question 14

Question 243 | NS0759

In Quality Function Deployment (QFD), which category of requirements represents features that go beyond customer expectations and provide great satisfaction?

A. Normal Requirements

B. Expected Requirements

C. Exciting Requirements

D. Implicit Requirements

Hint

Distinguish observable services, measurable qualities and implementation constraints. Check scope, stakeholder meaning and the requested level of specificity.

Answer C: Exciting requirements.

SE12 distinguishes explicitly stated normal needs, assumed expected needs and exciting needs that bring unanticipated benefit. Features exceeding expectations and producing additional satisfaction match the exciting category. Calling them merely implicit would confuse customer assumptions with unexpected added value rather than identify the QFD term.

Why each choice is right or wrong

A - Incorrect: Normal requirements are explicitly stated needs rather than unexpected extra benefits.

B - Incorrect: Expected requirements are assumed by customers and do not denote surprising added satisfaction.

C - Correct: Exciting requirements deliver unanticipated benefit beyond the customer's expectations.

D - Incorrect: Implicit describes assumed needs more generally, not the QFD category for unanticipated benefits.

Primary note proof

Study-note section SE12

> In the taught FAST technique, participants list environment elements, outputs and inputs, consolidate lists and develop smaller specifications. QFD prioritizes customer value: normal needs are explicitly stated, expected needs are assumed, and exciting needs provide unanticipated benefit. Brainstorm first to generate ideas, then evaluate and prioritize; do not confuse that with letting every idea become a committed requirement.

Question sources

Software Engineering review questions · Question 15

Question 244 | NS0760

Which validation property ensures that the requirements specification does not contain contradictory statements?

A. Completeness

B. Consistency

C. Clarity

D. Correctness

Hint

Distinguish observable services, measurable qualities and implementation constraints. Check scope, stakeholder meaning and the requested level of specificity.

Answer B: Consistency.

SE11 directly defines consistency as excluding contradictions. Completeness covers agreed scope, clarity gives one intended interpretation, and correctness reflects stakeholder needs. A specification can be complete yet inconsistent, or clear yet wrong, so these properties cannot substitute for the precise no-contradictions condition.

Why each choice is right or wrong

A - Incorrect: Completeness concerns covering scope and behavior, not whether requirements contradict each other.

B - Correct: Consistency requires the specification’s statements to coexist without contradiction.

C - Incorrect: Clarity addresses interpretive ambiguity rather than logical compatibility between requirements.

D - Incorrect: Correctness concerns actual stakeholder needs, a different validation property.

Primary note proof

Study-note section SE11

> Correct requirements reflect actual stakeholder needs. Complete requirements address the agreed scope, normal and exceptional behavior. Consistency excludes contradictions. Clarity/unambiguity gives one intended interpretation; feasibility/realism means achievable within constraints. Verifiability means objective evidence can check fulfillment. Replace “fast for most users” with a defined metric, workload and threshold.

Question sources

Software Engineering review questions · Question 16

Question 245 | NS0761

The Waterfall model is MOST appropriate when:

A. Requirements are expected to change frequently during development

B. The project is large and complex with evolving needs

C. Requirements are constant, the project is short, and technology is stable

D. The team needs to deliver working software in small increments

Hint

Identify whether the scenario prioritizes delivery, learning, adaptation or risk reduction. Several processes can share individual practices, so compare their defining emphasis.

Answer C: Stable requirements and familiar, stable technology.

SE03 says classical waterfall fits well-understood stable requirements and familiar technology, directly supporting C among these alternatives. Frequent change, evolving needs and early small deliveries call for feedback or incremental capability rather than waterfall's late feedback. Short duration alone is not a proof, but C also supplies the decisive stability conditions stated in the note.

Why each choice is right or wrong

A - Incorrect: Frequent requirement changes make late-feedback sequential planning a poor fit.

B - Incorrect: Large evolving needs do not establish the stable requirements that favor classical waterfall.

C - Correct: Constant requirements and stable technology match the note's stated waterfall selection conditions.

D - Incorrect: Prioritized usable small deliveries are the rationale for incremental delivery rather than a single sequential release.

Primary note proof

Study-note section SE03

> Classical waterfall separates planned phases with reviewed deliverables. It fits well-understood, stable requirements and familiar technology; late feedback makes changes costly. It does not make change physically impossible: real projects revisit work under control, and modified waterfall explicitly includes feedback. Rigidity offers milestone visibility but can freeze incorrect assumptions.

Question sources

Software Engineering review questions · Question 17

Question 246 | NS0762

Which is a characteristic drawback of classical waterfall compared with approaches that seek repeated early feedback?

A. Requires skilled developers

B. Late feedback can make requirement changes costly through rework of earlier phase deliverables.

C. No clear project milestones

D. Does not support documentation

Hint

Identify whether the scenario prioritizes delivery, learning, adaptation or risk reduction. Several processes can share individual practices, so compare their defining emphasis.

Answer B: Late feedback can make requirement changes costly through rework of earlier phase deliverables.

Classical waterfall separates planned phases and may receive important feedback late. Correcting earlier assumptions can then require costly rework across completed deliverables, which is its characteristic drawback here. Changes are still possible under control. Skilled developers are needed across approaches, and waterfall provides milestone visibility and documentation, so the other alternatives do not identify the stated comparative disadvantage.

Why each choice is right or wrong

A - Incorrect: Skill requirements are not unique to waterfall.

B - Correct: Late feedback can make requirement changes costly after earlier phases.

C - Incorrect: Waterfall provides clear reviewed milestones.

D - Incorrect: Waterfall supports planned documentation.

Primary note proof

Study-note section SE03

> Classical waterfall separates planned phases with reviewed deliverables. It fits well-understood, stable requirements and familiar technology; late feedback makes changes costly. It does not make change physically impossible: real projects revisit work under control, and modified waterfall explicitly includes feedback. Rigidity offers milestone visibility but can freeze incorrect assumptions.

Question sources

Software Engineering review questions · Question 18

Question 247 | NS0763

What is the key conceptual distinction between iteration and incremental delivery, even when a process combines both?

A. Iterative adds new features each cycle; Incremental refines the same set repeatedly

B. Iteration revisits and improves a solution; an increment adds usable functionality.

C. They are identical; the terms are interchangeable

D. Incremental involves risk analysis; Iterative does not

Hint

Identify whether the scenario prioritizes delivery, learning, adaptation or risk reduction. Several processes can share individual practices, so compare their defining emphasis.

Answer B: Iteration revisits and improves a solution; an increment adds usable functionality.

Iteration revisits and improves a solution, while an increment adds usable functionality. A process can refine existing capability and add new capability in the same cycle, so the concepts are compatible but not identical. Neither requires rebuilding the entire system or making every increment completely independent. Risk analysis is a separate concern rather than the structural distinction defining these two terms.

Why each choice is right or wrong

A - Incorrect: This reverses refinement and added functionality.

B - Correct: Iteration refines; increments add usable capability.

C - Incorrect: The terms differ even when combined in one process.

D - Incorrect: Risk analysis does not define their distinction.

Primary note proof

Study-note section SE04

> Choose incremental delivery when prioritized partial capability must reach users early. Smaller changes can be easier to debug and permit feedback, though architecture and integration still require planning. Iteration need not rebuild the whole system every time, and increments need not be perfectly independent modules. Broad descriptions of early working software can fit prototypes, iterative or Agile processes; identify the purpose of that early version.

Study-note section SE04

> Iteration revisits and improves a solution; an increment adds usable functionality. A process may do both.

Question sources

Software Engineering review questions · Question 19

Question 248 | NS0764

A large application already has its core capabilities. The main development goal is to revisit and improve that existing solution repeatedly as feedback and future changes arrive, rather than primarily add new capability in each delivery. Which concept most directly names that emphasis?

A. Waterfall Model

B. V-Model

C. Iterative Model

D. Incremental Model

Hint

Identify whether the scenario prioritizes delivery, learning, adaptation or risk reduction. Several processes can share individual practices, so compare their defining emphasis.

Answer C: Iterative Model

The stated emphasis is iterative: revisiting and improving an existing solution in response to feedback. Incremental development names the addition of usable functionality, which is not the primary goal specified, although both can coexist. Classical waterfall's stable staged planning and the V-model's paired assurance structure do not directly name this refinement emphasis. Large size and anticipated change alone would not have selected a unique model.

Why each choice is right or wrong

A - Incorrect: Classical waterfall does not directly name repeated refinement as the organizing emphasis.

B - Incorrect: The V-model emphasizes paired development and tests.

C - Correct: Iteration directly names revisiting and improving the existing solution.

D - Incorrect: Incremental describes added functionality rather than the specified primary emphasis.

Primary note proof

Study-note section SE04

> Choose incremental delivery when prioritized partial capability must reach users early. Smaller changes can be easier to debug and permit feedback, though architecture and integration still require planning. Iteration need not rebuild the whole system every time, and increments need not be perfectly independent modules. Broad descriptions of early working software can fit prototypes, iterative or Agile processes; identify the purpose of that early version.

Study-note section SE02

> A common lifecycle names requirements, design, implementation, testing, deployment and maintenance. Analysis clarifies the problem; system design chooses architecture; object/detail design specifies interfaces and algorithms; implementation writes code; testing evaluates behavior; deployment puts it into service. These activities may overlap and repeat.

Study-note section SE04

> Iteration revisits and improves a solution; an increment adds usable functionality. A process may do both.

Question sources

Software Engineering review questions · Question 20

Question 249 | NS0765

In the Agile SDLC, small units of functionality that the software needs to deliver are called:

A. Sprints

B. Iterations

C. User Stories

D. Epics

Hint

Identify whether the scenario prioritizes delivery, learning, adaptation or risk reduction. Several processes can share individual practices, so compare their defining emphasis.

Answer C: User stories.

SE05 defines a user story as a small user need and value supported by acceptance criteria. Sprints and iterations name cycles or timeboxes, not the need itself. An epic groups broader work. C therefore names the small functional work unit intended here, without claiming that Agile requirements consist only of story text.

Why each choice is right or wrong

A - Incorrect: A Sprint is a timeboxed development interval rather than the individual user need.

B - Incorrect: An iteration is a cycle of work or refinement, not a small functional requirement.

C - Correct: A user story states a small user need and its value with acceptance criteria.

D - Incorrect: An epic groups broader work rather than naming the smaller story-sized need.

Primary note proof

Study-note section SE05

> Scrum uses timeboxed Sprints of at most one month, with a Sprint Goal, selected work and a usable Increment meeting a Definition of Done. Scope is discussed before and during planning; it is not forbidden to agree scope. Timeboxes tend to stay fixed while content is adapted without endangering the goal. Agile can be combined with required assurance/documentation; safety-critical context alone cannot prove it is unsuitable.

Study-note section SE05

> A user story states a small user need and value, supported by acceptance criteria; an epic groups broader work.

Question sources

Software Engineering review questions · Question 21

Question 250 | NS0766

The Spiral Model distinguishes itself from other models primarily through its emphasis on:

A. Sequential phase completion

B. Risk Analysis at every cycle

C. Customer delivery at the end of the project

D. Strict adherence to initial requirements

Hint

Identify whether the scenario prioritizes delivery, learning, adaptation or risk reduction. Several processes can share individual practices, so compare their defining emphasis.

Answer B: Risk analysis and reduction in every spiral cycle.

SE06 defines spiral development as risk driven, with each cycle identifying objectives and alternatives, assessing and reducing risks, producing a result and planning commitment. That emphasis distinguishes it from merely repeating phases or delivering only at the end. It can adapt requirements and combine other activities rather than enforcing an unchangeable initial specification.

Why each choice is right or wrong

A - Incorrect: A spiral can contain staged work, but sequential completion is not its defining driver.

B - Correct: Risk assessment and reduction guide each cycle’s work and further commitment.

C - Incorrect: Only delivering at the end is not the distinguishing spiral principle.

D - Incorrect: A risk-driven cycle can revise plans and requirements rather than rigidly freeze them.

Primary note proof

Study-note section SE06

> Spiral development is risk driven. Each cycle identifies objectives and alternatives, assesses and reduces important risks, develops/verifies an appropriate next result, and plans further commitment. A prototype may test a risky technology before a large investment. The amount and type of work depend on the risks.

Question sources

Software Engineering review questions · Question 22

Question 251 | NS0767

The V-Model derives its name from its shape. What does the BOTTOM of the 'V' represent?

A. Requirements Gathering

B. Deployment

C. Coding/Implementation

D. Maintenance

Hint

Identify whether the scenario prioritizes delivery, learning, adaptation or risk reduction. Several processes can share individual practices, so compare their defining emphasis.

Answer C: Coding/implementation.

SE03 explicitly places coding at the bottom of the V while specification and design stages correspond to later testing levels. Requirements therefore begin the development side rather than occupy the bottom; deployment and maintenance are not that connecting implementation activity. This is a model-diagram convention, not a claim that all real work follows a perfect geometric sequence.

Why each choice is right or wrong

A - Incorrect: Requirements occur on the specification side, not at the coding bottom of the V.

B - Incorrect: Deployment is not the implementation activity joining the V-model's sides.

C - Correct: The note explicitly identifies coding as the bottom of the V.

D - Incorrect: Maintenance occurs in lifecycle evolution rather than at this implementation point.

Primary note proof

Study-note section SE03

> The V-model pairs specification/design stages with later test levels. Requirements inform acceptance tests; system design informs system tests; component/detail design informs integration/unit tests. Coding lies at the bottom. Test planning starts early. Stable requirements and strong assurance may favor this organization, but neither a V shape nor waterfall guarantees safety or correctness.

Question sources

Software Engineering review questions · Question 23

Question 252 | NS0768

Which organization standardizes and maintains UML as a modeling language?

A. IEEE

B. ISO

C. Object Management Group (OMG)

D. W3C

Hint

Match the information to be represented with each model's purpose. Read relationship direction, boundary and ownership conditions before classifying it.

Answer C: Object Management Group (OMG)

The note identifies the Object Management Group as UML's standardizing and maintaining organization. UML is a modeling language rather than a software lifecycle process. This stewardship question does not claim that the organization originally invented every contributing notation. IEEE, ISO and W3C are not the organization to which the supplied note attributes this particular standardization and maintenance role.

Why each choice is right or wrong

A - Incorrect: IEEE is not the attributed UML steward.

B - Incorrect: ISO is not the organization attributed this role in the note.

C - Correct: OMG is the stated standardizing and maintaining organization.

D - Incorrect: W3C is not the attributed UML steward.

Primary note proof

Study-note section SE17

> A class box lists name, attributes and operations; + public, - private, # protected and ~ package indicate visibility. A class diagram shows static types and relationships, while an object diagram shows particular instances/links. UML is maintained and standardized by OMG; it is a modeling language, not a lifecycle process. Structural things describe conceptual or physical structural elements.

Question sources

Software Engineering review questions · Question 24

Question 253 | NS0769

In a UML Use Case Diagram, the rectangle enclosing all use cases is called:

A. System Context

B. System Boundary Box

C. Package Container

D. Module Frame

Hint

Match the information to be represented with each model's purpose. Read relationship direction, boundary and ownership conditions before classifying it.

Answer B: The system boundary box.

SE14 says actors are outside the system-boundary rectangle and use-case ovals are inside. The enclosing rectangle therefore marks the modeled system's boundary. A context may be communicated by the diagram, but it is not the specific box name requested; packages and modules serve different grouping roles rather than defining this external actor boundary.

Why each choice is right or wrong

A - Incorrect: System context is broader information, not the specific name of this enclosing boundary rectangle.

B - Correct: The rectangle separates the modeled system's use cases from external actor roles.

C - Incorrect: A package groups modeling elements but is not the stated system/actor boundary.

D - Incorrect: Module frame is not the use-case system-boundary term defined in SE14.

Primary note proof

Study-note section SE14

> Draw actors outside the system boundary rectangle and use-case ovals inside. Name a goal with a verb and noun. The diagram shows roles, goals and relationships, not the full detailed algorithm or UI layout. Being an internal component is different from being an external actor; the chosen boundary determines which role applies.

Question sources

Software Engineering review questions · Question 25

Question 254 | NS0770

When execution reaches an include relationship’s inclusion point in a base use case, what does include require?

A. Optional behavior that may be added to the base use case

B. The included behavior is required whenever execution reaches the inclusion point.

C. An inheritance relationship between two use cases

D. A timing constraint between two use cases

Hint

Match the information to be represented with each model’s purpose. Read relationship direction, boundary and ownership conditions before classifying it.

Answer B: The included behavior is required whenever execution reaches the inclusion point.

Include factors required reused behavior into another use case. When the base reaches the inclusion point, the included behavior is incorporated and performed as specified. This does not imply that every possible conditional branch of the base reaches that point. Optional conditional additions correspond to extend, specialization to generalization, and timing constraints are separate from the inclusion relationship.

Why each choice is right or wrong

A - Incorrect: Conditional optional added behavior describes extend.

B - Correct: The included behavior is required when its inclusion point is reached.

C - Incorrect: Specialization is generalization rather than include.

D - Incorrect: Include is not a timing constraint.

Primary note proof

Study-note section SE16

> Generalization relates a specialized actor/use case to a more general one, with a hollow triangle toward the general element. An abstract use case specifies behavior for specialization and is not directly instantiated as a complete use case. It is not defined merely by reuse or lack of a direct actor line. Included behavior is incorporated where the inclusion is reached; do not infer every conditional branch in the base always executes.

Study-note section SE16

> Include factors required reused behavior: Submit Order includes Validate Order, with the dashed arrow from the including/base use case to the included one.

Question sources

Software Engineering review questions · Question 26

Question 255 | NS0771

In a UML class diagram, visibility marked with '#' indicates:

A. Public access

B. Private access

C. Protected access

D. Package-level access

Hint

Match the information to be represented with each model's purpose. Read relationship direction, boundary and ownership conditions before classifying it.

Answer C: Protected visibility.

SE17 lists + public, - private, # protected and ~ package. The requested hash marker therefore means protected access. These symbols indicate visibility of a class member; they do not express object multiplicity, inheritance direction or class ownership, and the other choices correspond to different explicit markers.

Why each choice is right or wrong

A - Incorrect: Public visibility is marked with + rather than #.

B - Incorrect: Private visibility is marked with - rather than #.

C - Correct: The note explicitly assigns # to protected visibility.

D - Incorrect: Package visibility uses ~ rather than the protected # marker.

Primary note proof

Study-note section SE17

> A class box lists name, attributes and operations; + public, - private, # protected and ~ package indicate visibility. A class diagram shows static types and relationships, while an object diagram shows particular instances/links. UML is maintained and standardized by OMG; it is a modeling language, not a lifecycle process. Structural things describe conceptual or physical structural elements.

Question sources

Software Engineering review questions · Question 27

Question 256 | NS0772

In UML, which relationship is represented by a HOLLOW diamond shape pointing toward the 'whole' class?

A. Composition

B. Dependency

C. Aggregation

D. Generalization

Hint

Match the information to be represented with each model’s purpose. Read relationship direction, boundary and ownership conditions before classifying it.

Answer C: Shared aggregation.

SE18 defines shared aggregation with a hollow diamond at the whole end. Composition instead uses a filled diamond; dependency is a dashed arrow and generalization uses a hollow triangle. The question’s whole-end description is consistent with the notation, so the hollow shape uniquely identifies aggregation among these alternatives.

Why each choice is right or wrong

A - Incorrect: Composition uses a filled diamond, not the specified hollow diamond.

B - Incorrect: Dependency is represented by a dashed arrow rather than a whole-part diamond.

C - Correct: Shared aggregation uses a hollow diamond placed at the whole end.

D - Incorrect: Generalization uses a hollow triangle toward the general element rather than a diamond.

Primary note proof

Study-note section SE18

> Composition uses a filled diamond at the whole end and strong ownership: a part is in at most one composite at a time, and parts still owned are destroyed with that composite. Parts may be detached/transferred under a defined model. Thus “cannot ever exist independently” is an oversimplification. For Car composing Engine, the diamond belongs beside Car; saying it points to Engine is imprecise. The Car-Engine example describes composition.

Study-note section SE18

> Shared aggregation uses a hollow diamond at the whole end and weak whole-part meaning;

Question sources

Software Engineering review questions · Question 28

Question 257 | NS0773

Which statement accurately distinguishes UML composition from shared aggregation while allowing model-defined detachment or transfer?

A. Aggregation is for classes; Composition is for interfaces

B. Composition has exclusive composite ownership at a time and destroys still-owned parts with the whole; shared aggregation gives weaker whole-part meaning.

C. Aggregation implies inheritance; Composition does not

D. They are synonymous in modern UML

Hint

Match the information to be represented with each model's purpose. Read relationship direction, boundary and ownership conditions before classifying it.

Answer B: Composition has exclusive composite ownership at a time and destroys still-owned parts with the whole; shared aggregation gives weaker whole-part meaning.

Composition gives strong ownership: a part is in at most one composite at a time, and still-owned parts are destroyed with that composite. Shared aggregation indicates weaker whole-part meaning without that detailed lifecycle policy. A model can permit detachment or transfer, so permanent inability to exist independently is too strong. Neither relationship is inheritance, and composition is not restricted to interfaces.

Why each choice is right or wrong

A - Incorrect: Composition is not restricted to interfaces.

B - Correct: This states strong ownership and destruction of still-owned parts, unlike weak shared aggregation.

C - Incorrect: Aggregation is not inheritance; generalization is separate.

D - Incorrect: The ownership meanings differ, so they are not synonyms.

Primary note proof

Study-note section SE18

> Composition uses a filled diamond at the whole end and strong ownership: a part is in at most one composite at a time, and parts still owned are destroyed with that composite. Parts may be detached/transferred under a defined model. Thus "cannot ever exist independently" is an oversimplification. For Car composing Engine, the diamond belongs beside Car; saying it points to Engine is imprecise. The Car-Engine example describes composition.

Question sources

Software Engineering review questions · Question 29

Question 258 | NS0774

Under the course's sequence-diagram layout heuristic-rather than a mandatory UML column rule-which participant belongs in the second column?

A. The control object managing the use case

B. The actor who initiated the use case

C. A boundary object the actor used to start the use case

D. An entity object central to the use case

Hint

Match the information to be represented with each model's purpose. Read relationship direction, boundary and ownership conditions before classifying it.

Answer C: A boundary object the actor used to start the use case

The course's heuristic places the initiating actor first, the boundary object second, the control object third and entity objects afterward. The boundary used by the actor therefore occupies the second column under that convention. UML itself does not mandate this column order; lifeline semantics come from the modeled participants and messages rather than their horizontal position alone.

Why each choice is right or wrong

A - Incorrect: The heuristic places control third.

B - Incorrect: The initiating actor is first.

C - Correct: The actor-facing boundary is second under the specified heuristic.

D - Incorrect: Entities follow the boundary and control in this heuristic.

Primary note proof

Study-note section SE19

> One interaction-diagram layout heuristic puts the initiating actor first, boundary second, control third, then entities. This is not a required UML column order. In ReportEmergency, FieldOfficer activates ReportEmergencyButton, enters details through EmergencyReportForm, and later sees AcknowledgmentNotice; DispatcherStation belongs to the dispatcher side. Choose the button for initiating this particular scenario.

Question sources

Software Engineering review questions · Question 30

Question 259 | NS0775

In a UML Activity Diagram, a diamond shape is used to represent:

A. Initial State

B. Final State

C. Action Box

D. Decision Box

Hint

Match the information to be represented with each model's purpose. Read relationship direction, boundary and ownership conditions before classifying it.

Answer D: A decision node, also usable as a merge node in the appropriate flow.

SE20 names the guarded decision diamond and separately notes that the same shape can merge alternative flows. D is therefore a correct use of the shape, without claiming decision is its only role. Initial nodes are filled circles, actions are rounded, and final-state notation is not the diamond described.

Why each choice is right or wrong

A - Incorrect: The initial node is a filled circle rather than a diamond.

B - Incorrect: The diamond is not the standard final-state marker in the described notation.

C - Incorrect: Actions are rounded nodes rather than guarded-flow diamonds.

D - Correct: A diamond can represent a guarded decision; it can also merge alternative flows.

Primary note proof

Study-note section SE20

> An activity diagram models workflow: filled circle start, rounded actions, guarded decision diamond, thick fork/join bars and partitions/swimlanes for responsibility. A diamond can also merge alternative flows; a join synchronizes concurrent flows. A state machine models states and transitions triggered by events, often with guards/actions, for one object's lifecycle.

Question sources

Software Engineering review questions · Question 31

Question 260 | NS0776

In system design, 'coupling' between subsystems refers to:

A. How well objects within a subsystem work toward a common goal

B. The number of operations a subsystem exposes

C. The degree of dependency between two subsystems

D. The architectural pattern chosen for the system

Hint

Separate responsibilities inside a component from dependencies across boundaries. Evaluate the stated structure, change and reuse goals without assuming guaranteed benefits.

Answer C: The degree of dependency between subsystems.

SE22 explicitly distinguishes cohesion within a module from coupling between modules. A describes cohesion; C describes coupling. Interface operation count can affect design complexity but is not the definition of dependence, and an architectural pattern may influence coupling without being the relationship measure itself. The goal is usually low coupling with high cohesion.

Why each choice is right or wrong

A - Incorrect: Related purpose inside a subsystem defines cohesion rather than between-subsystem coupling.

B - Incorrect: Operation count alone does not measure the actual dependencies between subsystems.

C - Correct: Coupling is the degree of dependency between modules or subsystems.

D - Incorrect: An architectural style can affect coupling but is not its definition.

Primary note proof

Study-note section SE22

> Cohesion measures how well elements inside a module serve a related purpose; coupling measures dependency between modules. Seek high cohesion and low coupling. Shared mutable data and knowledge of another module’s internal representation increase coupling. Information hiding exposes stable operations while concealing changeable decisions.

Question sources

Software Engineering review questions · Question 32

Question 261 | NS0777

In architectural design, a 'closed architecture' in a layered system means:

A. No external access to any layer is allowed

B. A layer can access any layer at deeper levels freely

C. A layer can only call the layer immediately below it

D. All layers communicate through a central repository

Hint

Separate responsibilities inside a component from dependencies across boundaries. Evaluate the stated structure, change and reuse goals without assuming guaranteed benefits.

Answer C: Calls are restricted to the immediately lower layer.

SE23 defines a closed layered architecture as allowing calls only to the immediately lower layer. Open layering may permit approved skipping, so B describes a different policy. Closed does not mean no external access or a shared repository; it concerns permitted dependencies between layers rather than the system's exposure or storage organization.

Why each choice is right or wrong

A - Incorrect: Closed layering restricts interlayer calls, not every form of external access.

B - Incorrect: Skipping freely to deeper layers contradicts the immediate-lower-layer restriction.

C - Correct: A layer calls only the immediately lower layer in the defined closed architecture.

D - Incorrect: A central repository is another architectural arrangement and does not define closed layering.

Primary note proof

Study-note section SE23

> A layer is a logical abstraction level; a tier is a deployment separation. A closed layered architecture permits calls only to the immediately lower layer; an open one permits approved skipping. For top-to-bottom A,B,C,D, A→B obeys closed layering, A→C skips, and lower-to-upper calls violate the simple dependency rule unless explicitly mediated by a defined mechanism.

Question sources

Software Engineering review questions · Question 33

Question 262 | NS0778

Which architectural style divides subsystems into Model, View, and Controller components?

A. Repository Style

B. Client/Server Style

C. Peer-to-Peer Style

D. Model-View-Controller Style

Hint

Separate responsibilities inside a component from dependencies across boundaries. Evaluate the stated structure, change and reuse goals without assuming guaranteed benefits.

Answer D: Model-View-Controller.

SE24 explicitly defines MVC as separating a domain model, display view and interaction controller. D names that exact style. Repository, client-server and peer-to-peer organize central data or interacting roles differently; any may be combined with MVC, but none is the name of this particular three-responsibility separation.

Why each choice is right or wrong

A - Incorrect: Repository style centers shared data rather than the specific model/view/controller separation.

B - Incorrect: Client-server separates requesters and service providers, not these three presentation-interaction responsibilities.

C - Incorrect: Peer-to-peer allows participants to play requester and provider roles rather than defining MVC components.

D - Correct: Model-View-Controller explicitly names the three responsibilities in the question.

Primary note proof

Study-note section SE24

> Repository style shares central data, simplifying common access but creating bottleneck/schema dependencies. MVC separates domain model, display view and interaction controller. Client-server separates requesters from service providers; peer-to-peer permits both roles. Pipe-and-filter applies successive transformations to data streams. Three-tier separates presentation, application logic and storage; some four-tier variants split presentation client/server.

Question sources

Software Engineering review questions · Question 34

Question 263 | NS0779

In the Three-Tier architectural style, which layer handles 'storing, retrieving, and querying persistent data'?

A. Interface Layer

B. Application Logic Layer

C. Storage Layer

D. Presentation Layer

Hint

Separate responsibilities inside a component from dependencies across boundaries. Evaluate the stated structure, change and reuse goals without assuming guaranteed benefits.

Answer C: The storage layer/tier.

SE24 separates three-tier presentation, application logic and storage. Persistent data storage and retrieval belong to the storage responsibility, whereas presentation handles interaction and application logic coordinates domain behavior. The question uses layer for a tier-style role; that terminology does not change which responsibility owns persistence.

Why each choice is right or wrong

A - Incorrect: The interface responsibility handles interaction rather than persistent storage and querying.

B - Incorrect: Application logic coordinates domain operations but delegates persistence to the storage responsibility.

C - Correct: The storage role handles persistent data, including retrieval and queries.

D - Incorrect: Presentation formats user interaction and output rather than owning persistent data storage.

Primary note proof

Study-note section SE24

> Repository style shares central data, simplifying common access but creating bottleneck/schema dependencies. MVC separates domain model, display view and interaction controller. Client-server separates requesters from service providers; peer-to-peer permits both roles. Pipe-and-filter applies successive transformations to data streams. Three-tier separates presentation, application logic and storage; some four-tier variants split presentation client/server.

Study-note section SE23

> A layer is a logical abstraction level; a tier is a deployment separation. A closed layered architecture permits calls only to the immediately lower layer; an open one permits approved skipping. For top-to-bottom A,B,C,D, A→B obeys closed layering, A→C skips, and lower-to-upper calls violate the simple dependency rule unless explicitly mediated by a defined mechanism.

Question sources

Software Engineering review questions · Question 35

Question 264 | NS0780

In the analysis model, which type of object represents the bridges between the system and the actors?

A. Entity Objects

B. Control Objects

C. Boundary Objects

D. Interface Objects

Hint

Distinguish observable services, measurable qualities and implementation constraints. Check scope, stakeholder meaning and the requested level of specificity.

Answer C: Boundary objects.

SE13 defines boundary objects as mediating interaction, with ReportForm as an example. That is the bridge between external actors and the system. Entity objects hold domain information, while controls coordinate use cases. Interface objects is a generic descriptive phrase, but boundary is the explicitly defined analysis-category name requested among these choices.

Why each choice is right or wrong

A - Incorrect: Entity objects represent domain information rather than the actor-facing interaction bridge.

B - Incorrect: Control objects coordinate use-case behavior rather than primarily mediate actor interaction.

C - Correct: Boundary objects are explicitly defined as mediating system-actor interaction.

D - Incorrect: Interface objects is not the named entity/boundary/control category specified here's analysis model.

Primary note proof

Study-note section SE13

> A scenario is one concrete execution; a use case abstracts the related successful and alternative scenarios. Analysis integrates functional (use cases/scenarios), structural/object (classes) and dynamic (states/interactions) models. Entity objects represent domain information such as Incident; boundary objects mediate interaction, such as ReportForm; control objects coordinate a use case. A UI form is normally boundary, not entity.

Question sources

Software Engineering review questions · Question 36

Question 265 | NS0781

Which heuristic rule states that there should be 'one control object per actor' in a use case?

A. CRC Card Heuristic

B. Control Object Identification Heuristic

C. Boundary Object Heuristic

D. Sequence Diagram Column Rule

Hint

Distinguish observable services, measurable qualities and implementation constraints. Check scope, stakeholder meaning and the requested level of specificity.

Answer B: The control-object identification heuristic.

SE13 permits one control per use case or participating actor as a useful starting point, while denying a mandatory UML rule. The stem already asks for a heuristic, so B correctly identifies the control-object selection guideline. CRC, boundary identification and column layout concern different tasks; none makes the count a required lifetime or architecture constraint.

Why each choice is right or wrong

A - Incorrect: CRC records class responsibilities and collaborators rather than prescribing this candidate-control count.

B - Correct: This is the heuristic for identifying candidate use-case control objects, not a universal UML constraint.

C - Incorrect: Boundary heuristics identify interaction-facing objects rather than coordinating controls.

D - Incorrect: Sequence-column layout orders participants visually and does not define candidate control-object counts.

Primary note proof

Study-note section SE13

> Use nouns as candidate objects, possessive descriptions as candidate attributes, and verbs such as manages/reports-to as candidate associations. These are heuristics, not automatic parsing rules. CRC means Class, Responsibilities, Collaborators. A control per use case or participating actor can be a useful starting point, not a mandatory UML rule or fixed object lifetime.

Question sources

Software Engineering review questions · Question 37

Question 266 | NS0782

CRC cards stand for:

A. Class, Requirements, Conditions

B. Component, Relationship, Constraints

C. Class, Responsibilities, Collaborators

D. Control, Reuse, Composition

Hint

Distinguish observable services, measurable qualities and implementation constraints. Check scope, stakeholder meaning and the requested level of specificity.

Answer C: Class, Responsibilities, Collaborators.

SE13 expands CRC directly as Class, Responsibilities, Collaborators. The card identifies the class, what it must do or know, and which other objects help fulfill those responsibilities. The distractors replace these terms with requirements, components or unrelated design concepts and therefore do not preserve the stated expansion.

Why each choice is right or wrong

A - Incorrect: Requirements and Conditions are not the R and final C in the stated expansion.

B - Incorrect: Component, Relationship and Constraints do not match the class-card terminology.

C - Correct: This is the exact CRC expansion supplied in SE13.

D - Incorrect: Control, Reuse and Composition are different concepts rather than the CRC card fields.

Primary note proof

Study-note section SE13

> Use nouns as candidate objects, possessive descriptions as candidate attributes, and verbs such as manages/reports-to as candidate associations. These are heuristics, not automatic parsing rules. CRC means Class, Responsibilities, Collaborators. A control per use case or participating actor can be a useful starting point, not a mandatory UML rule or fixed object lifetime.

Question sources

Software Engineering review questions · Question 38

Question 267 | NS0783

In UML association multiplicity, what does '0..*' mean?

A. Exactly one instance

B. Zero or exactly one instance

C. Zero or more instances

D. One or more instances

Hint

Match the information to be represented with each model’s purpose. Read relationship direction, boundary and ownership conditions before classifying it.

Answer C: Zero or more instances.

SE17 defines 0..* as any nonnegative number. Zero is allowed and the star places no finite upper bound, so C fits. The alternatives correspond to 1, 0..1 and 1..* respectively. Multiplicity at one end is interpreted relative to one object at the opposite end, not as a whole-system object count.

Why each choice is right or wrong

A - Incorrect: Exactly one corresponds to multiplicity 1 rather than 0..*.

B - Incorrect: Optional single-valued multiplicity is 0..1, not an unbounded star.

C - Correct: Zero is permitted and the upper star allows any number of related instances.

D - Incorrect: One or more requires lower bound 1, written 1..*.

Primary note proof

Study-note section SE17

> Multiplicity at one end counts how many objects there may correspond to one object at the opposite end: 1 exactly one, 0..1 optional, 0..* any nonnegative number, 1..* at least one. A one-to-many association does not automatically mean composition. Read each end separately before choosing cardinality.

Question sources

Software Engineering review questions · Question 39

Question 268 | NS0784

In Abbott's heuristics for identifying associations, which phrase pattern most directly suggests a relationship between classes?

A. Look for adjective phrases describing class properties

B. Examine verb phrases like 'has', 'is part of', 'manages', 'reports to'

C. Find all nouns that appear more than twice

D. Identify all user interface terms

Hint

Distinguish observable services, measurable qualities and implementation constraints. Check scope, stakeholder meaning and the requested level of specificity.

Answer B: Verb phrases expressing relationships, such as manages or reports to.

SE13 recommends nouns as candidate objects and verbs such as manages/reports-to as candidate associations. B is the relationship-phrase option. Adjectives generally describe properties, repeated nouns do not automatically imply an association, and UI terms suggest boundary concerns. These are candidate-identification heuristics rather than a proof that every verb must become a modeled link.

Why each choice is right or wrong

A - Incorrect: Property descriptions suggest attributes rather than directly identifying links between classes.

B - Correct: Relationship verbs are the note’s direct heuristic for candidate associations.

C - Incorrect: Noun frequency is not the stated association-identification rule; nouns instead suggest candidate objects.

D - Incorrect: UI terminology may suggest boundaries but does not directly establish an association between domain classes.

Primary note proof

Study-note section SE13

> Use nouns as candidate objects, possessive descriptions as candidate attributes, and verbs such as manages/reports-to as candidate associations. These are heuristics, not automatic parsing rules. CRC means Class, Responsibilities, Collaborators. A control per use case or participating actor can be a useful starting point, not a mandatory UML rule or fixed object lifetime.

Question sources

Software Engineering review questions · Question 40

Question 269 | NS0785

In software testing, which type of testing evaluates the software's behavior WITHOUT knowledge of its internal code structure?

A. White Box Testing

B. Grey Box Testing

C. Black Box Testing

D. Structural Testing

Hint

Separate testing scope, technique and purpose. Use the stated workload, observable result or coverage target rather than a universal ranking.

Answer C: Black-box testing.

SE36 contrasts black-box cases derived from required behavior with white-box cases derived from implementation structure. Grey-box uses partial internal knowledge. The question excludes internal-code knowledge, so black-box is the appropriate technique. Structural testing instead refers to the very internal paths or statements that this scenario does not inspect.

Why each choice is right or wrong

A - Incorrect: White-box testing explicitly uses internal implementation structure to derive cases.

B - Incorrect: Grey-box testing uses partial internal knowledge rather than excluding it.

C - Correct: Black-box testing derives cases from externally specified behavior without needing code structure.

D - Incorrect: Structural testing is based on internal control or code structure, contrary to the stem.

Primary note proof

Study-note section SE36

> Black-box techniques derive cases from specified behavior; white-box techniques derive them from internal structure; grey-box uses partial internal knowledge. Regression testing checks for unintended effects after change; confirmation testing checks the particular defect repair. Exploratory testing combines learning, design and execution and is experience based. Manual/automated describe execution support, not a compulsory black-/white-box classification.

Question sources

Software Engineering review questions · Question 41

Question 270 | NS0786

Which type of functional testing verifies that individual components work correctly in ISOLATION?

A. System Testing

B. Integration Testing

C. Regression Testing

D. Unit Testing

Hint

Separate testing scope, technique and purpose. Use the stated workload, observable result or coverage target rather than a universal ranking.

Answer D: Unit testing.

SE35 defines unit testing as isolating a function, class or small component, often replacing dependencies with stubs or mocks. Integration checks combined interactions and system testing evaluates the whole system. Regression describes testing after changes and can occur at different levels, so it is not the isolation level named by the question.

Why each choice is right or wrong

A - Incorrect: System testing evaluates the complete integrated system rather than an isolated component.

B - Incorrect: Integration testing focuses on interactions among combined parts, not isolation.

C - Incorrect: Regression checks unintended effects after change and is not inherently a component-isolation level.

D - Correct: Unit testing evaluates a small component in isolation, with dependencies replaceable by test doubles.

Primary note proof

Study-note section SE35

> Unit testing isolates a function, class or small component, often replacing dependencies with stubs/mocks; a driver invokes the unit and a stub substitutes a called dependency. Integration testing exercises interfaces and interactions among combined parts. System testing checks the complete integrated system against functional and nonfunctional requirements in a representative environment.

Question sources

Software Engineering review questions · Question 42

Question 271 | NS0787

Non-functional testing that evaluates how the system behaves under expected workloads and measures response speed is called:

A. Usability Testing

B. Reliability Testing

C. Performance Testing

D. Compatibility Testing

Hint

Separate testing scope, technique and purpose. Use the stated workload, observable result or coverage target rather than a universal ranking.

Answer C: Performance testing, specifically load-oriented testing under expected demand.

SE36 defines performance tests as assessing speed, throughput and resource use under a specified workload and distinguishes expected load from stress beyond normal limits. The stem explicitly adds workload and response speed, so it supports performance testing rather than merely a vague normal-condition test. Usability, reliability and compatibility target different quality questions.

Why each choice is right or wrong

A - Incorrect: Usability focuses on task success and ease of use rather than response-speed measurements under load.

B - Incorrect: Reliability concerns failure-free service, not primarily the stated response-time criterion.

C - Correct: Speed under an expected workload is performance/load testing as defined in SE36.

D - Incorrect: Compatibility examines cooperating environments rather than the specified speed-under-load behavior.

Primary note proof

Study-note section SE36

> Functional tests check required behavior against the SRS and acceptance criteria. Performance tests assess speed, throughput and resources under a specified workload; load uses expected demands and stress exceeds normal limits. Usability, security, compatibility and reliability tests target their respective qualities. “Normal operating conditions” alone does not distinguish functional from performance testing.

Question sources

Software Engineering review questions · Question 43

Question 272 | NS0788

In the analysis phase, which model type uses use cases and scenarios to describe what the software should do?

A. Dynamic Model

B. Analysis Object Model

C. Functional Model

D. Structural Model

Hint

Distinguish observable services, measurable qualities and implementation constraints. Check scope, stakeholder meaning and the requested level of specificity.

Answer C: The functional model.

SE13 explicitly associates use cases and scenarios with functional modeling, classes with structural/object modeling, and states/interactions with dynamic modeling. Thus C names the requested description of what the system should do. The alternatives describe state-dependent behavior or static object structure rather than this user-goal and scenario view.

Why each choice is right or wrong

A - Incorrect: Dynamic models emphasize states and interactions rather than the named use-case/scenario category.

B - Incorrect: The analysis object model captures classes and relationships rather than the functional use-case view.

C - Correct: Use cases and scenarios are explicitly the functional analysis model.

D - Incorrect: Structural modeling describes static classes and links rather than required user-goal flows.

Primary note proof

Study-note section SE13

> A scenario is one concrete execution; a use case abstracts the related successful and alternative scenarios. Analysis integrates functional (use cases/scenarios), structural/object (classes) and dynamic (states/interactions) models. Entity objects represent domain information such as Incident; boundary objects mediate interaction, such as ReportForm; control objects coordinate a use case. A UI form is normally boundary, not entity.

Question sources

Software Engineering review questions · Question 44

Question 273 | NS0789

In an analysis model, an object coordinates a use case and moves among Idle, WaitingForReply and Completing states as events arrive. Domain entities are passive records and the form has no persistent modes in this scenario. Which object category is the direct state-machine target described?

A. Entity Objects

B. Boundary Objects

C. Control Objects

D. All objects equally

Hint

Match the information to be represented with each model's purpose. Read relationship direction, boundary and ownership conditions before classifying it.

Answer C: Control Objects

A control object coordinates a use case, and the described coordinator has significant event-dependent states. A state machine is therefore directly useful for that control object in this scenario. Entities and boundaries can also have meaningful lifecycles in other systems, but here their stated behavior does not supply the modeled states. Suitability follows from responsibilities and lifecycle behavior, not equal need across all objects.

Why each choice is right or wrong

A - Incorrect: The scenario's entities are passive records rather than the stated coordinator.

B - Incorrect: The form has no persistent modes and is not the use-case coordinator.

C - Correct: The stateful coordinator is a control object.

D - Incorrect: The need depends on significant state behavior, not equality across every object.

Primary note proof

Study-note section SE20

> Choose a sequence diagram for message order between participants, a state machine for event-dependent state changes, and activity for workflow. Both sequence and state diagrams describe behavior over time. State machines are useful for objects with significant states, whether entity or control. A DFD shows data stores/flows and transformations from inputs to outputs; it is not a UML diagram.

Study-note section SE13

> A scenario is one concrete execution; a use case abstracts the related successful and alternative scenarios. Analysis integrates functional (use cases/scenarios), structural/object (classes) and dynamic (states/interactions) models. Entity objects represent domain information such as Incident; boundary objects mediate interaction, such as ReportForm; control objects coordinate a use case. A UI form is normally boundary, not entity.

Question sources

Software Engineering review questions · Question 45

Question 274 | NS0790

In the ReportEmergency use case example, which boundary object allows the FieldOfficer to initiate the reporting process?

A. EmergencyReportForm

B. AcknowledgmentNotice

C. ReportEmergencyButton

D. DispatcherStation

Hint

Match the information to be represented with each model's purpose. Read relationship direction, boundary and ownership conditions before classifying it.

Answer C: ReportEmergencyButton.

SE19 explicitly says FieldOfficer activates ReportEmergencyButton, supplies details through EmergencyReportForm and later sees AcknowledgmentNotice. DispatcherStation belongs to the dispatcher side. Therefore the button initiates this particular scenario; the form handles later input and the notice reports completion. This is grounded in the named example rather than a generic rule that every use case starts with a button.

Why each choice is right or wrong

A - Incorrect: The form receives incident details after initiation rather than starting the documented scenario.

B - Incorrect: The acknowledgment is seen later as feedback, not used to initiate reporting.

C - Correct: The note explicitly identifies this button as the FieldOfficer's initiating boundary object.

D - Incorrect: DispatcherStation is on the dispatcher side rather than the FieldOfficer's initiation interface.

Primary note proof

Study-note section SE19

> One interaction-diagram layout heuristic puts the initiating actor first, boundary second, control third, then entities. This is not a required UML column order. In ReportEmergency, FieldOfficer activates ReportEmergencyButton, enters details through EmergencyReportForm, and later sees AcknowledgmentNotice; DispatcherStation belongs to the dispatcher side. Choose the button for initiating this particular scenario.

Question sources

Software Engineering review questions · Question 46

Question 275 | NS0791

Generalization in UML modeling is best described as:

A. Dividing a class into multiple subclasses with no shared properties

B. Identifying a general concept where other concepts are more specific versions of it

C. Creating interfaces for external system communication

D. Grouping unrelated classes into a package for organization

Hint

Match the information to be represented with each model's purpose. Read relationship direction, boundary and ownership conditions before classifying it.

Answer B: A general concept with more-specific specializations.

SE16 relates a specialized actor or use case to a more general one; SE18 gives the corresponding class generalization toward a superclass. B expresses that abstraction/specialization relationship. It does not merely package unrelated classes, create an external interface or split classes while denying shared general properties.

Why each choice is right or wrong

A - Incorrect: Specialization is related through a general concept rather than requiring no shared properties.

B - Correct: Generalization identifies the common general element of which other concepts are more specific versions.

C - Incorrect: External communication interfaces do not by themselves define a generalization relationship.

D - Incorrect: Packaging unrelated classes is organizational grouping rather than specialization of a shared general concept.

Primary note proof

Study-note section SE18

> Association connects related instances. A dashed dependency arrow means a client uses a supplier. Generalization uses a solid line and hollow triangle pointing to the superclass/general element. Shared aggregation uses a hollow diamond at the whole end and weak whole-part meaning; it does not by itself define a detailed lifecycle policy.

Study-note section SE16

> Generalization relates a specialized actor/use case to a more general one, with a hollow triangle toward the general element. An abstract use case specifies behavior for specialization and is not directly instantiated as a complete use case. It is not defined merely by reuse or lack of a direct actor line. Included behavior is incorporated where the inclusion is reached; do not infer every conditional branch in the base always executes.

Question sources

Software Engineering review questions · Question 47

Question 276 | NS0792

The 'high cohesion, low coupling' principle in subsystem design means:

A. Subsystems should be tightly interconnected for maximum communication efficiency

B. Objects within a subsystem should be closely related, while subsystems themselves should be mostly independent

C. Each subsystem should have minimal internal functionality to reduce complexity

D. All subsystems should share a single central data repository

Hint

Separate responsibilities inside a component from dependencies across boundaries. Evaluate the stated structure, change and reuse goals without assuming guaranteed benefits.

Answer B: Related responsibilities within a subsystem, limited dependencies between subsystems.

SE22 defines cohesion as related purpose within a module and coupling as dependency across modules, then recommends high cohesion and low coupling. B states both dimensions. It does not require minimal functionality, tight cross-connections or one shared repository; those choices can undermine coherent responsibilities or increase dependency rather than establish the principle.

Why each choice is right or wrong

A - Incorrect: Tight interconnection increases coupling rather than meeting the low-coupling goal.

B - Correct: Closely related internal responsibilities and limited external dependencies express both parts of the principle.

C - Incorrect: Cohesion concerns related purpose, not simply having as little functionality as possible.

D - Incorrect: A shared repository is a style choice and can create dependencies; it does not define cohesion or coupling.

Primary note proof

Study-note section SE22

> Cohesion measures how well elements inside a module serve a related purpose; coupling measures dependency between modules. Seek high cohesion and low coupling. Shared mutable data and knowledge of another module’s internal representation increase coupling. Information hiding exposes stable operations while concealing changeable decisions.

Question sources

Software Engineering review questions · Question 48

Question 277 | NS0793

A safety-critical contract requires traceable assurance records and reviewed verification before release. Waterfall, V-model and spiral proposals include those obligations; the proposed lightweight Agile variant supplies working code but omits the required assurance records. Which proposal is least appropriate as specified?

A. Waterfall Model

B. V-Model

C. Agile Model

D. Spiral Model

Hint

Identify whether the scenario prioritizes delivery, learning, adaptation or risk reduction. Several processes can share individual practices, so compare their defining emphasis.

Answer C: Agile Model

The specified Agile proposal omits mandatory assurance records, so it cannot satisfy the stated contract without modification. The other proposals include those obligations and are not excluded on that ground. This is a judgment about the supplied lightweight variant, not Agile in general: the note explicitly allows Agile to incorporate required documentation and assurance. Stable requirements alone would not establish a universal ranking.

Why each choice is right or wrong

A - Incorrect: This proposal includes the required reviewed deliverables.

B - Incorrect: This proposal includes the required assurance obligations.

C - Correct: The specified lightweight variant omits mandatory records and is therefore least suitable as proposed.

D - Incorrect: This proposal includes the stated assurance obligations.

Primary note proof

Study-note section SE05

> Scrum uses timeboxed Sprints of at most one month, with a Sprint Goal, selected work and a usable Increment meeting a Definition of Done. Scope is discussed before and during planning; it is not forbidden to agree scope. Timeboxes tend to stay fixed while content is adapted without endangering the goal. Agile can be combined with required assurance/documentation; safety-critical context alone cannot prove it is unsuitable.

Study-note section SE03

> The V-model pairs specification/design stages with later test levels. Requirements inform acceptance tests; system design informs system tests; component/detail design informs integration/unit tests. Coding lies at the bottom. Test planning starts early. Stable requirements

and strong assurance may favor this organization, but neither a V shape nor waterfall guarantees safety or correctness.

Study-note section SE03

Classical waterfall separates planned phases with reviewed deliverables. It fits well-understood, stable requirements and familiar technology; late feedback makes changes costly.

Question sources

Software Engineering review questions · Question 49

Question 278 | NS0794

In a sequence diagram, what does an 'X' (cross) at the end of a lifeline dashed line indicate?

A. The object is temporarily inactive

B. The object is waiting for a message

C. The object ceases to exist at that point

D. The object is calling itself recursively

Hint

Match the information to be represented with each model's purpose. Read relationship direction, boundary and ownership conditions before classifying it.

Answer C: Modeled destruction of the object at that point.

SE19 explicitly identifies X as modeled destruction, so C is correct in UML diagram semantics. Temporary inactivity and waiting do not end an object's modeled existence, and a recursive message is represented by an interaction rather than destruction. The marker does not guarantee the runtime moment at which a garbage collector reclaims memory.

Why each choice is right or wrong

A - Incorrect: Temporary inactivity does not terminate the object's lifeline.

B - Incorrect: Waiting for a message does not mean the modeled object has been destroyed.

C - Correct: X marks the object's modeled destruction at that point, not necessarily immediate memory reclamation.

D - Incorrect: A recursive call is an interaction message and does not use the destruction marker.

Primary note proof

Study-note section SE19

> Sequence diagrams show interactions across lifelines, with order/time generally downward. Messages cross between participants; activation rectangles show execution. A creation message starts a lifeline; an X marks modeled destruction, not a guarantee about when a garbage collector runs. Synchronous calls wait for completion; asynchronous messages permit the sender to proceed.

Design and Analysis of Algorithms

Questions & Worked Answers

141 questions + 4 source variants

Question 1 | Q00065

Which one of the following is not an example of divide and conquer algorithm?

A. Quick sort

B. Binary searching

C. Merge sort

D. Heap sort

Hint

Identify the specification and cost model, then apply the relevant bound, invariant or strategy rule.

Answer D: Heap sort

DAA16 explicitly classifies heap sort as outside standard divide and conquer: it builds a heap and repeatedly extracts its maximum. Quicksort partitions and recursively sorts ranges; merge sort recursively sorts halves; binary search recursively or iteratively reduces to a smaller half. Thus heap sort is the single exclusion among the listed algorithms.

Why each choice is right or wrong

A - Incorrect: Quicksort partitions its input and recursively sorts the resulting smaller ranges, a standard divide-and-conquer pattern.

B - Incorrect: Binary search repeatedly reduces a sorted search interval to one half; the note treats this as divide-and-conquer.

C - Incorrect: Merge sort divides into halves, sorts each recursively, and combines them by merging.

D - Correct: Heap sort builds a heap and repeatedly restores it after extraction, rather than independently sorting and combining subinstances.

Primary note proof

Study-note section DAA12

> Divide and conquer solves smaller largely independent instances and combines results. DP reuses a defined set of subproblem states. Greedy commits to a feasible local choice only when a safety argument supports it. Backtracking grows/retracts candidates when constraints fail; branch and bound also rejects candidates whose best possible objective cannot beat an incumbent.

Study-note section DAA16

Heap sort builds a max-heap in Θ(n), then extracts/restores in O(log n) per item: O(n log n) total, Θ(1) auxiliary space, ordinarily unstable. It is not standard D&C. Merge sort offers stability/worst-case guarantees; quicksort's practical advantage depends on implementation/workload.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Design and Analysis of Algorithms module | PDF page 17 | lines 23-29

• Breaking large problems into smaller subproblems • Example of algorithms uses divide-and-conquer strategy : • Binary search, • Finding maximum and minimum • Merge sort • Quick sort • selection sort

Design and Analysis of Algorithms module | PDF page 23 | lines 19-29

QUICK SORT • The divide-and-conquer approach can be used to arrive at an efficient sorting method different from merge sort. • In merge sort, the file a[1:n] was divided at its midpoint into sub arrays which were independently sorted & later merged. • In Quick sort, the division into 2 sub arrays is made so that the sorted sub arrays do not need to be merged later. • This is accomplished by rearranging the elements in a[1:n] such that a[I]<=a[j] for all I between 1 & n and all j between (m+1) & n for some m, 1<=m<=n. • Thus the elements in a[1:m] & a[m+1:n] can be independently sorted. • No merge is needed. This rearranging is referred to as partitioning.

Design and Analysis of Algorithms module | PDF page 21 | lines 18-29

MERGE SORT • As another example divide-and-conquer, we investigate a sorting algorithm that has the nice property that is the worst case its complexity is O(n log n) • This algorithm is called merge sort • We assume throughout that the elements are to be sorted in non-decreasing order. • Given a sequence of ‗n' elements a[1],…,a[n] the general idea is to imagine then split into 2 sets a[1],…..,a[n/2] and a[[n/2]+1],….a[n]. • Each set is individually sorted, and the resulting sorted sequences are merged to produce a single sorted sequence of ‗n' elements. • Thus, we have another ideal example of the divide-and-conquer strategy in which the splitting is into 2 equal-sized sets & the combining operation is the merging of 2 sorted sets into one.

Question sources

MOE Computer Science Exit Exam · 2016 · Question 65

Question 2 | Q00149

For n≥2, determine the tight asymptotic running time of this syntax-repaired C++-style pseudocode under mathematical-integer, unit-cost arithmetic and output:
function(n) { a=0; print("Enter a positive integer"); for(i=1; i<n; i*=2) a=i; return 0; }

A. Θ(n log n)

B. $\Theta(n^2)$

C. Θ(log n)

D. Θ(n)

Hint

Identify the specification and cost model, then apply the relevant bound, invariant or strategy rule.

Answer C: Θ(log n)

The loop visits i=1,2,4,... while i<n, so it executes ceil($\log_2 n$) iterations. Each iteration has constant work under the stated arithmetic and output model, and initialization, the fixed prompt and return add constant overhead. The total is therefore Θ(log n).

Why each choice is right or wrong

A - Incorrect: n log n grows faster and is not the tight order.

B - Incorrect: Quadratic grows faster and is not the tight order.

C - Correct: The doubling loop takes logarithmically many constant-cost iterations.

D - Incorrect: Linear is a looser upper bound rather than the tight order.

Primary note proof

Study-note section DAA06

> Sequential costs add; independent nested loop counts multiply. A dependent loop requires summation. n iterations of a constant body give Θ(n); ∑i=1.. n i=n(n+1)/2 gives Θ(n^2). Doubling i=1,2,4,... until i≥n takes ceil(log 2 n) iterations for n>1. A 10n loop is linear under constant-cost output.

Study-note section DAA02

> Analysis counts operations and storage as functions of input size: array length n, graph vertices V/edges E, or the number of bits in integers. A RAM model commonly gives constant cost to bounded-word arithmetic/access. Arbitrarily large integer arithmetic and printing long outputs need their own costs. Elapsed measurements also depend on hardware, compiler, cache, I/O and competing load.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Design and Analysis of Algorithms module | PDF page 10 | lines 6-20

> Analysis Rules: 1. We assume an arbitrary time unit. 2. Execution of one of the following operations takes time 1: • Assignment Operation • Single Input/output Operation • Single Boolean Operations • Single Arithmetic Operations • Function Return 3. Running time of a selection statement (if, switch) is the time for the condition evaluation plus the maximum of the running times for the individual clauses in the selection. 4. Loops: Running time for a loop is equal to the running time for the statements inside the loop multiplied by the number of iterations. The total running time of a statement inside a group of nested loops is the running time of the statements multiplied by the product of the sizes of all the loops. For nested loops, analyze inside out.

Data Structure and Algorithms module | PDF page 3 | lines 23-31

Binary Searching • Works on ordered/sorted list • Uses divide and conquer method: it locates mid-point and identify which have the target belongs to since the list is sorted. It performs this recursively till the item found or the list is empty(target is not in the list • The computational time for this algorithm is proportional to log2 n.

Question sources

Addis Ababa University mock exam · Question 51

Question 3 | Q00173

Recursion is a method in which the solution of a problem depends on:

A. Larger instances of the same problem

B. Smaller instances of the same problem

C. Larger instances of different problems

D. Smaller instances of different problems

Hint

Identify the specification and cost model, then apply the relevant bound, invariant or strategy rule.

Answer B: Smaller instances of the same problem

Recursion reduces a problem to simpler instances of that same problem (PDF p.14). Thus smaller same-problem instances, with a terminating base case, match the definition.

Why each choice is right or wrong

A - Incorrect: Larger instances do not implement the reducing step on p.14.

B - Correct: Smaller instances preserve the problem while reducing its size (p.14).

C - Incorrect: Changing both size upward and problem identity fails the recursive reduction (p.14).

D - Incorrect: Smaller instances of a different problem are not the same-problem recursion described on p.14.

Primary note proof

Study-note section DAA09

Include every recursive call, nonrecursive work and base case. Expansion gives $T(n)=T(n-1)+\Theta(1)\rightarrow\Theta(n)$, and $T(n)=T(n/2)+\Theta(1)\rightarrow\Theta(\log n)$. For $2T(n/2)+\Theta(n)$, logarithmically many levels each cost $\Theta(n)$, giving $\Theta(n \log n)$.

Study-note section DAA01

Prove an invariant initially, after each step and at termination; for recursion prove base cases and the inductive reduction. Testing finds failures but finite tests do not prove correctness for all inputs.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Design and Analysis of Algorithms module | PDF page 14 | lines 30-33

> Recursion is a particularly powerful kind of reduction, which can be described loosely as follows: • If the given instance of the problem is small or simple enough, just solve it. • Otherwise, reduce the problem to one or more simpler instances of the same problem.

Computer Science Exit Exam practice collection · Question 96

Question 4 | Q00175

If an optimal solution can be created for a problem by constructing optimal solutions for its subproblems, the problem possesses property.

A. Overlapping subproblems

B. Optimal substructure

C. Memoization

D. Greedy

Hint

Identify the specification and cost model, then apply the relevant bound, invariant or strategy rule.

Answer B: Optimal substructure

Optimal substructure means an optimal solution contains optimal solutions to subproblems (PDF p.28). The principle of optimality on p.49 expresses exactly the construction in the stem.

Why each choice is right or wrong

A - Incorrect: Overlap concerns repeated subproblems, not optimality of their solutions (pp.28,49).

B - Correct: This is the named property defined on p.28.

C - Incorrect: Memoization stores computed answers; it is not the optimality property (p.49).

D - Incorrect: Greedy is a design strategy requiring additional choice conditions (p.28).

Primary note proof

Study-note section DAA25

> Define state meaning, choices, recurrence, bases and dependency order. Prove replacing a subsolution by a better one improves the full solution; otherwise state information may be

missing. Show the recurrence covers all legal final choices and generates feasible candidates, then induct in dependency order. Store choices for reconstruction.

Study-note section DAA19

A greedy algorithm repeatedly selects a locally attractive feasible option without later undoing it. Optimal substructure alone does not prove this safe. An exchange proof inserts the greedy choice into an optimum without worsening cost; recurse. MST cut proofs use this exchange.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Design and Analysis of Algorithms module | PDF page 28 | lines 3-4

• Optimal substructure: An optimal solution to the problem contains an optimal solution to sub problems.

Design and Analysis of Algorithms module | PDF page 49 | lines 2-12

The Principle of Optimality The dynamic programming relies on a principle of optimality. This principle states that in an optimal sequence of decisions or choices, each subsequence must also be optimal. For example, in matrix chain multiplication problem, not only the value we are interested in is optimal but all the other entries in the table are also represent optimal. The principle can be related as follows: the optimal solution to a problem is a combination of optimal solutions to some of its sub problems. The difficulty in turning the principle of optimally into an algorithm is that it is not usually obvious which sub problems are relevant to the problem under consideration. General method-multistage graphs-all pair shortest path algorithm-Optimal Binary Search trees- 0/1 knapsack Problem-Reliability design-traveling salesman problem

Question sources

Addis Ababa University mock exam · Question 77

Question 5 | Q00176

If a problem can be broken into subproblems that are reused several times, the problem possesses property.

A. Overlapping subproblems

B. Optimal substructure

C. Memoization

D. Greedy

Hint

Identify the specification and cost model, then apply the relevant bound, invariant or strategy rule.

Answer A: Overlapping subproblems

Reusing a subproblem several times means subproblems share sub-subproblems, the contrast made on PDF p.48. This is overlapping subproblems; storing an answer is a response to that property, not the property itself.

Why each choice is right or wrong

A - Correct: Shared sub-subproblems and repeated work are described on p.48.

B - Incorrect: Optimal substructure concerns optimal solutions rather than repetition (p.28).

C - Incorrect: Saving results in a table addresses repeated work; it is not the reuse property (p.48).

D - Incorrect: A greedy choice is unrelated to whether subproblems recur (pp.28,48).

Primary note proof

Study-note section DAA25

> Overlapping states motivate reuse; optimal substructure supports optimization. These are textbook signatures, not requirements that every DP problem optimize or every state have multiple users. DP also counts/decides. Cost=states×work per state and can remain exponential.

Study-note section DAA26

> Memoization recursively checks a cache before solving a state and stores its result. Tabulation orders dependencies explicitly; chosen domains may exclude irrelevant states. Cache keys include all relevant parameters; recursion/locality/sparsity affect implementation cost.

Design and Analysis of Algorithms module | PDF page 48 | lines 5-16

> Dynamic programming, like the divide-and-conquer method, solves problems by combining the solutions to subproblems. As we saw in Chapter 2 of binary search, divide-and-conquer algorithms partition the problem into independent subproblems, solve the subproblems recursively, and then combine their solutions to solve the original problem. In contrast, dynamic programming is applicable when the subproblems are not independent, that is, when subproblems share sub subproblems. In this context, a divide-and-conquer algorithm does more work than necessary, repeatedly solving the common sub subproblems. A dynamic-programming algorithm solves every subproblem just once and then saves its answer in a table, thereby avoiding the work of recomputing the answer every time the subproblem is encountered. Dynamic programming is typically applied to optimization problems. In such problems there can be many possible solutions. Each solution has a value, and we wish to find a solution with the optimal (minimum or maximum) value.

Design and Analysis of Algorithms module | PDF page 28 | lines 3-4

> • Optimal substructure: An optimal solution to the problem contains an optimal solution to sub problems.

Question sources

Addis Ababa University mock exam · Question 78

Question 6 | Q00177

If a problem can be solved by combining optimal solutions to non-overlapping sub-problems, the strategy is called _____.

A. Dynamic programming

B. Divide and Conquer

C. Recursion

D. Greedy

Hint

Identify the specification and cost model, then apply the relevant bound, invariant or strategy rule.

Answer B: Divide and Conquer

PDF p.48 explicitly contrasts independent subproblems in divide and conquer with shared sub-subproblems in dynamic programming. Combining independent solutions therefore identifies divide and conquer; optimality alone does not identify greedy.

Why each choice is right or wrong

A - Incorrect: Dynamic programming is motivated by non-independent shared subproblems (p.48).

B - Correct: Independent subproblems are recursively solved and combined (pp.17,48).

C - Incorrect: Recursion is a mechanism; the more specific independent-split-and-combine strategy is given on p.48.

D - Incorrect: Greedy needs a locally justified choice, which this stem does not specify (p.48 contrast).

Primary note proof

Study-note section DAA12

> Divide and conquer solves smaller largely independent instances and combines results. DP reuses a defined set of subproblem states. Greedy commits to a feasible local choice only when a safety argument supports it. Backtracking grows/retracts candidates when constraints fail; branch and bound also rejects candidates whose best possible objective cannot beat an incumbent.

Question 7 | Q00283

Suppose we want to determine the efficiency of the algorithm, then how we can measure the space factor

A. To count the maximum memory required by the algorithm

B. To count the average memory required by the algorithm

C. To count the minimum memory required by the algorithm

D. To count the maximum disk space needed by the algorithm

Hint

Identify the specification and cost model, then apply the relevant bound, invariant or strategy rule.

Answer A: To count the maximum memory required by the algorithm

Space needed to run to completion must allow the program to finish without exhausting memory (PDF p.6). Hence the required allocation is peak simultaneously needed memory for that execution; average or minimum use may underallocate.

Why each choice is right or wrong

A - Correct: Maximum simultaneously required memory supports completion (p.6).

B - Incorrect: Average use can fall below a later peak and cannot guarantee enough memory (p.6).

C - Incorrect: Minimum use cannot supply the full execution requirement (p.6).

D - Incorrect: Disk capacity alone does not measure the program memory requirement defined on p.6.

Primary note proof

Study-note section DAA08

> Space complexity measures peak simultaneously live storage, not the sum of every allocation ever made. Count input, auxiliary structures and stack according to the requested convention. n active recursion levels with constant-size frames need Θ(n) stack; depth log n with constant frames needs Θ(log n). The number of total calls does not determine peak depth.

Question 8 | Q00284

Two main measures for the efficiency of an algorithm are

A. Processor and memory

B. Data and space

C. Complexity and capacity

D. Time and space

Hint

Identify the specification and cost model, then apply the relevant bound, invariant or strategy rule.

Answer D: Time and space

Performance is stated in computer memory and time (PDF p.4), and complexity is expressed as space and time (p.6). The pair is therefore time and space.

Why each choice is right or wrong

A - Incorrect: Processor is a device, not the time measure paired with memory (p.4).

B - Incorrect: Data is the problem content, not one of the two resource measures (p.6).

C - Incorrect: Complexity and capacity are not the stated two measures (p.6).

D - Correct: Time and space are explicitly named on p.6.

Primary note proof

Study-note section DAA02

> Analysis counts operations and storage as functions of input size: array length n, graph vertices V/edges E, or the number of bits in integers. A RAM model commonly gives constant cost to bounded-word arithmetic/access. Arbitrarily large integer arithmetic and printing long outputs need their own costs. Elapsed measurements also depend on hardware, compiler, cache, I/O and competing load.

University of Gondar model exam · Question 15

Question 9 | Q00285

For the standard Floyd-Warshall implementation on an n-vertex weighted graph, using constant-time distance arithmetic and the full k,i,j loops, what is the tight running-time bound?

A. $\Theta(n^2)$

B. $\Theta(n^3)$

C. $\Theta(n)$

D. $\Theta(n^4)$

Hint

Identify the specification and cost model, then apply the relevant bound, invariant or strategy rule.

Answer B: $\Theta(n^3)$

Floyd-Warshall considers each intermediate vertex k and updates every ordered pair i,j. The three independent n-sized loop ranges perform $\Theta(n^3)$ constant-cost updates. The n^2 output table explains storage, not the time of this implementation. Other graph assumptions can support different algorithms, so this is the cost of the explicitly named method rather than a universal best-achievable APSP bound.

Why each choice is right or wrong

A - Incorrect: Quadratic counts pair storage but misses the intermediate-vertex loop.

B - Correct: Three full n-sized loops give cubic time.

C - Incorrect: Linear is too small even for the explicit pair table.

D - Incorrect: Quartic is a loose upper bound rather than the tight cost.

Primary note proof

Study-note section DAA28

> For all-pairs distances initialize D[i, i]=0, D[i, j] to the minimum direct edge weight, and missing edges to∞. Preserve a negative self-loop by taking min(0, its weight). For k outermost, update D[i, j]=min(D[i, j], D[i, k]+D[k, j]); before phase k, intermediates are restricted to earlier vertices. Guard unreachable sums and numeric overflow.

Study-note section DAA28

> Three loops give $\Theta(V^3)$ time and $\Theta(V^2)$ storage. A negative diagonal afterward identifies a negative cycle; pairs able to traverse it have no finite minimum walk distance. Warshall reachability replaces min/+ by OR/AND. Floyd's cost is not a universal best-achievable bound for all APSP settings; sparse nonnegative graphs permit repeated Dijkstra and other models permit other methods.

University of Gondar model exam · Question 16

Question 10 | Q00287

A recursive execution has n simultaneously active call levels, each retaining Theta(1) storage. Count only live call-frame storage. What is the tightest listed asymptotic upper bound on its peak space?

A. O(n'2)

B. O(n)

C. O(1)

D. O(log n)

Hint

Identify the specification and cost model, then apply the relevant bound, invariant or strategy rule.

Answer B: B. O(n)

All n call frames are live at the deepest point. Each frame retains a fixed positive amount of storage, so their combined peak space is proportional to n. This gives Theta(n) space and makes O(n) the tightest listed upper bound. $O(n^2)$ is a looser valid upper bound, while constant and logarithmic space cannot hold for n simultaneously live constant-size frames.

Why each choice is right or wrong

A - Incorrect: Quadratic is a valid but looser upper bound than the requested tightest one.

B - Correct: Linear space tightly bounds n live constant-size frames.

C - Incorrect: Constant space cannot hold as the number of live frames grows.

D - Incorrect: Logarithmic space cannot hold for n live constant-size frames.

Primary note proof

Study-note section DAA08

> Space complexity measures peak simultaneously live storage, not the sum of every allocation ever made. Count input, auxiliary structures and stack according to the requested convention. n active recursion levels with constant-size frames need Θ(n) stack; depth log n with constant frames needs Θ(log n). The number of total calls does not determine peak depth.

Question 11 | Q00295

Which of the following is a Divide and Conquer algorithm?

A. Merge Sort

B. Heap Sort

C. Selection Sort

D. Bubble Sort

Hint

Identify the specification and cost model, then apply the relevant bound, invariant or strategy rule.

Answer A: Merge sort

DAA14 splits into halves, recursively sorts each, and merges the results, directly implementing divide and conquer. DAA16 excludes standard heap sort from that category and describes selection's repeated minimum and bubble's adjacent passes. Only Merge Sort among these options has the specified independent recursive decomposition and combination mechanism.

Why each choice is right or wrong

A - Correct: Merge sort recursively solves halves and combines them through a merge.

B - Incorrect: Standard heapsort builds and repeatedly restores a heap rather than applying the standard independent-subproblem decomposition.

C - Incorrect: Selection repeatedly finds a suffix minimum instead of recursively sorting halves.

D - Incorrect: Bubble repeatedly swaps adjacent inversions instead of recursively decomposing subinstances.

Primary note proof

Study-note section DAA14

> Split by indices, recursively sort each half, then repeatedly copy the smaller remaining front element into a temporary result. The merge invariant says the output prefix is sorted and contains the smallest elements already consumed. Append the unexhausted suffix. Equal keys must be taken from the left half first to preserve stability.

Study-note section DAA16

> Insertion shifts larger sorted-prefix keys: stable with strict comparisons, $\Theta(n)$ best and $\Theta(n^2)$ worst. Optimized bubble sort swaps adjacent inversions and stops after a no-swap pass: stable, $\Theta(n)$ best, $\Theta(n^2)$ worst. Selection repeatedly finds a suffix minimum: $\Theta(n^2)$ comparisons in every order, normally unstable. These use $\Theta(1)$ auxiliary array space.

Design and Analysis of Algorithms module | PDF page 21 | lines 18-29

> MERGE SORT • As another example divide-and-conquer, we investigate a sorting algorithm that has the nice property that is the worst case its complexity is O(n log n) • This algorithm is called

merge sort • We assume throughout that the elements are to be sorted in non-decreasing order. • Given a sequence of _n' elements a[1],...,a[n] the general idea is to imagine then split into 2 sets a[1],.....,a[n/2] and a[[n/2]+1],....a[n]. • Each set is individually sorted, and the resulting sorted sequences are merged to produce a single sorted sequence of _n' elements. • Thus, we have another ideal example of the divide-and-conquer strategy in which the splitting is into 2 equal-sized sets & the combining operation is the merging of 2 sorted sets into one.

Data Structure and Algorithms module | PDF page 3 | lines 44-48

B. Selection Sort Loop through the list/array from i=0 to n-1 and select the smallest element in the list and swap this value with value at position i. Repeat this step for the rest of the items. • How many comparisons? => O(n2) and How many swaps? => O(n)

Question sources

Computer Science model exam · Question 26

University of Gondar model exam · Question 26

Question 12 | Q00373

In Average case, if operation takes ƒ(n) time in execution, then m operations will take?

A. ƒ(n)

B. f(m)

C. mf(n)

D. nf(m)

Hint

Identify the specification and cost model, then apply the relevant bound, invariant or strategy rule.

Answer C: mf(n)

Adding m execution costs each with mean f(n) gives mean total m*f(n) by the consecutive-block addition rule (PDF p.12), using the average-case meaning on p.14. This assumes n is fixed and each of the m operations has the stated mean; no independence is needed to add expected costs.

Why each choice is right or wrong

A - Incorrect: f(n) counts only one mean execution cost (pp.12,14).

B - Incorrect: f(m) changes the argument instead of adding m costs (p.12).

C - Correct: m equal mean costs sum to m*f(n) (p.12).

D - Incorrect: n*f(m) swaps operation count and input size without justification (p.12).

Primary note proof

Study-note section DAA06

If m operations each have expected cost f(n) at the same fixed size, expected total is m f(n), by linearity of expectation; independence is unnecessary. If sizes change, sum f(n_i). Exact coefficients depend on whether tests, increments, arithmetic and assignments count separately.

Data Structures & Algorithms practice questions · Question 3

Question 13 | Q00376

O(1) means computing time is _____

A. Constant

B. Quadratic

C. Linear

D. Cubic

Hint

Identify the specification and cost model, then apply the relevant bound, invariant or strategy rule.

Answer A: Constant

O(1) is a bounded constant upper growth rate independent of input size. The related PDF p.3 visually orders constant K before log n, n, n log n and n^2; the assigned PDF p.14 explains comparison by growth rate.

Why each choice is right or wrong

A - Correct: A constant bound does not increase with n (cross-module p.3 growth diagram).

B - Incorrect: Quadratic corresponds to n squared, which grows with n (assigned p.14).

C - Incorrect: Linear is proportional to n, unlike 1 (assigned p.14).

D - Incorrect: Cubic is proportional to n cubed, unlike 1 (assigned p.14).

Primary note proof

Study-note section DAA04

> For eventually nonnegative f, g, $f \in O(g)$ means $f(n) \le c \cdot g(n)$ for all $n \ge n_0$, with fixed $c > 0$. Ω reverses that inequality; Θ requires both bounds. Little-o means $f/g \to 0$, and little-ω means $f/g \to \infty$ where the ratio exists. Θ specifies growth up to constant factors, not exact seconds or identical best/worst cases.

Study-note section DAA05

> Representative growth is $1, \log n, n, n \log n, n^2, n^3, \ldots, b^n, n!$ for fixed $b > 1$. Log bases differ by a constant. Both $n \log n$ and n^2 are superlinear; $\log n$ is sublinear. Polynomial growth has a fixed exponent in input size.

Design and Analysis of Algorithms module | PDF page 14 | lines 11-21

> In analysis of algorithms, it is not important to know how many operations an algorithm does. Of greater concern is the rate of increase in operations for an algorithm to solve a problem as the size of the problem increases. This is referred to us the rate of growth of the algorithm. What happens with small sets of input data is not as interesting as what happens when the data set gets large. The rate of growth of an algorithm is dominated by the largest term in an equation; we will discard the terms that grow more slowly. When we strip all of these things away, we are left with what we call the order of the function or related algorithm. We then group algorithms based on their order. We group in three categories - those that grow at least as fast as some function, those that grow at the same rate, and those that grow no faster. The following are some of the classes of algorithms: - log2 n, n, n ∗ log2 n, n2,n3, 2n. Asymptotic analysis is concerned with how the running time of an algorithm increases with the size of the input in the limit, as the size of the input increases without bound.

Data Structures & Algorithms practice questions · Question 6

Question 14 | Q00378

Which of the following sorting algorithm is of divide-and-conquer type?

A. Bubble sort

B. Insertion sort

C. Quick sort

D. Selection sort

Hint

Identify the specification and cost model, then apply the relevant bound, invariant or strategy rule.

Answer C: Quicksort

DAA15 partitions around a pivot and recursively sorts smaller ranges, which is the divide-and-conquer strategy. The other ordinary methods in DAA16 use adjacent passes, sorted-prefix insertion, or repeated suffix-minimum selection. They do not use the same recursive partition decomposition. Thus Quick sort is the unique matching main choice.

Why each choice is right or wrong

A - Incorrect: Bubble uses repeated adjacent comparisons rather than recursive partitioning.

B - Incorrect: Insertion grows a sorted prefix by shifting larger preceding values.

C - Correct: Quicksort partitions and recursively sorts the resulting smaller ranges.

D - Incorrect: Selection repeatedly picks a suffix minimum rather than recursively partitioning and combining.

Primary note proof

Study-note section DAA15

> Choose a pivot, partition, then sort the resulting smaller ranges. In a two-pointer scheme, advance i while values are below pivot and j while above; when i≤j, swap and advance both. Bound the scans and ensure progress on equal values. Recurse on the resulting ranges. Hoare-style partition boundaries need not put the pivot at its final position; Lomuto-style partition commonly does. Do not mix their return conventions.

Study-note section DAA16

> Insertion shifts larger sorted-prefix keys: stable with strict comparisons, $\Theta(n)$ best and $\Theta(n^2)$ worst. Optimized bubble sort swaps adjacent inversions and stops after a no-swap pass: stable, $\Theta(n)$ best, $\Theta(n^2)$ worst. Selection repeatedly finds a suffix minimum: $\Theta(n^2)$ comparisons in every order, normally unstable. These use $\Theta(1)$ auxiliary array space.

Design and Analysis of Algorithms module | PDF page 23 | lines 19-29

QUICK SORT • The divide-and-conquer approach can be used to arrive at an efficient sorting method different from merge sort. • In merge sort, the file a[1:n] was divided at its midpoint into sub arrays which were independently sorted & later merged. • In Quick sort, the division into 2 sub arrays is made so that the sorted sub arrays do not need to be merged later. • This is accomplished by rearranging the elements in a[1:n] such that a[I]<=a[j] for all I between 1 & n and all j between (m+1) & n for some m, 1<=m<=n. • Thus the elements in a[1:m] & a[m+1:n] can be independently sorted. • No merge is needed. This rearranging is referred to as partitioning.

Design and Analysis of Algorithms module | PDF page 21 | lines 18-29

MERGE SORT • As another example divide-and-conquer, we investigate a sorting algorithm that has the nice property that is the worst case its complexity is O(n log n) • This algorithm is called merge sort • We assume throughout that the elements are to be sorted in non-decreasing order. • Given a sequence of _n' elements a[1],...,a[n] the general idea is to imagine then split into 2 sets a[1],.....,a[n/2] and a[[n/2]+1],....a[n]. • Each set is individually sorted, and the resulting sorted sequences are merged to produce a single sorted sequence of _n' elements. • Thus, we have another ideal example of the divide-and-conquer strategy in which the splitting is into 2 equal-sized sets & the combining operation is the merging of 2 sorted sets into one.

Data Structures & Algorithms practice questions · Question 8

Question 15 | Q00718

of an algorithm refers to defining the mathematical bound/framing of its run-time performance?

A. Space complexity

B. Asymptotic analysis

C. Time complexity

D. none of the above

Hint

Identify the specification and cost model, then apply the relevant bound, invariant or strategy rule.

Answer B: Asymptotic analysis

Asymptotic analysis studies the limiting growth of running time with input size and groups functions by growth bounds (PDF p.14). Time complexity is the resource function being studied; the bounding analysis is asymptotic analysis.

Why each choice is right or wrong

A - Incorrect: Space concerns memory, not bounding the stated runtime (p.14).

B - Correct: The growth-rate and bounding analysis is explicitly titled Asymptotic Analysis (p.14).

C - Incorrect: Time complexity describes runtime; asymptotic analysis classifies its growth as asked (p.14).

D - Incorrect: The bounding concept is provided by the p.14 section, so “none” fails.

Primary note proof

Study-note section DAA02

When we strip all of these things away, we are left with what we call the order of the function or related algorithm. We then group algorithms based on their order. We group in three categories - those that grow at least as fast as some function, those that grow at the same rate, and those that grow no faster. The following are some of the classes of algorithms: - log2 n, n, n ∗ log2 n, n2,n3, 2n. Asymptotic analysis is concerned with how the running time of an algorithm increases with the size of the input in the limit, as the size of the input increases without bound.

Computer Science model exam 2 · Question 59

Question 16 | Q00719

Which described implementation uses dynamic programming through stored dependent subproblem values?

A. Multistage DAG shortest paths using stored reverse-topological cost-to-go values

B. Single-source shortest paths by Dijkstra on nonnegative edges

C. Merge sort

D. Chess game-tree search without cached subproblem values

Hint

Identify the specification and cost model, then apply the relevant bound, invariant or strategy rule.

Answer A: Multistage DAG shortest paths using stored reverse-topological cost-to-go values

Multistage DAG paths can be solved by storing the best cost-to-go for each vertex and evaluating vertices in reverse topological order. Each value combines outgoing-edge costs with already solved successor values, which is dynamic programming. The specified Dijkstra implementation uses greedy finalization, merge sort uses independent halves, and uncached chess tree search does not reuse stored subproblem values as described.

Why each choice is right or wrong

A - Correct: The reverse-topological cost recurrence reuses solved successor values.

B - Incorrect: Dijkstra uses greedy minimum-distance finalization under nonnegative weights.

C - Incorrect: Merge sort divides into independent halves and merges them.

D - Incorrect: The stipulated uncached search does not reuse solved state values.

Primary note proof

Study-note section DAA12

> DP reuses a defined set of subproblem states. Greedy commits to a feasible local choice only when a safety argument supports it.

Study-note section DAA27

> For a DAG or multistage graph, compute cost-to-go in reverse topological order: F(t)=0 and F(u)=min over outgoing(u, v) of[w(u, v)+F(v)].

Study-note section DAA24

> Repeatedly extract the unsettled vertex u of minimum distance; relax each edge by dist[v]=min(dist[v], dist[u]+w(u, v)), updating predecessors when improved.

The Principle of Optimality The dynamic programming relies on a principle of optimality. This principle states that in an optimal sequence of decisions or choices, each subsequence must also be optimal. For example, in matrix chain multiplication problem, not only the value we are interested in is optimal but all the other entries in the table are also represent optimal. The principle can be related as follows: the optimal solution to a problem is a combination of optimal solutions to some of its sub problems. The difficulty in turning the principle of optimally into an algorithm is that it is not usually obvious which sub problems are relevant to the problem under consideration. Design and Analysis of Algorithms module | PDF page 48 | lines 5-16

Dynamic programming, like the divide-and-conquer method, solves problems by combining the solutions to subproblems. As we saw in Chapter 2 of binary search, divide-and-conquer algorithms partition the problem into independent subproblems, solve the subproblems recursively, and then combine their solutions to solve the original problem. In contrast, dynamic programming is applicable when the subproblems are not independent, that is, when subproblems share sub subproblems. In this context, a divide-and-conquer algorithm does more work than necessary, repeatedly solving the common sub subproblems. A dynamic-programming algorithm solves every subproblem just once and then saves its answer in a table, thereby avoiding the work of recomputing the answer every time the subproblem is encountered. Dynamic programming is typically applied to optimization problems. In such problems there can be many possible solutions. Each solution has a value, and we wish to find a solution with the optimal (minimum or maximum) value.

Computer Science model exam 2 · Question 60

Question 17 | Q00720

Optimal merge pattern is an example of _____ Algorithm design Approach

A. Dynamic Programming

B. Divide and Conquered

C. Greedy

D. Back tracking

Hint

Identify the specification and cost model, then apply the relevant bound, invariant or strategy rule.

Answer C: Greedy

The optimal-merge construction explicitly chooses the two smallest files at each step (PDF p.43). That repeated local selection is called a greedy attempt on the page and gives the listed example an optimal merge pattern.

Why each choice is right or wrong

A - Incorrect: No table of overlapping subproblems drives the p.43 construction.

B - Incorrect: The pairing order is chosen by repeated smallest-file selection, not a predetermined independent split (p.43).

C - Correct: The module explicitly calls this selection rule greedy (p.43).

D - Incorrect: The described rule does not backtrack over earlier pairings (p.43).

Primary note proof

Study-note section DAA22

> Combine the two smallest weights, add their sum to total cost, and reinsert it. A min-heap gives O(n log n) time/O(n) space. Cost p+q counts moved records; worst-case comparisons are p+q−1 for nonempty lists, and actual comparisons may be fewer.

Study-note section DAA19

> A greedy algorithm repeatedly selects a locally attractive feasible option without later undoing it. Optimal substructure alone does not prove this safe. An exchange proof inserts the greedy choice into an optimum without worsening cost; recurse. MST cut proofs use this exchange.

Design and Analysis of Algorithms module | PDF page 43 | lines 5-12

> A greedy attempt to obtain an optimal merge pattern is easy to formulate. Since merging an n record file and an m record file requires possibly n + m records moves, the obvious choice for a selection criterion is: at each step merge the two smallest size files together. Thus, if we have five files F , ••• , F 5) with sizes (20, 30, 10, 5, 30) our greedy rule would generate the following merge pattern: merge F4 and FJ to get Z1 (|Z1| = 15); merge Z1 and F1 to get Z2 (|Z2| = 35); merge Fi and Fs to get ZJ (|ZJ| = 60); merge Z2 and ZJ to get the answer Z4. The total number of record moves is 205. One can verify that this is an optimal merge pattern for the given problem instance.

Computer Science model exam 2 · Question 61

Question 18 | Q00898

For each input length n, a report records the smallest number of comparisons attained over all legal inputs of that length. Which case-analysis function is the report recording?

A. Average time

B. Small time

C. .

Worst time

D. Best time

Hint

Identify the specification and cost model, then apply the relevant bound, invariant or strategy rule.

Answer D: D. Best time

At each fixed length n, the report selects the legal input with the smallest comparison count. This records best-case time under a comparison-count model. Worst case would record the largest count, and average case would take an expectation under a specified distribution. Comparing different input lengths is a separate growth analysis, so the application preserves the fixed-size meaning of Best time.

Why each choice is right or wrong

A - Incorrect: Average time is an expectation, not the minimum.

B - Incorrect: Small time is not the standard case-analysis term.

C - Incorrect: Worst time is the maximum over inputs of the fixed size.

D - Correct: Best time is the minimum over legal inputs of that fixed size.

Primary note proof

Study-note section DAA03

> At fixed size n, best case minimizes cost, worst case maximizes it, and average case takes an expectation under a specified input distribution. Randomized expected cost may average internal choices for one fixed input. Smallest input size is not best case.

Module passages - related reading

Design and Analysis of Algorithms module | PDF page 14 | lines 3-9

> In order to determine the running time of an algorithm it is possible to define three functions Tbest(n), Tavg(n) and Tworst(n) as the best, the average and the worst case running time of the algorithm respectively. Average Case (Tavg): The amount of time the algorithm takes on an "average" set of inputs. Worst Case (Tworst): The amount of time the algorithm takes on the worst possible set of inputs. Best Case (Tbest): The amount of time the algorithm takes on the

smallest possible set of inputs. We are interested in the worst-case time, since it provides a bound for all input - this is called the ―Big-Oh‖ estimate.

Question sources

Computer Science Exit Exam · 2018 · Question 11

Question 19 | Q00925

Which statement about proving worst-case lower bounds for all comparison-based sorting algorithms is FALSE?

A. A comparison decision tree must distinguish n! possible orders of distinct keys.

B. Solving a recurrence for one chosen sorting algorithm, by itself, proves a lower bound for every algorithm in the comparison class.

C. Suppressing constant factors in asymptotic notation does not by itself invalidate a lower-bound proof.

D. A decision-tree argument can establish an Ω(n log n) worst-case comparison bound even when array indexing is allowed.

Hint

Identify the specification and cost model, then apply the relevant bound, invariant or strategy rule.

Answer B: B. A single algorithm’s recurrence alone does not prove a class-wide lower bound.

A recurrence describes the running time of the particular algorithm it models. An upper or tight bound for that algorithm does not exclude a different comparison algorithm using fewer operations, so B is false. The class-wide decision-tree argument instead distinguishes n! orders of distinct keys and needs height at least $\log_2(n!)$, giving Ω(n log n). Ignoring constants and allowing ordinary array access do not defeat that comparison-count argument.

Why each choice is right or wrong

A - Incorrect: This is a true premise of the comparison decision-tree lower-bound argument, so it is not the requested false statement.

B - Correct: This is false: a recurrence for one algorithm does not lower-bound every other algorithm.

C - Incorrect: This is true: asymptotic lower bounds intentionally disregard constant factors.

D - Incorrect: This is true: the bound concerns comparisons, not a prohibition on array indexing.

Primary note proof

Study-note section DAA11

A comparison decision tree needs at least n! leaves for distinct-key orderings. Height h allows at most 2^h leaves, so h≥log 2(n!)=Ω(n log n); merge sort matches this worst-case bound. Array indexing is not forbidden.

Computer Science Exit Exam · 2018 · Question 38

Question 20 | Q00929

For integer n≥0, treat the code below as mathematical-integer RAM pseudocode: arithmetic is exact and unit-cost, with no overflow. Charge 1 unit for each initialization, comparison, loop increment and return; charge 1 for the addition and 1 for assignment in sum=sum+1. Ignore declarations, parameter passing and function-call overhead. What is T(n)?
total(n) { sum=0; for(i=1;i<=n;i++) sum=sum+1; return sum; }

A. $5n+5$

B. $4n^2+4$

C. $6n+2$

D. 4n+4

Hint

Identify the specification and cost model, then apply the relevant bound, invariant or strategy rule.

Answer D: 4n+4

In this exact-integer model, the two initializations cost 2 units. The test i<=n runs n+1 times, the increment runs n times, and addition plus assignment costs 2n units. The return costs one unit. Thus T(n)=2+(n+1)+n+2n+1=4n+4, including n=0. Unbounded mathematical arithmetic keeps the final increment defined throughout the stated domain.

Why each choice is right or wrong

A - Incorrect: 5n+5 does not match the specified operation counts.

B - Incorrect: Quadratic growth does not match a single n-iteration constant-body loop.

C - Incorrect: 6n+2 charges operations differently from the stated model.

D - Correct: The complete count is 2+(n+1)+n+2n+1=4n+4.

Primary note proof

Study-note section DAA06

> If m operations each have expected cost f(n) at the same fixed size, expected total is m f(n), by linearity of expectation; independence is unnecessary. If sizes change, sum f(n_i). Exact coefficients depend on whether tests, increments, arithmetic and assignments count separately.

Study-note section DAA06

> For sum=0; for(i=1;i<=n;i++) sum=sum+1; return sum: counting two initializations, n+1 tests, n increments,2n body operations and one return gives 4n+4. A different primitive-cost convention changes this exact expression, not Θ(n).

Computer Science Exit Exam · 2018 · Question 42

Question 21 | Q01211

Which option most completely covers the listed factors that affect a program's exact elapsed running time, including its workload and execution environment?

A. Processor speed

B. Current processor load

C. Input size of the given algorithm

D. All

Hint

Identify the specification and cost model, then apply the relevant bound, invariant or strategy rule.

Answer D: All listed factors affect observed runtime.

Input size influences how many operations the algorithm performs. Processor speed influences how quickly that work executes, and competing processor load influences the resources available during the run. All three can therefore affect exact elapsed time. Each individual factor is true but incomplete as an answer to the combined-factor question; D includes the whole set without confusing elapsed measurements with an abstract operation-count bound.

Why each choice is right or wrong

A - Incorrect: True but incomplete: processor speed matters, but it omits current load and input size.

B - Incorrect: True but incomplete: competing load matters, but it omits processor speed and input size.

C - Incorrect: True but incomplete: input size matters, but it omits the execution-environment factors.

D - Correct: All three listed factors contribute to exact elapsed time.

Primary note proof

Study-note section DAA02

Analysis counts operations and storage as functions of input size: array length n, graph vertices V/edges E, or the number of bits in integers. A RAM model commonly gives constant cost to bounded-word arithmetic/access. Arbitrarily large integer arithmetic and printing long outputs

need their own costs. Elapsed measurements also depend on hardware, compiler, cache, I/O and competing load.

Question 22 | Q01230

Which of the following is an example of a Dynamic Programming algorithm?

A. Breadth First Search

B. Depth First Search

C. Dijkstra's Algorithm

D. Knapsack Problem

Hint

Identify the specification and cost model, then apply the relevant bound, invariant or strategy rule.

Answer D: Knapsack Problem

The module develops 0/1 knapsack in the dynamic-programming unit (PDF p.71; application list p.49), with alternatives of including or excluding an item. Dijkstra is placed in the greedy unit (p.46). BFS and DFS are traversal techniques, rather than the shared-subproblem optimization example intended here (p.85).

Why each choice is right or wrong

A - Incorrect: Breadth-first search is a traversal; p.85 separates graph search from the knapsack optimization example.

B - Incorrect: Depth-first search is a traversal; the dynamic-programming item-selection example is p.71.

C - Incorrect: Dijkstra appears under the greedy unit on p.46, not as the intended dynamic-programming example.

D - Correct: The 0/1 knapsack variant is explicitly developed in the dynamic-programming unit on p.71.

Primary note proof

Study-note section DAA29

For integer capacity W, K[i, w] is maximum value using the first i items within capacity w. Initialize K[0, w]=0. If weight_i>w, use K[i−1, w]; otherwise take max(K[i−1, w], value_i+K[i−1, w−weight_i]). The previous-row reference ensures each item is used at most once. Backtrack changed values to recover chosen items.

Study-note section DAA34

BFS/DFS being printed under a DP unit does not make ordinary traversal a DP optimization algorithm.

Computer Science model exam 2 · Question 58

Question 23 | Q01232

When designing an algorithm for a specified implementation environment, which option most completely covers the listed resource, correctness and alternative-method considerations?

A. Whether the method respects the chosen hardware/resource cost model.

B. Whether the software implementation correctly realizes the specified method.

C. If there is more than one way to solve the problem.

D. All of the above

Hint

Identify the specification and cost model, then apply the relevant bound, invariant or strategy rule.

Answer D: All of the above

Algorithm design starts with inputs, outputs, constraints and correctness, then evaluates resource use under a stated model. For an implementation, respecting the selected hardware/resource assumptions and ensuring the program implements the method correctly both matter. Comparing alternative solution methods is also legitimate. Thus the all-of-the-above option combines all three considerations; none of the individual choices alone covers the entire set.

Why each choice is right or wrong

A - Incorrect: Respecting the resource model matters but is only one consideration.

B - Incorrect: Implementation correctness matters but is only one consideration.

C - Incorrect: Comparing alternatives matters but is only one consideration.

D - Correct: All three stated considerations belong in the implementation-aware design.

Primary note proof

Study-note section DAA01

> State inputs, output, constraints and empty-solution policy. Algorithms are finite, definite executable methods independent of source language; feasible satisfies constraints, optimal is best feasible. Conditional branches are legitimate control flow.

Study-note section DAA02

Question 24 | SM0007

Assume you have a weighted graph G with a set of vertices V and set of edges E. Which one of the following is an optimization problem on the graph?

A. Traverse all vertices in graph G

B. Is vertex p in V reachable from vertex q in V in graph G

C. Find minimum spanning tree from graph G

D. How many cycles are there in graph G

Hint

Identify the specification and cost model, then apply the relevant bound, invariant or strategy rule.

Answer C: Find minimum spanning tree from graph G

An optimization problem seeks a feasible solution minimizing or maximizing an objective (PDF p.27). The minimum spanning tree minimizes total edge weight while connecting every vertex (p.36); the other tasks ask for traversal, a yes/no fact or a count.

Why each choice is right or wrong

A - Incorrect: Traversal asks to visit vertices rather than optimize a weight (pp.27,36).

B - Incorrect: Reachability is a decision question rather than minimization (pp.27,85).

C - Correct: Minimum total tree weight is the optimization objective (p.36).

D - Incorrect: Counting cycles asks for a number, with no minimization or maximization criterion (p.27).

Primary note proof

Study-note section DAA01

> State inputs, output, constraints and empty-solution policy. Algorithms are finite, definite executable methods independent of source language; feasible satisfies constraints, optimal is best feasible. Conditional branches are legitimate control flow.

Study-note section DAA23

> For a connected weighted undirected graph, an MST spans every vertex without cycles and minimizes total edge weight; it has V−1 edges. Negative edges are allowed. Equal weights may yield multiple MSTs; distinct weights suffice for uniqueness. A tree is itself a graph.

o Minimum Cost Spanning Tree- Prim's Algorithm ✓ Let G(V,E) be an undirected connected graph with vertices v and edge E . ✓ A sub-graph t=(V,E) of the G is a Spanning tree of G iff t is a tree.3 ✓ The problem is to generate a graph G = (V,E) where E is the subset of E,G is a Minimum spanning tree. ✓ Each and every edge will contain the given non-negative length. connect all the nodes with edge present in set E and weight has to be minimum. NOTE: ✓ We have to visit all the nodes. ✓ The subset tree (i.e) any connected graph with N vertices must have at least N-1 edges and also it does not form a cycle. Definition: 1. A spanning tree of a graph is an undirected tree consisting of only those edge that are necessary to connect all the vertices in the original graph. 2. A Spanning tree has a property that for any pair of vertices there exist only one path between them and the insertion of an edge to a spanning tree form a unique cycle.

Design and Analysis of Algorithms module | PDF page 85 | lines 14-20

4.7. BASIC SEARCH AND TRAVERSAL TECHNIQUE DEFINING GRAPH: A graphs g consists of a set V of vertices (nodes) and a set E of edges (arcs). We write G=(V,E). V is a finite and non-empty set of vertices. E is a set of pair of vertices; these pairs are called as edges. Therefore, V(G) is read as V of G, is a set of vertices and E(G),read as E of G is a set of edges. An edge e= (v, w) is a pair of vertices v and w, and to be incident with v and w.

Question 25 | SM0031

For an average-cost function f(n)=E[T(n)] under a specified input distribution, which notation expresses a tight constant-factor growth bound relative to g(n)?

A. $f(n) \in \Omega(g(n))$

B. $f(n) \in O(g(n))$

C. $f(n) \in \omega(g(n))$

D. $f(n) \in \Theta(g(n))$

Hint

Identify the specification and cost model, then apply the relevant bound, invariant or strategy rule.

Answer D: f(n)∈Θ(g(n))

Average case first takes an expectation under the specified distribution. A tight growth relation for that resulting function requires both an eventual upper and lower constant-factor bound relative to g, which is Θ. Big-O supplies only an upper bound, Ω only a lower bound, and little-ω a strict asymptotic lower relation. None of the symbols intrinsically means average case.

Why each choice is right or wrong

A - Incorrect: Ω supplies a lower bound without the matching upper bound.

B - Incorrect: O supplies an upper bound without the matching lower bound.

C - Incorrect: Little-ω means f/g tends to infinity rather than constant-factor equivalence.

D - Correct: Θ states both constant-factor upper and lower bounds.

Primary note proof

Study-note section DAA03

> At fixed size n, best case minimizes cost, worst case maximizes it, and average case takes an expectation under a specified input distribution. Randomized expected cost may average internal choices for one fixed input. Smallest input size is not best case.

Study-note section DAA04

> For eventually nonnegative f, g, f∈O(g) means f(n)≤c·g(n) for all n≥n 0, with fixed c>0. Ω reverses that inequality; Θ requires both bounds. Little-o means f/g→0, and little-ω means f/g→∞ where the ratio exists. Θ specifies growth up to constant factors, not exact seconds or identical best/worst cases.

Question 26 | SM0065

Size of large data files can be reduced to save storage disk space. Which algorithm is appropriate to reduce the size of large files?

A. Heap sort algorithm

B. Prim's algorithm

C. Merge sort algorithm

D. Huffman encoding algorithm

Hint

Identify the specification and cost model, then apply the relevant bound, invariant or strategy rule.

Answer D: D. Huffman encoding algorithm

Huffman coding assigns prefix-free bit strings to symbols using their frequencies, minimizing the weighted code length in its model. It can therefore reduce the storage required for data represented with those codes. Heap sort and merge sort instead reorder items, while Prim builds a minimum spanning tree of a weighted graph. Those other objectives do not encode file contents more compactly. Metadata overhead still prevents a universal compression guarantee for every file.

Why each choice is right or wrong

A - Incorrect: Heap sort reorders items by repeatedly extracting a heap extreme; it does not encode file symbols.

B - Incorrect: Prim minimizes graph-connection weight, not encoded file length.

C - Incorrect: Merge sort orders records by recursively sorting and merging, rather than encoding symbols.

D - Correct: Huffman builds a frequency-based prefix code minimizing its weighted length.

Primary note proof

Study-note section DAA22

> Huffman uses frequencies as weights and 0/1 branches to leaf symbols, making a prefix-free code. Cost is∑frequency×depth.

Study-note section DAA16

> Heap sort builds a max-heap in Θ(n), then extracts/restores in O(log n) per item: O(n log n) total, Θ(1) auxiliary space, ordinarily unstable.

Study-note section DAA23

> For a connected weighted undirected graph, an MST spans every vertex without cycles and minimizes total edge weight; it has V−1 edges.

Study-note section DAA14

> Split by indices, recursively sort each half, then repeatedly copy the smaller remaining front element into a temporary result.

Question 27 | SM0083

For the worst-cost function f(n)=max over size-n inputs T(input), which notation expresses a tight constant-factor bound relative to g(n)?

A. $f(n) \in \omega(g(n))$

B. $f(n) \in \Theta(g(n))$

C. $f(n) \in o(g(n))$

D. $f(n) \in \Omega(g(n))$

Hint

Identify the specification and cost model, then apply the relevant bound, invariant or strategy rule.

Answer B: $f(n) \in \Theta(g(n))$

Worst case maximizes cost over all inputs of a fixed size. Once that function is defined, Θ expresses matching constant-factor upper and lower bounds relative to g. Little-o and little-ω describe strict asymptotic relations, and Ω alone supplies only a lower bound. The answer concerns tightness of the bound, not a claim that any notation inherently selects the worst input case.

Why each choice is right or wrong

A - Incorrect: Little-ω gives a strict lower-growth relation.

B - Correct: Θ gives matching constant-factor upper and lower bounds.

C - Incorrect: Little-o gives a strict upper-growth relation.

D - Incorrect: Ω alone lacks the required upper bound.

Primary note proof

Study-note section DAA03

At fixed size n, best case minimizes cost, worst case maximizes it, and average case takes an expectation under a specified input distribution. Randomized expected cost may average internal choices for one fixed input. Smallest input size is not best case.

Study-note section DAA04

For eventually nonnegative f, g, f∈O(g) means f(n)≤c·g(n) for all n≥n 0, with fixed c>0. Ω reverses that inequality; Θ requires both bounds. Question 28 | SM0087

Which one of the following algorithms can be used to extract a Minimum Spanning Tree from an input graph?

A. Prim's algorithm

B. Huffman encoding algorithm

C. Dijkstra's algorithm

D. Merge sort algorithm

Hint

Identify the specification and cost model, then apply the relevant bound, invariant or strategy rule.

Answer A: Prim's algorithm

The module explicitly names Prim among the two minimum-cost spanning-tree methods (PDF p.37). Huffman codes optimize expected message length (p.45), Dijkstra is single-source path search (p.46), and merge sort orders arrays (p.21).

Why each choice is right or wrong

A - Correct: Prim is explicitly a minimum-cost spanning-tree method (p.37).

B - Incorrect: Huffman builds codes, not a spanning tree of the input graph (p.45).

C - Incorrect: Dijkstra targets source-to-vertex paths, a different objective (p.46).

D - Incorrect: Merge sort combines sorted sequences, not graph edges (p.21).

Primary note proof

Study-note section DAA23

> For a connected weighted undirected graph, an MST spans every vertex without cycles and minimizes total edge weight; it has V−1 edges. Negative edges are allowed. Equal weights may yield multiple MSTs; distinct weights suffice for uniqueness. A tree is itself a graph.

Which analysis case calculates the upper bound on running time of an algorithm?

A. Optimal case

B. Best case

C. Average case

D. Worst case

Hint

Identify the specification and cost model, then apply the relevant bound, invariant or strategy rule.

Answer D: Worst case

Worst-case time is the maximum time over the inputs under consideration and therefore bounds all their runtimes (PDF p.14). This is the case-analysis upper bound, distinct from the separate question of an asymptotic bound on that maximum.

Why each choice is right or wrong

A - Incorrect: Optimal case is not a defined case function on p.14.

B - Incorrect: Best case minimizes rather than bounds all runtime values from above (p.14).

C - Incorrect: An average need not exceed every observation (p.14).

D - Correct: Worst case supplies the all-input bound explicitly described on p.14.

Primary note proof

Study-note section DAA03

> At fixed size n, best case minimizes cost, worst case maximizes it, and average case takes an expectation under a specified input distribution. Randomized expected cost may average internal choices for one fixed input. Smallest input size is not best case.

Question 30 | SM0249

An algorithm has unit-cost running-time function $T(n)=3n^k+7n+12$, where k is a fixed integer with $k\geq 2$ independent of n. Which listed growth class describes it?

A. Linear

B. Polynomial

C. Constant

D. Exponential

Hint

Identify the specification and cost model, then apply the relevant bound, invariant or strategy rule.

Answer B: Polynomial

A fixed exponent $k \geq 2$ makes the leading term $3n^k$ dominate $7n+12$. The resulting function has $\Theta(n^k)$ growth, which is polynomial. It is not linear because k exceeds one, and the positive growing terms exclude constant growth. Exponential growth would instead put the input in an exponent of a fixed base, a different form from the fixed-degree polynomial here.

Why each choice is right or wrong

A - Incorrect: $k \geq 2$ prevents linear growth.

B - Correct: A fixed degree k gives polynomial growth.

C - Incorrect: The positive n-dependent terms prevent constant growth.

D - Incorrect: A fixed-degree power is not exponential growth.

Primary note proof

Study-note section DAA05

> Representative growth is 1,log n,n,n log n,n^2,n^3,...,b^n,n! for fixed b>1. Log bases differ by a constant. Both n log n and n^2 are superlinear; log n is sublinear. Polynomial growth has a fixed exponent in input size.

Module passages - related reading

Design and Analysis of Algorithms module | PDF page 14 | lines 11-21

> In analysis of algorithms, it is not important to know how many operations an algorithm does. Of greater concern is the rate of increase in operations for an algorithm to solve a problem as the size of the problem increases. This is referred to us the rate of growth of the algorithm. What happens with small sets of input data is not as interesting as what happens when the data set gets large. The rate of growth of an algorithm is dominated by the largest term in an equation; we will discard the terms that grow more slowly. When we strip all of these things away, we are left with what we call the order of the function or related algorithm. We then group algorithms based on their order. We group in three categories - those that grow at least as fast as some function, those that grow at the same rate, and those that grow no faster. The following are some of the classes of algorithms: - log2 n, n, n * log2 n, n2,n3, 2n. Asymptotic analysis is concerned with how the running time of an algorithm increases with the size of the input in the limit, as the size of the input increases without bound.

Question 31 | SM0302

The amount of memory needed to run an algorithm to completion is known as:

A. Space complexity

B. Time complexity

C. Worst case

D. Best case

Hint

Identify the specification and cost model, then apply the relevant bound, invariant or strategy rule.

Answer A: Space complexity

Space complexity is explicitly defined as the memory needed to run to completion (PDF p.6). This is a resource quantity, not an input-case category.

Why each choice is right or wrong

A - Correct: This is the exact definition on p.6.

B - Incorrect: Time measures duration rather than memory (p.6 contrast).

C - Incorrect: Worst case selects inputs; it is not the memory-resource name (p.6).

D - Incorrect: Best case selects inputs; it is not the memory-resource name (p.6).

Primary note proof

Study-note section DAA08

> Space complexity measures peak simultaneously live storage, not the sum of every allocation ever made. Count input, auxiliary structures and stack according to the requested convention. n active recursion levels with constant-size frames need Θ(n) stack; depth log n with constant frames needs Θ(log n). The number of total calls does not determine peak depth.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Design and Analysis of Algorithms module | PDF page 6 | lines 4-10

> The complexity of an algorithm can be expressed in terms of its space and time complexity. Space Complexity of a program: - is the amount of memory space it needs to run to completion. We are interested in the space complexity of a program for the following reasons: • If a program is to run on a multiuser computer system, then we may need to specify the amount of memory to be allocated for the program. • For any computer system, we would like to know in advance whether or not sufficient memory is available to run the program.

Computer Science Exit Exam practice collection · Question 120

Question 32 | SS116

Interpret the following as mathematical-integer pseudocode with constant-cost arithmetic and print operations. Which offered Big-O upper bounds on the full running time are valid? Select all that apply; the bounds need not be tight.
for i=0,...,n−1:
for j=i,...,i^2−1:
if j mod i == 0:
for k=0,...,j−1: print("*")
An upper limit below the lower limit makes an empty loop.

A. $O(n^5)$

B. $O(n^7)$

C. O(n log n)

D. $O(n^2)$

Hint

Identify the specification and cost model, then apply the relevant bound, invariant or strategy rule.

Answer A, B: $O(n^5)$; $O(n^7)$

For i=0 and i=1 the j loop is empty, so no division by zero occurs. For i≥2, successful j values are i,2i,...,(i−1)i. Their k-loop work totals $i^2(i-1)/2=\Theta(i^3)$, and summing over i yields $\Theta(n^4)$. Consequently both $O(n^5)$ and $O(n^7)$ are valid loose upper bounds, while the two smaller offered rates cannot bound the work.

Why each choice is right or wrong

A - Correct: A quartic function is also $O(n^5)$.

B - Correct: A quartic function is also $O(n^7)$.

C - Incorrect: n log n is too small to upper-bound quartic work.

D - Incorrect: n^2 is too small to upper-bound quartic work.

Primary note proof

Study-note section DAA07

> For the loop i=0.. n−1, j=i.. i^2−1, and k=0.. j−1 only when j%i==0, i=0 and 1 have empty j ranges, so no remainder by zero is evaluated. For i≥2, successful j values are i,2i,...,(i−1)i. The inner work is $i\sum m=1..\ i-1\ m=i^2(i-1)/2=\Theta(i^3)$. Summing over i gives $\Theta(n^4)$; condition checks add only $\Theta(n^3)$.

Study-note section DAA07

> Neither n^5 nor n^7 is tight for this loop, though both are valid Big-O upper bounds. This assumes mathematical integers and constant-cost output; literal signed C++ overflow in i*i is undefined,

and executable runtime analysis requires valid syntax in a specified language. Redeclaring parameter n and using return @;3 are syntax errors; neither establishes logarithmic complexity.

Module passages - related reading

Question sources

Computer Science model exam collection · Question 23

Question 33 | SS120

Which claims about abstract algorithms are NOT true? Select all that apply. In C, platform considerations mean choosing realistic resource constraints, not making source language part of the definition.

A. Is step wise logical description of how to solve the problem

B. ls equivalent to the programming language code

C. Should be developed by considering the platforms on which it runs

D. Its abstract definition requires the details of a particular programming language.

Hint

Identify the specification and cost model, then apply the relevant bound, invariant or strategy rule.

Answer B, D: Is equivalent to the programming language code; Its abstract definition requires the details of a particular programming language.

An algorithm is a definite executable method independent of a particular source language. Equating it with programming-language code, or making that language's details essential to its abstract definition, is therefore false. A stepwise logical description is appropriate. Resource constraints and a platform-aware cost model can legitimately inform implementation choices without changing the underlying method's language independence. Thus B and D are the false claims.

Why each choice is right or wrong

A - Incorrect: A stepwise logical description is compatible with an algorithm.

B - Correct: The abstract method is not identical to a source-language implementation.

C - Incorrect: Realistic resource constraints may inform design, so C is not selected.

D - Correct: Programming-language details are not essential to the abstract method.

Primary note proof

Study-note section DAA01

> State inputs, output, constraints and empty-solution policy. Algorithms are finite, definite executable methods independent of source language; feasible satisfies constraints, optimal is best feasible. Conditional branches are legitimate control flow.

Study-note section DAA02

> Analysis counts operations and storage as functions of input size: array length n, graph vertices V/edges E, or the number of bits in integers. A RAM model commonly gives constant cost to bounded-word arithmetic/access. Arbitrarily large integer arithmetic and printing long outputs need their own costs. Elapsed measurements also depend on hardware, compiler, cache, I/O and competing load.

Computer Science model exam collection · Question 27

Question 34 | SS132

For integer n>=0, determine the tightest listed growth bound for this mathematical-integer pseudocode. Arithmetic, loop-control operations and each print operation have unit cost; ignore output-digit length.

```
function someFunction(n) {
for (i=0; i<10*n; i=i+1) {
print(n);
}
}
```

A. O(n)

B. $O(n^2)$

C. O(log n)

D. O(log(2n))

Hint

Identify the specification and cost model, then apply the relevant bound, invariant or strategy rule.

Answer A: A. O(n)

The loop body runs 10n times. Each iteration performs a constant amount of loop-control work and one unit-cost print, while initialization and the final failed condition check contribute only constant additional work. The total therefore has linear growth. Quadratic is a looser upper bound, while logarithmic growth is too small. The explicit mathematical and output-cost model avoids syntax and representation-cost distractions.

Why each choice is right or wrong

A - Correct: A constant multiple of n iterations gives the tight linear bound.

B - Incorrect: Quadratic is a looser bound rather than the requested tightest one.

C - Incorrect: Logarithmic growth is too small for 10n body executions.

D - Incorrect: log(2n) differs from log n only by a constant and is also too small.

Primary note proof

Study-note section DAA06

Sequential costs add; independent nested loop counts multiply. A dependent loop requires summation. n iterations of a constant body give $\Theta(n)$; $\sum i=1..\ n\ i=n(n+1)/2$ gives $\Theta(n^2)$. Doubling i=1,2,4,... until i≥n takes ceil(log 2 n) iterations for n>1. A 10n loop is linear under constant-cost output.

Question 35 | SS141

Which of the following analysis mechanism defines the input for which the algorithm takes the least time (fastest time to complete)?

A. Standard Case

B. Average case

C. Worst case

D. Best case

Hint

Identify the specification and cost model, then apply the relevant bound, invariant or strategy rule.

Answer D: Best case

The least runtime among inputs of a fixed size is best-case time, the fastest case in the p.14 three-case classification. It is not the average or worst case.

Why each choice is right or wrong

A - Incorrect: Standard case is not a defined category on p.14.

B - Incorrect: Average case concerns a distribution or average set, not a minimum (p.14).

C - Incorrect: Worst case takes the slowest input (p.14).

D - Correct: Best case is the minimum-time case intended by p.14.

Primary note proof

Study-note section DAA03

> At fixed size n, best case minimizes cost, worst case maximizes it, and average case takes an expectation under a specified input distribution. Randomized expected cost may average internal choices for one fixed input. Smallest input size is not best case.

Computer Science model exam collection · Question 48

Question 36 | AM0344

Which described activity is outside analysis of an algorithm’s resource costs? Interpret dynamic analysis as measuring executed operations or storage.

A. Asymptotic analysis

B. Experimental analysis

C. Dynamic analysis

D. Graph connectivity analysis of the input data, without examining algorithm resource costs

Hint

Identify the specification and cost model, then apply the relevant bound, invariant or strategy rule.

Answer D: Graph connectivity analysis of the input data, without examining algorithm resource costs

Asymptotic analysis studies resource growth, experimental analysis measures runs, and dynamic observation can measure executed operations or storage. The graph alternative asks only a mathematical connectivity question about input data, expressly without examining algorithm costs. It is outside the resource-analysis task as described, although graph-based representations can certainly support valid resource analysis in other contexts. This scope avoids an unsupported universal taxonomy.

Why each choice is right or wrong

A - Incorrect: Asymptotic analysis studies resource growth.

B - Incorrect: Experimental analysis measures resource costs of actual runs.

C - Incorrect: The stipulated dynamic analysis observes executed costs.

D - Correct: The stated connectivity-only task does not examine algorithm resource costs.

Primary note proof

Study-note section DAA02

> Experimental/dynamic measurement observes actual runs; asymptotic analysis abstracts growth; probabilistic analysis studies expectations. There is no universal taxonomy proving “graph analysis” or “dynamic analysis” is invalid. Auxiliary space excludes input; I/O complexity counts transfers. Representation affects costs; “data type complexity” is not a standard metric name.

> In analysis of algorithms, it is not important to know how many operations an algorithm does. Of greater concern is the rate of increase in operations for an algorithm to solve a problem as the size of the problem increases. This is referred to us the rate of growth of the algorithm. What happens with small sets of input data is not as interesting as what happens when the data set gets large. The rate of growth of an algorithm is dominated by the largest term in an equation; we will discard the terms that grow more slowly. When we strip all of these things away, we are left with what we call the order of the function or related algorithm. We then group algorithms based on their order. We group in three categories - those that grow at least as fast as some

function, those that grow at the same rate, and those that grow no faster. The following are some of the classes of algorithms: - log2 n, n, n * log2 n, n2,n3, 2n. Asymptotic analysis is concerned with how the running time of an algorithm increases with the size of the input in the limit, as the size of the input increases without bound.

Design and Analysis of Algorithms module | PDF page 85 | lines 14-20

4.7. BASIC SEARCH AND TRAVERSAL TECHNIQUE DEFINING GRAPH: A graphs g consists of a set V of vertices (nodes) and a set E of edges (arcs). We write G=(V,E). V is a finite and non-empty set of vertices. E is a set of pair of vertices; these pairs are called as edges. Therefore, V(G) is read as V of G, is a set of vertices and E(G),read as E of G is a set of edges. An edge e= (v, w) is a pair of vertices v and w, and to be incident with v and w.

Question sources

Computer Science MCQ practice collection · Question 344

Question 37 | AM0345

What is the primary growth-related purpose of asymptotic analysis?

A. To measure the actual running time of an algorithm

B. To determine the best-case scenario for an algorithm

C. To analyze the behavior of an algorithm as the input size increases

D. To evaluate the correctness of an algorithm

Hint

Identify the specification and cost model, then apply the relevant bound, invariant or strategy rule.

Answer C: To analyze the behavior of an algorithm as the input size increases

Asymptotic analysis abstracts how resource use grows with input size. It can analyze best-, average- or worst-cost functions, but does not itself choose one input case or measure actual elapsed seconds. Those measurements depend on environment and workload. Correctness is a separate obligation to meet the specification. Hence C states the primary growth-related purpose among these choices.

Why each choice is right or wrong

A - Incorrect: Actual elapsed-time measurement is experimental.

B - Incorrect: Asymptotic analysis is not restricted to the best case.

C - Correct: It analyzes resource behavior as input size grows.

D - Incorrect: Growth bounds do not prove correctness.

Primary note proof

Study-note section DAA02

Analysis counts operations and storage as functions of input size: array length n, graph vertices V/edges E, or the number of bits in integers. A RAM model commonly gives constant cost to bounded-word arithmetic/access. Arbitrarily large integer arithmetic and printing long outputs need their own costs. Elapsed measurements also depend on hardware, compiler, cache, I/O and competing load.

Study-note section DAA03

At fixed size n, best case minimizes cost, worst case maximizes it, and average case takes an expectation under a specified input distribution. Randomized expected cost may average internal choices for one fixed input. Smallest input size is not best case.

Variant 1 | Alternative version 1

Which are valid uses of asymptotic resource analysis? Select all that apply. In B, performance comparison means comparing growth under a common cost model, rather than predicting exact elapsed time.

A. To determine the actual running time of an algorithm

B. To compare the performance of different algorithms

C. To evaluate the correctness of an algorithm

D. To analyze the behavior of an algorithm as the input size increases

Answer B, D: To compare the performance of different algorithms; To analyze the behavior of an algorithm as the input size increases

Asymptotic analysis studies how cost grows with input size and can compare that scaling across algorithms under a common model. Thus both the growth description and the performance-comparison application are valid. It does not give actual elapsed seconds, and a favorable resource bound does not establish correctness. The explicit growth-based meaning of performance makes the two valid variant choices definite.

Why each choice is right or wrong

A - Incorrect: Actual elapsed time needs execution-environment measurements.

B - Correct: Comparing cost growth under a common model is a valid use.

C - Incorrect: Resource bounds do not establish correctness.

D - Correct: Behavior as input size grows is the direct purpose.

Primary note proof

Study-note section DAA02

> Analysis counts operations and storage as functions of input size: array length n, graph vertices V/edges E, or the number of bits in integers. A RAM model commonly gives constant cost to bounded-word arithmetic/access. Arbitrarily large integer arithmetic and printing long outputs need their own costs. Elapsed measurements also depend on hardware, compiler, cache, I/O and competing load.

Computer Science MCQ practice collection · Question 345

Computer Science MCQ practice collection · Question 356

Question 38 | AM0346

Which notation expresses a general asymptotic upper bound on an algorithm’s worst-cost function, allowing equality up to constant factors and not requiring a matching lower bound?

A. Big O notation (O)

B. Theta notation (Θ)

C. Omega notation (Ω)

D. Small o notation (o)

Hint

Identify the specification and cost model, then apply the relevant bound, invariant or strategy rule.

Answer A: Big O notation (O)

Big-O states an eventual constant-factor upper bound and allows the bounded function to have the same order as its comparator. Θ additionally requires a lower bound, Ω is a lower-bound relation, and little-o requires strictly slower growth. The worst-case function is selected separately by maximizing over equal-size inputs; Big-O itself does not mean worst case. The explicit upper-bound requirement uniquely identifies A.

Why each choice is right or wrong

A - Correct: O gives the requested non-strict upper bound.

B - Incorrect: Θ requires a matching lower bound as well.

C - Incorrect: Ω gives a lower bound.

D - Incorrect: Little-o requires strictly slower growth.

Primary note proof

Study-note section DAA04

> For eventually nonnegative f, g, f∈O(g) means f(n)≤c·g(n) for all n≥n 0, with fixed c>0. Ω reverses that inequality; Θ requires both bounds. Little-o means f/g→0, and little-ω means f/g→∞ where the ratio exists. Θ specifies growth up to constant factors, not exact seconds or identical best/worst cases.

Data Structure and Algorithms module | PDF page 3 | lines 6-12

> II. Big-Omega Notation (Ω): provides an asymptotic lower bound; f(n)= Ω(g (n)) means that the growth rate of f(n) is greater than or equal to g(n). III. Theta Notation (Θ): If f(n)= Θ (g(n)), then g(n) is an asymptotically tight bound for f(n) i.e f(n) and g(n) have the same rate of growth. IV. Little-o Notation (o): f(n)=o(g(n)) means f(n) has less growth rate compared to g(n). V. Little-Omega Notation (ω): ω notation used to denote a lower bound that is not asymptotically tight.

Variant 1 | Alternative version 1

For ordinary array insertion sort on n distinct keys, count comparisons and shifts as constant-time operations. Which is the tightest listed Big-O upper bound for its worst case?

A. O(1)

B. O(n)

C. O(log n)

D. O(n^2)

Answer D: O(n^2)

In the worst input order, each inserted key shifts past the entire sorted prefix. The total work is proportional to $1+2+\cdots+(n-1)=\Theta(n^2)$. Thus $O(n^2)$ is the tightest listed worst-case upper bound. Constant, logarithmic and linear bounds are too small. The supplied algorithm and cost model make this growth-class variant answerable without inventing a universal worst-case rate.

Why each choice is right or wrong

A - Incorrect: Constant cannot bound the quadratic worst-case work.

B - Incorrect: Linear cannot bound the summed prefix shifts.

C - Incorrect: Logarithmic is too small for quadratic work.

D - Correct: Insertion sort has $\Theta(n^2)$ worst work, so $O(n^2)$ is tight.

Primary note proof

Study-note section DAA16

> Insertion shifts larger sorted-prefix keys: stable with strict comparisons, Θ(n) best and $\Theta(n^2)$ worst.

Related reading (context, not primary note proof)

Computer Science MCQ practice collection · Question 386

Question 39 | AM0347

For binary search on a nonempty sorted random-access array, what is the tight best-case time when the key may be at the initial midpoint? Use constant-time comparisons.

A. $\Theta(1)$

B. $\Theta(\log n)$

C. $\Theta(n)$

D. $\Theta(n^2)$

Hint

Identify the specification and cost model, then apply the relevant bound, invariant or strategy rule.

Answer A: Θ(1)

If the sought key is at the first midpoint, binary search finds it after one constant-time comparison and returns. This is $\Theta(1)$ best-case time, regardless of the array length. The logarithmic bound describes its worst case, not this fastest legal input at fixed size. The linear and quadratic alternatives are likewise not tight for the midpoint-match case.

Why each choice is right or wrong

A - Correct: An initial midpoint match takes constant work.

B - Incorrect: Logarithmic describes worst-case search depth, not the tight best case.

C - Incorrect: Linear is not tight for a one-comparison match.

D - Incorrect: Quadratic is not tight for a one-comparison match.

Primary note proof

Study-note section DAA13

> Binary search requires sorted random-access data. Maintain inclusive low/high bounds, compute mid=low+(high−low)//2, and replace high with mid−1 or low with mid+1 according to the comparison. Stop when found or low>high. $T(n)=T(n/2)+\Theta(1)$: worst $\Theta(\log n)$, best $\Theta(1)$; iterative auxiliary space $\Theta(1)$, recursive $\Theta(\log n)$.

Question sources

Computer Science MCQ practice collection · Question 347

Question 40 | AM0348

For ordinary array insertion sort on n distinct keys, with constant-time comparisons and shifts, what is the tight worst-case running time?

A. $\Theta(\log n)$

B. $\Theta(n)$

C. $\Theta(n \log n)$

D. $\Theta(n^2)$

Hint

Identify the specification and cost model, then apply the relevant bound, invariant or strategy rule.

Answer D: $\Theta(n^2)$

A descending input makes each inserted key move across every earlier key in the sorted prefix. The work sums as $1+2+\cdots+(n-1)$, which is $\Theta(n^2)$. This establishes the tight worst case for the specified insertion-sort implementation. The smaller alternatives cannot upper-bound that quadratic work, and the answer is not a general claim about worst-case complexity of every algorithm.

Why each choice is right or wrong

A - Incorrect: Logarithmic is too small for the summed shifts.

B - Incorrect: Linear is too small for the summed shifts.

C - Incorrect: n log n is too small for quadratic worst-case shifts.

D - Correct: The sum of prefix lengths gives quadratic work.

Primary note proof

Study-note section DAA16

Insertion shifts larger sorted-prefix keys: stable with strict comparisons, $\Theta(n)$ best and $\Theta(n^2)$ worst. Optimized bubble sort swaps adjacent inversions and stops after a no-swap pass: stable, $\Theta(n)$ best, $\Theta(n^2)$ worst. Selection repeatedly finds a suffix minimum: $\Theta(n^2)$ comparisons in every order, normally unstable. These use $\Theta(1)$ auxiliary array space.

Study-note section DAA06

Sequential costs add; independent nested loop counts multiply. A dependent loop requires summation. n iterations of a constant body give $\Theta(n)$; $\sum i=1..\ n\ i=n(n+1)/2$ gives $\Theta(n^2)$. Doubling i=1,2,4,... until i≥n takes ceil(log 2 n) iterations for n>1. A 10n loop is linear under constant-cost output.

Question 41 | AM0349

Which of the following time complexities represents an algorithm with logarithmic growth?

A. O(1)

B. O(log n)

C. O(n)

D. O(n^2)

Hint

Identify the specification and cost model, then apply the relevant bound, invariant or strategy rule.

Answer B: O(log n)

Binary search takes time proportional to log_2 n. B matches logarithmic growth.

Why each choice is right or wrong

A - Incorrect: 1 is a constant, not a logarithm (p.14 growth comparison).

B - Correct: log n is the logarithmic class named on p.14 and instantiated in cross-module p.3.

C - Incorrect: n is linear rather than logarithmic (p.14).

D - Incorrect: n^2 is quadratic rather than logarithmic (p.14).

Primary note proof

Study-note section DAA05

> Representative growth is 1,log n,n,n log n,n^2,n^3,...,b^n,n! for fixed b>1. Log bases differ by a constant. Both n log n and n^2 are superlinear; log n is sublinear. Polynomial growth has a fixed exponent in input size.

Question 42 | AM0350

Which of the following time complexities represents an algorithm with linear growth?

A. O(1)

B. O(log n)

C. O(n)

D. O(n^2)

Hint

Identify the specification and cost model, then apply the relevant bound, invariant or strategy rule.

Answer C: O(n)

Linear growth means work proportional to input size n; sequential search takes O(n) time. The growth classes n, log n and n^2 are distinct.

Why each choice is right or wrong

A - Incorrect: 1 stays bounded instead of increasing proportionally to n (p.14).

B - Incorrect: log n increases more slowly than n (p.14 growth classes).

C - Correct: O(n) is the linear class illustrated by sequential search (cross-module p.3).

D - Incorrect: n^2 scales with the square rather than the first power (p.14).

Primary note proof

> In analysis of algorithms, it is not important to know how many operations an algorithm does. Of greater concern is the rate of increase in operations for an algorithm to solve a problem as the size of the problem increases. This is referred to us the rate of growth of the algorithm. What happens with small sets of input data is not as interesting as what happens when the data set gets large. The rate of growth of an algorithm is dominated by the largest term in an equation; we will discard the terms that grow more slowly. When we strip all of these things away, we are left with what we call the order of the function or related algorithm. We then group algorithms based on their order. We group in three categories - those that grow at least as fast as some function, those that grow at the same rate, and those that grow no faster. The following are some of the classes of algorithms: - log2 n, n, n ∗ log2 n, n2,n3, 2n. Asymptotic analysis is concerned with how the running time of an algorithm increases with the size of the input in the limit, as the size of the input increases without bound.

Data Structure and Algorithms module | PDF page 3 | lines 16-22

> Linear/Sequential searching • Works with unsorted List • Loop through the list starting at the first element • Time is proportional to the size of input (n) and we call this time complexity O(n).

Question sources

Computer Science MCQ practice collection · Question 350

Question 43 | AM0351

Which tight running-time growth rates are strictly superlinear, meaning f(n)/n→∞? Select all that apply.

A. Θ(log n)

B. Θ(n)

C. Θ(n log n)

D. Θ(n^2)

Hint

Identify the specification and cost model, then apply the relevant bound, invariant or strategy rule.

Answer C, D: Θ(n log n); Θ(n^2)

For n log n, dividing by n gives log n, which grows without bound. For n^2, the ratio is n, also unbounded. Both are therefore superlinear. The logarithmic representative is sublinear and n itself has constant ratio one, so neither meets the strict condition. Using tight rates prevents a loose upper-bound label from being mistaken for an algorithm's actual growth.

Why each choice is right or wrong

A - Incorrect: log n grows more slowly than n.

B - Incorrect: n is linear, with ratio one.

C - Correct: The ratio to n is log n and diverges.

D - Correct: The ratio to n is n and diverges.

Primary note proof

Computer Science MCQ practice collection · Question 351

Question 44 | AM0352

What is the purpose of experimental analysis in algorithm analysis?

A. To measure the actual running time of an algorithm

B. To determine the best-case scenario for an algorithm

C. To analyze the behavior of an algorithm as the input size increases

D. To evaluate the correctness of an algorithm

Hint

Identify the specification and cost model, then apply the relevant bound, invariant or strategy rule.

Answer A: To measure the actual running time of an algorithm

The module distinguishes analytical performance analysis from conducting experiments for performance measurement (PDF p.4). Experimental analysis therefore measures actual performance on chosen executions rather than deriving a limiting rate or proving correctness.

Why each choice is right or wrong

A - Correct: Direct runtime measurement is the performance-measurement purpose (p.4).

B - Incorrect: An experiment might include favorable inputs but does not inherently determine a universal best case (p.4).

C - Incorrect: Growth analysis is analytical; experiments can sample sizes but are not the defining limiting argument (p.4).

D - Incorrect: Correctness tests can accompany experiments, but the stated performance-measurement purpose is separate (p.4).

Primary note proof

Study-note section DAA02

> Experimental/dynamic measurement observes actual runs; asymptotic analysis abstracts growth; probabilistic analysis studies expectations. There is no universal taxonomy proving “graph analysis” or “dynamic analysis” is invalid. Auxiliary space excludes input; I/O complexity counts transfers. Representation affects costs; “data type complexity” is not a standard metric name.

Variant 1 | Alternative version 1

What is the purpose of experimental analysis in algorithm analysis?

A. To determine the best-case time complexity of an algorithm.

B. To compare algorithms based on their theoretical analysis.

C. To evaluate the correctness of an algorithm.

D. To measure the actual performance of an algorithm on real data.

Answer D: To measure the actual performance of an algorithm on real data.

Apply the same study-note rule to this alternative source set; the choice contrasts below show the derivation.

Why each choice is right or wrong

A - Incorrect: Experiments do not by themselves prove the minimum cost for every input size (p.4 distinction).

B - Incorrect: Comparison based on theoretical analysis uses the analytical approach (p.4).

C - Incorrect: Functional correctness is not the stated performance-measurement objective (p.4).

D - Correct: Measured performance on real data is the experimental approach (p.4).

Primary note proof

Study-note section DAA02

Experimental/dynamic measurement observes actual runs; asymptotic analysis abstracts growth; probabilistic analysis studies expectations. There is no universal taxonomy proving “graph analysis” or “dynamic analysis” is invalid. Auxiliary space excludes input; I/O complexity counts transfers. Computer Science MCQ practice collection · Question 362

Question 45 | AM0353

Which offered phrase is not a standard resource-metric name in the course's time/space/I-O cost model? This does not ask whether representation affects cost.

A. Space complexity

B. Auxiliary space

C. Input-output complexity

D. Data type complexity

Hint

Identify the specification and cost model, then apply the relevant bound, invariant or strategy rule.

Answer D: Data type complexity

Space complexity measures storage, auxiliary space isolates additional storage beyond input, and I/O complexity counts transfers. These are resource metrics in the stated model. Data type complexity is not the standard metric name used for representation effects; those effects are accounted for through arithmetic, storage or bit-operation costs. Therefore D is the terminology exception without asserting that data representation is irrelevant.

Why each choice is right or wrong

A - Incorrect: Space complexity is a standard storage metric.

B - Incorrect: Auxiliary space is a standard additional-storage metric.

C - Incorrect: I/O complexity is a standard transfer metric.

D - Correct: Data type complexity is not the standard metric name in this model.

Primary note proof

Study-note section DAA02

Question 46 | AM0354

What is the purpose of algorithm analysis in computer science?

A. To design algorithms for specific problems

B. To implement algorithms using programming languages

C. To analyze the efficiency and performance of algorithms

D. To test algorithms for correctness

Hint

Identify the specification and cost model, then apply the relevant bound, invariant or strategy rule.

Answer C: To analyze the efficiency and performance of algorithms

Performance analysis estimates computer memory and time requirements (PDF p.4), and studying those requirements helps choose between algorithms (p.6). Thus efficiency/performance is the direct purpose asked for.

Why each choice is right or wrong

A - Incorrect: Design creates a method; p.4 analysis estimates resources of a method.

B - Incorrect: Implementation expresses a method in code; p.4 analysis estimates performance.

C - Correct: This directly matches the memory-and-time performance definition (p.4).

D - Incorrect: Correctness is necessary but is distinct from the p.4 performance analysis objective.

Primary note proof

Study-note section DAA02

Analysis counts operations and storage as functions of input size: array length n, graph vertices V/edges E, or the number of bits in integers. A RAM model commonly gives constant cost to

bounded-word arithmetic/access. Arbitrarily large integer arithmetic and printing long outputs need their own costs. Elapsed measurements also depend on hardware, compiler, cache, I/O and competing load.

Computer Science MCQ practice collection · Question 354

Question 47 | AM0355

Which can be legitimate techniques for analyzing algorithm resource costs? Select all that apply. Dynamic means observing actual executions; empirical means measuring runs.

A. Asymptotic analysis

B. Empirical analysis

C. Dynamic analysis

D. Probabilistic analysis

Hint

Identify the specification and cost model, then apply the relevant bound, invariant or strategy rule.

Answer A, B, C, D: Asymptotic analysis; Empirical analysis; Dynamic analysis; Probabilistic analysis

Asymptotic reasoning studies growth, empirical measurements observe actual runs, and dynamic analysis under the stated meaning also observes execution costs. Probabilistic analysis studies expected cost under a distribution or internal randomness. All four can therefore be legitimate resource-analysis techniques. Empirical and dynamic may overlap; they do not have to be disjoint categories for their methods to be useful.

Why each choice is right or wrong

A - Correct: Asymptotic analysis studies cost growth.

B - Correct: Empirical analysis measures actual runs.

C - Correct: Dynamic observation measures actual execution costs under the given definition.

D - Correct: Probabilistic analysis studies expectations.

Primary note proof

Study-note section DAA02

Question 48 | AM0358

What does a time complexity of O(1) indicate?

A. The algorithm runs in constant time.

B. The algorithm runs in logarithmic time.

C. The algorithm runs in linear time.

D. The algorithm runs in quadratic time.

Hint

Identify the specification and cost model, then apply the relevant bound, invariant or strategy rule.

Answer A: The algorithm runs in constant time.

A constant upper bound O(1) does not grow with input size; it is the constant K at the start of the visually inspected growth ordering in Data Structures and Algorithms PDF p.3. The assigned PDF p.14 motivates classifying by growth rather than exact operation count.

Why each choice is right or wrong

A - Correct: Constant time has a fixed upper bound independent of n (cross-module p.3).

B - Incorrect: Logarithmic time grows with n, unlike 1 (assigned p.14).

C - Incorrect: Linear time grows proportionally to n (assigned p.14).

D - Incorrect: Quadratic time grows as n^2 (assigned p.14).

Primary note proof

Study-note section DAA04

For eventually nonnegative f, g, f∈O(g) means f(n)≤c·g(n) for all n≥n 0, with fixed c>0. Ω reverses that inequality; Θ requires both bounds. Little-o means f/g→0, and little-ω means f/g→∞ where the ratio exists. Θ specifies growth up to constant factors, not exact seconds or identical best/worst cases.

Study-note section DAA05

Representative growth is 1,log n,n,n log n,n^2,n^3,...,b^n,n! for fixed b>1. Log bases differ by a constant. Both n log n and n^2 are superlinear; log n is sublinear. Polynomial growth has a fixed exponent in input size.

Question 49 | AM0359

Which of the following time complexities indicates the most efficient algorithm?

A. O(1)

B. O(log n)

C. O(n)

D. O(n^2)

Hint

Identify the specification and cost model, then apply the relevant bound, invariant or strategy rule.

Answer A: O(1)

When comparing the listed representative growth rates for the same task and cost model as n becomes large, constant growth is smallest. The visually inspected related-module PDF p.3 ordering places K before log n, n and n^2; assigned p.14 focuses on large-input growth. This is not a guarantee about clock time for every finite input.

Why each choice is right or wrong

A - Correct: Constant is the smallest representative listed growth (cross-module p.3 diagram).

B - Incorrect: log n grows beyond any fixed constant (p.14 growth interpretation).

C - Incorrect: n grows faster than constant and logarithmic rates (p.14).

D - Incorrect: n^2 grows fastest among these listed rates (p.14).

Primary note proof

Computer Science MCQ practice collection · Question 359

Question 50 | AM0360

What does a time complexity of O(n^2) signify?

A. The algorithm runs in linear time.

B. The algorithm runs in logarithmic time.

C. The algorithm runs in quadratic time.

D. The algorithm runs in exponential time.

Hint

Identify the specification and cost model, then apply the relevant bound, invariant or strategy rule.

Answer C: The algorithm runs in quadratic time.

The exponent 2 identifies the quadratic representative growth class n^2, listed on PDF p.14. Strictly O(n^2) is an upper bound (cross-module p.3), so it does not prove that an algorithm actually requires quadratic time. C is the conventional class-name answer.

Why each choice is right or wrong

A - Incorrect: Linear is the n class, not the name of n^2 (p.14).

B - Incorrect: Logarithmic is the log n class, distinct from n^2 (p.14).

C - Correct: Quadratic names the squared-input growth class (p.14).

D - Incorrect: Exponential uses a growing exponent, such as 2^n, separately listed on p.14.

Primary note proof

Study-note section DAA04

Question 51 | AM0363

In fixed unit-cost RAM analysis of operation count and storage as functions of input size, which factor is abstracted away rather than being a parameter of the analysis?

A. Time complexity

B. Space complexity

C. Input size

D. Hardware configuration

Hint

Match the defining mechanism and its assumptions to the required claim; keep resource bounds separate from correctness.

Answer D: Hardware configuration

The fixed RAM model counts operations and storage relative to input size. Time complexity, space complexity and input size are therefore central to the analysis. The particular hardware configuration is abstracted away by the stipulated unit costs. It would matter for actual elapsed measurements, alongside compiler, cache, I/O and load, but that is a different analysis setting from the one explicitly requested.

Why each choice is right or wrong

A - Incorrect: Operation-count time complexity is a central resource.

B - Incorrect: Space complexity is a central resource.

C - Incorrect: Costs are expressed as functions of input size.

D - Correct: The fixed unit-cost abstraction hides the specific hardware configuration.

Primary note proof

Study-note section DAA02

> Analysis counts operations and storage as functions of input size: array length n, graph vertices V/edges E, or the number of bits in integers. A RAM model commonly gives constant cost to bounded-word arithmetic/access. Arbitrarily large integer arithmetic and printing long outputs need their own costs. Question 52 | AM0364

Which technique solves smaller largely independent instances recursively and then combines their results, without relying on reuse of overlapping states?

A. Divide and conquer

B. Greedy algorithm

C. Dynamic programming

D. Backtracking

Hint

Match the defining mechanism and its assumptions to the required claim; keep resource bounds separate from correctness.

Answer A: Divide and conquer

Divide and conquer separates a problem into smaller largely independent instances, solves them and combines the results. Dynamic programming instead emphasizes defined reusable states when subproblems overlap. Greedy commits to safe local choices, while backtracking explores and retracts partial candidates. The independence and combination conditions distinguish the requested technique from these other ways of reducing or extending a problem.

Why each choice is right or wrong

A - Correct: Independent recursive subinstances and combination define divide and conquer.

B - Incorrect: Greedy is defined by safe irrevocable local choices.

C - Incorrect: DP emphasizes reusable subproblem states rather than this independent structure.

D - Incorrect: Backtracking is defined by candidate extension and retraction.

Primary note proof

Study-note section DAA12

Divide and conquer solves smaller largely independent instances and combines results. DP reuses a defined set of subproblem states. Greedy commits to a feasible local choice only when a safety argument supports it. Backtracking grows/retracts candidates when constraints fail; branch and bound also rejects candidates whose best possible objective cannot beat an incumbent.

Design and Analysis of Algorithms module | PDF page 17 | lines 5-9

2.1 Divide and Conquer Algorithm In this approach, we solve a problem recursively by applying 3 steps 1. DIVIDE-break the problem into several sub problems of smaller size. 2. CONQUER-solve the problem recursively. 3. COMBINE-combine these solutions to create a solution to the original problem.

Design and Analysis of Algorithms module | PDF page 48 | lines 5-16

Dynamic programming, like the divide-and-conquer method, solves problems by combining the solutions to subproblems. As we saw in Chapter 2 of binary search, divide-and-conquer algorithms partition the problem into independent subproblems, solve the subproblems recursively, and then combine their solutions to solve the original problem. In contrast, dynamic programming is applicable when the subproblems are not independent, that is, when subproblems share sub subproblems. In this context, a divide-and-conquer algorithm does more work than necessary, repeatedly solving the common sub subproblems. A dynamic-programming algorithm solves every subproblem just once and then saves its answer in a table, thereby avoiding the work of recomputing the answer every time the subproblem is encountered. Dynamic programming is typically applied to optimization problems. In such problems there can be many possible solutions. Each solution has a value, and we wish to find a solution with the optimal (minimum or maximum) value.

Design and Analysis of Algorithms module | PDF page 95 | lines 3-17

5. Introduction to Backtracking 5.1 Backtracking: • It is one of the most general algorithm design techniques. • Many problems which deal with searching for a set of solutions or for a optimal solution satisfying some constraints can be solved using the backtracking formulation. • To apply backtracking method, the desired solution must be expressible as an n- tuple (x1…xn) where xi is chosen from some finite set Si. • The problem is to find a vector, which maximizes or minimizes a criterion function P(x1….xn). • The major advantage of this method is, once we know that a partial vector (x1,…xi) will not lead to an optimal solution that (mi+1…….mn) possible test

vectors may be ignored entirely. • Many problems solved using backtracking require that all the solutions satisfy a complex set of constraints.

Computer Science MCQ practice collection · Question 364

Question 53 | AM0365

Which algorithm design technique guarantees finding the optimal solution at each step but may not lead to the overall optimal solution?

A. Greedy algorithm

B. Divide and conquer

C. Dynamic programming

D. Backtracking

Hint

Match the defining mechanism and its assumptions to the required claim; keep resource bounds separate from correctness.

Answer A: Greedy algorithm

Greedy makes the best available local choice based on current information (PDF p.27), and the module explicitly warns that such choices can fail to yield a global optimum (p.30). “Optimal at each step” must mean locally best, not globally guaranteed.

Why each choice is right or wrong

A - Correct: Local short-sighted choices and possible global failure match pp.27,30.

B - Incorrect: Independent splitting and combining does not define a locally best choice (p.27 contrast).

C - Incorrect: Dynamic programming retains subproblem alternatives rather than irrevocably picking only the local best (p.30 contrast).

D - Incorrect: Backtracking revisits choices, unlike non-recoverable greedy choices on p.30.

Primary note proof

Study-note section DAA19

A greedy algorithm repeatedly selects a locally attractive feasible option without later undoing it. Optimal substructure alone does not prove this safe. An exchange proof inserts the greedy choice into an optimum without worsening cost; recurse. MST cut proofs use this exchange.

• Greedy method is the most straightforward designed technique. • As the name suggest they are short sighted in their approach taking decision on the basis of the information immediately at the hand without worrying about the effect these decisions may have in the future. DEFINITION: • A problem with N inputs will have some constraints. Any subsets that satisfy these constraints are called a feasible solution. • A feasible solution that either maximize can minimize a given objectives function is called an optimal solution. Greedy is a strategy that works well on optimization problems with the following characteristics: • Greedy-choice property: A global optimum can be arrived at by selecting a local

Design and Analysis of Algorithms module | PDF page 30 | lines 10-14

Greedy algorithms sometimes fail to produce the optimal solution, and may even produce the unique worst possible solution. One example is the travelling salesman problem. Greedy algorithms can be characterized as being 'short sighted', and as 'non-recoverable'. They are ideal only for problems which have 'optimal substructure'. Despite this, greedy algorithms are best suited for simple problems (e.g. giving change). It is important, however, to note that

Question 54 | AM0366

Which algorithm design technique is used to solve problems by exploring all possible solutions?

A. Divide and conquer

B. Greedy algorithm

C. Dynamic programming

D. Backtracking

Hint

Match the defining mechanism and its assumptions to the required claim; keep resource bounds separate from correctness.

Answer D: Backtracking

Backtracking generates solution tuples and explores choices with constraints, returning to earlier positions when needed (PDF pp.95-96). It can enumerate all valid solutions while pruning branches proved unpromising, so “all possible solutions” should not be read as requiring every invalid tuple to be visited.

Why each choice is right or wrong

A - Incorrect: Divide and conquer combines independent solved parts rather than enumerating candidate tuples (pp.95-96 contrast).

B - Incorrect: Greedy follows one selection sequence rather than revisiting alternatives (pp.95-96 contrast).

C - Incorrect: Dynamic programming caches subproblems rather than being the tuple-enumeration method shown on p.96.

D - Correct: The p.96 schema generates all solutions and backtracks over choices.

Primary note proof

Study-note section DAA36

Represent a partial assignment x[1.. k]. For each allowed next choice: assign it, test whether an extension remains possible, recurse if promising, and undo the assignment on return. Report complete feasible candidates; stop after one only if the task requests existence/a single answer. Explicit constraints restrict each variable’s domain; implicit constraints relate choices.

Question 55 | AM0367

Which algorithm design technique is suitable for problems with overlapping subproblems and optimal substructure?

A. Divide and conquer

B. Greedy algorithm

C. Dynamic programming

D. Backtracking

Hint

Match the defining mechanism and its assumptions to the required claim; keep resource bounds separate from correctness.

Answer C: Dynamic programming

Shared sub-subproblems motivate saving results once (PDF p.48); optimal substructure makes an optimal solution a combination of optimal subsolutions (pp.28,49). Together these are the properties for the module's dynamic-programming optimization method.

Why each choice is right or wrong

A - Incorrect: Independent subproblems distinguish divide and conquer in p.48.

B - Incorrect: Optimal substructure alone does not prove the greedy-choice property (pp.28,49).

C - Correct: Caching shared subproblem solutions with optimal substructure is exactly the method on pp.48-49.

D - Incorrect: Backtracking searches constrained tuples; it need not exploit repeated subproblems via a table (p.48 contrast).

Primary note proof

Study-note section DAA25

> Define state meaning, choices, recurrence, bases and dependency order. Prove replacing a subsolution by a better one improves the full solution; otherwise state information may be missing. Show the recurrence covers all legal final choices and generates feasible candidates, then induct in dependency order. Store choices for reconstruction.

Study-note section DAA26

> Memoization recursively checks a cache before solving a state and stores its result. Tabulation orders dependencies explicitly; chosen domains may exclude irrelevant states. Cache keys include all relevant parameters; recursion/locality/sparsity affect implementation cost.

Question 56 | AM0368

Which technique builds an optimum by repeatedly making a locally attractive feasible choice, never undoing it, when an exchange or safety proof justifies each commitment?

A. Divide and conquer

B. Greedy algorithm

C. Dynamic programming

D. Backtracking

Hint

Match the defining mechanism and its assumptions to the required claim; keep resource bounds separate from correctness.

Answer B: Greedy algorithm

Greedy algorithms repeatedly commit to locally attractive feasible choices without later undoing them. An exchange or related safety proof is needed to show that these commitments can form an optimum. Dynamic programming compares reusable states, backtracking revises candidates, and divide and conquer combines independent subinstances. The explicit safety and irrevocability conditions distinguish greedy from the broad idea of an optimal choice sequence.

Why each choice is right or wrong

A - Incorrect: Divide and conquer relies on independent decomposition and combination.

B - Correct: Safe irrevocable local commitments define greedy.

C - Incorrect: DP evaluates state alternatives rather than requiring irrevocable local choices.

D - Incorrect: Backtracking undoes choices, contrary to the stated rule.

Primary note proof

Study-note section DAA19

> A greedy algorithm repeatedly selects a locally attractive feasible option without later undoing it. Optimal substructure alone does not prove this safe. An exchange proof inserts the greedy choice into an optimum without worsening cost; recurse. MST cut proofs use this exchange.

• The essential difference between the greedy method and dynamic programming is that the greedy method only one decision sequence is ever generated. • In dynamic programming, many decision sequences may be generated. However, sequences containing sub-optimal sub-sequences cannot be optimal and so will not be generated.

Question sources

Computer Science MCQ practice collection · Question 368

Question 57 | AM0369

Which algorithm design technique is suitable for solving problems with optimal substructure but does not involve overlapping subproblems?

A. Divide and conquer

B. Greedy algorithm

C. Dynamic programming

D. Backtracking

Hint

Match the defining mechanism and its assumptions to the required claim; keep resource bounds separate from correctness.

Answer A: Divide and conquer is the supported independent-subproblem strategy.

DAA12 characterizes divide and conquer by smaller largely independent instances. The stated absence of overlapping subproblems fits that structure. Optimal substructure alone does not establish greedy safety, as DAA19 warns, while DP's main reuse motivation is overlap. Backtracking needs a candidate-and-constraint search description absent here. A is therefore the supported textbook structural match, rather than a proof that only it can ever apply.

Why each choice is right or wrong

A - Correct: Independent smaller instances with combinable optimal results fit divide and conquer.

B - Incorrect: Optimal substructure alone does not prove a safe greedy local choice.

C - Incorrect: Without overlapping states, the stated premise does not motivate DP reuse.

D - Incorrect: No candidate retraction or constraint-based enumeration is specified to identify backtracking.

Primary note proof

Study-note section DAA12

Divide and conquer solves smaller largely independent instances and combines results. DP reuses a defined set of subproblem states. Greedy commits to a feasible local choice only when a safety argument supports it. Backtracking grows/retracts candidates when constraints fail;

branch and bound also rejects candidates whose best possible objective cannot beat an incumbent.

Study-note section DAA19

Optimal substructure alone does not prove this safe.

Computer Science MCQ practice collection · Question 369

Question 58 | AM0370

Which technique explores a series of candidate choices, retracting a choice when constraints show that its partial candidate cannot extend to a solution?

A. Divide and conquer

B. Greedy algorithm

C. Dynamic programming

D. Backtracking

Hint

Match the defining mechanism and its assumptions to the required claim; keep resource bounds separate from correctness.

Answer D: Backtracking

Backtracking extends a partial assignment, tests whether a feasible completion remains possible, and undoes the assignment when returning to try alternatives. That matches the stated constraint-driven retraction. Greedy keeps its choices, DP stores reusable state values, and divide and conquer combines independent instances. Merely having a series of choices would not distinguish them; the explicit undo-and-retry mechanism does.

Why each choice is right or wrong

A - Incorrect: Independent decomposition is not the described candidate retraction.

B - Incorrect: Greedy does not undo committed choices.

C - Incorrect: DP is characterized by reuse of states rather than this search rule.

D - Correct: Backtracking extends, checks, retracts and tries alternatives.

Primary note proof

Study-note section DAA36

> Represent a partial assignment x[1.. k]. For each allowed next choice: assign it, test whether an extension remains possible, recurse if promising, and undo the assignment on return. Report complete feasible candidates; stop after one only if the task requests existence/a single answer. Explicit constraints restrict each variable’s domain; implicit constraints relate choices.

Question 59 | AM0371

Which listed techniques can support exact optimization when their required structural or exhaustive-search conditions hold? Select all that apply; consider maximum subarray, fractional knapsack, 0/1 knapsack and complete tour enumeration as examples.

A. Divide and conquer

B. Greedy algorithm

C. Dynamic programming

D. Backtracking

Hint

Match the defining mechanism and its assumptions to the required claim; keep resource bounds separate from correctness.

Answer A, B, C, D: Divide and conquer; Greedy algorithm; Dynamic programming; Backtracking

Divide and conquer optimizes maximum subarray by comparing left, right and crossing results. Greedy optimizes fractional knapsack under divisibility, DP optimizes 0/1 knapsack states, and complete backtracking can enumerate tours and retain the cheapest. All four techniques therefore have exact optimization applications under their own conditions. None becomes universally appropriate merely because the task asks for an optimum.

Why each choice is right or wrong

A - Correct: Maximum-subarray divide and conquer is an exact optimizer.

B - Correct: Density-greedy is exact for divisible fractional knapsack.

C - Correct: 0/1 knapsack DP computes an exact optimum.

D - Correct: Complete tour enumeration can retain the exact minimum.

Primary note proof

Study-note section DAA18

> Divide-and-conquer compares the best left, best right and best crossing result.

Study-note section DAA20

> For positive weights/profits and divisible items, sort by decreasing value/weight, take complete items while they fit, then the fitting fraction of the next.

Study-note section DAA29

> For integer capacity W, K[i, w] is maximum value using the first i items within capacity w.

Study-note section DAA33

> Greedy nearest-neighbor is a heuristic without a general exactness guarantee; backtracking and branch and bound can also solve exact TSP.

Question sources

Computer Science MCQ practice collection · Question 371

Question 60 | AM0372

An exponential recursive optimization repeatedly solves the same well-defined states. Optimal substructure holds and there are only polynomially many distinct states with polynomial work per state. Which technique avoids the repeated work by storing state results?

A. Divide and conquer

B. Greedy algorithm

C. Dynamic programming

D. Backtracking

Hint

Match the defining mechanism and its assumptions to the required claim; keep resource bounds separate from correctness.

Answer C: Dynamic programming

Dynamic programming stores the result for each distinct state, through memoization or tabulation, and reuses it instead of repeating equivalent recursive work. With the stated polynomial state count and polynomial work per state, this yields polynomial total work. Greedy needs an additional local-choice safety argument, divide and conquer targets independent instances, and plain backtracking does not provide the specified reuse.

Why each choice is right or wrong

A - Incorrect: Independent subproblem decomposition does not address the stated repeated states.

B - Incorrect: No safe irrevocable local-choice rule is supplied.

C - Correct: DP stores and reuses the repeated state results.

D - Incorrect: Plain candidate backtracking does not supply the requested cache reuse.

Primary note proof

Study-note section DAA25

Overlapping states motivate reuse; optimal substructure supports optimization. These are textbook signatures, not requirements that every DP problem optimize or every state have multiple users. DP also counts/decides. Cost=states×work per state and can remain exponential.

Study-note section DAA26

Memoization recursively checks a cache before solving a state and stores its result. Tabulation orders dependencies explicitly; chosen domains may exclude irrelevant states. Cache keys include all relevant parameters; recursion/locality/sparsity affect implementation cost.

Computer Science MCQ practice collection · Question 372

Question 61 | AM0373

Which technique combines solutions of overlapping subproblems using a defined state recurrence and reuses each solved state rather than solving it repeatedly?

A. Divide and conquer

B. Greedy algorithm

C. Dynamic programming

D. Backtracking

Hint

Match the defining mechanism and its assumptions to the required claim; keep resource bounds separate from correctness.

Answer C: Dynamic programming

Dynamic programming defines states and a recurrence, solves dependencies in a valid order and reuses the resulting values. Combining those values forms larger solutions without repeating the same state work. Divide and conquer combines largely independent instances instead, greedy keeps safe local commitments, and backtracking grows and retracts candidates. The explicit overlap and reuse conditions make DP the specific match.

Why each choice is right or wrong

A - Incorrect: Divide and conquer emphasizes independent instances rather than reused overlapping states.

B - Incorrect: Greedy is defined by safe local commitments.

C - Correct: DP combines stored dependent state values.

D - Incorrect: Backtracking is defined by candidate search and retraction.

Primary note proof

Study-note section DAA25

> Define state meaning, choices, recurrence, bases and dependency order. Prove replacing a subsolution by a better one improves the full solution; otherwise state information may be missing. Show the recurrence covers all legal final choices and generates feasible candidates, then induct in dependency order. Store choices for reconstruction.

> 2.1 Divide and Conquer Algorithm In this approach, we solve a problem recursively by applying 3 steps 1. DIVIDE-break the problem into several sub problems of smaller size. 2. CONQUER-solve the problem recursively. 3. COMBINE-combine these solutions to create a solution to the original problem.

Design and Analysis of Algorithms module | PDF page 48 | lines 5-16

> Dynamic programming, like the divide-and-conquer method, solves problems by combining the solutions to subproblems. As we saw in Chapter 2 of binary search, divide-and-conquer algorithms partition the problem into independent subproblems, solve the subproblems recursively, and then combine their solutions to solve the original problem. In contrast, dynamic programming is applicable when the subproblems are not independent, that is, when subproblems share sub subproblems. In this context, a divide-and-conquer algorithm does more work than necessary, repeatedly solving the common sub subproblems. A dynamic-programming algorithm solves every subproblem just once and then saves its answer in a table, thereby avoiding the work of recomputing the answer every time the subproblem is encountered. Dynamic programming is typically applied to optimization problems. In such problems there can be many possible solutions. Each solution has a value, and we wish to find a solution with the optimal (minimum or maximum) value.

Computer Science MCQ practice collection · Question 373

Question 62 | AM0374

For nonnegative weighted edges, an algorithm repeatedly finalizes the unsettled vertex with minimum current source distance and relaxes its outgoing edges. Which design technique describes this Dijkstra procedure?

A. Divide and conquer

B. Greedy algorithm

C. Dynamic programming

D. Backtracking

Hint

Match the defining mechanism and its assumptions to the required claim; keep resource bounds separate from correctness.

Answer B: Greedy algorithm

Dijkstra chooses the unsettled vertex of minimum distance and commits to its finalized value. Nonnegative edges ensure that a later path through other unsettled vertices cannot improve it. That safe irrevocable minimum choice is greedy. DP methods also solve other shortest-path settings, but they are not the explicitly described finalization procedure; independent decomposition and retracting path search are likewise different designs.

Why each choice is right or wrong

A - Incorrect: The procedure does not solve independent graph subinstances and combine them.

B - Correct: Safe minimum-distance finalization is a greedy choice.

C - Incorrect: A DP path recurrence is a different method from the specified Dijkstra procedure.

D - Incorrect: The algorithm finalizes distances rather than retracting path candidates.

Primary note proof

Study-note section DAA24

> Initialize dist[source]=0, others∞ and predecessors unset. Repeatedly extract the unsettled vertex u of minimum distance; relax each edge by dist[v]=min(dist[v], dist[u]+w(u, v)), updating predecessors when improved. Once the minimum is∞, remaining vertices are unreachable. A destination may be finalized before stopping, not merely discovered.

Study-note section DAA19

> A greedy algorithm repeatedly selects a locally attractive feasible option without later undoing it.

Question sources

Computer Science MCQ practice collection · Question 374

Question 63 | AM0375

Which algorithm design technique is commonly used for sorting algorithms?

A. Divide and conquer

B. Greedy algorithm

C. Dynamic programming

D. Backtracking

Hint

Match the defining mechanism and its assumptions to the required claim; keep resource bounds separate from correctness.

Answer A: Divide and conquer

Merge sort splits into independent halves and merges (PDF p.21), and quick sort partitions into independently sorted subarrays (p.23). These provide the concrete common sorting examples for divide and conquer. The answer is about those taught examples, not a claim that every sort uses this technique.

Why each choice is right or wrong

A - Correct: Both merge sort and quick sort are explicitly divide and conquer (pp.21,23).

B - Incorrect: No greedy-choice sorting construction is the taught example in pp.21-23.

C - Incorrect: No tabulated shared-subproblem sorting construction is presented in pp.21-23.

D - Incorrect: No candidate-solution backtracking sort is the taught example in pp.21-23.

Primary note proof

Study-note section DAA14

Split by indices, recursively sort each half, then repeatedly copy the smaller remaining front element into a temporary result. The merge invariant says the output prefix is sorted and contains the smallest elements already consumed. Append the unexhausted suffix. Equal keys must be taken from the left half first to preserve stability.

Study-note section DAA15

Choose a pivot, partition, then sort the resulting smaller ranges. In a two-pointer scheme, advance i while values are below pivot and j while above; when i≤j, swap and advance both. Bound the scans and ensure progress on equal values. Recurse on the resulting ranges. Hoare-style partition boundaries need not put the pivot at its final position; Lomuto-style partition commonly does. Do not mix their return conventions.

Design and Analysis of Algorithms module | PDF page 21 | lines 18-29

MERGE SORT • As another example divide-and-conquer, we investigate a sorting algorithm that has the nice property that is the worst case its complexity is O(n log n) • This algorithm is called merge sort • We assume throughout that the elements are to be sorted in non-decreasing order. • Given a sequence of _n' elements a[1],...,a[n] the general idea is to imagine then split into 2 sets a[1],.....,a[n/2] and a[[n/2]+1],....a[n]. • Each set is individually sorted, and the resulting sorted sequences are merged to produce a single sorted sequence of _n' elements. • Thus, we have another ideal example of the divide-and-conquer strategy in which the splitting is into 2 equal-sized sets & the combining operation is the merging of 2 sorted sets into one.

Design and Analysis of Algorithms module | PDF page 23 | lines 19-29

QUICK SORT • The divide-and-conquer approach can be used to arrive at an efficient sorting method different from merge sort. • In merge sort, the file a[1:n] was divided at its midpoint into sub arrays which were independently sorted & later merged. • In Quick sort, the division into 2 sub arrays is made so that the sorted sub arrays do not need to be merged later. • This is accomplished by rearranging the elements in a[1:n] such that a[I]<=a[j] for all I between 1 & n and all j between (m+1) & n for some m, 1<=m<=n. • Thus the elements in a[1:m] & a[m+1:n] can be independently sorted. • No merge is needed. This rearranging is referred to as partitioning.

Computer Science MCQ practice collection · Question 375

Question 64 | AM0376

A sequence-decision problem has overlapping state subproblems and optimal substructure. Which technique evaluates all legal next choices through a recurrence and stores the best value for each state for reuse?

A. Divide and conquer

B. Greedy algorithm

C. Dynamic programming

D. Backtracking

Hint

Match the defining mechanism and its assumptions to the required claim; keep resource bounds separate from correctness.

Answer C: Dynamic programming

Dynamic programming defines enough state to summarize the remaining decision problem, evaluates all legal choices and stores the best resulting value. Optimal substructure justifies using the stored optimal subsolutions, and overlap makes reuse useful. A mere decision sequence would not identify a technique; the explicit recurrence and reuse distinguish DP from greedy commitments, independent divide-and-conquer instances and backtracking without cached state values.

Why each choice is right or wrong

A - Incorrect: Independent decomposition does not describe the stated state reuse.

B - Incorrect: Greedy does not generally evaluate all choices through cached state recurrences.

C - Correct: DP evaluates and reuses best state values.

D - Incorrect: Backtracking without state caching revisits candidate choices rather than implementing this reuse rule.

Primary note proof

Study-note section DAA25

> Define state meaning, choices, recurrence, bases and dependency order. Prove replacing a subsolution by a better one improves the full solution; otherwise state information may be missing. Show the recurrence covers all legal final choices and generates feasible candidates, then induct in dependency order. Store choices for reconstruction.

Study-note section DAA26

> Memoization recursively checks a cache before solving a state and stores its result. Tabulation orders dependencies explicitly; chosen domains may exclude irrelevant states. Cache keys include all relevant parameters; recursion/locality/sparsity affect implementation cost.

Design and Analysis of Algorithms module | PDF page 48 | lines 17-22

> Dynamic programming is a stage-wise search method suitable for optimization problems whose solutions may be viewed as the result of a sequence of decisions. The most attractive property of this strategy is that during the search for a solution it avoids full enumeration by pruning early partial decision solutions that cannot possibly lead to optimal solution. In many practical situations, this strategy hits the optimal solution in a polynomial number of decision steps. However, in the worst case, such a strategy may end up performing full enumeration.

Design and Analysis of Algorithms module | PDF page 49 | lines 27-31

> • The essential difference between the greedy method and dynamic programming is that the greedy method only one decision sequence is ever generated. • In dynamic programming, many decision sequences may be generated. However, sequences containing sub-optimal sub-sequences cannot be optimal and so will not be generated.

Design and Analysis of Algorithms module | PDF page 95 | lines 3-17

> 5. Introduction to Backtracking 5.1 Backtracking: • It is one of the most general algorithm design techniques. • Many problems which deal with searching for a set of solutions or for a optimal solution satisfying some constraints can be solved using the backtracking formulation. • To apply backtracking method, the desired solution must be expressible as an n- tuple (x1…xn) where xi is chosen from some finite set Si. • The problem is to find a vector, which maximizes or minimizes a criterion function P(x1….xn). • The major advantage of this method is, once we know that a partial vector (x1,…xi) will not lead to an optimal solution that (mi+1…….mn) possible test vectors may be ignored entirely. • Many problems solved using backtracking require that all the solutions satisfy a complex set of constraints.

Question sources

Computer Science MCQ practice collection · Question 376

Question 65 | AM0377

Which technique builds a candidate incrementally, checks constraints after each addition and undoes the last addition when it cannot lead to a complete feasible solution?

A. Divide and conquer

B. Greedy algorithm

C. Dynamic programming

D. Backtracking

Hint

Match the defining mechanism and its assumptions to the required claim; keep resource bounds separate from correctness.

Answer D: Backtracking

Backtracking keeps a partial candidate, adds a choice, checks whether completion remains possible, and recursively explores promising extensions. On return it undoes the choice so other alternatives can be tried. Greedy also grows solutions but does not undo committed choices; DP builds reusable states rather than this candidate stack. Independent divide-and-conquer combination does not describe the specified constraint-search mechanism.

Why each choice is right or wrong

A - Incorrect: Independent subinstance combination is a different mechanism.

B - Incorrect: Greedy keeps rather than undoes its commitments.

C - Incorrect: DP is defined by state reuse rather than this candidate undo rule.

D - Correct: Constraint checks and undoing partial choices are backtracking.

Primary note proof

Study-note section DAA36

Represent a partial assignment x[1.. k]. For each allowed next choice: assign it, test whether an extension remains possible, recurse if promising, and undo the assignment on return. Report complete feasible candidates; stop after one only if the task requests existence/a single answer. Explicit constraints restrict each variable’s domain; implicit constraints relate choices.

Computer Science MCQ practice collection · Question 377

Question 66 | AM0379

Which technique finds maximum contiguous subarray by recursively comparing the best left-half, right-half and crossing subarray, with a linear-time crossing computation?

A. Divide and conquer

B. Greedy algorithm

C. Dynamic programming

D. Backtracking

Hint

Match the defining mechanism and its assumptions to the required claim; keep resource bounds separate from correctness.

Answer A: Divide and conquer

The stated construction splits the array, recursively solves each half and combines those results with the best crossing interval. This is divide and conquer, with recurrence $2T(n/2)+\Theta(n)=\Theta(n \log n)$. Kadane also solves the same problem, but uses a best-sum-ending-at-index DP recurrence rather than this construction. Greedy commitments and extend/retract search do not describe the specified three-way comparison.

Why each choice is right or wrong

A - Correct: Independent halves plus the crossing combination define divide and conquer.

B - Incorrect: No irrevocable local-choice rule defines this construction.

C - Incorrect: Kadane is DP, but it is not the described left/right/crossing algorithm.

D - Incorrect: The construction does not extend and retract candidate assignments.

Primary note proof

Study-note section DAA18

> A maximum subarray is contiguous; it is not an arbitrary subsequence. Divide-and-conquer compares the best left, best right and best crossing result. The crossing result is the best suffix of the left half plus best prefix of the right, found in $\Theta(n)$. This yields $2T(n/2)+\Theta(n)=\Theta(n \log n)$.

Computer Science MCQ practice collection · Question 379

Question 67 | AM0380

Which listed techniques describe exact TSP algorithms using either (i) cached subset-and-endpoint states or (ii) complete extend-and-retract enumeration of feasible tours while retaining the cheapest? Select all that apply.

A. Divide and conquer

B. Greedy algorithm

C. Dynamic programming

D. Backtracking

Hint

Match the defining mechanism and its assumptions to the required claim; keep resource bounds separate from correctness.

Answer C, D: Dynamic programming; Backtracking

Held-Karp stores the best cost for a visited subset and endpoint, which is dynamic programming. Complete backtracking extends feasible tours, retracts choices and retains the least-cost complete tour. Both are exact constructions described by the stem. Greedy nearest-neighbor can produce a tour but has no general optimality guarantee, while independent divide-and-conquer combination is not either specified construction.

Why each choice is right or wrong

A - Incorrect: Neither specified construction is independent divide-and-conquer combination.

B - Incorrect: A greedy tour heuristic is not a general exact optimizer.

C - Correct: Cached subset-and-endpoint states form Held-Karp DP.

D - Correct: Complete extend-and-retract tour search is backtracking.

Primary note proof

Study-note section DAA33

Let F(S, j) be minimum cost from s through exactly S, ending at j∈S.

Study-note section DAA33

Held-Karp uses O(V²2^V) time and O(V 2^V) space, improving factorial enumeration but remaining exponential. Greedy nearest-neighbor is a heuristic without a general exactness guarantee; backtracking and branch and bound can also solve exact TSP.

Study-note section DAA36

For each allowed next choice: assign it, test whether an extension remains possible, recurse if promising, and undo the assignment on return.

Design and Analysis of Algorithms module | PDF page 30 | lines 10-14

Greedy algorithms sometimes fail to produce the optimal solution, and may even produce the unique worst possible solution. One example is the travelling salesman problem. Greedy algorithms can be characterized as being 'short sighted', and as 'non-recoverable'. They are ideal only for problems which have 'optimal substructure'. Despite this, greedy algorithms are best suited for simple problems (e.g. giving change). It is important, however, to note that

Design and Analysis of Algorithms module | PDF page 130 | lines 18-23

TRAVELLING SALESMAN PROBLEM INTRODUCTION: It is algorithmic procedures similar to backtracking in which a new branch is chosen and is there (bound there) until new branch is choosing for advancing. Travelling salesman is a minimization problem. It can be solved using Branch and bound by generating state space tree by calculating cost and upper bound.

Question sources

Computer Science MCQ practice collection · Question 380

Question 68 | AM0381

Which algorithm design technique is used for solving problems that can be solved by making the best local choice at each step?

A. Divide and conquer

B. Greedy algorithm

C. Dynamic programming

D. Backtracking

Hint

Match the defining mechanism and its assumptions to the required claim; keep resource bounds separate from correctness.

Answer B: Greedy algorithm

The greedy-choice property selects a local optimum, and the method uses immediately available information (PDF p.27). The stem's best local choice identifies greedy. PDF p.30 warns that this is not automatically a global optimality proof.

Why each choice is right or wrong

A - Incorrect: Independent splitting is not the p.27 local-choice criterion.

B - Correct: Greedy directly matches the p.27 short-sighted local-selection description.

C - Incorrect: Dynamic programming compares subproblem solutions rather than committing solely to the best current choice (p.30 contrast).

D - Incorrect: Backtracking revisits choices rather than making the non-recoverable choices described on p.30.

Primary note proof

Study-note section DAA19

> A greedy algorithm repeatedly selects a locally attractive feasible option without later undoing it. Optimal substructure alone does not prove this safe. An exchange proof inserts the greedy choice into an optimum without worsening cost; recurse. MST cut proofs use this exchange.

Module passages - related reading

Computer Science MCQ practice collection · Question 381

Question 69 | AM0382

Which algorithm design technique is used for finding the longest common subsequence between two sequences?

A. Divide and conquer

B. Greedy algorithm

C. Dynamic programming

D. Backtracking

Hint

Match the defining mechanism and its assumptions to the required claim; keep resource bounds separate from correctness.

Answer C: Dynamic programming using prefix-pair states.

DAA30 defines a state for each pair of prefix lengths. A match extends a diagonal state; a mismatch takes the larger of two neighboring prefix solutions. Filling states in dependency order avoids recomputing overlapping subproblems and gives $\Theta(mn)$ time. This is the note's dynamic-programming solution; no greedy safety rule or backtracking enumeration is supplied.

Why each choice is right or wrong

A - Incorrect: The given LCS construction reuses overlapping prefix states rather than only independently solving and combining disjoint pieces.

B - Incorrect: No rule for committing to a locally best character is justified; prefix alternatives must be compared.

C - Correct: The prefix-pair table and recurrence reuse optimal subproblem lengths, exactly the dynamic-programming technique described.

D - Incorrect: The note computes stored prefix states instead of exhaustively extending and undoing candidate subsequences.

Primary note proof

Study-note section DAA30

A subsequence preserves order but need not be contiguous. For prefixes of lengths i, j define L[i, j]. Empty-prefix rows/columns are 0. If X[i−1]=Y[j−1], set L[i, j]=1+L[i−1, j−1]; otherwise use max(L[i−1, j], L[i, j−1]). Keep prefix lengths i and j distinct from the zero-based character indices i−1 and j−1.

Computer Science MCQ practice collection · Question 382

Question 70 | AM0383

Which algorithm design technique is used for solving problems that can be divided into smaller independent subproblems?

A. Divide and conquer

B. Greedy algorithm

C. Dynamic programming

D. Backtracking

Hint

Match the defining mechanism and its assumptions to the required claim; keep resource bounds separate from correctness.

Answer A: Divide and conquer

PDF p.48 explicitly describes divide and conquer as partitioning into independent subproblems, solving recursively, and combining solutions. The independence qualification makes this stem more specific than merely saying “subproblems.”

Why each choice is right or wrong

A - Correct: A directly matches independent partitioning and recursive solution (pp.17,48).

B - Incorrect: Greedy is distinguished by local feasible selection, not independent recursive partitioning (p.48 contrast).

C - Incorrect: Dynamic programming is motivated by subproblems sharing sub-subproblems (p.48).

D - Incorrect: Backtracking searches constrained assignments rather than the independent partition framework (p.48).

Primary note proof

Study-note section DAA12

> Divide and conquer solves smaller largely independent instances and combines results. DP reuses a defined set of subproblem states. Greedy commits to a feasible local choice only when a safety argument supports it. Backtracking grows/retracts candidates when constraints fail; branch and bound also rejects candidates whose best possible objective cannot beat an incumbent.

Computer Science MCQ practice collection · Question 383

Question 71 | AM0384

Which term refers to the amount of resources, such as time and memory, required by an algorithm to solve a problem?

A. Efficiency

B. Complexity

C. Optimality

D. Completeness

Hint

Match the defining mechanism and its assumptions to the required claim; keep resource bounds separate from correctness.

Answer B: Complexity

Complexity expresses algorithm requirements in time and space (PDF p.6), with performance defined as needed computer memory and time (p.4). Efficiency is an evaluation of those requirements; complexity names the resource requirement being quantified.

Why each choice is right or wrong

A - Incorrect: Efficiency evaluates how economically resources are used, while p.6 calls their expression complexity.

B - Correct: Complexity is explicitly expressed in time and space requirements (p.6).

C - Incorrect: Optimality concerns the objective value of a solution, not the resources used to find it (p.6 contrast).

D - Incorrect: Completeness concerns fully solving a problem, not its memory/time quantity (p.4 context).

Primary note proof

Study-note section DAA02

Analysis counts operations and storage as functions of input size: array length n, graph vertices V/edges E, or the number of bits in integers. A RAM model commonly gives constant cost to bounded-word arithmetic/access. Arbitrarily large integer arithmetic and printing long outputs need their own costs. Elapsed measurements also depend on hardware, compiler, cache, I/O and competing load.

Question 72 | AM0385

What is the purpose of analyzing the computational complexity of algorithms?

A. To determine the correctness of an algorithm

B. To measure the size of the input data

C. To evaluate the performance of an algorithm

D. To compare different programming languages

Hint

Match the defining mechanism and its assumptions to the required claim; keep resource bounds separate from correctness.

Answer C: To evaluate the performance of an algorithm

Analysis estimates memory and time needed to solve an input problem (PDF p.4); these estimates help select between possible algorithms (p.6). Evaluating performance is therefore the direct purpose.

Why each choice is right or wrong

A - Incorrect: Correctness concerns whether the result is right; the p.4 performance definition concerns resources.

B - Incorrect: Input size is an argument of the analysis, not the ultimate performance-evaluation purpose (pp.4,6).

C - Correct: Evaluating resource performance directly matches pp.4,6.

D - Incorrect: The comparison is between algorithms and their requirements, not primarily programming languages (p.6).

Primary note proof

Study-note section DAA02

Question sources

Computer Science MCQ practice collection · Question 385

Question 73 | AM0387

What does f(n)∈O(g(n)) mean, independently of whether f measures best, average, worst or space cost?

A. The best-case time complexity of an algorithm

B. The average-case time complexity of an algorithm

C. An eventual constant-factor upper bound: f(n)≤c·g(n) for fixed c>0 and all sufficiently large n.

D. The space complexity of an algorithm

Hint

Match the defining mechanism and its assumptions to the required claim; keep resource bounds separate from correctness.

Answer C: An eventual constant-factor upper bound: f(n)≤c·g(n) for fixed c>0 and all sufficiently large n.

Big-O gives an eventual constant-factor upper bound: for some fixed c>0 and n_0, f(n)≤c·g(n) whenever n≥n_0. It does not choose best, average or worst inputs, nor does it specify time rather than space. Those choices determine the function being bounded. Option C states the general mathematical relation that applies across all of those analyses.

Why each choice is right or wrong

A - Incorrect: Best case is a way to define f, not the meaning of Big-O.

B - Incorrect: Average case defines an expectation, not the bound relation.

C - Correct: The eventual upper inequality is the definition of Big-O.

D - Incorrect: Space is one possible resource for f, not the definition of the notation.

Primary note proof

Study-note section DAA04

> For eventually nonnegative f, g, f∈O(g) means f(n)≤c·g(n) for all n≥n 0, with fixed c>0. Ω reverses that inequality; Θ requires both bounds. Little-o means f/g→0, and little-ω means f/g→∞ where the ratio exists. Θ specifies growth up to constant factors, not exact seconds or identical best/worst cases.

Study-note section DAA03

> At fixed size n, best case minimizes cost, worst case maximizes it, and average case takes an expectation under a specified input distribution. Randomized expected cost may average internal choices for one fixed input. Smallest input size is not best case.

Question 74 | AM0388

Which time complexity indicates an algorithm that executes in constant time regardless of the input size?

A. O(1)

B. O(n)

C. O(log n)

D. O(n^2)

Hint

Match the defining mechanism and its assumptions to the required claim; keep resource bounds separate from correctness.

Answer A: O(1)

A bound independent of input size is constant O(1). This is the constant K in the visually inspected related-module p.3 growth diagram and agrees with classifying growth rather than exact operation count on assigned PDF p.14.

Why each choice is right or wrong

A - Correct: 1 is independent of n and gives the constant upper bound (cross-module p.3).

B - Incorrect: n grows as the input increases, unlike a constant (assigned p.14).

C - Incorrect: log n still grows, though slowly (assigned p.14).

D - Incorrect: n^2 increases quadratically rather than staying fixed (assigned p.14).

Primary note proof

Study-note section DAA04

For eventually nonnegative f, g, f∈O(g) means f(n)≤c·g(n) for all n≥n 0, with fixed c>0. Ω reverses that inequality; Θ requires both bounds. Design and Analysis of Algorithms module | PDF page 14 | lines 11-21

In analysis of algorithms, it is not important to know how many operations an algorithm does. Of greater concern is the rate of increase in operations for an algorithm to solve a problem as the size of the problem increases. This is referred to us the rate of growth of the algorithm. What happens with small sets of input data is not as interesting as what happens when the data set gets large. The rate of growth of an algorithm is dominated by the largest term in an equation; we will discard the terms that grow more slowly. When we strip all of these things away, we are left with what we call the order of the function or related algorithm. We then group algorithms based on their order. We group in three categories - those that grow at least as fast as some function, those that grow at the same rate, and those that grow no faster. The following are some of the classes of algorithms: - log2 n, n, n ∗ log2 n, n2,n3, 2n. Asymptotic analysis is concerned with how the running time of an algorithm increases with the size of the input in the limit, as the size of the input increases without bound.

Question sources

Computer Science MCQ practice collection · Question 388

Question 75 | AM0389

Which term describes the amount of memory required by an algorithm to solve a problem?

A. Time complexity

B. Space complexity

C. Computational complexity

D. Algorithmic complexity

Hint

Match the defining mechanism and its assumptions to the required claim; keep resource bounds separate from correctness.

Answer B: Space complexity

PDF p.6 explicitly defines space complexity as the amount of memory space needed to run a program to completion. B is the specific resource name, while the other complexity terms are broader or refer to duration.

Why each choice is right or wrong

A - Incorrect: Time complexity measures time rather than memory (p.6).

B - Correct: Space complexity is the precise definition on p.6.

C - Incorrect: Computational complexity is broader than the memory-specific measure asked for (p.6 distinguishes resources).

D - Incorrect: Algorithmic complexity is broader; p.6 names the particular memory measure space complexity.

Primary note proof

Study-note section DAA08

> Space complexity measures peak simultaneously live storage, not the sum of every allocation ever made. Count input, auxiliary structures and stack according to the requested convention. n active recursion levels with constant-size frames need Θ(n) stack; depth log n with constant frames needs Θ(log n). The number of total calls does not determine peak depth.

Question 76 | AM0390

What does the term "worst-case analysis" refer to in computational complexity?

A. Analyzing the best-case performance of an algorithm

B. Analyzing the average-case performance of an algorithm

C. Analyzing the worst possible input for an algorithm

D. Analyzing the expected performance of an algorithm

Hint

Match the defining mechanism and its assumptions to the required claim; keep resource bounds separate from correctness.

Answer C: Analyzing the worst possible input for an algorithm

Worst-case analysis considers the worst possible input among inputs of a fixed size, giving a bound covering all their runtimes (PDF p.14). C describes that selection; average and expected costs answer different questions.

Why each choice is right or wrong

A - Incorrect: Best case considers the fastest rather than slowest input (p.14).

B - Incorrect: Average case uses an average input rather than the maximizing one (p.14).

C - Correct: The worst possible input is precisely the p.14 definition.

D - Incorrect: Expected performance requires averaging rather than selecting the slowest input (p.14).

Primary note proof

Study-note section DAA03

> At fixed size n, best case minimizes cost, worst case maximizes it, and average case takes an expectation under a specified input distribution. Randomized expected cost may average internal choices for one fixed input. Smallest input size is not best case.

Computer Science MCQ practice collection · Question 390

Question 77 | AM0391

What is the significance of logarithmic time complexity, such as O(log n)?

A. It indicates linear time complexity.

B. It indicates constant time complexity.

C. It indicates exponential time complexity.

D. It indicates sublinear time complexity.

Hint

Match the defining mechanism and its assumptions to the required claim; keep resource bounds separate from correctness.

Answer D: It indicates sublinear time complexity.

For increasing positive n, log n grows more slowly than n: repeated halving reaches unit size in only log_2 n stages, as illustrated by binary search (Data Structures and Algorithms PDF p.3). Assigned PDF p.14 separately lists logarithmic and linear classes. Therefore logarithmic growth is sublinear.

Why each choice is right or wrong

A - Incorrect: Linear is proportional to n, faster than log n (cross-module p.3 search comparison).

B - Incorrect: Logarithms remain unbounded, so they are not constant (assigned p.14).

C - Incorrect: Exponential growth is represented by 2^n, not log n (assigned p.14).

D - Correct: Log n grows slower than n, so it is sublinear (cross-module p.3 search comparison).

Primary note proof

Study-note section DAA05

> Representative growth is 1,log n,n,n log n,n^2,n^3,...,b^n,n! for fixed b>1. Log bases differ by a constant. Both n log n and n^2 are superlinear; log n is sublinear. Polynomial growth has a fixed exponent in input size.

Data Structure and Algorithms module | PDF page 3 | lines 23-31

Binary Searching • Works on ordered/sorted list • Uses divide and conquer method: it locates mid-point and identify which have the target belongs to since the list is sorted. It performs this recursively till the item found or the list is empty(target is not in the list • The computational time for this algorithm is proportional to log2 n.

Data Structure and Algorithms module | PDF page 3 | lines 16-22

Linear/Sequential searching • Works with unsorted List • Loop through the list starting at the first element • Time is proportional to the size of input (n) and we call this time complexity O(n).

Question sources

Computer Science MCQ practice collection · Question 391

Question 78 | AM0392

What does the term "P versus NP problem" refer to in computational complexity theory?

A. The problem of distinguishing between parallel and non-parallel algorithms.

B. The problem of determining the runtime of algorithms.

C. The problem of comparing the efficiency of programming languages.

D. The problem of determining if certain types of problems have efficient algorithms.

Hint

Match the defining mechanism and its assumptions to the required claim; keep resource bounds separate from correctness.

Answer D: Whether efficiently verifiable decision problems also have efficient solving algorithms.

DAA44 defines P by deterministic polynomial-time decision solving and NP by polynomial-time certificate verification, equivalently nondeterministic polynomial solving. The P-versus-NP problem asks whether these classes coincide. Option D captures the question of efficient algorithms for this particular class of problems, although its wording is broad. It does not concern parallelism, language comparisons, or timing one program.

Why each choice is right or wrong

A - Incorrect: P and NP refer to polynomial solving and verification classes, not parallel versus non-parallel execution.

B - Incorrect: The question concerns equality of decision-problem classes, not merely determining a particular algorithm runtime.

C - Incorrect: Programming-language efficiency is unrelated to whether polynomial-time solvability and verifiability coincide.

D - Correct: This broadly expresses whether NP problems have deterministic polynomial-time solving algorithms, the P-versus-NP question.

Primary note proof

Study-note section DAA44

> P contains decision problems solvable deterministically in polynomial input-bit time. NP contains decision problems with polynomial-length certificates verifiable in polynomial time, equivalently solvable by a nondeterministic polynomial-time machine. NP does not mean non-polynomial; P⊆NP. Whether P=NP remains open.

Question 79 | AM0393

Which complexity class includes problems that can be solved by a non-deterministic Turing machine in polynomial time?

A. P

B. NP

C. NP-complete

D. Exponential

Hint

Match the defining mechanism and its assumptions to the required claim; keep resource bounds separate from correctness.

Answer B: NP

DAA44 identifies NP with decision problems solvable by a nondeterministic polynomial-time machine. P is a contained class defined using deterministic machines; NP-complete adds hardness, which the stem never requires. Exponential is a time-growth description rather than the requested definition. The alternate set replaces Exponential with NP-hard, which likewise does not change the defining NP answer.

Why each choice is right or wrong

A - Incorrect: P is defined through deterministic polynomial time; it is contained in NP but does not name the full defined class.

B - Correct: NP exactly names decision problems solvable by a nondeterministic polynomial-time Turing machine.

C - Incorrect: NP-complete requires both NP membership and NP-hardness; hardness is absent from the stem.

D - Incorrect: Exponential describes time growth, not the class defined by nondeterministic polynomial-time computation.

Primary note proof

Study-note section DAA44

> P contains decision problems solvable deterministically in polynomial input-bit time. NP contains decision problems with polynomial-length certificates verifiable in polynomial time, equivalently solvable by a nondeterministic polynomial-time machine. NP does not mean non-polynomial; P⊆NP. Whether P=NP remains open.

Study-note section DAA44

> A polynomial many-one reduction A≤p B transforms each A-instance into a B-instance preserving yes/no. To prove B NP-hard, reduce a known hard A to B, not the reverse.
> NP-complete means NP-hard and in NP; optimization TSP is normally called NP-hard, while its bounded-tour decision form is NP-complete. A valid proposed tour and its cost are easy to check,

but certifying global optimality is another task. Pseudo-polynomial O(nW) knapsack is not polynomial in the bit length of W.

Asymptotic analysis is concerned with how the running time of an algorithm increases with the size of the input in the limit, as the size of the input increases without bound.

Variant 1 | Alternative version 1

Which complexity class includes problems that can be solved by a non-deterministic Turing machine in polynomial time?

A. P

B. NP

C. NP-complete

D. NP-hard

Answer B: NP

The variant retains P, NP, and NP-complete and replaces the fourth option with NP-hard. DAA44 still defines NP by nondeterministic polynomial-time computation. NP-hard is a reduction-based hardness property and need not imply NP membership, so the answer remains NP after independently examining this set.

Why each choice is right or wrong

A - Incorrect: P specifies deterministic polynomial solving, a subclass rather than the full nondeterministic polynomial class.

B - Correct: NP is exactly the class defined by nondeterministic polynomial-time decision computation.

C - Incorrect: NP-complete additionally requires NP-hardness; the stem imposes no such condition.

D - Incorrect: NP-hardness alone does not imply membership in NP or a nondeterministic polynomial-time algorithm.

Primary note proof

Study-note section DAA44

> P contains decision problems solvable deterministically in polynomial input-bit time. NP contains decision problems with polynomial-length certificates verifiable in polynomial time, equivalently solvable by a nondeterministic polynomial-time machine. NP does not mean non-polynomial; P⊆NP. Whether P=NP remains open.

Study-note section DAA44

> A polynomial many-one reduction A≤p B transforms each A-instance into a B-instance preserving yes/no. To prove B NP-hard, reduce a known hard A to B, not the reverse. Computer Science MCQ practice collection · Question 393

Computer Science MCQ practice collection · Question 750

Question 80 | CS0114

For p=10 and n=5, execute if(n>p){print(n+p);}. Treat the comparison, branch and possible output as executable constant-cost operations. Which assessment is correct without adding an unstated output requirement?

A. Feasibility is violated.

B. Finiteness is violated.

C. Sequential control flow is violated.

D. No violation is demonstrated by this fragment.

Hint

Match the defining mechanism and its assumptions to the required claim; keep resource bounds separate from correctness.

Answer D: No violation is demonstrated by this fragment.

The condition 5>10 is false, so the print is skipped and the fragment terminates after constant work. Its operations are executable and its conditional control flow is legitimate. Nothing in this specified fragment violates feasibility or finiteness, and an unrequired output is not a correctness obligation. Thus the accurate assessment is that no property violation is demonstrated by this fragment.

Why each choice is right or wrong

A - Incorrect: The specified operations are executable, so feasibility is satisfied.

B - Incorrect: The fragment terminates, so finiteness is satisfied.

C - Incorrect: A conditional branch is legitimate algorithmic control flow.

D - Correct: The false branch skips output and terminates without the claimed property violations.

Primary note proof

Study-note section DAA45

For p=10,n=5, if(n>p) cout<<(n+p) skips output and terminates. Skipping this output does not by itself violate feasibility, finiteness or control flow. Efficiency or a missing required output needs a specification.

Study-note section DAA01

State inputs, output, constraints and empty-solution policy. Algorithms are finite, definite executable methods independent of source language; feasible satisfies constraints, optimal is best feasible. Conditional branches are legitimate control flow.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Design and Analysis of Algorithms module | PDF page 4 | lines 6-19

• Finiteness: Algorithm must complete after a finite number of steps. • Definiteness: Each step must be clearly defined, having one and only one interpretation. At each point in computation, one should be able to tell exactly what happens next. • Sequence: Each step must have a unique defined preceding and succeeding step. The first step (start step) and last step (halt step) must be clearly noted. • Feasibility: It must be possible to perform each instruction. • Correctness: It must compute correct answer for all possible legal inputs. • Language Independence: It must not depend on any one programming language. • Completeness: It must solve the problem completely. • Effectiveness: It must be possible to perform each step exactly and in a finite amount of time. • Efficiency: It must solve with the least amount of computational resources such as time and space. • Generality: Algorithm should be valid on all possible inputs • Input/Output: There must be a specified number of input values, and one or more result values.

Computer Science Exit Exam practice collection · Question 114

Question 81 | CS0115

Assume it is given that f(n) = 4n^2, g(n) = 8n. Which asymptotic notation is correct?

A. f(n) = Big-Oh(g(n))

B. f(n) = Little-Oh(g(n))

C. f(n) = Big-Omega(g(n))

D. f(n) = Theta(g(n))

Hint

Match the defining mechanism and its assumptions to the required claim; keep resource bounds separate from correctness.

Answer C: f(n) = Big-Omega(g(n))

Compare f/g=(4n^2)/(8n)=n/2, which grows without bound. Thus f eventually exceeds a constant multiple of g, establishing Omega(g) and excluding O(g), little-o(g) and Theta(g). The assigned PDF p.14 introduces growth comparison; the precise upper/lower/tight definitions are in Data Structures and Algorithms PDF p.3. For example n>=2 gives f>=g.

Why each choice is right or wrong

A - Incorrect: O(g) requires an eventual constant upper multiple; n/2 is unbounded, so it fails (cross-module p.3).

B - Incorrect: Little-o(g) requires slower growth; the ratio instead grows without bound (cross-module p.3).

C - Correct: Omega(g) is a lower growth bound; f>=g for every n>=2 establishes it (cross-module p.3).

D - Incorrect: Theta(g) requires the same growth rate; quadratic and linear differ by unbounded n/2 (cross-module p.3).

Primary note proof

Study-note section DAA04

> For eventually nonnegative f, g, $f \in O(g)$ means $f(n) \le c \cdot g(n)$ for all $n \ge n_0$, with fixed $c>0$. Ω reverses that inequality; Θ requires both bounds. Little-o means $f/g \to 0$, and little-ω means $f/g \to \infty$ where the ratio exists. Θ specifies growth up to constant factors, not exact seconds or identical best/worst cases.

Study-note section DAA05

> For $f=4n^2$ and $g=8n$, $f/g=n/2 \to \infty$. Therefore $f \in \Omega(g)$ and even $\omega(g)$, while f is neither $O(g)$ nor $\Theta(g)$.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Design and Analysis of Algorithms module | PDF page 14 | lines 11-21

In analysis of algorithms, it is not important to know how many operations an algorithm does. Of greater concern is the rate of increase in operations for an algorithm to solve a problem as the size of the problem increases. This is referred to us the rate of growth of the algorithm. What happens with small sets of input data is not as interesting as what happens when the data set gets large. The rate of growth of an algorithm is dominated by the largest term in an equation; we will discard the terms that grow more slowly. When we strip all of these things away, we are left with what we call the order of the function or related algorithm. We then group algorithms based on their order. We group in three categories - those that grow at least as fast as some function, those that grow at the same rate, and those that grow no faster. The following are some of the classes of algorithms: - log2 n, n, n ∗ log2 n, n2,n3, 2n. Asymptotic analysis is concerned with how the running time of an algorithm increases with the size of the input in the limit, as the size of the input increases without bound.

Data Structure and Algorithms module | PDF page 3 | lines 2-5

I. Big-Oh Notation (O): It's only concerned with what happens for very a large value of n. Big-O expresses an upper bound on the growth rate of a function, for sufficiently large values of n. An upper bound is the best algorithmic solution that has been found for a problem. NB: Each of the following functions is big-O of its successors:

Data Structure and Algorithms module | PDF page 3 | lines 6-12

II. Big-Omega Notation (Ω): provides an asymptotic lower bound; f(n)= Ω(g (n)) means that the growth rate of f(n) is greater than or equal to g(n). III. Theta Notation (Θ): If f(n)= Θ (g(n)), then g(n) is an asymptotically tight bound for f(n) i.e f(n) and g(n) have the same rate of growth. IV. Little-o Notation (o): f(n)=o(g(n)) means f(n) has less growth rate compared to g(n). V. Little-Omega Notation (ω): ω notation used to denote a lower bound that is not asymptotically tight.

Computer Science Exit Exam practice collection · Question 115

Question 82 | CS0116

For a connected weighted undirected graph, which statements about its minimum spanning trees are true? Select all that apply; weights may tie.

A. Minimum spanning tree contains all vertices from an input graph

B. We can have only one unique minimum spanning tree for a graph

C. Minimum spanning trees are graphs

D. Minimum spanning trees form a cycle

Hint

Match the defining mechanism and its assumptions to the required claim; keep resource bounds separate from correctness.

Answer A, C: Minimum spanning tree contains all vertices from an input graph; Minimum spanning trees are graphs

An MST contains every vertex and is a tree, hence is itself a graph. It is acyclic and has V−1 edges. Equal edge weights may permit multiple different MSTs, so uniqueness is not guaranteed. These properties make A and C true, while B's universal uniqueness claim and D's cycle claim are false. Distinct edge weights would be a sufficient additional uniqueness condition.

Why each choice is right or wrong

A - Correct: Spanning includes every input vertex.

B - Incorrect: Tied weights may yield multiple MSTs.

C - Correct: A tree is a particular kind of graph.

D - Incorrect: An MST is acyclic.

Primary note proof

Study-note section DAA23

> For a connected weighted undirected graph, an MST spans every vertex without cycles and minimizes total edge weight; it has V−1 edges. Negative edges are allowed. Equal weights may yield multiple MSTs; distinct weights suffice for uniqueness. A tree is itself a graph.

Module passages - related reading

Computer Science Exit Exam practice collection · Question 116

Question 83 | NS0294

At a fixed input size n, what is the minimum running time over all legal inputs of that size called?

A. Average time

B. Small time

C. Worst time

D. Best time

Hint

Match the defining mechanism and its assumptions to the required claim; keep resource bounds separate from correctness.

Answer D: Best time

Best-case time is the minimum cost among legal inputs of a fixed size. Worst case takes the maximum, and average case takes an expectation under a specified distribution. Choosing a smaller input size would ask a different question and would not define best case. The revised wording explicitly holds n fixed, making best time the unique standard case term.

Why each choice is right or wrong

A - Incorrect: Average time takes an expectation rather than a minimum.

B - Incorrect: Small time is not the defined input-case category.

C - Incorrect: Worst time takes the maximum at fixed size.

D - Correct: Best time takes the minimum at fixed size.

Primary note proof

Study-note section DAA03

> At fixed size n, best case minimizes cost, worst case maximizes it, and average case takes an expectation under a specified input distribution. Randomized expected cost may average internal choices for one fixed input. Smallest input size is not best case.

Question sources

Computer Science Exit Exam · 2018 · Question 11

Question 84 | NS0314

A researcher solves mergesort's recurrence $T(n)=2T(n/2)+\Theta(n)$, obtaining $\Theta(n \log n)$, and claims that this calculation alone proves every comparison-based sorting algorithm requires $\Omega(n \log n)$ worst-case time. What is the flaw in that reasoning?

A. The proof fails because comparison decision trees allow only array indexing.

B. The recurrence describes one algorithm; a separate argument is needed to lower-bound the whole comparison class.

C. The proof fails only because Θ notation ignores constant factors.

D. There is no flaw: any upper bound for one comparison sort automatically lower-bounds all comparison sorts.

Hint

Match the defining mechanism and its assumptions to the required claim; keep resource bounds separate from correctness.

Answer B: B. One algorithm's recurrence is not a universal lower-bound argument.

Solving the given recurrence establishes mergesort's $\Theta(n \log n)$ running time, but it does not rule out a different comparison algorithm with less work. The unsupported step is extending one algorithm's recurrence to a lower bound for the whole class. A separate decision-tree argument supplies the universal result: $n!$ possible orders require height at least $\log_2(n!)$. Discarding constants and permitting array indexing do not invalidate that argument.

Why each choice is right or wrong

A - Incorrect: The comparison model does not impose the stated array-indexing-only restriction.

B - Correct: The recurrence bounds mergesort; the $n!$-leaf decision-tree argument is what supplies a class-wide lower bound.

C - Incorrect: Ignoring constants is not the logical error; the unsupported extension from one algorithm to every algorithm is.

D - Incorrect: An upper bound for one available algorithm does not exclude a faster different algorithm, so it is not automatically a universal lower bound.

Primary note proof

Study-note section DAA11

> A comparison decision tree needs at least n! leaves for distinct-key orderings. Height h allows at most 2^h leaves, so h≥log 2(n!)=Ω(n log n); merge sort matches this worst-case bound. Array indexing is not forbidden.

Study-note section DAA14

> Ordinary array merge sort has $T(n)=2T(n/2)+\Theta(n)=\Theta(n \log n)$ across input orders, $\Theta(n)$ auxiliary buffer and $\Theta(\log n)$ recursion depth. A written $+O(n)$ recurrence alone establishes an upper bound; the tight result also uses linear merge work. Empty/singleton subarrays are base cases.

Question sources

Computer Science Exit Exam · 2018 · Question 38

Question 85 | NS0317

A routine sums the integers from n down to 1. For integer n≥0, use mathematical-integer RAM pseudocode with exact unit-cost arithmetic and no overflow. Charge 1 unit for each initialization, comparison, compound decrement i-- and return; charge 1 for addition and 1 for assignment in sum=sum+i. Ignore declarations, parameter passing and function-call overhead. What is T(n)? total(n) { sum=0; for(i=n;i>0;i--) sum=sum+i; return sum; }

A. 5n+5

B. $4n^2+4$

C. 6n+2

D. 4n+4

Hint

Match the defining mechanism and its assumptions to the required claim; keep resource bounds separate from correctness.

Answer D: 4n+4

The descending loop executes n times. Initializing sum and i costs 2 units; i>0 is tested n+1 times; the compound decrement costs n units; and adding i then assigning the result costs 2n. One return gives T(n)=2+(n+1)+n+2n+1=4n+4. Although the returned sum grows quadratically with n, the number of unit-cost operations grows linearly. Exact mathematical integers prevent accumulator or loop-control overflow.

Why each choice is right or wrong

A - Incorrect: This overcounts the specified model by one unit per iteration and one fixed unit.

B - Incorrect: The numeric sum grows quadratically, but there are only n constant-cost loop iterations.

C - Incorrect: The stated iteration has one test, one compound decrement and two accumulator operations, not six units of iteration work.

D - Correct: Two initializations, n+1 tests, n decrements, 2n body units and one return total 4n+4.

Primary note proof

Study-note section DAA06

> Exact coefficients depend on whether tests, increments, arithmetic and assignments count separately.

Study-note section DAA06

For sum=0; for(i=1;i<=n;i++) sum=sum+1; return sum: counting two initializations, n+1 tests, n increments,2n body operations and one return gives 4n+4. A different primitive-cost convention changes this exact expression, not Θ(n).

Study-note section DAA02

A RAM model commonly gives constant cost to bounded-word arithmetic/access.

Question sources

Computer Science Exit Exam · 2018 · Question 42

Question 86 | NS0468

Which strategy breaks a problem into smaller largely independent subinstances, solves them recursively and combines their results, without caching repeated overlapping states?

A. Greedy

B. Backtracking

C. Divide and Conquer

D. Dynamic Programming

Hint

Match the defining mechanism and its assumptions to the required claim; keep resource bounds separate from correctness.

Answer C: Divide and Conquer

Divide and conquer solves smaller largely independent instances and combines their results into the original solution. Dynamic programming can also recurse and combine values, but its distinguishing mechanism is reusable state values when subproblems overlap. Greedy is defined by safe irrevocable local choices, and backtracking by revising partial candidates. Independence and the lack of overlap-based caching resolve the original broad decomposition wording.

Why each choice is right or wrong

A - Incorrect: Greedy is defined by safe local choices.

B - Incorrect: Backtracking extends and retracts candidates.

C - Correct: Independent recursive subinstances and combination define divide and conquer.

D - Incorrect: The specified independence excludes the overlapping-state reuse emphasized by DP.

Primary note proof

Study-note section DAA12

> Divide and conquer solves smaller largely independent instances and combines results. DP reuses a defined set of subproblem states. Greedy commits to a feasible local choice only when a safety argument supports it. Backtracking grows/retracts candidates when constraints fail; branch and bound also rejects candidates whose best possible objective cannot beat an incumbent.

Question sources

Algorithm Design & Analysis review questions · Question 1

Question 87 | NS0469

What is the formal definition of Big-O notation? State the roles of constants c and k.

Hint

Match the defining mechanism and its assumptions to the required claim; keep resource bounds separate from correctness.

Answer: $f \in O(g)$ iff $\exists c>0, k$ such that $0 \le f(n) \le c\, g(n)$ for all $n \ge k$.

DAA04 requires one fixed positive multiplier and one threshold covering the entire tail of the eventually nonnegative functions. c permits constant-factor scaling; k excludes a finite initial prefix. Neither may be chosen anew for each n. This defines an eventual upper bound, independently of input case or whether the resource is time or space.

Primary note proof

Study-note section DAA04

> For eventually nonnegative f, g, $f \in O(g)$ means $f(n) \le c \cdot g(n)$ for all $n \ge n_0$, with fixed $c>0$. Ω reverses that inequality; Θ requires both bounds. Little-o means $f/g \to 0$, and little-ω means $f/g \to \infty$ where the ratio exists. Θ specifies growth up to constant factors, not exact seconds or identical best/worst cases.

Question sources

Algorithm Design & Analysis review questions · Question 2

Question 88 | NS0470

Show that f(n) = 10n + 5 is O(n). What values of c and k satisfy the definition?

Hint

Match the defining mechanism and its assumptions to the required claim; keep resource bounds separate from correctness.

Answer: c=15 and k=1 work.

For every $n \geq 1$, $5 \leq 5n$, so $10n+5 \leq 15n$. Choosing $c=15$ and $k=1$ therefore satisfies the Big-O upper inequality for the whole tail. DAA04 gives this exact worked example. These witnesses need not be unique; the goal is one valid fixed constant and threshold, not the smallest pair.

Primary note proof

Study-note section DAA04

> For eventually nonnegative f, g, $f \in O(g)$ means $f(n) \leq c \cdot g(n)$ for all $n \geq n_0$, with fixed $c>0$. Ω reverses that inequality; Θ requires both bounds. Little-o means $f/g \to 0$, and little-ω means $f/g \to \infty$ where the ratio exists. Θ specifies growth up to constant factors, not exact seconds or identical best/worst cases.

Study-note section DAA04

> $10n+5 \leq 15n$ for $n \geq 1$, so $c=15, n_0=1$ works.

Question sources

Algorithm Design & Analysis review questions · Question 3

Question 89 | NS0471

Show that $f(n) = 3n^2 + 4n + 1$ is $O(n^2)$. What are the constants?

Hint

Match the defining mechanism and its assumptions to the required claim; keep resource bounds separate from correctness.

Answer: c=8 and k=1 work.

For $n \geq 1$, replace $4n$ by at most $4n^2$ and 1 by at most n^2. The sum is then at most $8n^2$, satisfying DAA04's upper-bound definition. Thus $c=8$ and $k=1$ are valid witnesses. They are not uniquely required constants; larger multipliers or thresholds can also satisfy the inequality.

Primary note proof

Study-note section DAA04

> For eventually nonnegative f, g, $f \in O(g)$ means $f(n) \leq c \cdot g(n)$ for all $n \geq n_0$, with fixed $c>0$. Ω reverses that inequality; Θ requires both bounds. Little-o means $f/g \to 0$, and little-ω means $f/g \to \infty$ where the ratio exists. Θ specifies growth up to constant factors, not exact seconds or identical best/worst cases.

Study-note section DAA04

> Also $3n^2+4n+1 \leq 8n^2$ for $n \geq 1$.

Question sources

Algorithm Design & Analysis review questions · Question 4

Question 90 | NS0472

Rank these complexity classes from slowest to fastest growing: O(n!), O(n^2), O(log n), O(2^n), O(n log n)

Hint

Match the defining mechanism and its assumptions to the required claim; keep resource bounds separate from correctness.

Answer: Increasing representative growth: log n, n log n, n^2, 2^n, n!.

DAA05 orders logarithmic, polynomial, exponential, and factorial rates. A log factor above n is still dominated by n^2; fixed-base exponential eventually exceeds any fixed polynomial, and factorial exceeds fixed-base exponential. This ranks representative functions, not mutually exclusive Big-O sets, since a slower function can also satisfy a looser larger upper bound.

Primary note proof

Study-note section DAA05

> Representative growth is 1,log n,n,n log n,n^2,n^3,...,b^n,n! for fixed b>1. Log bases differ by a constant. Both n log n and n^2 are superlinear; log n is sublinear. Polynomial growth has a fixed exponent in input size.

Question sources

Algorithm Design & Analysis review questions · Question 5

Question 91 | NS0473

Big-Theta Θ(h(n)) provides what kind of bound on an algorithm's complexity?

Hint

Match the defining mechanism and its assumptions to the required claim; keep resource bounds separate from correctness.

Answer: A tight asymptotic bound: both upper and lower constant-factor bounds.

DAA04 requires positive constants c1,c2 and a threshold k with c1 h(n)≤f(n)≤c2 h(n) for all n≥k. Theta therefore specifies growth up to constant factors, not exact seconds. It can describe best, average, worst, or space functions; choosing Theta does not itself choose an input case.

Primary note proof

Study-note section DAA04

> For eventually nonnegative f, g, f∈O(g) means f(n)≤c·g(n) for all n≥n 0, with fixed c>0. Ω reverses that inequality; Θ requires both bounds. Little-o means f/g→0, and little-ω means f/g→∞ where the ratio exists. Θ specifies growth up to constant factors, not exact seconds or identical best/worst cases.

Question sources

Algorithm Design & Analysis review questions · Question 6

Question 92 | NS0474

What does Big-Omega Ω(g(n)) represent and how does it differ from Big-O?

Hint

Match the defining mechanism and its assumptions to the required claim; keep resource bounds separate from correctness.

Answer: Ω is an eventual lower bound; O is an eventual upper bound.

DAA04 gives $f \in \Omega(g)$ when $f(n) \geq c\, g(n)$ beyond a fixed threshold for some $c>0$, reversing the Big-O inequality. The relations describe functions independently of best or worst case. A function may satisfy both, giving Theta, or only one for a particular comparator; they are not literal fastest-versus-slowest input labels.

Primary note proof

Study-note section DAA04

> For eventually nonnegative f, g, $f \in O(g)$ means $f(n) \leq c \cdot g(n)$ for all $n \geq n_0$, with fixed $c>0$. Ω reverses that inequality; Θ requires both bounds. Little-o means $f/g \to 0$, and little-ω means $f/g \to \infty$ where the ratio exists. Θ specifies growth up to constant factors, not exact seconds or identical best/worst cases.

Question sources

Algorithm Design & Analysis review questions · Question 7

Question 93 | NS0475

State the Transitivity Theorem of Big-O and explain why it is useful.

Hint

Match the defining mechanism and its assumptions to the required claim; keep resource bounds separate from correctness.

Answer: If f∈O(g) and g∈O(h), then f∈O(h).

DAA04 permits chained upper bounds. If f≤c g past k1 and g≤d h past k2, then f≤cd h for every n beyond max(k1,k2). Multiplying constants and combining thresholds proves transitivity. It is useful for replacing a complicated intermediate expression by a simpler known bound without redoing the entire comparison.

Primary note proof

Study-note section DAA04

> Prove the inequality for the whole tail, not selected values. Transitivity allows chained upper bounds; sums are dominated by the largest nonnegative growth term.

Study-note section DAA04

> For eventually nonnegative f, g, f∈O(g) means f(n)≤c·g(n) for all n≥n 0, with fixed c>0. Ω reverses that inequality; Θ requires both bounds. Little-o means f/g→0, and little-ω means f/g→∞ where the ratio exists. Θ specifies growth up to constant factors, not exact seconds or identical best/worst cases.

Question sources

Algorithm Design & Analysis review questions · Question 8

Question 94 | NS0476

According to Big-O Theorem 6, order the following correctly: n!, 2^n, n^2, n log n, n, log n, constant k

Hint

Match the defining mechanism and its assumptions to the required claim; keep resource bounds separate from correctness.

Answer: Increasing growth: k, log n, n, n log n, n^2, 2^n, n!.

For fixed positive k, DAA05 places constant growth first, followed by logarithmic and linear rates, then n log n, quadratic, exponential, and factorial growth. The ordering is eventual, not a promise of speed for every small input. It concerns representative functions; Big-O memberships can overlap when upper bounds are loose.

Primary note proof

Study-note section DAA05

> Representative growth is 1,log n,n,n log n,n^2,n^3,...,b^n,n! for fixed b>1. Log bases differ by a constant. Both n log n and n^2 are superlinear; log n is sublinear. Polynomial growth has a fixed exponent in input size.

Question sources

Algorithm Design & Analysis review questions · Question 9

Question 95 | NS0477

How is algorithm validation different from algorithm analysis?

Hint

Match the defining mechanism and its assumptions to the required claim; keep resource bounds separate from correctness.

Answer: Validation checks required behavior; analysis measures resource costs.

DAA01 specifies legal inputs, required outputs, and correctness proof through invariants or recursive induction. DAA02 counts operations and storage as input size grows. A procedure can be fast yet incorrect, or correct yet expensive. Testing can reveal failures but finite tests do not prove correctness for all inputs, so resource analysis does not replace validation.

Primary note proof

Study-note section DAA01

> State inputs, output, constraints and empty-solution policy. Algorithms are finite, definite executable methods independent of source language; feasible satisfies constraints, optimal is best feasible. Conditional branches are legitimate control flow.

Study-note section DAA02

> Analysis counts operations and storage as functions of input size: array length n, graph vertices V/edges E, or the number of bits in integers. A RAM model commonly gives constant cost to bounded-word arithmetic/access. Arbitrarily large integer arithmetic and printing long outputs need their own costs. Elapsed measurements also depend on hardware, compiler, cache, I/O and competing load.

Question sources

Algorithm Design & Analysis review questions · Question 10

Question 96 | NS0478

What is the general recurrence equation for a divide-and-conquer algorithm?

Hint

Match the defining mechanism and its assumptions to the required claim; keep resource bounds separate from correctness.

Answer: For equal-size splits, T(n)=aT(n/b)+f(n), with an explicit base case.

DAA10 uses a recursive subcalls of size n/b and f(n) nonrecursive divide/combine work, with a≥1 and b>1. Include a base such as T(1)=Θ(1). Unequal or decrementing subproblems require a more general sum of subproblem costs; the equal-split form is a common model, not every possible divide-and-conquer recurrence.

Primary note proof

Study-note section DAA10

> For T(n)=aT(n/b)+f(n), a≥1, b>1, let p=log_b a. Level i has a^i nodes of size n/b^i. Compare f with n^p: a polynomial gap below gives Θ(n^p); f=Θ(n^p) gives Θ(n^p log n); a polynomial gap above gives Θ(f(n)) if a f(n/b)≤c f(n) for fixed c<1. The third case needs this regularity condition.

Question sources

Algorithm Design & Analysis review questions · Question 11

Question 97 | NS0479

What is the time complexity of Merge Sort and how is it derived?

Hint

Match the defining mechanism and its assumptions to the required claim; keep resource bounds separate from correctness.

Answer: Ordinary array merge sort is Θ(n log n).

DAA14 gives $T(n)=2T(n/2)+\Theta(n)$: two half-size sorts and linear merging. There are logarithmically many levels, each totaling linear merge work, with linear total leaf work. Therefore the tight result is n log n across input orders, assuming the ordinary algorithm rather than a variant that skips already ordered merges.

Primary note proof

Study-note section DAA14

> Ordinary array merge sort has $T(n)=2T(n/2)+\Theta(n)=\Theta(n \log n)$ across input orders, $\Theta(n)$ auxiliary buffer and $\Theta(\log n)$ recursion depth. A written $+O(n)$ recurrence alone establishes an upper bound; the tight result also uses linear merge work. Empty/singleton subarrays are base cases.

Question sources

Algorithm Design & Analysis review questions · Question 12

Question 98 | NS0480

Explain the three steps of Merge Sort in order.

Hint

Match the defining mechanism and its assumptions to the required claim; keep resource bounds separate from correctness.

Answer: Split into halves, recursively sort each half, then merge the sorted halves.

DAA14 stops at empty or singleton ranges. During combination it repeatedly takes the smaller remaining front item, then appends the unexhausted suffix. Left-first equal-key selection preserves stability. These steps separate division, recursive solution, and combination; the merge assumes each half is already sorted rather than that the original full array was sorted.

Primary note proof

Study-note section DAA14

> Split by indices, recursively sort each half, then repeatedly copy the smaller remaining front element into a temporary result. The merge invariant says the output prefix is sorted and contains the smallest elements already consumed. Append the unexhausted suffix. Equal keys must be taken from the left half first to preserve stability.

Question sources

Algorithm Design & Analysis review questions · Question 13

Question 99 | NS0481

What property makes Merge Sort a 'stable' sorting algorithm?

Hint

Match the defining mechanism and its assumptions to the required claim; keep resource bounds separate from correctness.

Answer: Take equal keys from the left half first while merging.

DAA14 explicitly requires left-first equal-key handling for stability. Recursive halves retain their internal equal-key order, and choosing a left equal before a right equal preserves their original cross-half order. Inductively the entire output retains the relative order of equal-key records. Choosing the right equal first can break that property.

Primary note proof

Study-note section DAA14

> Split by indices, recursively sort each half, then repeatedly copy the smaller remaining front element into a temporary result. The merge invariant says the output prefix is sorted and contains the smallest elements already consumed. Append the unexhausted suffix. Equal keys must be taken from the left half first to preserve stability.

Question sources

Algorithm Design & Analysis review questions · Question 14

Question 100 | NS0482

What is the average and worst-case time complexity of Quick Sort, and when does the worst case occur?

Hint

Match the defining mechanism and its assumptions to the required claim; keep resource bounds separate from correctness.

Answer: Expected average $\Theta(n \log n)$; worst $\Theta(n^2)$ from repeated highly unbalanced partitions.

DAA15 gives logarithmic partition depth when splits are balanced and expected n log n with random pivots. Repeated extreme pivots leave sizes $n-1, n-2, \ldots$, causing $n+(n-1)+\ldots$ work. Sorted input can trigger this with certain fixed endpoint pivots, but input order alone is not a universal worst-case characterization across partition rules.

Primary note proof

Study-note section DAA15

> Balanced splits give $\Theta(n \log n)$; repeatedly highly unbalanced splits give $\Theta(n^2)$. Random pivots give expected $\Theta(n \log n)$, not a deterministic guarantee. Median-of-three does not eliminate adversarial cases; three-way partitioning helps repeated keys. Standard quicksort is unstable, uses expected $\Theta(\log n)$ stack but worst $\Theta(n)$; recursing on the smaller side and iterating on the larger bounds stack by $O(\log n)$.

Question sources

Algorithm Design & Analysis review questions · Question 15

Question 101 | NS0483

Describe the partitioning step of Quick Sort using indices i and j.

Hint

State the model and invariant, then derive the result from the cited procedure or recurrence, checking base cases and limitations.

Answer: Advance i over values below the pivot and j over values above; swap while i≤j, then advance both.

DAA15's two-pointer partition bounds its scans and ensures progress even on equal values. After pointers cross, recurse on the resulting smaller ranges. Hoare-style boundaries need not put the pivot in its final position, whereas Lomuto commonly does. The chosen return convention and recursion ranges must match; mixing them can miss elements or fail to terminate.

Primary note proof

Study-note section DAA15

> Choose a pivot, partition, then sort the resulting smaller ranges. In a two-pointer scheme, advance i while values are below pivot and j while above; when i≤j, swap and advance both. Bound the scans and ensure progress on equal values. Recurse on the resulting ranges. Hoare-style partition boundaries need not put the pivot at its final position; Lomuto-style partition commonly does. Do not mix their return conventions.

Algorithm Design & Analysis review questions · Question 16

Question 102 | NS0484

Compare Merge Sort and Quick Sort on: stability, worst-case complexity, and space usage.

Hint

State the model and invariant, then derive the result from the cited procedure or recurrence, checking base cases and limitations.

Answer: Merge: stable, Θ(n log n) worst, Θ(n) buffer. Quick: unstable, Θ(n^2) worst, expected Θ(log n) and worst Θ(n) stack.

DAA14 provides merge's linear buffer and logarithmic recursion depth, with left-first ties for stability. DAA15 gives quicksort's in-array partitioning but nonconstant recursive storage and potentially linear depth. Recursing only on the smaller side can bound that stack logarithmically. These describe ordinary implementations; ignoring recursive frames would misstate total auxiliary space.

Primary note proof

Study-note section DAA14

> Ordinary array merge sort has T(n)=2T(n/2)+Θ(n)=Θ(n log n) across input orders, Θ(n) auxiliary buffer and Θ(log n) recursion depth. A written +O(n) recurrence alone establishes an upper bound; the tight result also uses linear merge work. Empty/singleton subarrays are base cases.

Study-note section DAA15

> Balanced splits give Θ(n log n); repeatedly highly unbalanced splits give Θ(n^2). Random pivots give expected Θ(n log n), not a deterministic guarantee. Median-of-three does not eliminate adversarial cases; three-way partitioning helps repeated keys. Standard quicksort is unstable, uses expected Θ(log n) stack but worst Θ(n); recursing on the smaller side and iterating on the larger bounds stack by O(log n).

Study-note section DAA14

> Equal keys must be taken from the left half first to preserve stability.

Question 103 | NS0485

Why is Binary Search classified as a Divide and Conquer algorithm?

Hint

State the model and invariant, then derive the result from the cited procedure or recurrence, checking base cases and limitations.

Answer: Each midpoint comparison reduces the ordered-search instance to one half.

DAA13 maintains sorted low/high bounds and excludes the half that cannot contain the target. The recurrence $T(n)=T(n/2)+\Theta(1)$ gives logarithmic worst work. Unlike sorting two halves, binary search solves only one surviving subinstance and requires no substantial combination step; this is the common divide-and-conquer or decrease-by-factor classification.

Primary note proof

Study-note section DAA13

> Binary search requires sorted random-access data. Maintain inclusive low/high bounds, compute mid=low+(high−low)//2, and replace high with mid−1 or low with mid+1 according to the comparison. Stop when found or low>high. $T(n)=T(n/2)+\Theta(1)$: worst $\Theta(\log n)$, best $\Theta(1)$; iterative auxiliary space $\Theta(1)$, recursive $\Theta(\log n)$.

Study-note section DAA12

> Divide and conquer solves smaller largely independent instances and combines results.

Question sources

Algorithm Design & Analysis review questions · Question 18

Question 104 | NS0486

What is the core principle of the Greedy algorithmic paradigm?

Hint

State the model and invariant, then derive the result from the cited procedure or recurrence, checking base cases and limitations.

Answer: Repeatedly make a locally attractive feasible choice and keep it.

DAA19 defines greedy decisions as irrevocable rather than exploring and undoing alternatives. To obtain a global optimum, the local choice needs a problem-specific safety argument, often an exchange proof. Optimal substructure alone is insufficient. Thus local attractiveness is the mechanism, while global optimality is a separate correctness obligation rather than an automatic consequence.

Primary note proof

Study-note section DAA19

> A greedy algorithm repeatedly selects a locally attractive feasible option without later undoing it. Optimal substructure alone does not prove this safe. An exchange proof inserts the greedy choice into an optimum without worsening cost; recurse. MST cut proofs use this exchange.

Question sources

Algorithm Design & Analysis review questions · Question 19

Question 105 | NS0487

What is the difference between a feasible solution and an optimal solution in the context of Greedy algorithms?

Hint

State the model and invariant, then derive the result from the cited procedure or recurrence, checking base cases and limitations.

Answer: Feasible satisfies constraints; optimal is best among feasible solutions.

DAA01 separates constraint satisfaction from objective quality. For example, a legal set of knapsack items may fit capacity but have less value than another legal set. DAA19 warns that greedy choices require a safety proof to reach an optimum; constructing a feasible result alone does not prove global optimality.

Primary note proof

Study-note section DAA01

> State inputs, output, constraints and empty-solution policy. Algorithms are finite, definite executable methods independent of source language; feasible satisfies constraints, optimal is best feasible. Conditional branches are legitimate control flow.

Study-note section DAA19

> A greedy algorithm repeatedly selects a locally attractive feasible option without later undoing it. Optimal substructure alone does not prove this safe. An exchange proof inserts the greedy choice into an optimum without worsening cost; recurse. MST cut proofs use this exchange.

Question sources

Algorithm Design & Analysis review questions · Question 20

Question 106 | NS0488

Name two advantages and two disadvantages of Greedy algorithms.

Hint

State the model and invariant, then derive the result from the cited procedure or recurrence, checking base cases and limitations.

Answer: Advantages: simple choices and low overhead. Disadvantages: irrevocable mistakes and problem-specific applicability.

DAA19 identifies these benefits and limitations. Greedy can avoid maintaining a large state table, but a locally attractive choice can prevent an optimum and cannot later be undone within the paradigm. An exchange or other safety proof is therefore essential. A greedy heuristic has no approximation guarantee solely because it uses local choices.

Primary note proof

Study-note section DAA19

> Advantages are often simple decisions and low overhead; limitations are irrevocable errors and problem-specific applicability. A heuristic has no approximation guarantee merely because it is greedy. For coins{1,3,4} and target 6, largest-first gives 4+1+1 while 3+3 uses fewer coins. Activity selection instead has a safe earliest-finish rule for maximizing the number of nonoverlapping unweighted intervals; replacing the first chosen activity in an optimum with an earlier-finishing one leaves at least as much room.

Question sources

Algorithm Design & Analysis review questions · Question 21

Question 107 | NS0489

In the Job Sequencing with Deadlines algorithm, why are jobs sorted in decreasing order of profit first?

Hint

State the model and invariant, then derive the result from the cited procedure or recurrence, checking base cases and limitations.

Answer: Profit-first gives high-value feasible jobs priority under the unit-duration scheduling assumptions.

DAA21 processes nonnegative-profit jobs in decreasing profit and places each in its latest free slot meeting its deadline. This preserves earlier slots for tighter deadlines, while an exchange argument supports profit-first selection for feasible unit-job sets. The rule needs one machine, initially available unit jobs, and on-time profit; variable durations can invalidate it.

Primary note proof

Study-note section DAA21

> Assume one machine, initially available jobs, unit durations, integer deadlines and profit only for on-time completion. Process nonnegative-profit jobs by decreasing profit; place each in the latest free slot finishing by its deadline, or reject it. Latest placement preserves earlier slots for tighter deadlines; feasible unit-job sets support profit-first exchange.

Question sources

Algorithm Design & Analysis review questions · Question 22

Question 108 | NS0490

Given jobs J4(deadline=2, profit=300), J1(deadline=5, profit=200), J3(deadline=3, profit=190), J2(deadline=3, profit=180), J5(deadline=4, profit=120), J6(deadline=2, profit=100) - what is the optimal schedule and maximum profit?

Hint

State the model and invariant, then derive the result from the cited procedure or recurrence, checking base cases and limitations.

Answer: Slots 1-5: J2,J4,J3,J5,J1; maximum profit 990.

DAA21's greedy placement gives J4 at slot2, J1 at5, J3 at3, J2 at1, and J5 at4; J6 cannot fit before deadline2. Every accepted deadline holds. Their profits sum to 180+300+190+120+200=990. Since these are the five largest profits and only five slots exist, 990 also matches an upper bound.

Primary note proof

Study-note section DAA21

> Assume one machine, initially available jobs, unit durations, integer deadlines and profit only for on-time completion. Process nonnegative-profit jobs by decreasing profit; place each in the latest free slot finishing by its deadline, or reject it. Latest placement preserves earlier slots for tighter deadlines; feasible unit-job sets support profit-first exchange.

Study-note section DAA21

> Slots finishing 1…5 contain J 2,J 4,J 3,J 5,J 1. Profits 180+300+190+120+200=990; deadlines hold. J 6 cannot finish by 2. The five largest profits sum to 990, giving a matching upper bound.

Question sources

Algorithm Design & Analysis review questions · Question 23

Question 109 | NS0491

What is the Optimal Merge Pattern and what greedy strategy does it apply?

Hint

State the model and invariant, then derive the result from the cited procedure or recurrence, checking base cases and limitations.

Answer: Repeatedly merge the two smallest files or weights, reinsert their sum, and minimize total merge cost.

DAA22 charges p+q for combining file sizes p and q, adds that charge to total cost, and returns the merged size to a min-heap. Combining small weights early avoids repeatedly charging large weights at deep levels. The min-heap implementation costs O(n log n); actual comparison counts are a distinct cost model.

Primary note proof

Study-note section DAA22

> Combine the two smallest weights, add their sum to total cost, and reinsert it. A min-heap gives O(n log n) time/O(n) space. Cost p+q counts moved records; worst-case comparisons are p+q−1 for nonempty lists, and actual comparisons may be fewer.

Question sources

Algorithm Design & Analysis review questions · Question 24

Question 110 | NS0492

What is a Minimum Spanning Tree (MST) and what problem does it solve?

Hint

State the model and invariant, then derive the result from the cited procedure or recurrence, checking base cases and limitations.

Answer: An MST connects all vertices without cycles using minimum total edge weight.

DAA23 assumes a connected undirected weighted graph and gives an MST V−1 edges. It minimizes total connection cost, not every source-to-vertex route. Prim and Kruskal find such trees through safe light edges. Equal weights can allow several optima, and disconnected input instead yields a minimum spanning forest rather than one spanning tree.

Primary note proof

Study-note section DAA23

> For a connected weighted undirected graph, an MST spans every vertex without cycles and minimizes total edge weight; it has V−1 edges. Negative edges are allowed. Equal weights may yield multiple MSTs; distinct weights suffice for uniqueness. A tree is itself a graph.

Question sources

Algorithm Design & Analysis review questions · Question 25

Question 111 | NS0493

Compare Prim's Algorithm and Kruskal's Algorithm: approach, edge selection, and best use case.

Hint

State the model and invariant, then derive the result from the cited procedure or recurrence, checking base cases and limitations.

Answer: Prim grows one tree across a cut; Kruskal accepts globally light edges joining distinct components.

DAA23 gives matrix Prim $O(V^2)$, heap/list Prim $O(E \log V)$, and edge-sorting Kruskal $O(E \log E)$. Matrix Prim can favor dense graphs because it avoids sorting quadratically many edges; Kruskal naturally uses an edge list and union-find. Best use depends on representation and implementation, not a universal measured-speed ranking.

Primary note proof

Study-note section DAA23

> Prim repeatedly adds the cheapest edge crossing from its current tree to an outside vertex. Kruskal sorts edges globally, accepting one only when union-find says its endpoints are in different components. The cut proof exchanges a light crossing edge into some optimum without raising its weight. Matrix Prim costs $O(V^2)$; binary-heap Prim $O(E \log V)$, and Kruskal $O(E \log E)$. Dense-graph comparisons depend on these implementations. Disconnected input gives a minimum spanning forest.

Question sources

Algorithm Design & Analysis review questions · Question 26

Question 112 | NS0494

How does Kruskal's Algorithm detect and avoid cycles when building the MST?

Hint

State the model and invariant, then derive the result from the cited procedure or recurrence, checking base cases and limitations.

Answer: Use union-find: reject an edge if its endpoints already belong to the same component.

DAA23 processes edges globally in increasing weight. If the endpoint representatives differ, the edge joins components without creating a cycle, so accept it and union the sets. If they match, a path already connects the endpoints and adding the edge would close a cycle. The light-edge exchange property supports minimum total weight.

Primary note proof

Study-note section DAA23

> Prim repeatedly adds the cheapest edge crossing from its current tree to an outside vertex. Kruskal sorts edges globally, accepting one only when union-find says its endpoints are in different components. The cut proof exchanges a light crossing edge into some optimum without raising its weight. Matrix Prim costs $O(V^2)$; binary-heap Prim O(E log V), and Kruskal O(E log E). Dense-graph comparisons depend on these implementations. Disconnected input gives a minimum spanning forest.

Question sources

Algorithm Design & Analysis review questions · Question 27

Question 113 | NS0495

What is Dijkstra's Algorithm used for and what is its key limitation?

Hint

State the model and invariant, then derive the result from the cited procedure or recurrence, checking base cases and limitations.

Answer: Single-source shortest paths with nonnegative edge weights; negative edges break its general guarantee.

DAA24 finalizes the least unsettled tentative distance and relaxes outgoing edges. Nonnegative weights ensure a later route through unsettled vertices cannot improve a finalized distance. A negative edge can violate that proof even without a negative cycle. This differs from MST construction, and unreachable vertices retain infinite distance.

Primary note proof

Study-note section DAA24

> Nonnegative edges ensure a later path through unsettled vertices cannot improve a finalized distance. With $s \to a=2$, $s \to b=5$, $b \to a=-4$, finalizing a at 2 misses the later distance 1. Binary-heap/list implementation costs $O((V+E)\log V)$, matrix scanning $O(V^2)$. An MST minimizes total connection cost; Dijkstra minimizes each source-path distance, a different objective.

Question sources

Algorithm Design & Analysis review questions · Question 28

Question 114 | NS0496

List the steps of Dijkstra's Algorithm in order.

Hint

State the model and invariant, then derive the result from the cited procedure or recurrence, checking base cases and limitations.

Answer: Initialize distances; repeatedly finalize the smallest unsettled distance and relax its outgoing edges.

DAA24 starts source at zero, all others at infinity, with predecessors unset. Extract the minimum unsettled vertex; update dist[v] and its predecessor when dist[u]+w(u,v) improves it. Stop when none remain or the minimum is infinite. For an early destination stop, finalize it first rather than stopping merely on discovery.

Primary note proof

Study-note section DAA24

> Initialize dist[source]=0, others∞ and predecessors unset. Repeatedly extract the unsettled vertex u of minimum distance; relax each edge by dist[v]=min(dist[v], dist[u]+w(u, v)), updating predecessors when improved. Once the minimum is∞, remaining vertices are unreachable. A destination may be finalized before stopping, not merely discovered.

Question sources

Algorithm Design & Analysis review questions · Question 29

Question 115 | NS0497

What is the difference between MST (Minimum Spanning Tree) and SSSP (Single-Source Shortest Path)?

Hint

State the model and invariant, then derive the result from the cited procedure or recurrence, checking base cases and limitations.

Answer: MST minimizes total connection weight; SSSP minimizes each source-to-vertex path distance.

DAA23's spanning tree connects every vertex with minimum sum of selected edge weights. DAA24's source shortest paths optimize a different objective for a designated source and can choose a different tree. An MST need not contain shortest source routes. Standard MST permits negative weights, while Dijkstra's particular SSSP algorithm needs nonnegative weights.

Primary note proof

Study-note section DAA23

> For a connected weighted undirected graph, an MST spans every vertex without cycles and minimizes total edge weight; it has V−1 edges. Negative edges are allowed. Equal weights may yield multiple MSTs; distinct weights suffice for uniqueness. A tree is itself a graph.

Study-note section DAA24

> Nonnegative edges ensure a later path through unsettled vertices cannot improve a finalized distance. With s→a=2, s→b=5, b→a=−4, finalizing a at 2 misses the later distance 1. Binary-heap/list implementation costs $O((V+E)\log V)$, matrix scanning $O(V^2)$. An MST minimizes total connection cost; Dijkstra minimizes each source-path distance, a different objective.

Question sources

Algorithm Design & Analysis review questions · Question 30

Question 116 | NS0498

Which two textbook structural properties justify and motivate the usual dynamic-programming approach to optimization? Explain their different roles rather than treating them as universal requirements for every use of DP.

Hint

State the model and invariant, then derive the result from the cited procedure or recurrence, checking base cases and limitations.

Answer: Optimal substructure and overlapping subproblems: the first justifies composing optimal subsolutions, while the second motivates reusing stored state results.

Optimal substructure means an optimal solution can be built using appropriate optimal subsolutions. Overlap means the same state problem occurs repeatedly, making saved results useful. These properties justify and motivate the familiar optimization pattern, provided the state captures all relevant information and the recurrence is correct. DP can also count or decide, so the two properties are not stated here as universal necessities for every DP computation.

Primary note proof

Study-note section DAA25

> Overlapping states motivate reuse; optimal substructure supports optimization. These are textbook signatures, not requirements that every DP problem optimize or every state have multiple users. DP also counts/decides. Cost=states×work per state and can remain exponential.

Question sources

Algorithm Design & Analysis review questions · Question 31

Question 117 | NS0499

How does Dynamic Programming differ from Divide and Conquer?

Hint

State the model and invariant, then derive the result from the cited procedure or recurrence, checking base cases and limitations.

Answer: Divide and conquer solves largely independent instances; DP reuses dependent or overlapping states.

DAA12 distinguishes independent recursive decomposition and combination from a defined set of reused states. DP requires state meaning, transitions, bases, and dependency order so each needed state is computed without redundant recomputation. Divide and conquer usually does not need a shared-state cache. Merely splitting a problem into smaller parts is common to both and does not distinguish them.

Primary note proof

Study-note section DAA12

> Divide and conquer solves smaller largely independent instances and combines results. DP reuses a defined set of subproblem states. Greedy commits to a feasible local choice only when a safety argument supports it. Backtracking grows/retracts candidates when constraints fail; branch and bound also rejects candidates whose best possible objective cannot beat an incumbent.

Study-note section DAA25

> Define state meaning, choices, recurrence, bases and dependency order. Prove replacing a subsolution by a better one improves the full solution; otherwise state information may be missing. Show the recurrence covers all legal final choices and generates feasible candidates, then induct in dependency order. Store choices for reconstruction.

Question sources

Algorithm Design & Analysis review questions · Question 32

Question 118 | NS0500

How does Dynamic Programming differ from the Greedy approach?

Hint

State the model and invariant, then derive the result from the cited procedure or recurrence, checking base cases and limitations.

Answer: Greedy commits to a proved-safe local choice; DP compares stored subproblem alternatives.

DAA19 makes greedy choices irrevocable and requires a safety argument. DAA25 defines states and recurrence choices, then computes optimal state values in dependency order. DP can retain alternatives that a greedy rule would discard. Optimal substructure does not itself make greedy safe, and neither approach is universally preferable without the problem's structural conditions.

Primary note proof

Study-note section DAA19

> A greedy algorithm repeatedly selects a locally attractive feasible option without later undoing it. Optimal substructure alone does not prove this safe. An exchange proof inserts the greedy choice into an optimum without worsening cost; recurse. MST cut proofs use this exchange.

Study-note section DAA25

> Define state meaning, choices, recurrence, bases and dependency order. Prove replacing a subsolution by a better one improves the full solution; otherwise state information may be missing. Show the recurrence covers all legal final choices and generates feasible candidates, then induct in dependency order. Store choices for reconstruction.

Question sources

Algorithm Design & Analysis review questions · Question 33

Question 119 | NS0501

What are the four development steps of a Dynamic Programming algorithm?

Hint

State the model and invariant, then derive the result from the cited procedure or recurrence, checking base cases and limitations.

Answer: Define and justify optimal states; derive recurrence and bases; compute dependencies once; reconstruct retained choices.

DAA25 first requires a state meaning and legal choices, then a correctness argument for the recurrence and feasible candidates. Evaluate states in dependency order, accounting for states times work per state. Store decisions so the chosen solution can be reconstructed afterward. These provide the requested four development stages without assuming DP is automatically polynomial.

Primary note proof

Study-note section DAA25

> Define state meaning, choices, recurrence, bases and dependency order. Prove replacing a subsolution by a better one improves the full solution; otherwise state information may be missing. Show the recurrence covers all legal final choices and generates feasible candidates, then induct in dependency order. Store choices for reconstruction.

Question sources

Algorithm Design & Analysis review questions · Question 34

Question 120 | NS0502

Explain memoization and tabulation - the two DP implementation strategies.

Hint

State the model and invariant, then derive the result from the cited procedure or recurrence, checking base cases and limitations.

Answer: Memoization solves requested states recursively with a cache; tabulation fills states in explicit dependency order.

DAA26 checks the cache before recursively solving a memoized state and stores its result. Tabulation schedules prerequisite states first without that demand-driven recursion. Keys must include all relevant parameters, and chosen domains may avoid irrelevant states. Both reuse results, but sparsity, recursion overhead, and locality can affect which implementation is preferable.

Primary note proof

Study-note section DAA26

> Memoization recursively checks a cache before solving a state and stores its result. Tabulation orders dependencies explicitly; chosen domains may exclude irrelevant states. Cache keys include all relevant parameters; recursion/locality/sparsity affect implementation cost.

Question sources

Algorithm Design & Analysis review questions · Question 35

Question 121 | NS0503

In the Fibonacci sequence, why is naive recursion inefficient and how does DP improve it?

Hint

State the model and invariant, then derive the result from the cited procedure or recurrence, checking base cases and limitations.

Answer: Naive recursion repeats Fibonacci states; DP computes each required state once.

DAA26 shows that F(n−2) reappears across recursion branches, causing Θ(φ^n) calls, with O(2^n) a valid loose bound. Memoization or tabulation uses the two preceding values and only Θ(n) unit-cost additions. Two rolling values reduce working machine words to constant, though arbitrary-precision values require growing bit costs.

Primary note proof

Study-note section DAA26

> Naive Fibonacci recomputes F(n−2) across branches: call count is Θ(φ^n), with O(2^n) a valid loose upper bound. F(0)=0, F(1)=1 and F(i)=F(i−1)+F(i−2) yield Θ(n) unit-cost additions with memoization/tabulation. Keeping only two recent values uses Θ(1) machine words; arbitrary-precision output needs growing bit storage. This naive overlapping recursion is not the independent-subproblem ideal of D&C.

Question sources

Algorithm Design & Analysis review questions · Question 36

Question 122 | NS0504

What is the 0/1 knapsack optimization problem with positive integer weights, nonnegative values and integer capacity W, and why does its item-and-capacity state formulation suit dynamic programming? Each item may be chosen at most once.

Hint

State the model and invariant, then derive the result from the cited procedure or recurrence, checking base cases and limitations.

Answer: Choose a subset with total weight at most W and maximum total value. DP compares excluding each item with including it once and reuses item/capacity state results.

Define K[i,w] as the best value using the first i items within capacity w. An item that fits can be excluded or included with its value added to K[i-1,w-weight_i]; taking the larger value gives the recurrence. The previous-row reference enforces at-most-once use, and repeated states are reused. The O(nW) running time is pseudo-polynomial in binary-encoded capacity, unlike the separate fractional-knapsack greedy method.

Primary note proof

Study-note section DAA29

> For integer capacity W, K[i, w] is maximum value using the first i items within capacity w. Initialize K[0, w]=0. If weight_i>w, use K[i−1, w]; otherwise take max(K[i−1, w], value_i+K[i−1, w−weight_i]). The previous-row reference ensures each item is used at most once. Backtrack changed values to recover chosen items.

Study-note section DAA20

> This proof depends on divisibility. With capacity 10 and items(6,12),(5,8),(5,8), ratio-greedy chooses value 12; the two weight 5 items give 16 under 0/1 rules. Specify whether the knapsack problem is fractional,0/1 or unbounded. Feasibility alone does not guarantee optimality.

Question sources

Algorithm Design & Analysis review questions · Question 37

Question 123 | NS0505

What is the All Pairs Shortest Path (APSP) problem and which algorithm solves it?

Hint

State the model and invariant, then derive the result from the cited procedure or recurrence, checking base cases and limitations.

Answer: APSP finds shortest distances for every ordered vertex pair; Floyd-Warshall is one DP algorithm.

DAA28 initializes direct-edge costs and progressively allows each vertex as an intermediate. Its min-plus recurrence gives $\Theta(V^3)$ time and $\Theta(V^2)$ storage. Negative cycles make affected pair distances lack a finite minimum; Floyd detects them through negative diagonals. Its cost is a taught solution rather than a universal best-achievable APSP bound.

Primary note proof

Study-note section DAA28

> For all-pairs distances initialize D[i, i]=0, D[i, j] to the minimum direct edge weight, and missing edges to∞. Preserve a negative self-loop by taking min(0, its weight). For k outermost, update D[i, j]=min(D[i, j], D[i, k]+D[k, j]); before phase k, intermediates are restricted to earlier vertices. Guard unreachable sums and numeric overflow.

Study-note section DAA28

> Three loops give $\Theta(V^3)$ time and $\Theta(V^2)$ storage. A negative diagonal afterward identifies a negative cycle; pairs able to traverse it have no finite minimum walk distance. Warshall reachability replaces min/+ by OR/AND. Floyd's cost is not a universal best-achievable bound for all APSP settings; sparse nonnegative graphs permit repeated Dijkstra and other models permit other methods.

Question sources

Algorithm Design & Analysis review questions · Question 38

Question 124 | NS0506

Describe the APSP initialization step. What values fill the matrix initially?

Hint

State the model and invariant, then derive the result from the cited procedure or recurrence, checking base cases and limitations.

Answer: Initialize D[i,i]=0, direct pairs to minimum edge weights, and missing edges to infinity.

DAA28 uses zero for the empty self-path, but preserves a negative self-loop by taking min(0, its weight). Parallel direct edges use their minimum. Infinity denotes no known route, so later arithmetic must guard unreachable sums and overflow. This is Floyd's initialization before intermediate vertices are considered, not an adjacency-only final answer.

Primary note proof

Study-note section DAA28

> For all-pairs distances initialize D[i, i]=0, D[i, j] to the minimum direct edge weight, and missing edges to∞. Preserve a negative self-loop by taking min(0, its weight). For k outermost, update D[i, j]=min(D[i, j], D[i, k]+D[k, j]); before phase k, intermediates are restricted to earlier vertices. Guard unreachable sums and numeric overflow.

Question sources

Algorithm Design & Analysis review questions · Question 39

Question 125 | NS0507

What is the DP update rule used in the APSP algorithm for each intermediate vertex k?

Hint

State the model and invariant, then derive the result from the cited procedure or recurrence, checking base cases and limitations.

Answer: D[i,j] ← min(D[i,j], D[i,k]+D[k,j]), with k outermost.

DAA28's phase invariant permits only earlier vertices as intermediates before phase k. Each pair then compares its current route with a route through k. Guard infinite operands and overflow rather than adding unreachable values blindly. Keeping k as the outer phase index is essential to the stated dependency proof.

Primary note proof

Study-note section DAA28

> For all-pairs distances initialize D[i, i]=0, D[i, j] to the minimum direct edge weight, and missing edges to∞. Preserve a negative self-loop by taking min(0, its weight). For k outermost, update D[i, j]=min(D[i, j], D[i, k]+D[k, j]); before phase k, intermediates are restricted to earlier vertices. Guard unreachable sums and numeric overflow.

Question sources

Question 126 | NS0508

Which design strategy explores ALL possible solutions by incrementally building candidates and abandoning invalid ones?

Hint

State the model and invariant, then derive the result from the cited procedure or recurrence, checking base cases and limitations.

Answer: Backtracking

DAA36 assigns the next choice, checks whether a feasible extension remains possible, recurses, and undoes the choice on return. A complete search reports every required candidate while pruning only impossible branches. Stop after one solution only if the task asks for existence or a single solution; otherwise early stopping would fail the ALL requirement.

Primary note proof

Study-note section DAA36

> Represent a partial assignment x[1.. k]. For each allowed next choice: assign it, test whether an extension remains possible, recurse if promising, and undo the assignment on return. Report complete feasible candidates; stop after one only if the task requests existence/a single answer. Explicit constraints restrict each variable’s domain; implicit constraints relate choices.

Algorithm Design & Analysis review questions · Question 41

Question 127 | NS0509

Explain why Greedy algorithms are not guaranteed to give a globally optimal solution, with an example.

Hint

State the model and invariant, then derive the result from the cited procedure or recurrence, checking base cases and limitations.

Answer: A locally attractive choice can block the optimum; coins {1,3,4} for target 6 are a counterexample.

DAA19's largest-first choice produces 4+1+1, using three coins, while 3+3 uses two. Once the greedy method keeps 4, it cannot repair the earlier choice within its irrevocable policy. Therefore local feasibility and attractiveness do not prove global optimality; a problem-specific exchange or safety proof is needed.

Primary note proof

Study-note section DAA19

> Advantages are often simple decisions and low overhead; limitations are irrevocable errors and problem-specific applicability. A heuristic has no approximation guarantee merely because it is greedy. For coins{1,3,4} and target 6, largest-first gives 4+1+1 while 3+3 uses fewer coins. Activity selection instead has a safe earliest-finish rule for maximizing the number of nonoverlapping unweighted intervals; replacing the first chosen activity in an optimum with an earlier-finishing one leaves at least as much room.

Question 128 | NS0510

For ordinary array quicksort, what partition pattern causes quadratic worst-case time, and how can randomized pivot selection or three-way partitioning mitigate relevant workloads? Distinguish expected-time improvements from worst-case and stack-space guarantees.

Hint

State the model and invariant, then derive the result from the cited procedure or recurrence, checking base cases and limitations.

Answer: Repeated very unbalanced partitions cause quadratic work. Random pivots give expected Theta(n log n) time; three-way partitioning helps repeated keys, and smaller-side recursion can limit stack space.

Extreme pivots can leave subproblems of sizes n-1,n-2 and so on, giving quadratic total partition work. Random pivots improve expected time to Theta(n log n) but do not remove quadratic possible executions. Three-way partitioning helps repeated keys, while median-of-three still admits adversarial inputs. Recursing only on the smaller side and iterating on the larger separately bounds stack depth by O(log n). No universal rarity claim is needed.

Primary note proof

Study-note section DAA15

> Balanced splits give $\Theta(n \log n)$; repeatedly highly unbalanced splits give $\Theta(n^2)$. Random pivots give expected $\Theta(n \log n)$, not a deterministic guarantee. Median-of-three does not eliminate adversarial cases; three-way partitioning helps repeated keys. Standard quicksort is unstable, uses expected $\Theta(\log n)$ stack but worst $\Theta(n)$; recursing on the smaller side and iterating on the larger bounds stack by $O(\log n)$.

Question sources

Algorithm Design & Analysis review questions · Question 43

Question 129 | NS0511

For the Job Sequencing algorithm, if two jobs have the same profit, how should ties be broken?

Hint

State the model and invariant, then derive the result from the cited procedure or recurrence, checking base cases and limitations.

Answer: Equal-profit jobs may be processed in any order under the stated unit-job assumptions.

DAA21 explicitly permits arbitrary equal-profit ordering; earlier deadline is an optional tie convention rather than a correctness requirement. Each accepted job still goes into its latest free slot finishing by its deadline. The freedom relies on the one-machine, initially available unit-duration model and does not automatically extend to variable durations or release times.

Primary note proof

Study-note section DAA21

> Sorting plus slot scans costs O(n log n+nD), with D capped at n. Equal-profit order is arbitrary; earlier deadline is optional. Variable durations/release times invalidate this rule.

Algorithm Design & Analysis review questions · Question 44

Question 130 | NS0512

Using the note's worst-case bounds, compare matrix-based Prim with Kruskal that comparison-sorts all edges on a dense simple undirected graph, where E=Theta(V^2). Why can this implementation pairing favor Prim asymptotically?

Hint

State the model and invariant, then derive the result from the cited procedure or recurrence, checking base cases and limitations.

Answer: Matrix Prim has O(V^2) time; edge-sorting Kruskal has O(E log E)=O(V^2 log V). The matrix implementation avoids the all-edge sorting factor.

The matrix-based Prim implementation scans vertex connections in O(V^2) time. Kruskal's stated bound includes sorting all E edges, giving O(E log E). For dense simple graphs E has order V^2, so that expression becomes O(V^2 log V), whereas matrix Prim retains its quadratic bound. This explains the advantage of the specified implementations and does not claim that every version of Prim is always faster in measured runtime.

Primary note proof

Study-note section DAA23

> Prim repeatedly adds the cheapest edge crossing from its current tree to an outside vertex. Kruskal sorts edges globally, accepting one only when union-find says its endpoints are in different components. The cut proof exchanges a light crossing edge into some optimum without raising its weight. Matrix Prim costs O(V^2); binary-heap Prim O(E log V), and Kruskal O(E log E). Dense-graph comparisons depend on these implementations. Disconnected input gives a minimum spanning forest.

Question sources

Algorithm Design & Analysis review questions · Question 45

Question 131 | NS0513

Can Dijkstra's Algorithm be applied to a graph with negative edge weights? Why or why not?

Hint

State the model and invariant, then derive the result from the cited procedure or recurrence, checking base cases and limitations.

Answer: Standard Dijkstra is not generally correct with negative edges.

DAA24's example $s \to a=2$, $s \to b=5$, $b \to a=-4$ finalizes a at 2 but a later route improves it to 1. That violates the nonnegative-edge finalization proof even without a negative cycle. Some instances may happen to work, but no general guarantee remains. Bellman-Ford or DAG DP supplies an appropriate alternative under its assumptions.

Primary note proof

Study-note section DAA24

> Nonnegative edges ensure a later path through unsettled vertices cannot improve a finalized distance. With $s \to a=2$, $s \to b=5$, $b \to a=-4$, finalizing a at 2 misses the later distance 1. Binary-heap/list implementation costs $O((V+E)\log V)$, matrix scanning $O(V^2)$. An MST minimizes total connection cost; Dijkstra minimizes each source-path distance, a different objective.

Study-note section DAA27

> For a general graph, Bellman-Ford relaxes all edges for up to $V-1$ passes and tests an additional pass for a reachable negative cycle: $O(VE)$. Thus "single-source shortest path" does not uniquely imply greedy; graph assumptions determine the algorithm.

Question sources

Algorithm Design & Analysis review questions · Question 46

Question 132 | NS0514

What is the time complexity of APSP using the Floyd-Warshall approach and why?

Hint

State the model and invariant, then derive the result from the cited procedure or recurrence, checking base cases and limitations.

Answer: $\Theta(V^3)$ time and $\Theta(V^2)$ distance storage.

DAA28 runs one intermediate-vertex phase for every k and examines every ordered pair i,j during each phase. V phases times V^2 constant-cost relaxations gives cubic time. The matrix has V^2 entries. These bounds assume bounded-cost arithmetic and do not claim that Floyd is universally optimal among all APSP algorithms or models.

Primary note proof

Study-note section DAA28

> For all-pairs distances initialize D[i, i]=0, D[i, j] to the minimum direct edge weight, and missing edges to∞. Preserve a negative self-loop by taking min(0, its weight). For k outermost, update D[i, j]=min(D[i, j], D[i, k]+D[k, j]); before phase k, intermediates are restricted to earlier vertices. Guard unreachable sums and numeric overflow.

Algorithm Design & Analysis review questions · Question 47

Question 133 | NS0515

Explain the difference between 'Divide and Conquer' and 'Dynamic Programming' using the Fibonacci problem.

Hint

State the model and invariant, then derive the result from the cited procedure or recurrence, checking base cases and limitations.

Answer: Naive Fibonacci has overlapping recursive calls; DP reuses them instead of treating them as independent.

DAA26 explicitly says naive Fibonacci is not the independent-subproblem ideal of divide and conquer. Both branches recompute states such as F(n−2), causing exponential calls. A cache or increasing-index table computes each state once, giving linear unit-cost additions. Recursion alone therefore does not establish a well-structured independent divide-and-conquer algorithm.

Primary note proof

Study-note section DAA26

> Naive Fibonacci recomputes F(n−2) across branches: call count is Θ(φ^n), with O(2^n) a valid loose upper bound. F(0)=0, F(1)=1 and F(i)=F(i−1)+F(i−2) yield Θ(n) unit-cost additions with memoization/tabulation. Keeping only two recent values uses Θ(1) machine words; arbitrary-precision output needs growing bit storage. This naive overlapping recursion is not the independent-subproblem ideal of D&C.

Study-note section DAA12

> Divide and conquer solves smaller largely independent instances and combines results.

Question sources

Algorithm Design & Analysis review questions · Question 48

Question 134 | NS0516

What does the recurrence T(n) = 2T(n/2) + O(n) represent and what is its solution?

Hint

State the model and invariant, then derive the result from the cited procedure or recurrence, checking base cases and limitations.

Answer: Two half-size recursive calls plus at most linear combine work; O(n log n), tight Θ(n log n) if combine work is Θ(n).

DAA14 warns that a written +O(n) term alone gives an upper bound rather than a matching lower bound. Expanding logarithmically many levels with at most linear aggregate work gives O(n log n). Ordinary merging actually costs Θ(n), supplying the tight result, but a cheaper unspecified combine function need not do so.

Primary note proof

Study-note section DAA14

> Ordinary array merge sort has T(n)=2T(n/2)+Θ(n)=Θ(n log n) across input orders, Θ(n) auxiliary buffer and Θ(log n) recursion depth. A written +O(n) recurrence alone establishes an upper bound; the tight result also uses linear merge work. Empty/singleton subarrays are base cases.

Question sources

Algorithm Design & Analysis review questions · Question 49

Question 135 | NS0517

How does the Optimal Merge Pattern relate to Huffman Coding?

Hint

State the model and invariant, then derive the result from the cited procedure or recurrence, checking base cases and limitations.

Answer: Both repeatedly combine the two smallest weights; Huffman interprets the resulting tree as a prefix code.

DAA22 uses file sizes as merge weights and frequencies as Huffman weights. Reinsert each combined weight so large values avoid unnecessary depth. In Huffman the weighted path length is ∑frequency×depth, the same merge-tree objective. Equal-weight choices can change codewords without changing the optimal total cost.

Primary note proof

Study-note section DAA22

> Combine the two smallest weights, add their sum to total cost, and reinsert it. A min-heap gives O(n log n) time/O(n) space. Cost p+q counts moved records; worst-case comparisons are p+q−1 for nonempty lists, and actual comparisons may be fewer.

Study-note section DAA22

> Huffman uses frequencies as weights and 0/1 branches to leaf symbols, making a prefix-free code. Cost is∑frequency×depth. An exchange makes the two least frequencies deepest siblings; contract them and induct. Ties can change codes without changing optimal cost. Header overhead can outweigh tiny-file savings.

Question sources

Algorithm Design & Analysis review questions · Question 50

Question 136 | NS0518

In Dynamic Programming, what is 'optimal substructure' and give one example.

Hint

State the model and invariant, then derive the result from the cited procedure or recurrence, checking base cases and limitations.

Answer: An optimal solution contains suitable optimal subsolutions; a DAG shortest path has an optimal suffix.

DAA25 justifies replacing a subsolution with a better one without breaking feasibility. For DAA27's DAG cost-to-go, if a chosen u→v route used a nonoptimal v-to-target suffix, replacing it with the cheaper suffix would improve the whole route, contradicting optimality. The state must retain enough information for this replacement argument to be valid.

Primary note proof

Study-note section DAA25

> Define state meaning, choices, recurrence, bases and dependency order. Prove replacing a subsolution by a better one improves the full solution; otherwise state information may be missing. Show the recurrence covers all legal final choices and generates feasible candidates, then induct in dependency order. Store choices for reconstruction.

Study-note section DAA27

> For a DAG or multistage graph, compute cost-to-go in reverse topological order: F(t)=0 and F(u)=min over outgoing(u, v) of[w(u, v)+F(v)]. Missing routes have∞. Record the minimizing next vertex. Equivalently propagate source distances forward. Complexity is Θ(V+E) with adjacency lists; negative edges are harmless without cycles. Follow the recurrence's dependencies when choosing the evaluation direction.

Question sources

Algorithm Design & Analysis review questions · Question 51

Question 137 | NS0622

What is the difference between Big O, Big Omega, and Big Theta notation? Provide examples.

Hint

State the model and invariant, then derive the result from the cited procedure or recurrence, checking base cases and limitations.

Answer: O is an eventual upper bound, Ω a lower bound, and Θ both.

DAA04 defines the relations by fixed constant-factor inequalities beyond a threshold. For $f=3n^2+4n+1$ and $n\geq 1$, $3n^2\leq f\leq 8n^2$, so $f\in\Theta(n^2)$, and consequently both $O(n^2)$ and $\Omega(n^2)$. It is also $O(n^3)$, showing that upper bounds need not be tight or name an input case.

Primary note proof

Study-note section DAA04

> For eventually nonnegative f, g, $f\in O(g)$ means $f(n)\leq c\cdot g(n)$ for all $n\geq n_0$, with fixed $c>0$. Ω reverses that inequality; Θ requires both bounds. Little-o means $f/g\to 0$, and little-ω means $f/g\to\infty$ where the ratio exists. Θ specifies growth up to constant factors, not exact seconds or identical best/worst cases.

Study-note section DAA04

> Also $3n^2+4n+1\leq 8n^2$ for $n\geq 1$.

Study-note section DAA05

> $O(n^2)$ also implies $O(n^3)$: upper bounds need not be tight.

Question sources

Algorithm Design & Analysis review questions · Question 1

Question 138 | NS0623

Why is Merge Sort $\Theta(n \log n)$ in all cases while Quick Sort can be $O(n^2)$?

Hint

State the model and invariant, then derive the result from the cited procedure or recurrence, checking base cases and limitations.

Answer: Merge has balanced halves with linear merging per level; quicksort can repeatedly keep an n−1 side.

DAA14 yields logarithmically many full linear-work merge levels across input orders. DAA15 allows extreme pivots creating the sum $n+(n-1)+\ldots$ and quadratic work. Random pivots improve expected quicksort performance without a worst-case guarantee. The comparison concerns ordinary merge sorting; optimizations that skip merges require their own best-case analysis.

Primary note proof

Study-note section DAA14

> Ordinary array merge sort has $T(n)=2T(n/2)+\Theta(n)=\Theta(n \log n)$ across input orders, $\Theta(n)$ auxiliary buffer and $\Theta(\log n)$ recursion depth. A written $+O(n)$ recurrence alone establishes an upper bound; the tight result also uses linear merge work. Empty/singleton subarrays are base cases.

Study-note section DAA15

> Balanced splits give $\Theta(n \log n)$; repeatedly highly unbalanced splits give $\Theta(n^2)$. Random pivots give expected $\Theta(n \log n)$, not a deterministic guarantee. Median-of-three does not eliminate adversarial cases; three-way partitioning helps repeated keys. Standard quicksort is unstable, uses expected $\Theta(\log n)$ stack but worst $\Theta(n)$; recursing on the smaller side and iterating on the larger bounds stack by $O(\log n)$.

Question sources

Algorithm Design & Analysis review questions · Question 2

Question 139 | NS0624

When would you choose a greedy algorithm over dynamic programming?

Hint

State the model and invariant, then derive the result from the cited procedure or recurrence, checking base cases and limitations.

Answer: Choose greedy when a local-choice safety proof exists and its lower overhead meets the task.

DAA19 supports exchange arguments that insert the greedy choice into some optimum without worsening it. With that proof, irrevocable decisions can avoid a DP table and simplify implementation. If local safety is absent but a correct reusable-state recurrence exists, DP is a stronger candidate. Optimal substructure alone is not enough to justify greedy.

Primary note proof

Study-note section DAA19

> A greedy algorithm repeatedly selects a locally attractive feasible option without later undoing it. Optimal substructure alone does not prove this safe. An exchange proof inserts the greedy choice into an optimum without worsening cost; recurse. MST cut proofs use this exchange.

Study-note section DAA19

> Advantages are often simple decisions and low overhead; limitations are irrevocable errors and problem-specific applicability.

Question sources

Algorithm Design & Analysis review questions · Question 3

Question 140 | NS0625

Why is naive recursive Fibonacci $O(2^n)$ while DP Fibonacci is O(n)?

Hint

State the model and invariant, then derive the result from the cited procedure or recurrence, checking base cases and limitations.

Answer: Naive recursion repeats states exponentially; DP computes n states once.

DAA26 gives tight naive call growth Θ(φ^n), so O(2^n) is a valid loose upper bound rather than the exact rate. Memoization or tabulation needs Θ(n) unit-cost additions and can keep two rolling values for value-only output. Arbitrary-precision arithmetic grows with output bit length and is not truly constant cost per addition.

Primary note proof

Study-note section DAA26

> Naive Fibonacci recomputes F(n−2) across branches: call count is Θ(φ^n), with O(2^n) a valid loose upper bound. F(0)=0, F(1)=1 and F(i)=F(i−1)+F(i−2) yield Θ(n) unit-cost additions with memoization/tabulation. Keeping only two recent values uses Θ(1) machine words; arbitrary-precision output needs growing bit storage. This naive overlapping recursion is not the independent-subproblem ideal of D&C.

Question sources

Algorithm Design & Analysis review questions · Question 5

Question 141 | NS0626

Apply the Master Theorem to $T(n) = 4T(n/2) + n^2$. What is the solution?

Hint

State the model and invariant, then derive the result from the cited procedure or recurrence, checking base cases and limitations.

Answer: $\Theta(n^2 \log n)$

DAA10 has a=4, b=2, so n^(log_b a)=n^2. The additive f(n)=n^2 matches that power, selecting the balanced second case. Its logarithmically many levels each contribute $\Theta(n^2)$, including the appropriate base work, so the total is $\Theta(n^2 \log n)$. The polynomial-gap regularity condition belongs to the larger-f third case and is unnecessary here.

Primary note proof

Study-note section DAA10

> For T(n)=aT(n/b)+f(n), a≥1, b>1, let p=log_b a. Level i has a^i nodes of size n/b^i. Compare f with n^p: a polynomial gap below gives Θ(n^p); f=Θ(n^p) gives Θ(n^p log n); a polynomial gap above gives Θ(f(n)) if a f(n/b)≤c f(n) for fixed c<1. The third case needs this regularity condition.

Study-note section DAA10

> Also $4T(n/2)+n^2$ gives $\Theta(n^2 \log n)$, case 2.

Question 1 | Q00001

Which one of the following is concerned with the meaning of a sentence in knowledge representation?

A. Structure

B. Computational aspect

C. Semantics

D. Syntax

Hint

Read the definition and the classification axis requested; distinguish the defining purpose from supporting techniques or implementation resources.

Answer C: Semantics

Semantics assigns meaning to sentences; syntax restricts their legal construction (PDF p. 43). The stem asks about meaning rather than representation layout or computational efficiency.

Why each choice is right or wrong

A - Incorrect: Structure concerns arrangement, not the stated meaning rule. See PDF p. 43.

B - Incorrect: Computational aspects concern processing rather than the interpretation definition. See PDF p. 43.

C - Correct: This is precisely the module definition of assigning meaning. See PDF p. 43.

D - Incorrect: Syntax decides legal symbols and sentence construction. See PDF p. 43.

Primary note proof

Study-note section AI24

> Knowledge representation encodes facts, objects, relations, events and rules so a machine can use them. Syntax defines legal expressions; semantics defines their meaning. A knowledge base stores assertions; an inference system derives consequences. Declarative knowledge says what is true; procedural knowledge specifies how to act.

> o Semantic also involves assigning a meaning to each sentence.
> o It can be two logics : Propositional Logics and Predicate logics

Question sources

MOE Computer Science Exit Exam · 2016 · Question 1

Question 2 | Q00007

Which one of the following agents works by searching and matching the rules defined by percent and stored internal state?

A. Model-based reflex agent

B. Goal-based agent

C. Simple reflex agent

D. Utility based agent

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer A: Model-based reflex agent

Taking “percent” as a typographical error for percept, the stored internal state records percept history and the model specifies world evolution (PDF p. 14). That distinguishes model-based reflex selection from a simple current-percept rule.

Why each choice is right or wrong

A - Correct: Combines a model and retained internal state. See PDF p. 14, 14.

B - Incorrect: Goal-based selection needs a desired goal, absent here. See PDF p. 14, 14.

C - Incorrect: Ignores percept history and therefore cannot account for the stated memory. See PDF p. 14, 14.

D - Incorrect: Requires a utility measurement, absent here. See PDF p. 14, 14.

Primary note proof

Study-note section AI06

> A simple reflex agent matches condition-action rules against the current percept only: if dirty, clean. It has no persistent world-state memory. This is adequate when the current observation contains everything needed for its rule, but partial observability can make the same percept require different actions.

Study-note section AI06

> A model-based reflex agent maintains internal state using the previous state, previous action, current percept, and models of world change and action effects. It then applies rules to that state. Both kinds can use condition-action rules; memory and a world model distinguish them.

Study-note section AI07

> A goal-based agent considers future action sequences that reach a desired state. A utility-based agent compares degrees of desirability and trade-offs, choosing maximum expected utility: $EU(a)=\Sigma s\ P(s|a,evidence)U(s)$. Reaching the destination is a goal; balancing arrival time, safety and cost requires preferences among outcomes.

Question sources

MOE Computer Science Exit Exam · 2016 · Question 7

Question 3 | Q00028

Assume the entire state space and transition model are known for every task below, despite any hidden current state. Which problem/environment coupling is incorrect?

A. Contingency problem -> partially observable, non-deterministic

B. Multiple state problem deterministic, partially observable

C. Exploration problem -> partially observable, deterministic

D. Single state problem-> fully observable, deterministic

Hint

Read the definition and the classification axis requested; distinguish the defining purpose from supporting techniques or implementation resources.

Answer C: Exploration problem -> partially observable, deterministic

A known deterministic model with incomplete observation can be handled by a belief state representing several possible current states. Unknown state spaces or transition models create the need for exploration; partial observability alone does not. Nondeterministic partial observation can require contingency branches, while full observation with known deterministic transitions supports a single-state formulation. The explicit knowledge assumption therefore makes the exploration pairing the incorrect one.

Why each choice is right or wrong

A - Incorrect: This is a valid coupling: partial observation and nondeterminism can require contingency branches, so it is not the incorrect pairing.

B - Incorrect: This is valid under the known-model assumption: incomplete observation can require a belief state, so it is not selected.

C - Correct: This is the incorrect coupling: hidden state with a known deterministic model does not by itself require exploration.

D - Incorrect: This is valid: full observation and known deterministic transitions support a single current state.

Primary note proof

Study-note section AI10

> With a known deterministic model and full observation, a single current state can be used. Without observation but with known deterministic transitions, a sensorless or multiple-state problem tracks a belief state: a set of possible states.

Study-note section AI10

> Nondeterminism or partial observation may require a contingency plan with branches based on later percepts. Exploration or online search is required when the state space or transition model is unknown; observation alone does not identify this category. These classifications can overlap. A pairing based only on “partially observable, deterministic” cannot distinguish a known sensorless problem from an unknown exploration problem.

Question sources

MOE Computer Science Exit Exam · 2016 · Question 28

Question 4 | Q00033

Which one of the following is correct first order logic for the statement "There is someone standing at the door and is tall"?

A. ∀x (StandingAt (x; door)

B. ∀x (StandingAt (x; door)^ tall(x))

C. ∃x (StandingAt (x; door)^ tall(x))

D. ∃x (StandingAt (x; door) -> toll(x))

Hint

Translate the statement carefully, then check the scope of its quantifiers, connectives or inference rule. Distinguish guaranteed consequences from plausible generalizations or explanations.

Answer C: ∃x (StandingAt (x; door)^ tall(x))

“There is someone” requires ∃x, and “standing ... and ... tall” requires StandingAt(x,door) ∧ tall(x), so C asserts one witness with both properties (PDF pp. 46, 49). An implication does not assert its antecedent and therefore cannot assert that anyone is at the door.

Why each choice is right or wrong

A - Incorrect: Incomplete formula with a universal quantifier and no tall predicate. See PDF p. 49, 46.

B - Incorrect: Claims everyone has both properties rather than at least one person. See PDF p. 49, 46.

C - Correct: Existentially binds the same x in both conjuncts. See PDF p. 49, 46.

D - Incorrect: Uses implication instead of conjunction and also spells the predicate toll. See PDF p. 49, 46.

Primary note proof

Study-note section AI26

> Use ∀x(Human(x)→Mortal(x)) for all humans, and ∃x(Student(x)∧Tall(x)) for at least one tall student. These are useful translation patterns, not rules forbidding other connectives. ∀x∃y Likes(x,y) allows a different y for each x; ∃y∀x Likes(x,y) requires one shared y. Negation swaps quantifiers: ¬∀x P(x) ≡ ∃x¬P(x). Only occurrences within the correct quantifier’s scope are bound.

Study-note section AI25

> Propositional atoms represent whole true-or-false claims. ¬P negates; P∧Q requires both; P∨Q requires at least one; P→Q is false only when P is true and Q false; P↔Q requires matching truth values. Thus P→Q ≡ ¬P∨Q. De Morgan gives ¬(P∧Q) ≡ ¬P∨¬Q.

Question sources

MOE Computer Science Exit Exam · 2016 · Question 33

Question 5 | Q00057

Which statements are incorrect? Interpret rational action as maximizing expected performance given available information; do not assume a successful action always exists. Select all that apply.

A. A rational agent know the result of its action, but unrealistic

B. Rational agent take action but not 100% sure of success

C. Rational agent act to achieve utmost success based on information

D. An omniscience agent takes actions for 100% sure of success

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer A, D: A rational agent know the result of its action, but unrealistic; An omniscience agent takes actions for 100% sure of success

Rationality concerns choosing the action with the best expected performance given the agent's information. It does not mean knowing actual outcomes in advance, so the first claim incorrectly attributes omniscience to a rational agent. Even omniscience would not ensure success if all available actions fail. The remaining statements correctly allow uncertainty while requiring the best expected choice under the available evidence.

Why each choice is right or wrong

A - Correct: This is false: rationality does not imply knowing actual action outcomes in advance.

B - Incorrect: This is true: a rational action need not guarantee success.

C - Incorrect: This is true when utmost success means best expected performance given the available information.

D - Correct: This is false: complete outcome knowledge cannot guarantee that a successful action exists.

Primary note proof

Study-note section AI04

> A performance measure defines success externally: safety, useful deliveries, elapsed time, or cost. Rationality depends on that measure, prior knowledge, percept history, and available actions. A rational agent selects the action with the best expected performance given its information.

Study-note section AI04

> Omniscience would mean knowing actual action outcomes in advance. Rationality does not require omniscience or guaranteed success. Even complete outcome knowledge cannot create a successful action when every available action fails. Information gathering and exploration may therefore be rational actions.

Question sources

MOE Computer Science Exit Exam · 2016 · Question 57

Question 6 | Q00059

_____ finds the shortest path to the goal based on cost.

A. Depth first search

B. Iterative deepening

C. Uniform cost search

D. Breath first search

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer C: Uniform cost search

Uniform-cost search explicitly seeks the goal path with lowest cumulative cost and uses a priority queue (PDF p. 21). “Shortest” here means minimum cost, under the usual nonnegative-cost setting; minimum depth alone is not sufficient when edge costs vary.

Why each choice is right or wrong

A - Incorrect: Follows depth and is explicitly nonoptimal on p. 19. See PDF p. 21, 21.

B - Incorrect: Increases depth limits, not cumulative-cost priority. See PDF p. 21, 21.

C - Correct: Directly minimizes cumulative path cost. See PDF p. 21, 21.

D - Incorrect: Minimizes steps; equivalent to UCS only when all edge costs are equal. See PDF p. 21, 21.

Primary note proof

Study-note section AI15

UCS uses a priority queue ordered by actual accumulated path cost g(n). Remove a minimum-g node; accept a goal when removed, not when first generated. Relax each edge: if a cheaper path is found, update its frontier cost and parent.

Study-note section AI15

With finite branching and each step at least ε>0, UCS is complete and optimal. Finite graphs permit nonnegative edges with proper duplicate handling. Dijkstra uses the same minimum-distance principle, often computing all reachable distances; UCS commonly stops at a goal and generates states on demand. Queue initialization is an implementation choice, not a fundamental distinction. Negative edges invalidate the usual finalized-distance argument.

Study-note section AI13

BFS removes the oldest frontier entry using a FIFO queue. Start with the root, remove the head, test it, append unseen successors at the tail, and repeat. It explores depths 0,1,2,... and is complete for finite b and a finite-depth goal. It minimizes number of edges, so minimum cost requires equal positive step costs.

Study-note section AI16

DLS runs DFS to depth l and reports cutoff separately from failure. It misses goals deeper than l. Iterative deepening runs DLS with limits 0,1,2,...; for finite b it finds the shallowest solution with O(b^d) time and O(bd) frontier space, optimal for equal step costs. Repeated shallow work is small compared with the deepest level.

MOE Computer Science Exit Exam · 2016 · Question 59

Question 7 | Q00172

The data structure used in the standard implementation of Depth First Search is ?

A. Stack

B. Array

C. Linked List

D. Queue

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer A: Stack

DFS uses a stack (PDF p. 18): the newest pending state is explored first. Arrays or linked lists could implement a stack, but they do not themselves specify the required access order.

Why each choice is right or wrong

A - Correct: Explicitly named implementation structure. See PDF p. 18.

B - Incorrect: May store a stack but does not specify LIFO behavior. See PDF p. 18.

C - Incorrect: May implement a stack but is not the stated abstract structure. See PDF p. 18.

D - Incorrect: FIFO queue is used for BFS on p. 20. See PDF p. 18.

Primary note proof

Study-note section AI14

> DFS follows the deepest pending branch using a LIFO stack or recursion. FILO means the same order as LIFO. With the same children as BFS, a left-first DFS visits S,A,C before B; push rightmost children first to pop the leftmost first.

Study-note section AI13

> BFS removes the oldest frontier entry using a FIFO queue. Start with the root, remove the head, test it, append unseen successors at the tail, and repeat. It explores depths 0,1,2,... and is complete for finite b and a finite-depth goal. It minimizes number of edges, so minimum cost requires equal positive step costs.

Study-note section AI-S02

> Binary search exploits the order of a sorted sequence: a comparison narrows the remaining candidate interval instead of exploring arbitrary successor states. Array bisection therefore differs from breadth-first or depth-first traversal of a general state-space graph. A storage container such as an array does not by itself specify FIFO or LIFO frontier behavior.

Question sources

Addis Ababa University mock exam · Question 74

Question 8 | Q00178

Among the following, which kind of algorithm is used in the Game tree to make decisions of Win/Lose?

A. Heuristic Search Algorithm

B. Min/Max Algorithm

C. Depth First Search Algorithm

D. Greedy Search Algorithm

Hint

Read the definition and the classification axis requested; distinguish the defining purpose from supporting techniques or implementation resources.

Answer B: Min/Max Algorithm

Minimax recursively backs up utilities, choosing maxima on MAX turns and minima on MIN turns, so it selects moves against an optimal opponent (PDF pp. 33-34). DFS is its traversal mechanism rather than the adversarial decision rule.

Why each choice is right or wrong

A - Incorrect: A broad category, not the specified alternating-player rule. See PDF p. 33, 34.

B - Correct: Provides the game-tree decision procedure. See PDF p. 33, 34.

C - Incorrect: Traverses the tree but alone does not compare opponent utilities. See PDF p. 33, 34.

D - Incorrect: Chooses local heuristic promise rather than alternating MAX/MIN decisions. See PDF p. 33, 34.

Primary note proof

Study-note section AI22

> Minimax assigns terminal utilities, takes minima at MIN nodes and maxima at MAX nodes, then chooses a maximum-valued root action. It gives the best guaranteed outcome against optimal opposition within the modeled tree. For stochastic outcomes add chance nodes weighted by probabilities.

Study-note section AI23

> At a depth cutoff use an evaluation function estimating position desirability. Positive favors the designated MAX player, negative MIN; the scale is a convention, with +1/0/−1 often win/draw/loss. Material counts weighted pieces; mobility counts legal options; territory scores controlled regions. These are different features, often combined. Heuristics improve limited computation, not guarantee victory.

Question 9 | Q00179

Agents' behavior can be best described by

A. Perception sequence

B. Agent function is performing

C. Sensors and Actuators

D. Environment in which agent

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer B: Agent function is performing

The module evaluates behavior and performance through the agent function, a mapping from perception history to action (PDF p. 11). B is grammatically incomplete but identifies that function.

Why each choice is right or wrong

A - Incorrect: Input history alone does not specify the selected actions. See PDF p. 11.

B - Correct: Names the function that describes action behavior. See PDF p. 11.

C - Incorrect: Describe input/output mechanisms, not the complete action mapping. See PDF p. 11.

D - Incorrect: Provides context, not the mapping. See PDF p. 11.

Primary note proof

Study-note section AI03

A percept is one observation; a percept sequence is the entire observation history. An agent function maps percept sequences to actions: f:P*→A. An agent program implements that mapping on an architecture; agent = architecture + program. Environment means the setting in

> which it senses and acts, not merely the search space. Autonomy means relying substantially on experience rather than only a designer's prior instructions.

Study-note section AI03

> An agent perceives an environment through sensors and acts through actuators or effectors. Cameras sense; motors move. Software sensors may be incoming messages and software actions may be API requests. Humans are agents but are not artificial agents.

> • The behaviour and performance of intelligent agents have to be evaluated in terms of the agent function.

Question sources

Addis Ababa University mock exam · Question 81

Question 10 | Q00180

Which type of agent deals with happy and unhappy states?

A. Simple reflex agent

B. Model based agent

C. Utility based agent

D. Learning agent

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer C: Utility based agent

Happy/unhappy is an informal description of desirability. The utility function assigns each state a real number measuring how well actions achieve goals (PDF p. 15). The module does not literally use those emotional terms.

Why each choice is right or wrong

A - Incorrect: Selects current-percept rules, not ranked desirability. See PDF p. 15.

B - Incorrect: Tracks world state, without requiring desirability scores. See PDF p. 15.

C - Correct: Uses the state preference measure described in the stem. See PDF p. 15.

D - Incorrect: Improves through experience rather than defining state desirability. See PDF p. 15.

Primary note proof

Study-note section AI07

A goal-based agent considers future action sequences that reach a desired state. A utility-based agent compares degrees of desirability and trade-offs, choosing maximum expected utility: EU(a)=Σs P(s | a,evidence)U(s). Reaching the destination is a goal; balancing arrival time, safety and cost requires preferences among outcomes.

Study-note section AI06

A simple reflex agent matches condition-action rules against the current percept only: if dirty, clean. It has no persistent world-state memory. This is adequate when the current observation contains everything needed for its rule, but partial observability can make the same percept require different actions.

Study-note section AI08

The performance element selects actions. The learning element changes the agent to improve future performance. The critic evaluates behavior against a performance standard and supplies feedback. The problem generator suggests exploratory actions likely to yield useful experience.

Module passages - related reading

the goals.

Question sources

Addis Ababa University mock exam · Question 82

Question 11 | Q00181

What is the purpose of "Agent" in Artificial Intelligence?

A. Mapping of goal sequence to an action

B. Work without the direct interference of the people

C. Mapping of environment sequence to an action

D. Mapping of precept sequence to an action

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer D: Mapping of precept sequence to an action

The module defines Agent Function as a map from the percept sequence to an action (PDF p. 10). “Precept” is a spelling error for percept. D matches the definition in the current option order.

Why each choice is right or wrong

A - Incorrect: Goals are not the input sequence in the definition. See PDF p. 10.

B - Incorrect: Describes autonomy, not the function sought. See PDF p. 10.

C - Incorrect: The environment itself is not a percept sequence. See PDF p. 10.

D - Correct: Matches the stated percept-sequence-to-action mapping. See PDF p. 10.

Primary note proof

Study-note section AI03

> A percept is one observation; a percept sequence is the entire observation history. An agent function maps percept sequences to actions: f:P*→A. An agent program implements that mapping on an architecture; agent = architecture + program. Environment means the setting in which it senses and acts, not merely the search space. Autonomy means relying substantially on experience rather than only a designer’s prior instructions.

Study-note section AI04

> A performance measure defines success externally: safety, useful deliveries, elapsed time, or cost. Rationality depends on that measure, prior knowledge, percept history, and available actions. A rational agent selects the action with the best expected performance given its information.

Question sources

Addis Ababa University mock exam · Question 83

Artificial Intelligence practice questions · Question 25

Question 12 | Q00182

Here “exploratory learning” means discovering structure in data without target labels, oracle labeling or reward-driven interaction. Which learning regime is meant?

A. Supervised learning

B. Active learning

C. Unsupervised learning

D. Reinforcement learning

E. None of the Above

Hint

Identify the training feedback, prediction target or measured error. Keep learning objectives separate from model architecture and data modality.

Answer C: Unsupervised learning

Unsupervised learning seeks patterns such as clusters or associations without target labels. Active learning asks an oracle to label selected cases, supervised learning fits labeled input-target examples, and reinforcement learning improves behavior from reward-driven interaction. Specifying the feedback makes the intended use of exploratory precise. The term alone would have several usages, but the stated unlabeled structure-discovery task identifies a definite learning regime.

Why each choice is right or wrong

A - Incorrect: Supervised learning uses labeled targets, excluded by the stem.

B - Incorrect: Active learning obtains oracle labels, excluded by the stem.

C - Correct: Unsupervised learning discovers structure without target labels.

D - Incorrect: Reinforcement learning uses reward-driven interaction, excluded here.

E - Incorrect: The specified regime is present among the choices.

Primary note proof

Study-note section AI32

> Unsupervised learning seeks structure without target labels: clustering groups similar examples; association finds co-occurrence; dimensionality reduction compresses features. Good clusters have high within-cluster similarity and low between-cluster similarity under an appropriate distance. K-means alternates assignment to nearest centroids and centroid updates.

Study-note section AI32

> Semi-supervised learning combines some labels with additional unlabeled data. Active learning chooses informative cases for an oracle to label; it still uses labels. “Exploratory learning” is not an exclusive standard synonym: it can mean unsupervised exploration or active data acquisition, so define the feedback. A task named summarization or time-series analysis is not automatically supervised; its training targets determine that.

Study-note section AI33

> An RL agent observes state information, takes an action, receives reward and a new observation, and improves its policy to maximize expected cumulative reward. Rewards evaluate outcomes rather than supply the correct action label. Rewards may be delayed; not every correct-looking action receives immediate reward.

Question sources

Addis Ababa University mock exam · Question 84

Question 13 | Q00183

Let F(x,y,t) mean that person x can fool person y at time t. Over nonempty person and time domains, which statement is equivalent to ∀x∃y∃t ¬F(x,y,t)?

A. Everyone can fool some person at some time

B. Every person has someone whom they cannot fool at any time.

C. No person can fool any person at any time.

D. No one can fool everyone all the time

Hint

Translate the statement carefully, then check the scope of its quantifiers, connectives or inference rule. Distinguish guaranteed consequences from plausible generalizations or explanations.

Answer D: No one can fool everyone all the time

For each person x, the formula requires a person y and a time t for which fooling fails. Moving negation across the quantifiers gives ¬∃x∀y∀t F(x,y,t): nobody can fool everyone all the time. The witness and time can depend on x. Requiring failure at every time, or forbidding all fooling events, would be stronger claims.

Why each choice is right or wrong

A - Incorrect: This asserts a successful fooling event for each person, rather than an unsuccessful event.

B - Incorrect: This requires one witness person who cannot be fooled at every time, a stronger time scope than the formula requires.

C - Incorrect: This forbids all fooling events, much stronger than requiring one unsuccessful event for each person.

D - Correct: Negating someone fooling everyone at every time yields, for each person, someone and some time when fooling fails.

Primary note proof

Study-note section AI26

> Use ∀x(Human(x)→Mortal(x)) for all humans, and ∃x(Student(x)∧Tall(x)) for at least one tall student. These are useful translation patterns, not rules forbidding other connectives. ∀x∃y Likes(x,y) allows a different y for each x; ∃y∀x Likes(x,y) requires one shared y. Negation swaps quantifiers: ¬∀x P(x) ≡ ∃x¬P(x). Only occurrences within the correct quantifier's scope are bound.

Study-note section AI44

> The formula ∀x∃y∃t¬F(x,y,t) means that for each person there is a person and time at which fooling fails. By quantifier negation this is ¬∃x∀y∀t F(x,y,t), so nobody fools everybody all the time. Forbidding every successful instance is a much stronger claim than this formula.

Question sources

Addis Ababa University mock exam · Question 85

Question 14 | Q00184

A language system must decide which interpretation is intended when a sentence permits more than one meaning or grammatical attachment. Which NLP challenge does this describe?

A. Handling Tokenization

B. Handling Ambiguity of Sentences

C. Handling POS-Tagging

D. Handling Semantics of Sentences

E. All of the mentioned

Hint

Match the input, output and purpose to the appropriate language, perception or physical-action task.

Answer B: Handling Ambiguity of Sentences

The difficulty described is ambiguity: a word or sentence can permit multiple meanings or structural attachments. Tokenization creates units, POS tagging assigns grammatical roles, and semantic analysis concerns meaning. These tasks can help resolve ambiguity, but they are not synonymous with the particular obstacle. The question therefore asks for the named challenge rather than ranking all NLP difficulties.

Why each choice is right or wrong

A - Incorrect: Tokenization decides processing units; it does not name the existence of multiple interpretations.

B - Correct: Ambiguity means that more than one interpretation is possible.

C - Incorrect: POS tagging assigns grammatical categories rather than naming the competing interpretations.

D - Incorrect: Semantics studies meaning generally; the specific obstacle described is multiplicity of interpretations.

E - Incorrect: This includes tokenization, tagging and semantic analysis in general, which do not all name the specific multiple-interpretation obstacle.

Primary note proof

Study-note section AI37

> Tokenization divides text into processing units; tokens may be words, punctuation or subwords. POS tagging assigns grammatical roles; named-entity recognition identifies people, organizations and locations. Parsing identifies grammatical structure; semantics concerns meaning; discourse links sentences; pragmatics uses context and speaker intent. Sentiment analysis predicts evaluative tone. Ambiguity can occur at every level: “bank” has multiple senses, and “I saw the man with a telescope” has multiple attachments.

Study-note section AI37

NLP interprets and generates human language: translation, dialogue, summarization, question answering and text generation. Speech recognition converts audio to text; speech synthesis generates speech. They overlap language processing but solve different input/output tasks.

Introduction to Artificial Intelligence module | PDF page 81 | lines 6-7

- NLP is difficult because Ambiguity and Uncertainty exist in the language.
- Ambiguity

Introduction to Artificial Intelligence module | PDF page 80 | lines 18-19

- Semantic analysis is concerned with the meaning representation. It mainly focuses on the literal meaning of words, phrases, and sentences.

Question sources

Addis Ababa University mock exam · Question 86

Question 15 | Q00199

A goal-directed search strategy uses a problem-specific estimate of remaining cost to order current frontier candidates. Which category is it?

A. Uninformed search

B. Informed search

C. Circular traversal without heuristic estimates

D. Binary search

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer B: Informed search

Informed search uses problem-specific heuristic information to estimate remaining cost or promise. Merely retaining the current state would not establish that category, because uninformed search also uses states, successors and known costs. The revised stem supplies the missing estimate. Binary search concerns an ordered interval rather than this state-space frontier, and circular traversal does not identify the heuristic-informed category being tested.

Why each choice is right or wrong

A - Incorrect: Uninformed search lacks the extra remaining-cost heuristic specified here.

B - Correct: Informed search uses problem-specific heuristic estimates to guide the frontier.

C - Incorrect: Traversal without heuristic estimates does not meet the specified remaining-cost-guided strategy.

D - Incorrect: Binary search needs an ordered search interval, not merely goal-directed state exploration.

Primary note proof

Study-note section AI17

A heuristic h(n) estimates remaining cost or evaluates promise using problem-specific knowledge. It can reduce explored work, but computing it also costs time. Uninformed algorithms use only the problem definition and known costs; UCS remains uninformed despite using g.

Study-note section AI-S02

Binary search exploits the order of a sorted sequence: a comparison narrows the remaining candidate interval instead of exploring arbitrary successor states. Array bisection therefore differs from breadth-first or depth-first traversal of a general state-space graph. A storage container such as an array does not by itself specify FIFO or LIFO frontier behavior.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Introduction to Artificial Intelligence module | PDF page 18 | lines 23-24

• The uninformed search does not contain any domain knowledge such as closeness, the location of
the goal. It is also called level order traversal.

Introduction to Artificial Intelligence module | PDF page 24 | lines 14-15

• It uses domain knowledge. In an informed search, problem information is available which can guide
the search.

Question sources

Mock exam 4 · Question 1

Question 16 | Q00200

An agent’s actions affect later decisions; identical state-action pairs can have different outcomes; and the world changes while the agent deliberates. Which list describes these three properties?

A. Deterministic, fully observable, static

B. Fully observable, sequential, deterministic

C. Partially observable, static, continuous

D. Sequential, non-deterministic, dynamic

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer D: Sequential, non-deterministic, dynamic

The scenario establishes three independent dimensions. Earlier actions affect later decisions, so it is sequential. Outcomes are not fixed by the state-action pair, so it is non-deterministic. Change during deliberation makes it dynamic. It gives no complete observation or continuity specification. Classifying the stated properties avoids an unsupported universal ranking of how difficult different environments must be.

Why each choice is right or wrong

A - Incorrect: Determinism and a static world contradict the uncertain outcomes and ongoing change.

B - Incorrect: Sequential fits, but deterministic outcomes contradict the scenario.

C - Incorrect: A static environment cannot change while the agent deliberates; this list also omits the stated action dependence.

D - Correct: Sequential captures dependent decisions, non-deterministic captures uncertain outcomes, and dynamic captures change during deliberation.

Primary note proof

Study-note section AI09

> Fully observable means sensors reveal relevant state; partially observable means relevant information is hidden or noisy. Deterministic means state and action determine the next state; stochastic means outcomes involve randomness. Strategic uncertainty about an opponent is distinct from dice-like randomness.

Study-note section AI09

> Episodic decisions are independent; sequential decisions affect later situations. Static worlds do not change while deliberating; dynamic ones do. A clock affecting score makes an otherwise static game semidynamic. Discrete quantities have distinct alternatives; continuous quantities vary along real-valued ranges. Known versus unknown concerns knowledge of the transition model, not observability.

Variant 1 | Alternative version 1

An agent's actions affect later decisions; identical state-action pairs can have different outcomes; and the world changes while the agent deliberates. Which list describes these three properties?

A. Partially observable, non-deterministic, sequential, dynamic

B. Deterministic, sequential (non-episodic), dynamic, continuous

C. Static, episodic, continuous, partially observable

D. Fully observable, discrete, episodic, static

Answer A: Partially observable, non-deterministic, sequential, dynamic

Incomplete observations establish partial observability, uncertain transitions establish non-determinism, consequences for later decisions establish sequentiality, and change during deliberation establishes dynamics. The other lists contradict at least one of those conditions. No universal difficulty comparison is needed.

Why each choice is right or wrong

A - Correct: All four properties match the stated scenario.

B - Incorrect: Determinism contradicts uncertain transition outcomes.

C - Incorrect: Static and episodic contradict ongoing change and consequences for later decisions.

D - Incorrect: Full observability, episodicity and static conditions each contradict the scenario.

Primary note proof

Study-note section AI09

> Fully observable means sensors reveal relevant state; partially observable means relevant information is hidden or noisy. Deterministic means state and action determine the next state; stochastic means outcomes involve randomness. Strategic uncertainty about an opponent is distinct from dice-like randomness.

Study-note section AI09

> Episodic decisions are independent; sequential decisions affect later situations. Static worlds do not change while deliberating; dynamic ones do. A clock affecting score makes an otherwise static game semidynamic. Discrete quantities have distinct alternatives; continuous quantities vary along real-valued ranges. Known versus unknown concerns knowledge of the transition model, not observability.

Question 17 | Q00201

An agent which mainly operates based on a knowledge about "how things happen in the world" and representation of the current state based on percept history is

A. Simple reflex agent

B. Goal based agent

C. Utility based agent

D. Model based agent

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer D: Model based agent

The wording reproduces the two model-based factors: knowledge of how the world changes and a current-state representation based on percept history (PDF p. 14). No explicit goal or utility comparison is requested.

Why each choice is right or wrong

A - Incorrect: Ignores history. See PDF p. 14, 14.

B - Incorrect: Adds goals, which are not specified. See PDF p. 14, 14.

C - Incorrect: Adds a utility measure, which is not specified. See PDF p. 14, 14.

D - Correct: Both defining factors match directly. See PDF p. 14, 14.

Primary note proof

Study-note section AI06

> A model-based reflex agent maintains internal state using the previous state, previous action, current percept, and models of world change and action effects. It then applies rules to that state. Both kinds can use condition-action rules; memory and a world model distinguish them.

Study-note section AI07

> A goal-based agent considers future action sequences that reach a desired state. A utility-based agent compares degrees of desirability and trade-offs, choosing maximum expected utility: $EU(a)=\Sigma s\ P(s|a,evidence)U(s)$. Reaching the destination is a goal; balancing arrival time, safety and cost requires preferences among outcomes.

C. Stratified cross-validation

D. Holdout method

Hint

Identify the training feedback, prediction target or measured error. Keep learning objectives separate from model architecture and data modality.

Answer B: k-fold cross-validation.

AI35 describes exactly the rotation in the stem: build k models, each trained on all folds except one, evaluate on that held-out fold, then average the scores. The stem does not say class proportions are preserved, so stratification is not established. A single holdout split or generic random sampling does not specify this complete rotation.

Why each choice is right or wrong

A - Incorrect: Random sampling alone does not specify the disjoint k-fold rotation of training and test subsets.

B - Correct: The described repeated use of each fold as the held-out subset is k-fold cross-validation.

C - Incorrect: Stratification additionally preserves label proportions, a condition not supplied by equal fold sizes alone.

D - Incorrect: A holdout method uses a fixed split rather than rotating through all k disjoint test folds.

Primary note proof

Study-note section AI35

Train data fits parameters; validation data selects models or settings; a held-out test set estimates final performance. In k-fold validation, train k models, each on k−1 folds and evaluate on the remaining fold, then average scores. Stratification approximately preserves label proportions. Fit preprocessing within each training fold. Time-ordered data needs splits respecting time; repeated tuning on the final test set leaks information.

These source passages provide context; the primary note proof is identified separately above.

Introduction to Artificial Intelligence module | PDF page 69 | lines 2-3

with a set of training examples consisting of inputs and corresponding outputs, and is required to
discover the relation or mapping between then, e.g. as a series of rules, or a neural network.
Agent

Question sources

Mock exam 4 · Question 4

Question 19 | Q00203

An intelligent agent is characterized by

A. Learning

B. Reasoning

C. All of them are answers

D. Perception

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer C: All of them are answers

Perception, reasoning and learning all appear in the intelligent-behavior list (PDF p. 6). C aggregates those three capabilities; it does not imply every individual agent must implement every technique.

Why each choice is right or wrong

A - Incorrect: Listed capability, included in C. See PDF p. 6, 6.

B - Incorrect: Listed capability, included in C. See PDF p. 6, 6.

C - Correct: Collects the three listed capabilities. See PDF p. 6, 6.

D - Incorrect: Listed capability, included in C. See PDF p. 6, 6.

Primary note proof

Study-note section AI01

Artificial intelligence studies systems that perform tasks requiring intelligence: reasoning, learning, planning, perception and language. Applied AI builds useful solutions; cognitive AI uses computational models to investigate biological intelligence. A model should be compared with human behavior or experimental observations before claiming it explains human thought.

Study-note section AI03

An agent perceives an environment through sensors and acts through actuators or effectors. Cameras sense; motors move. Software sensors may be incoming messages and software actions may be API requests. Humans are agents but are not artificial agents.

Question sources

Mock exam 4 · Question 5

Question 20 | Q00323

An agent type which has condition-action rule and memory to remind the current state of the world and its evolution is called

A. Simple reflex

B. Model based reflex

C. Goal based

D. Utility based

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer B: Model based reflex

The internal state records percept history; updating it requires how the world evolves and how actions affect it (PDF p. 14). A model-based reflex agent therefore matches the rule-plus-memory description.

Why each choice is right or wrong

A - Incorrect: Uses current percept and ignores the rest of the history. See PDF p. 14, 14.

B - Correct: Has the stated model and internal memory. See PDF p. 14, 14.

C - Incorrect: Would additionally require goal-directed lookahead. See PDF p. 14, 14.

D - Incorrect: Would additionally require utility measurement. See PDF p. 14, 14.

Primary note proof

Study-note section AI06

> A simple reflex agent matches condition-action rules against the current percept only: if dirty, clean. It has no persistent world-state memory. This is adequate when the current observation contains everything needed for its rule, but partial observability can make the same percept require different actions.

Study-note section AI06

> A model-based reflex agent maintains internal state using the previous state, previous action, current percept, and models of world change and action effects. It then applies rules to that state. Both kinds can use condition-action rules; memory and a world model distinguish them.

Module passages - related reading

Question sources

Computer Science model exam · Question 54

University of Gondar model exam · Question 54

Question 21 | Q00324

Assume that you are employed as a machine learning expert at the Ministry of Education (MoE). Which machine learning technique you would apply for the task of describing the existing higher education institutions as first generation, second generation and third generation.

A. Reinforcement Learning

B. Regression

C. Classification

D. Clustering

Hint

Identify the training feedback, prediction target or measured error. Keep learning objectives separate from model architecture and data modality.

Answer C: Classification

First, second and third generation are supplied category names. Treating the task as assigning institutions to these predefined labels makes it classification, which the module lists under supervised learning (PDF p. 69). If categories were to be discovered without labels, clustering would instead be relevant.

Why each choice is right or wrong

A - Incorrect: Requires action-dependent rewards, absent here. See PDF p. 69, 69.

B - Incorrect: A regression output is not the category assignment requested. See PDF p. 69, 69.

C - Correct: Matches assignment to the supplied categories. See PDF p. 69, 69.

D - Incorrect: Discovers groupings from inputs rather than assigning known labels. See PDF p. 69, 69.

Primary note proof

Study-note section AI31

> Supervised learning fits a mapping from labeled input-target examples. Classification predicts discrete labels, such as institution generations or spam/nonspam; regression predicts numeric quantities, such as prices. Predictive analytics uses historical patterns to forecast outcomes and can use either. Specify the target before choosing a method.

Study-note section AI32

> Unsupervised learning seeks structure without target labels: clustering groups similar examples; association finds co-occurrence; dimensionality reduction compresses features. Good clusters have high within-cluster similarity and low between-cluster similarity under an appropriate distance. K-means alternates assignment to nearest centroids and centroid updates.

Study-note section AI33

> An RL agent observes state information, takes an action, receives reward and a new observation, and improves its policy to maximize expected cumulative reward. Rewards evaluate outcomes rather than supply the correct action label. Rewards may be delayed; not every correct-looking action receives immediate reward.

Question sources

Computer Science model exam · Question 55

University of Gondar model exam · Question 55

Question 22 | Q00325

Consider the definition of AI: "The effort to design and implement intelligent software that solves problems by identifying best action sequence to achieve the desired goal" can be views AI as

A. A system that acts humanly

B. A system that thinks humanly

C. A system that acts rationally

D. A system that thinks rationally

Hint

Read the definition and the classification axis requested; distinguish the defining purpose from supporting techniques or implementation resources.

Answer C: A system that acts rationally

The definition emphasizes the best action sequence for a goal. The acting-rationally view evaluates how a system acts and performs (PDF p. 6), rather than imitation of people or the internal laws of thought.

Why each choice is right or wrong

A - Incorrect: Would emphasize humanlike external behavior. See PDF p. 6.

B - Incorrect: Would model human thought processes. See PDF p. 6.

C - Correct: Matches goal-directed best possible action. See PDF p. 6.

D - Incorrect: Emphasizes inference and reasoning soundness rather than the action criterion. See PDF p. 6.

Primary note proof

Study-note section AI02

Thinking humanly models human mental processes; thinking rationally derives conclusions by valid logic. Acting humanly seeks humanlike behavior; acting rationally selects actions expected to achieve objectives. Thought processes and observed behavior are different evaluation targets.

Study-note section AI02

The conversational Turing test asks whether a judge can reliably distinguish a machine from a human through their dialogue. It requires language use, knowledge, reasoning and often learning. It tests an operational behavior criterion, not proof of consciousness. Cognitive models can be tested against response times, errors and psychological experiments.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Introduction to Artificial Intelligence module | PDF page 6 | lines 2-3

machines that act rationally. The focus is on how the system acts and performs, and not so much on the reasoning process. A rational agent is one that acts rationally, that is, is in the best possible

Question sources

Computer Science model exam · Question 56

University of Gondar model exam · Question 56

Question 23 | Q00326

What is completeness of search algorithms?

A. If there is a difference between the quality of goal states, the agent will find the best one

B. An estimate of how much information the algorithm needs to store for finding a solution

C. An estimate of how many search steps it takes to find a solution

D. Provided that a solution exists, the algorithm will find it

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer D: Provided that a solution exists, the algorithm will find it

Completeness is the guarantee of finding a solution when an appropriately reachable solution exists; the BFS paragraph illustrates it using a finite-depth goal (PDF p. 20). It is distinct from finding the lowest-cost solution and from time or memory requirements.

Why each choice is right or wrong

A - Incorrect: Defines optimality, not completeness. See PDF p. 20, 18.

B - Incorrect: Describes space complexity. See PDF p. 20, 18.

C - Incorrect: Describes time complexity. See PDF p. 20, 18.

D - Correct: Matches solution-finding guarantee. See PDF p. 20, 18.

Primary note proof

Study-note section AI12

Completeness means finding a solution if one exists under stated assumptions; optimality means returning the best solution. Time counts work, often generated nodes; space counts simultaneous storage. Let b be branching factor, d shallowest goal depth, m maximum search depth, and l a depth limit. Graph-search bounds in vertices V and edges E differ from implicit-tree bounds.

Study-note section AI13

BFS removes the oldest frontier entry using a FIFO queue. Start with the root, remove the head, test it, append unseen successors at the tail, and repeat. It explores depths 0,1,2,... and is complete for finite b and a finite-depth goal. It minimizes number of edges, so minimum cost requires equal positive step costs.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Introduction to Artificial Intelligence module | PDF page 20 | lines 26-27

Completeness: BFS is complete, which means if the shallowest goal node is at some finite depth, then
BFS will find a solution.

Optimal Solution: If a solution has the lowest cost among all solutions.
3.5 Search Strategies

Question sources

Computer Science model exam · Question 57

University of Gondar model exam · Question 57

Question 24 | Q00327

Which one of the view of defining AI concerned with thought processing

A. Viewing AI as a system which has complete autonomous

B. Viewing AI as a system that think either humanly or think rationally

C. Viewing AI as a system that act either humanly or think rationally

D. Viewing AI as a system that act omnisciently to its environment

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer B: Viewing AI as a system that think either humanly or think rationally

Thinking humanly models human cognition; thinking rationally examines ideal inference (PDF p. 5). Both concern thought processing, so B is the complete pairing.

Why each choice is right or wrong

A - Incorrect: Autonomy alone does not specify thought processing. See PDF p. 5, 5.

B - Correct: Includes both thought-oriented approaches. See PDF p. 5, 5.

C - Incorrect: Mixes an action view with a thought view. See PDF p. 5, 5.

D - Incorrect: Omniscience is not one of the four views. See PDF p. 5, 5.

Primary note proof

Study-note section AI02

> Thinking humanly models human mental processes; thinking rationally derives conclusions by valid logic. Acting humanly seeks humanlike behavior; acting rationally selects actions expected to achieve objectives. Thought processes and observed behavior are different evaluation targets.

Study-note section AI04

> Omniscience would mean knowing actual action outcomes in advance. Rationality does not require omniscience or guaranteed success. Even complete outcome knowledge cannot create a successful action when every available action fails. Information gathering and exploration may therefore be rational actions.

Computer Science model exam · Question 58

University of Gondar model exam · Question 58

Question 25 | Q00328

Which one of the following statement is false

A. Turing test is a mechanism to validate AI system that act humanly

B. Validating AI system that act rationally can be made by its performance

C. Validating AI system that thinks humanly is impossible

D. Validating AI system that think rationally can be made by using its reasoning logic

Hint

Read the definition and the classification axis requested; distinguish the defining purpose from supporting techniques or implementation resources.

Answer C: Validating AI system that thinks humanly is impossible

C makes an absolute impossibility claim. The module describes understanding and modeling human thought as the cognitive-science approach (PDF p. 5), and p. 7 explicitly says computers test theories of the human mind. That contradicts treating validation as inherently impossible.

Why each choice is right or wrong

A - Incorrect: Turing's imitation game tests humanlike behavior. See PDF p. 5, 5, 6.

B - Incorrect: Rational-agent view focuses on actions and performance. See PDF p. 5, 5, 6.

C - Correct: This is the false assertion requested: page7 explicitly says computers can test theories about how the human mind works, contradicting an absolute impossibility claim.

D - Incorrect: This statement accords with the rational-thought view on page5: inference mechanisms, reasoning, soundness and completeness are assessment criteria. It is therefore not the false choice.

Primary note proof

Study-note section AI02

> Thinking humanly models human mental processes; thinking rationally derives conclusions by valid logic. Acting humanly seeks humanlike behavior; acting rationally selects actions expected to achieve objectives. Thought processes and observed behavior are different evaluation targets.

Study-note section AI02

> The conversational Turing test asks whether a judge can reliably distinguish a machine from a human through their dialogue. It requires language use, knowledge, reasoning and often learning. Question sources

Computer Science model exam · Question 59

University of Gondar model exam · Question 59

Question 26 | Q00534

Which one of the following is evaluating the degrees of success of an agent?

A. Performance measure

B. Action

C. Knowledge

D. Perception

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer A: Performance measure

The performance measure determines how successful an agent is (PDF p. 10). Actions, knowledge and percepts influence behavior, but evaluating that behavior needs the criterion. In the alternative option order the answer is B.

Why each choice is right or wrong

A - Correct: Explicit success criterion. See PDF p. 10.

B - Incorrect: A selected operation, not its evaluation criterion. See PDF p. 10.

C - Incorrect: Supports decisions but does not define success. See PDF p. 10.

D - Incorrect: Supplies sensed inputs rather than the measure. See PDF p. 10.

Primary note proof

Study-note section AI04

> A performance measure defines success externally: safety, useful deliveries, elapsed time, or cost. Rationality depends on that measure, prior knowledge, percept history, and available actions. A rational agent selects the action with the best expected performance given its information.

Study-note section AI03

> A percept is one observation; a percept sequence is the entire observation history. An agent function maps percept sequences to actions: f:P*→A. An agent program implements that mapping on an architecture; agent = architecture + program. Environment means the setting in which it senses and acts, not merely the search space. Autonomy means relying substantially on experience rather than only a designer's prior instructions.

Module passages - related reading

Introduction to Artificial Intelligence module | PDF page 10 | lines 16-17

> • Performance Measure of Agent -It is the criteria, which determines how successful an agent is.
> • Behavior of Agent – It is the action that agent performs after any given sequence of percepts.

Variant 1 | Alternative version 1

Which one of the following is evaluating the degrees of success of an agent?

A. Its Perception

B. Its Performance measure

C. Its action

D. Its prior kowled

Answer B: Its Performance measure

Apply the same study-note rule to this alternative source set; the choice contrasts below show the derivation.

Why each choice is right or wrong

A - Incorrect: Perception supplies input, not the success criterion (PDF p. 10).

B - Correct: The performance measure determines success (PDF p. 10).

C - Incorrect: An action is assessed by the criterion (PDF p. 10).

D - Incorrect: Prior knowledge helps action selection, but is not the success criterion (PDF p. 12).

Primary note proof

Study-note section AI04

> A performance measure defines success externally: safety, useful deliveries, elapsed time, or cost. Rationality depends on that measure, prior knowledge, percept history, and available actions. A rational agent selects the action with the best expected performance given its information.

Study-note section AI03

> A percept is one observation; a percept sequence is the entire observation history. An agent function maps percept sequences to actions: f:P*→A. An agent program implements that mapping on an architecture; agent = architecture + program. Environment means the setting in which it senses and acts, not merely the search space. Autonomy means relying substantially on experience rather than only a designer's prior instructions.

Question 27 | Q00541

The component of Expert system which provide interaction between user expert system and Expert system

A. Kowledge base

B. Inference engine

C. User interface

D. Human expert

Hint

Read the definition and the classification axis requested; distinguish the defining purpose from supporting techniques or implementation resources.

Answer C: User interface

The user interface explicitly provides interaction between the user and the expert system (PDF p. 64). Knowledge storage and rule application serve different roles.

Why each choice is right or wrong

A - Incorrect: Stores domain knowledge. See PDF p. 64.

B - Incorrect: Applies rules to derive conclusions. See PDF p. 64.

C - Correct: Directly provides user-system interaction. See PDF p. 64.

D - Incorrect: Provides expertise rather than the interaction component. See PDF p. 64.

Primary note proof

Study-note section AI40

> An expert system applies specialized knowledge to a domain such as equipment diagnosis. The domain expert supplies expertise; the knowledge engineer elicits and encodes it; the inference engine reasons over a knowledge base and working facts. The user interface handles interaction; an explanation facility presents why or how a conclusion was reached.

Study-note section AI24

> Knowledge representation encodes facts, objects, relations, events and rules so a machine can use them. Syntax defines legal expressions; semantics defines their meaning. A knowledge base stores assertions; an inference system derives consequences. Declarative knowledge says what is true; procedural knowledge specifies how to act.

Question sources

Computer Science model exam · 2015 · Question 10

Question 28 | Q00557

Which Terminology of Natural language processing study about meaning full components of word

A. Phonetics

B. Phonology

C. Morphology

D. Pragmatics

Hint

Match the input, output and purpose to the appropriate language, perception or physical-action task.

Answer C: Morphology.

AI38 defines morphology through prefixes, stems and suffixes, such as un-happi-ness and cat plus plural -s. These are the meaningful components of words requested by the stem. Phonetics concerns physical sounds, phonology sound patterns, and pragmatics intended meaning in context; none names the study of internal meaningful word parts.

Why each choice is right or wrong

A - Incorrect: Phonetics studies the physical properties of speech sounds rather than meaningful word components.

B - Incorrect: Phonology studies a language's sound patterns and contrasts rather than morpheme structure.

C - Correct: Morphology analyzes meaningful internal parts such as prefixes, stems and suffixes.

D - Incorrect: Pragmatics interprets intended meaning in context, not the internal components of a word.

Primary note proof

Study-note section AI38

> Morphology studies meaningful word parts: un-happi-ness contains a prefix, stem and suffix; cats contains cat and plural -s. It differs from tokenization, which identifies processing boundaries. Phonetics studies physical speech sounds; phonology studies a language's sound patterns and contrasts.

Study-note section AI38

> Prosody concerns stress, rhythm, timing, prominence and intonation across syllables and phrases. A pitch rise can help signal a question; shifting stress can change emphasis. These cues assist dialogue and speech processing. Pragmatics concerns intended meaning in context, not the internal components of words.

Question sources

Computer Science model exam · 2015 · Question 26

Question 29 | Q00577

The application area of AI which focus on recognize objects based on patterns in the same way as the human visual system does.

A. Expert System

B. Speech recogition

C. Computer vison

D. Robotics

Hint

Match the input, output and purpose to the appropriate language, perception or physical-action task.

Answer C: Computer vison

Computer vision extracts and interprets image information and explicitly includes object recognition (PDF p. 84). That is the application directly matching visual pattern recognition.

Why each choice is right or wrong

A - Incorrect: Uses domain expertise, not specifically image interpretation. See PDF p. 84, 84.

B - Incorrect: Converts spoken language rather than images. See PDF p. 84, 84.

C - Correct: Directly addresses visual objects. See PDF p. 84, 84.

D - Incorrect: Robotics may use vision but is the broader physical-agent domain. See PDF p. 84, 84.

Primary note proof

Study-note section AI39

> Computer vision interprets images or video: classification names image content, detection locates objects, segmentation labels pixels, and recognition identifies objects or people. Occlusion, lighting change, noise, unfamiliar conditions and incomplete context make open-world perception difficult even when a face detector works well.

Study-note section AI39

> Robotics combines mechanical, electrical, control and computing systems to sense, plan and act physically. Components include sensors, controller, power supply, actuators and an end effector. Locomotion may be legged, wheeled or tracked, with trade-offs in terrain, stability and efficiency. Software can act autonomously without being a robot. Humanoid shape is not evidence of general intelligence.

Study-note section AI37

> NLP interprets and generates human language: translation, dialogue, summarization, question answering and text generation. Speech recognition converts audio to text; speech synthesis generates speech. They overlap language processing but solve different input/output tasks.

Computer Science model exam · 2015 · Question 46

Question 30 | Q00581

From steps of problem solving which one is concerned on looking various sequence of action which lead to the goal state, evaluate it and chose the sequence of optimal action?

A. Execute

B. Goal Formulation

C. problem formulation

D. Search

Hint

Read the definition and the classification axis requested; distinguish the defining purpose from supporting techniques or implementation resources.

Answer D: Search

The module defines a solution as an action sequence from start to goal and an optimal solution as the lowest-cost such solution (PDF p. 18). Searching is the process of finding/evaluating those sequences, so D matches the activity described.

Why each choice is right or wrong

A - Incorrect: Carries out a selected sequence rather than finding one. See PDF p. 18, 18.

B - Incorrect: Specifies a desired outcome rather than searching paths. See PDF p. 18, 18.

C - Incorrect: Sets up states/actions rather than choosing a path. See PDF p. 18, 18.

D - Correct: Finds the goal-reaching sequence. See PDF p. 18, 18.

Primary note proof

Study-note section AI11

First formulate the goal; then formulate the problem by specifying initial state, legal actions, transition model, goal test, and action costs. Search selects a sequence; execution applies it. A state abstracts away irrelevant world details.

Study-note section AI11

In route finding, states are cities, actions are roads, successors are neighboring cities, and path cost is accumulated distance or time. A solution is a legal path ending at a goal; an optimal solution has minimum cost. Automatic programming or program synthesis searches for a program satisfying a specification; conditional plans and loops require richer representations than a fixed action list.

Question sources

Computer Science model exam · 2015 · Question 50

Question 31 | Q00600

Which types of rule used in phonology to interpretation of the fluctuation in stress and intonation across the sentences?

A. Phonetic rule

B. Phonemic rule

C. Prosodic rule

D. Morpheme rule

Hint

Match the input, output and purpose to the appropriate language, perception or physical-action task.

Answer C: Prosodic rules.

AI38 identifies stress and intonation as prosodic phenomena, alongside rhythm, timing and prominence. That directly matches the sentence-level variations in the question. Physical sound production and phonemic contrasts describe other aspects of speech; morphemes are meaningful word parts. The phrase phonology in the stem does not change the specific prosodic level requested.

Why each choice is right or wrong

A - Incorrect: Phonetic rules concern physical speech sounds, while the stated stress and intonation patterns are specifically prosodic.

B - Incorrect: Phonemic contrasts distinguish sound categories; they are not the specific stress-and-intonation rule category requested.

C - Correct: Prosodic rules address stress, prominence, rhythm and intonation across syllables and phrases.

D - Incorrect: Morphemes are meaningful word parts, not the rule category for sentence intonation.

Primary note proof

Study-note section AI38

> Morphology studies meaningful word parts: un-happi-ness contains a prefix, stem and suffix; cats contains cat and plural -s. It differs from tokenization, which identifies processing boundaries. Phonetics studies physical speech sounds; phonology studies a language's sound patterns and contrasts.

Study-note section AI38

> Prosody concerns stress, rhythm, timing, prominence and intonation across syllables and phrases. A pitch rise can help signal a question; shifting stress can change emphasis. These cues assist dialogue and speech processing. Pragmatics concerns intended meaning in context, not the internal components of words.

Question sources

Computer Science model exam · 2015 · Question 69

Question 32 | Q00611

A system is evaluated by whether a judge can distinguish its natural-language conversation from a human's. Which of the four AI approaches supplies this evaluation criterion?

A. Thinking humanly

B. Acting Humanly

C. Thinking rationally

D. Acting rationally

Hint

Read the definition and the classification axis requested; distinguish the defining purpose from supporting techniques or implementation resources.

Answer B: Acting Humanly

The criterion is observable humanlike behavior: a judge compares the system's conversation with a human's. That is the acting-humanly approach underlying the conversational Turing test. Natural-language ability alone would not establish this classification; the evaluation criterion does. Thinking approaches concern internal processes, while rational approaches judge valid conclusions or effective actions rather than resemblance to humans.

Why each choice is right or wrong

A - Incorrect: Thinking humanly concerns internal mental processes, not only observed conversation.

B - Correct: Acting humanly evaluates humanlike observable behavior, as in the conversational Turing test.

C - Incorrect: Thinking rationally evaluates valid reasoning, not indistinguishability from human dialogue.

D - Incorrect: Acting rationally evaluates expected objective achievement, which need not resemble a human.

Primary note proof

Study-note section AI02

> Thinking humanly models human mental processes; thinking rationally derives conclusions by valid logic. Acting humanly seeks humanlike behavior; acting rationally selects actions expected to achieve objectives. Thought processes and observed behavior are different evaluation targets.

Study-note section AI02

> The conversational Turing test asks whether a judge can reliably distinguish a machine from a human through their dialogue. It requires language use, knowledge, reasoning and often learning. It tests an operational behavior criterion, not proof of consciousness. Cognitive models can be tested against response times, errors and psychological experiments.

Question 33 | Q00619

From which components Intelligence is composed of

A. Reasoning

B. Problem solving

C. Linguistic perception

D. All

Hint

Match the input, output and purpose to the appropriate language, perception or physical-action task.

Answer D: All

Reasoning, learning, language understanding, problem solving and perception are all listed aspects of intelligent behavior (PDF p. 6). D aggregates the capabilities named by the question.

Why each choice is right or wrong

A - Incorrect: One listed capability. See PDF p. 6.

B - Incorrect: Another listed capability. See PDF p. 6.

C - Incorrect: Interpreted as language understanding/perception, both listed. See PDF p. 6.

D - Correct: Includes all three capabilities. See PDF p. 6.

Primary note proof

Study-note section AI01

> Artificial intelligence studies systems that perform tasks requiring intelligence: reasoning, learning, planning, perception and language. Applied AI builds useful solutions; cognitive AI uses computational models to investigate biological intelligence. A model should be compared with human behavior or experimental observations before claiming it explains human thought.

Study-note section AI37

> NLP interprets and generates human language: translation, dialogue, summarization, question answering and text generation. Speech recognition converts audio to text; speech synthesis generates speech. They overlap language processing but solve different input/output tasks.

Question sources

Computer Science model exam · 2015 · Question 88

Question 34 | Q00622

An individual who involve in solving problems regarding a certain profession and are considered as knowledge providers in a certain field of study known as ----------

A. Domain Expert

B. Knowledge Engineer

C. User

D. All

Hint

Read the definition and the classification axis requested; distinguish the defining purpose from supporting techniques or implementation resources.

Answer A: Domain Expert

The knowledge engineer acquires information from a subject expert and organizes it into rules (PDF p. 63). The professional who supplies specialist problem-solving knowledge is therefore the domain expert.

Why each choice is right or wrong

A - Correct: Supplies the subject/domain expertise. See PDF p. 63.

B - Incorrect: Elicits and organizes knowledge from the expert. See PDF p. 63.

C - Incorrect: Uses the system rather than necessarily providing expert knowledge. See PDF p. 63.

D - Incorrect: Does not preserve the distinct roles. See PDF p. 63.

Primary note proof

Study-note section AI40

> An expert system applies specialized knowledge to a domain such as equipment diagnosis. The domain expert supplies expertise; the knowledge engineer elicits and encodes it; the inference engine reasons over a knowledge base and working facts. The user interface handles interaction; an explanation facility presents why or how a conclusion was reached.

Question sources

Computer Science model exam · 2015 · Question 91

Question 35 | Q00623

Which statement best describes a rational artificial agent?

A. An artificial agent that selects actions for the best expected performance given its percept history and knowledge.

B. It used only sensors and effectors to be effective

C. It is a combination of software and hardware agents

D. All

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer A: An artificial agent that selects actions for the best expected performance given its percept history and knowledge.

A rational artificial agent senses its environment and chooses actions expected to maximize its performance measure given its information. It need not know actual outcomes in advance. Sensors and effectors alone do not supply an action-selection policy, and combining two vaguely named agent categories is not the architecture-plus-program definition. The choice gives the intended rational-agent criterion without imposing omniscience.

Why each choice is right or wrong

A - Correct: This states the rational action-selection criterion without requiring omniscience.

B - Incorrect: Sensors and effectors provide interaction, but alone do not establish intelligent action selection.

C - Incorrect: Architecture plus program is not a combination of a software agent and a hardware agent.

D - Incorrect: The component statements are defective, so their aggregate is not a valid definition.

Primary note proof

Study-note section AI03

> An agent perceives an environment through sensors and acts through actuators or effectors. Cameras sense; motors move. Software sensors may be incoming messages and software actions may be API requests. Humans are agents but are not artificial agents.

Study-note section AI03

> A percept is one observation; a percept sequence is the entire observation history. An agent function maps percept sequences to actions: f:P*→A. An agent program implements that mapping on an architecture; agent = architecture + program. Environment means the setting in which it senses and acts, not merely the search space. Autonomy means relying substantially on experience rather than only a designer’s prior instructions.

Study-note section AI04

A performance measure defines success externally: safety, useful deliveries, elapsed time, or cost. Rationality depends on that measure, prior knowledge, percept history, and available actions. A rational agent selects the action with the best expected performance given its information.

Module passages - related reading

Question sources

Computer Science model exam · 2015 · Question 92

Question 36 | Q00625

Which option gives the complete set of correct descriptions of robotics?

A. It is application area of AI emphasis of creation of intelligent and Efficient robot

B. It is a multi disciplinary area of AI

C. It focus on Electrical, Mechanical and software part of robot

D. All

Hint

Match the input, output and purpose to the appropriate language, perception or physical-action task.

Answer D: All

Robotics integrates mechanical, electrical, control and computing systems to sense, plan and act physically. Building intelligent robots is an AI application, and the required disciplines extend across hardware and software. Thus the three individual descriptions are true. Because this is a single-choice question requesting the complete set, the aggregate is selected and each individual description is an incomplete selection.

Why each choice is right or wrong

A - Incorrect: Creating intelligent, efficient robots is a valid application description, but this alone omits the other true descriptions.

B - Incorrect: Robotics is multidisciplinary, but this alone omits the other true descriptions.

C - Incorrect: Electrical, mechanical and software systems are part of robotics, but this alone omits the other true descriptions.

D - Correct: All three descriptions are compatible with robotics as an integrated discipline that builds physical sensing and acting systems.

Primary note proof

Study-note section AI39

> Robotics combines mechanical, electrical, control and computing systems to sense, plan and act physically. Components include sensors, controller, power supply, actuators and an end effector. Locomotion may be legged, wheeled or tracked, with trade-offs in terrain, stability and efficiency. Software can act autonomously without being a robot. Humanoid shape is not evidence of general intelligence.

Study-note section AI01

> Artificial intelligence studies systems that perform tasks requiring intelligence: reasoning, learning, planning, perception and language. Applied AI builds useful solutions; cognitive AI uses computational models to investigate biological intelligence. A model should be compared with human behavior or experimental observations before claiming it explains human thought.

Question sources

Computer Science model exam · 2015 · Question 94

Question 37 | Q00646

Which option describes a conventional computer’s instruction-driven storage and retrieval of information, without making a universal comparison with human intelligence?

A. Machine can figure out complete objects even some part is missed

B. Machines are Naturally intelligent

C. Store and Recall information with set of instruction

D. Take precepts from environment with pattern

Hint

Identify the training feedback, prediction target or measured error. Keep learning objectives separate from model architecture and data modality.

Answer C: Store and Recall information with set of instruction

A conventional computer manipulates information according to program instructions, including instructions for storage and retrieval. This describes a mode of computation rather than a universal difference in intelligence between humans and machines. Programs can also implement pattern learning and object recognition. Those capabilities do not change which option names the particular storage-and-retrieval operation requested.

Why each choice is right or wrong

A - Incorrect: Recognizing an occluded object is a perception capability, not the definition of instruction-driven storage and retrieval.

B - Incorrect: A computer's programmed operations do not establish natural biological intelligence.

C - Correct: Storing and recalling information by executing instructions matches the operation described.

D - Incorrect: Processing perceptual patterns is a sensing or recognition task, not specifically storage and retrieval.

Primary note proof

Study-note section AI-S01

> A conventional computer manipulates digital information according to a program or sequence of instructions. Programs can implement storage, retrieval and learning operations. Neural networks can learn pattern recognition from examples, so executing instructions and learning patterns are not mutually exclusive descriptions. This provides no universal claim that every machine is better or worse than every human at completing missing information.

Study-note section AI34

> Feedforward networks pass signals toward outputs without recurrent state loops; recurrent networks carry state across sequence steps. Training adjusts weights, often through gradients and backpropagation. Backpropagation is not the same as a recurrent connection. Deep learning uses multiple representation layers and can learn features from images, sound and text. CNNs share filters across image locations. ANN is a brain-inspired abstraction, not a literal brain simulation; DL⊂ML⊂AI.

Question sources

Computer Science model exam · 2015 · Question 115

Question 38 | Q00651

Which types of searching strategies is not grouped under blind search?

A. Breadth first search

B. Uniform cost search

C. Constraint satisfaction search

D. Depth limited search

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer C: Constraint satisfaction search

BFS, UCS and depth-limited search appear in the uninformed-search sequence (PDF pp. 18-22). Constraint satisfaction is treated separately, so C is the item not grouped under blind search.

Why each choice is right or wrong

A - Incorrect: BFS is in the uninformed sequence. See PDF p. 18, 21, 36.

B - Incorrect: UCS is in the uninformed sequence. See PDF p. 18, 21, 36.

C - Correct: A separately presented constraint-based problem formulation/search topic. See PDF p. 18, 21, 36.

D - Incorrect: Depth-limited search is in the uninformed sequence. See PDF p. 18, 21, 36.

Primary note proof

Study-note section AI21

Backtracking assigns a variable, tries a legal value, and undoes the choice on failure. Choose the variable with fewest remaining values; break ties by degree; try values that rule out fewest neighbor choices. Forward checking removes incompatible neighbor values. Arc consistency removes a value when a binary constraint offers it no support in the other domain. CSP is a problem framework using search and propagation, not a universal fourth uninformed traversal.

Study-note section AI17

A heuristic h(n) estimates remaining cost or evaluates promise using problem-specific knowledge. It can reduce explored work, but computing it also costs time. Uninformed

algorithms use only the problem definition and known costs; UCS remains uninformed despite using g.

Study-note section AI13

BFS removes the oldest frontier entry using a FIFO queue. Start with the root, remove the head, test it, append unseen successors at the tail, and repeat. It explores depths 0,1,2,... and is complete for finite b and a finite-depth goal. It minimizes number of edges, so minimum cost requires equal positive step costs.

Study-note section AI16

DLS runs DFS to depth l and reports cutoff separately from failure. It misses goals deeper than l. Iterative deepening runs DLS with limits 0,1,2,...; for finite b it finds the shallowest solution with O(b^d) time and O(bd) frontier space, optimal for equal step costs. Repeated shallow work is small compared with the deepest level.

Question sources

Computer Science model exam · 2015 · Question 120

Question 39 | Q00655

Which statement correctly distinguishes propositional logic from first-order logic?

A. It evaluates whole propositions using a truth assignment, without quantifying over objects in a domain.

B. It is predicate logic

C. It assigns truth to open predicates without assigning values to their object variables.

D. It contains quantifier

Hint

Translate the statement carefully, then check the scope of its quantifiers, connectives or inference rule. Distinguish guaranteed consequences from plausible generalizations or explanations.

Answer A: It evaluates whole propositions using a truth assignment, without quantifying over objects in a domain.

Propositional logic treats atoms as whole true-or-false claims and evaluates compound formulas from a truth assignment. It does not quantify over individual objects. First-order logic adds predicates, object variables, interpretations and quantifiers. The distinction does not mean that propositional truth needs no assignment: the truth values of its atoms still matter.

Why each choice is right or wrong

A - Correct: Propositional evaluation uses atom truth values rather than object-domain quantification.

B - Incorrect: Propositional logic is not identical to first-order predicate logic.

C - Incorrect: Open predicates need interpretation and variable assignments; this is not a propositional truth rule.

D - Incorrect: Object quantifiers belong to first-order logic, not propositional syntax.

Primary note proof

Study-note section AI26

> First-order logic adds objects, predicates, functions and quantified object variables. Human(a) is a property; Likes(a,b) a relation; father(a) a function term. Propositional logic has no object quantifiers, but its truth still depends on the assigned atom values.

Study-note section AI25

> Propositional atoms represent whole true-or-false claims. ¬P negates; P∧Q requires both; P∨Q requires at least one; P→Q is false only when P is true and Q false; P↔Q requires matching truth values. Thus P→Q ≡ ¬P∨Q. De Morgan gives ¬(P∧Q) ≡ ¬P∨¬Q.

Question sources

Computer Science model exam · 2015 · Question 124

Question 40 | Q00658

Which option names the complete set of dataset roles used across model fitting, model selection and final held-out evaluation?

A. Validation dataset

B. Train dataset

C. Test dataset

D. All

Hint

Identify the training feedback, prediction target or measured error. Keep learning objectives separate from model architecture and data modality.

Answer D: All

Training fits parameters, validation selects models or settings, and a held-out test set estimates final performance. The overall workflow uses all three roles, with the test set kept separate from fitting and repeated tuning. Each individual option is true about one role, but only the aggregate gives the complete set requested by this single-choice question.

Why each choice is right or wrong

A - Incorrect: Validation supports model selection, but alone does not cover fitting and final held-out evaluation.

B - Incorrect: Training fits model parameters, but alone does not cover model selection and final evaluation.

C - Incorrect: Held-out test data estimates final performance, but alone omits fitting and model selection.

D - Correct: Training, validation and test sets together cover the three distinct workflow roles.

Primary note proof

Study-note section AI35

> Train data fits parameters; validation data selects models or settings; a held-out test set estimates final performance. In k-fold validation, train k models, each on k−1 folds and evaluate on the remaining fold, then average scores. Stratification approximately preserves label proportions. Fit preprocessing within each training fold. Time-ordered data needs splits respecting time; repeated tuning on the final test set leaks information.

Question sources

Computer Science model exam · 2015 · Question 127

Question 41 | Q00721

algorithm traverses a graph in a Breadth-ward motion and uses a
queue to remember to get the next vertex to start a search, when a dead end occurs in
any iteration.

A. Breadth first search

B. Binary search

C. Depth first search

D. A&C

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer A: Breadth first search

Expanding a graph breadthwise with a FIFO queue is precisely BFS (PDF pp. 19-20). DFS follows a path deeply and uses a stack; binary search is not this traversal.

Why each choice is right or wrong

A - Correct: Matches breadthwise expansion and FIFO frontier. See PDF p. 19, 20.

B - Incorrect: Not the stated graph traversal. See PDF p. 19, 20.

C - Incorrect: DFS uses a stack and goes deeply first. See PDF p. 19, 20.

D - Incorrect: DFS does not meet the queue/breadthwise description. See PDF p. 19, 20.

Primary note proof

Study-note section AI13

BFS removes the oldest frontier entry using a FIFO queue. Start with the root, remove the head, test it, append unseen successors at the tail, and repeat. It explores depths 0,1,2,... and is complete for finite b and a finite-depth goal. It minimizes number of edges, so minimum cost requires equal positive step costs.

Study-note section AI14

DFS follows the deepest pending branch using a LIFO stack or recursion. FILO means the same order as LIFO. With the same children as BFS, a left-first DFS visits S,A,C before B; push rightmost children first to pop the leftmost first.

Study-note section AI-S02

> Binary search exploits the order of a sorted sequence: a comparison narrows the remaining candidate interval instead of exploring arbitrary successor states. Array bisection therefore differs from breadth-first or depth-first traversal of a general state-space graph. A storage container such as an array does not by itself specify FIFO or LIFO frontier behavior.

Question 42 | Q00889

Which Al approach most directly supports understanding biological intelligence behavior as a scientific goal?

A. Weak AI

B. Applied AI

C. .
Cognitive Al

D. Strong AI

Hint

Read the definition and the classification axis requested; distinguish the defining purpose from supporting techniques or implementation resources.

Answer C: .
Cognitive Al

Cognitive AI tests theories of how minds recognize objects and solve problems; the science-based goal is understanding biological intelligence (PDF pp. 7-8). C links these two descriptions.

Why each choice is right or wrong

A - Incorrect: Simulating cognition does not by itself specify the scientific-theory-testing aim. See PDF p. 7, 8.

B - Incorrect: Commercially viable systems are the stated focus of applied AI. See PDF p. 7, 8.

C - Correct: Directly tests theories of mind and cognition. See PDF p. 7, 8.

D - Incorrect: Aims for genuine human-level reasoning rather than specifically theory testing. See PDF p. 7, 8.

Primary note proof

Study-note section AI01

> Artificial intelligence studies systems that perform tasks requiring intelligence: reasoning, learning, planning, perception and language. Applied AI builds useful solutions; cognitive AI uses computational models to investigate biological intelligence. A model should be compared with human behavior or experimental observations before claiming it explains human thought.

Study-note section AI01

> Narrow or weak AI addresses bounded tasks, such as face recognition, spam filtering or a voice assistant. General AI denotes broad competence transferable across domains; strong AI also has a philosophical meaning involving actual understanding. Do not equate a humanoid body, autonomous vehicle, or many features with general intelligence.

Question sources

Computer Science Exit Exam · 2018 · Question 2

Question 43 | Q00895

Why is Greedy Best-First Search not guaranteed to be optimal or complete?

A. It ignores path cost g(n) and relies only on h(n)

B. It always chooses the shallowest node

C. .
It expands nodes in FIFO order

D. It requires full knowledge of the goal state in advance

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer A: It ignores path cost g(n) and relies only on h(n)

Greedy chooses by estimated remaining cost h(n), ignoring accumulated path cost g(n), so a promising estimate can hide an expensive route. The module also warns of loops and nonoptimality (PDF pp. 25-26). Completeness depends on implementation and state-space assumptions; the general guarantee is absent.

Why each choice is right or wrong

A - Correct: Its h-only choice gives the stated lack of a general guarantee. See PDF p. 25, 26.

B - Incorrect: Shallowest-first describes BFS. See PDF p. 25, 26.

C - Incorrect: FIFO order describes BFS, not heuristic priority. See PDF p. 25, 26.

D - Incorrect: Not the reason the module gives for greedy failures. See PDF p. 25, 26.

Primary note proof

Study-note section AI17

> Best-first is a family that orders OPEN by an evaluation function. Greedy best-first uses f=h and removes the smallest estimate, ignoring the cost already paid. It can choose an expensive route, loop without duplicate checks, or follow an infinite misleading branch. On a finite graph with full duplicate handling it is complete, but not generally optimal. Its implicit finite-tree worst case can be O(b^m).

Study-note section AI18

> A* orders by f(n)=g(n)+h(n). Admissibility means 0≤h(n)≤h*(n), the true cheapest remaining cost. Consistency means h(n)≤c(n,n′)+h(n′) on every edge, with h(goal)=0; it implies admissibility on states with goal paths. Consistency makes f nondecreasing along a path.

Module passages - related reading

> • Time Complexity: The worst case time complexity of Greedy best first search is O(bm).

Question sources

Computer Science Exit Exam · 2018 · Question 8

Question 44 | Q00910

Which search strategy tries to expand the node that is closest to the goal, on the grounds that this is likely to lead to a solution quickly; Thus, it evaluates nodes by using just the heuristic function: f (n)=h (n).

A. Uniform-cost search

B. Greedy best-first search

C. ¢.
Depth-first search

D. A* search

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer B: Greedy best-first search

Selecting the node estimated closest to the goal uses h(n) alone, as the pure-heuristic and lowest-h OPEN-list rules state (PDF p. 25). The same page prints f(n)=g(n), an internal typo contradicted by those rules; visual inspection confirms the typo is in the PDF.

Why each choice is right or wrong

A - Incorrect: Uses g(n), accumulated cost. See PDF p. 25, 25.

B - Correct: Matches h-only priority. See PDF p. 25, 25.

C - Incorrect: Uses depth priority. See PDF p. 25, 25.

D - Incorrect: Uses g(n)+h(n) rather than h alone. See PDF p. 25, 25.

Primary note proof

Study-note section AI17

> Best-first is a family that orders OPEN by an evaluation function. Greedy best-first uses f=h and removes the smallest estimate, ignoring the cost already paid. It can choose an expensive route, loop without duplicate checks, or follow an infinite misleading branch. On a finite graph with full duplicate handling it is complete, but not generally optimal. Its implicit finite-tree worst case can be O(b^m).

Study-note section AI15

> UCS uses a priority queue ordered by actual accumulated path cost g(n). Remove a minimum-g node; accept a goal when removed, not when first generated. Relax each edge: if a cheaper path is found, update its frontier cost and parent.

Question sources

Computer Science Exit Exam · 2018 · Question 23

Question 45 | Q00922

Which of the following best defines a heuristic in the context of AI search?

A. A function that estimates how close a state is to the goal

B. A guaranteed optimal path to the goal

C. .
A method that always avoids revisiting states

D. A brute-force enumeration of all possible states

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer A: A function that estimates how close a state is to the goal

The module says a heuristic estimates how close a state is to the goal (PDF p. 25). An estimate guides node ordering but is neither a path nor a guarantee against revisiting states.

Why each choice is right or wrong

A - Correct: Direct definition. See PDF p. 25.

B - Incorrect: An estimate does not itself specify a guaranteed optimal path. See PDF p. 25.

C - Incorrect: Repeated-state management is a separate search concern. See PDF p. 25.

D - Incorrect: Brute force is the uninformed contrast. See PDF p. 25.

Primary note proof

Study-note section AI17

> A heuristic h(n) estimates remaining cost or evaluates promise using problem-specific knowledge. It can reduce explored work, but computing it also costs time. Uninformed algorithms use only the problem definition and known costs; UCS remains uninformed despite using g.

Study-note section AI17

Best-first is a family that orders OPEN by an evaluation function. Greedy best-first uses f=h and removes the smallest estimate, ignoring the cost already paid. It can choose an expensive route, loop without duplicate checks, or follow an infinite misleading branch. On a finite graph with full duplicate handling it is complete, but not generally optimal. Its implicit finite-tree worst case can be O(b^m).

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Introduction to Artificial Intelligence module | PDF page 25 | lines 2-3

• Heuristic function estimates how close a state is to the goal. It is represented by h(n), and it calculates
the cost of an optimal path between the pair of states. Its value is always positive.

Question sources

Computer Science Exit Exam · 2018 · Question 35

Question 46 | Q00939

Which type of heuristic search strategy that evaluates nodes by combining g (n), the cost to reach the node, and h (n.), the cost to get from the node to the goal: f (n) = g (n) +h (n) Since g(n) gives the path cost from the start node to node n, and h(n) is the estimated cost of the cheapest path from n to the goal, we have f (n) = estimated cost of the cheapest solution through n ?

A. A* search

B. Greedy Best-First Search

C. Uniform-cost search

D. Depth-first search

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer A: A* search

A* uses f(n)=g(n)+h(n), combining the cost already paid with an estimate of the remaining cost. Greedy best-first uses only h; uniform-cost search uses only g; depth-first search follows its stack discipline. The sum is the distinguishing rule. The stray answer annotation attached to the depth-first option has been removed from the practice choices.

Why each choice is right or wrong

A - Correct: A* ranks by accumulated path cost plus estimated remaining cost.

B - Incorrect: Greedy best-first ranks by h alone and omits accumulated cost.

C - Incorrect: Uniform-cost search ranks by g alone and omits the heuristic estimate.

D - Incorrect: DFS follows a stack order rather than minimum g+h.

Primary note proof

Study-note section AI18

A* orders by f(n)=g(n)+h(n). Admissibility means 0≤h(n)≤h*(n), the true cheapest remaining cost. Consistency means h(n)≤c(n,n′)+h(n′) on every edge, with h(goal)=0; it implies admissibility on states with goal paths. Consistency makes f nondecreasing along a path.

Study-note section AI17

Best-first is a family that orders OPEN by an evaluation function. Greedy best-first uses f=h and removes the smallest estimate, ignoring the cost already paid. It can choose an expensive route, loop without duplicate checks, or follow an infinite misleading branch. On a finite graph with full duplicate handling it is complete, but not generally optimal. Its implicit finite-tree worst case can be O(b^m).

Study-note section AI15

UCS uses a priority queue ordered by actual accumulated path cost g(n). Remove a minimum-g node; accept a goal when removed, not when first generated. Relax each edge: if a cheaper path is found, update its frontier cost and parent.

Study-note section AI14

DFS follows the deepest pending branch using a LIFO stack or recursion. FILO means the same order as LIFO. With the same children as BFS, a left-first DFS visits S,A,C before B; push rightmost children first to pop the leftmost first.

Introduction to Artificial Intelligence module | PDF page 26 | lines 25-26

• A* search is the most commonly known form of best-first search.
• It uses heuristic function h(n), and cost to reach the node n from the start state g(n). It has combined

Introduction to Artificial Intelligence module | PDF page 28 | lines 4-5

the formula f(n)= g(n) + h(n), where g(n) is the cost to reach any node from start state.
• Here we will use OPEN and CLOSED list.

Question sources

Computer Science Exit Exam · 2018 · Question 52

Question 47 | Q00961

Why is perception still a challenge for AI-even though systems can recognize faces?

A. Because perception is unrelated to reasoning

B. Because AI lacks actuators

C. Because open-world inputs may contain occlusion, noise, unfamiliar conditions and incomplete context.

D. Because sensors are too expensive

Hint

Match the input, output and purpose to the appropriate language, perception or physical-action task.

Answer C: Because open-world inputs may contain occlusion, noise, unfamiliar conditions and incomplete context.

Recognizing faces in some settings does not solve all perception problems. Occlusion can hide relevant features, noise can corrupt observations, and unfamiliar conditions or missing context can make an interpretation unreliable. These are difficulties in interpreting sensory information. They do not require every perception task to use natural-language understanding, and they are distinct from actuator availability or sensor price.

Why each choice is right or wrong

A - Incorrect: Perception can use context and support reasoning; it is not unrelated to it.

B - Incorrect: Actuators implement actions, while the question concerns difficulty interpreting sensory input.

C - Correct: Occlusion, noise and unfamiliar or incomplete context can defeat otherwise successful recognition systems.

D - Incorrect: Cost is not the conceptual reason that open-world interpretation remains difficult.

Primary note proof

Study-note section AI39

> Computer vision interprets images or video: classification names image content, detection locates objects, segmentation labels pixels, and recognition identifies objects or people. Occlusion, lighting change, noise, unfamiliar conditions and incomplete context make open-world perception difficult even when a face detector works well.

Study-note section AI01

> Narrow or weak AI addresses bounded tasks, such as face recognition, spam filtering or a voice assistant. General AI denotes broad competence transferable across domains; strong AI also has a philosophical meaning involving actual understanding. Do not equate a humanoid body, autonomous vehicle, or many features with general intelligence.

Question sources

Computer Science Exit Exam · 2018 · Question 74

Question 48 | Q00970

In which of the following Learning methods an agent receives feedback in the form of rewards or penalties to maximize cumulative reward?

A. Supervised learning

B. Reinforcement learning

C. .
Semi-supervised learning

D. Unsupervised learning

Hint

Identify the training feedback, prediction target or measured error. Keep learning objectives separate from model architecture and data modality.

Answer B: Reinforcement learning

Reinforcement learning gives rewards for right actions and penalties for wrong ones, with the goal of obtaining the most reward points (PDF p. 69). B matches both interaction and feedback.

Why each choice is right or wrong

A - Incorrect: Supervised learning uses input-target labels rather than action-reward feedback.

B - Correct: Reinforcement learning improves decisions to maximize cumulative reward from interaction.

C - Incorrect: Semi-supervised learning mixes labeled and unlabeled examples; that mixture does not define cumulative-reward learning.

D - Incorrect: Unsupervised learning discovers unlabeled structure rather than defining an action-reward objective.

Primary note proof

Study-note section AI33

An RL agent observes state information, takes an action, receives reward and a new observation, and improves its policy to maximize expected cumulative reward. Rewards evaluate outcomes rather than supply the correct action label. Rewards may be delayed; not every correct-looking action receives immediate reward.

Study-note section AI32

Semi-supervised learning combines some labels with additional unlabeled data. Active learning chooses informative cases for an oracle to label; it still uses labels. “Exploratory learning” is not an exclusive standard synonym: it can mean unsupervised exploration or active data acquisition, so define the feedback. A task named summarization or time-series analysis is not automatically supervised; its training targets determine that.

Study-note section AI31

Supervised learning fits a mapping from labeled input-target examples. Classification predicts discrete labels, such as institution generations or spam/nonspam; regression predicts numeric quantities, such as prices. Predictive analytics uses historical patterns to forecast outcomes and can use either. Specify the target before choosing a method.

Module passages - related reading

Introduction to Artificial Intelligence module | PDF page 69 | lines 15-18

⇒ Reinforcement learning is a feedback-based learning method, in which a learning agent gets a reward for each right action and gets a penalty for each wrong action.
The agent learns automatically with these feedbacks and improves its performance. In reinforcement
learning, the agent interacts with the environment and explores it. The goal of an agent is to get the

Question sources

Computer Science Exit Exam · 2018 · Question 83

Question 49 | Q00995

Which one of the following is wrongly matched as AI environment property pairs?

A. Fully observable <-> Partially observable

B. Discrete <-> Continuous

C. Deterministic <-> Stochastic

D. Static <-> Stochastic

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer D: Static <-> Stochastic

The module pairs static with dynamic, and deterministic with nondeterministic (PDF p. 13). Thus static versus stochastic mixes two independent dimensions; D is the wrong pairing.

Why each choice is right or wrong

A - Incorrect: Opposite observability properties. See PDF p. 13, 13.

B - Incorrect: Opposite state/action granularity properties. See PDF p. 13, 13.

C - Incorrect: Stochastic is the question's term for nondeterministic transition uncertainty. See PDF p. 13, 13.

D - Correct: Incorrect pair: static's counterpart is dynamic. See PDF p. 13, 13.

Primary note proof

Study-note section AI09

> Fully observable means sensors reveal relevant state; partially observable means relevant information is hidden or noisy. Deterministic means state and action determine the next state; stochastic means outcomes involve randomness. Strategic uncertainty about an opponent is distinct from dice-like randomness.

Study-note section AI09

> Episodic decisions are independent; sequential decisions affect later situations. Static worlds do not change while deliberating; dynamic ones do. A clock affecting score makes an otherwise static game semidynamic. Discrete quantities have distinct alternatives; continuous quantities vary along real-valued ranges. Known versus unknown concerns knowledge of the transition model, not observability.

National Exit Exam practice questions · Question 9

Computer Science Exit Exam practice collection · Question 199

Question 50 | Q01007

Which option describes general data processing without AI learning or inference, rather than naming an AI-related field?

A. Machine learning

B. Robotics

C. Data analysis limited to fixed arithmetic summaries, without learning or inference.

D. Natural language processing

Hint

Match the input, output and purpose to the appropriate language, perception or physical-action task.

Answer C: Data analysis limited to fixed arithmetic summaries, without learning or inference.

Machine learning develops systems that improve from experience, natural language processing interprets or generates language, and robotics combines sensing, planning and physical action. Data analysis is broader: it may use AI, but fixed arithmetic summaries alone need not involve learning or inference. The option restricts that broad category to ordinary non-AI processing, avoiding the incorrect claim that all data analysis lies outside AI.

Why each choice is right or wrong

A - Incorrect: Machine learning is part of AI, and AI43 explicitly places learning architectures and regimes within it.

B - Incorrect: Robotics combines sensing, planning and physical action and is treated as an AI-related field in AI39.

C - Correct: The restricted fixed-summary task need not use AI; this does not exclude learning-based data analysis.

D - Incorrect: Natural language processing interprets and generates human language and is covered as an AI field in AI37.

Primary note proof

Study-note section AI01

> Artificial intelligence studies systems that perform tasks requiring intelligence: reasoning, learning, planning, perception and language. Applied AI builds useful solutions; cognitive AI uses computational models to investigate biological intelligence. A model should be compared with human behavior or experimental observations before claiming it explains human thought.

Study-note section AI39

> Robotics combines mechanical, electrical, control and computing systems to sense, plan and act physically. Components include sensors, controller, power supply, actuators and an end effector. Locomotion may be legged, wheeled or tracked, with trade-offs in terrain, stability and

efficiency. Software can act autonomously without being a robot. Humanoid shape is not evidence of general intelligence.

Study-note section AI37

NLP interprets and generates human language: translation, dialogue, summarization, question answering and text generation. Speech recognition converts audio to text; speech synthesis generates speech. They overlap language processing but solve different input/output tasks.

Question sources

Artificial Intelligence practice questions · Question 1

Question 51 | Q01008

Which techniques can improve learned parameters, candidate solutions or policies using training experience, fitness feedback or reward? Select all that apply. Treat D as a fixed knowledge-based expert system.

A. Artificial neural networks

B. Genetic algorithms

C. Reinforcement learning

D. Expert systems

Hint

Read the definition and the classification axis requested; distinguish the defining purpose from supporting techniques or implementation resources.

Answer A, B, C: Artificial neural networks; Genetic algorithms; Reinforcement learning

Neural-network training adjusts weights from experience, genetic algorithms evolve candidates using fitness and variation, and reinforcement learning improves policies using rewards from interaction. These are different improvement mechanisms that satisfy the broader capability requested. A fixed expert system applies encoded domain knowledge and does not inherently revise itself through experience. The fixed-system assumption distinguishes using knowledge from learning or optimizing with feedback.

Why each choice is right or wrong

A - Correct: Training adjusts neural weights from examples or feedback and can improve performance.

B - Correct: Genetic search improves a candidate population through fitness-based experience and variation.

C - Correct: RL improves policies from action outcomes and rewards.

D - Incorrect: A conventional fixed expert system applies encoded knowledge without inherently learning from experience.

Primary note proof

Study-note section AI43

> ANNs, genetic search and reinforcement learning all improve candidate behavior or performance through experience in different ways. Deep learning is an architecture family usable with supervised, unsupervised or reinforcement objectives. Decision trees and deep models may both be supervised. To distinguish learning regimes, specify labels, reward or unlabeled structure.

Study-note section AI40

> An expert system applies specialized knowledge to a domain such as equipment diagnosis. The domain expert supplies expertise; the knowledge engineer elicits and encodes it; the inference engine reasons over a knowledge base and working facts. The user interface handles interaction; an explanation facility presents why or how a conclusion was reached.

Question sources

Artificial Intelligence practice questions · Question 2

Question 52 | Q01009

Which listed programming languages can implement AI or machine-learning algorithms? Select all that apply; this asks about implementation capability, not an exclusive popularity ranking.

A. C++

B. Java

C. Python

D. Ruby

Hint

Read the definition and the classification axis requested; distinguish the defining purpose from supporting techniques or implementation resources.

Answer A, B, C, D: C++; Java; Python; Ruby

All four languages can implement AI or machine-learning algorithms. The note explicitly identifies Python, C++ and Java as implementation languages. The supplementary primary Rumale project documentation supplies the missing Ruby fact by documenting a Ruby machine-learning library with classifiers and clustering algorithms. This establishes capability rather than a popularity ranking, and avoids treating one widely used language as the only valid implementation choice.

Why each choice is right or wrong

A - Correct: The note explicitly identifies C++ as an AI implementation language.

B - Correct: The note explicitly identifies Java as an AI implementation language.

C - Correct: The note identifies Python as widely used for AI implementation.

D - Correct: Rumale’s primary project documentation demonstrates machine-learning algorithms implemented for Ruby.

Primary note proof

Study-note section AI43

Face recognition is both an applied task and a narrow capability. Broad machine-intelligence goals can include emulating human intelligence and building systems that learn. Humanlike problem-solving alone does not uniquely select expert systems. Python is widely used, but C++ and Java also implement AI; “commonly used” does not isolate one language. McCarthy is associated with naming AI, not its sole invention.

Study-note section AI-S01

AI algorithms are not exclusive to one programming language. Rumale is a Ruby machine-learning library with classification and clustering implementations, demonstrating that Ruby can implement learning algorithms as well as the general-purpose languages already discussed. Language choice and learning regime are different decisions.

Introduction to Artificial Intelligence module | PDF page 8 | lines 21-23

1.10 AI Techniques
Various techniques that have involved can be applied to a variety of AI tasks. The techniques are concerned with how we represent, manipulate and reason with knowledge in order to solve problem.

Question sources

Artificial Intelligence practice questions · Question 3

Question 53 | Q01010

Which listed goal specifically expresses the humanlike approaches to AI, rather than autonomy, general automation or replacement of workers?

A. To replace humans with machines

B. To develop autonomous systems

C. To simulate human intelligence

D. To automate tasks and improve efficiency

Hint

Read the definition and the classification axis requested; distinguish the defining purpose from supporting techniques or implementation resources.

Answer C: To simulate human intelligence

Humanlike AI approaches aim to model human thought or produce humanlike behavior. Simulating aspects of human intelligence expresses that goal. Autonomous action, automation and efficiency can also be useful AI objectives, but none requires human imitation. Replacing workers is a social or deployment choice rather than the field’s defining aim. This classification does not impose one primary goal on every AI system.

Why each choice is right or wrong

A - Incorrect: Replacing humans is a deployment choice, not the defining goal of humanlike AI.

B - Incorrect: Autonomy concerns independent action and need not emulate human intelligence.

C - Correct: Simulating human intelligence expresses the humanlike approach to thought or behavior.

D - Incorrect: Automation and efficiency can be achieved without modeling human intelligence.

Primary note proof

Study-note section AI01

> Artificial intelligence studies systems that perform tasks requiring intelligence: reasoning, learning, planning, perception and language. Applied AI builds useful solutions; cognitive AI uses computational models to investigate biological intelligence. A model should be compared with human behavior or experimental observations before claiming it explains human thought.

Study-note section AI02

> Thinking humanly models human mental processes; thinking rationally derives conclusions by valid logic. Acting humanly seeks humanlike behavior; acting rationally selects actions expected to achieve objectives. Thought processes and observed behavior are different evaluation targets.

Study-note section AI43

> Face recognition is both an applied task and a narrow capability. Broad machine-intelligence goals can include emulating human intelligence and building systems that learn. Humanlike problem-solving alone does not uniquely select expert systems. Python is widely used, but C++ and Java also implement AI; “commonly used” does not isolate one language. McCarthy is associated with naming AI, not its sole invention.

Question 54 | Q01011

Which AI application is used to understand and interpret human language?

A. Computer vision

B. Speech recognition

C. Natural language processing

D. Expert systems

Hint

Match the input, output and purpose to the appropriate language, perception or physical-action task.

Answer C: Natural language processing

NLP is technology for machines to understand, analyze, manipulate and interpret human language (PDF p. 79). Speech recognition is narrower: converting spoken words into text (p. 82).

Why each choice is right or wrong

A - Incorrect: Works with image information. See PDF p. 79.

B - Incorrect: Transcribes spoken words; narrower than language interpretation. See PDF p. 79.

C - Correct: Matches the language-understanding definition. See PDF p. 79.

D - Incorrect: Uses domain expertise, not specifically language interpretation. See PDF p. 79.

Primary note proof

Study-note section AI37

> NLP interprets and generates human language: translation, dialogue, summarization, question answering and text generation. Speech recognition converts audio to text; speech synthesis generates speech. They overlap language processing but solve different input/output tasks.

Study-note section AI39

> Computer vision interprets images or video: classification names image content, detection locates objects, segmentation labels pixels, and recognition identifies objects or people. Occlusion, lighting change, noise, unfamiliar conditions and incomplete context make open-world perception difficult even when a face detector works well.

Study-note section AI40

> An expert system applies specialized knowledge to a domain such as equipment diagnosis. Question sources

Artificial Intelligence practice questions · Question 5

Question 55 | Q01012

Which technique is defined by a specialized knowledge base of conventional domain facts and rules, with an inference engine applying them to solve domain problems?

A. Genetic algorithms

B. Fuzzy logic

C. Expert systems

D. Reinforcement learning

Hint

Read the definition and the classification axis requested; distinguish the defining purpose from supporting techniques or implementation resources.

Answer C: Expert systems

An expert system is characterized by specialized domain knowledge and an inference engine that reasons over its knowledge base and working facts. Merely saying that a method uses rules would not distinguish it from fuzzy systems, which may also use rules. Genetic algorithms instead evolve populations, and reinforcement learning uses reward feedback. The architecture in the question supplies the specific distinction.

Why each choice is right or wrong

A - Incorrect: Genetic algorithms evolve candidate populations through selection and variation rather than defining a knowledge-base inference architecture.

B - Incorrect: Fuzzy logic represents graded membership and can use rules, but rules alone do not make it the specialized architecture described.

C - Correct: Expert systems apply domain knowledge through an inference engine operating on a knowledge base and working facts.

D - Incorrect: Reinforcement learning improves decisions from rewards rather than defining the described knowledge-base architecture.

Primary note proof

Study-note section AI40

An expert system applies specialized knowledge to a domain such as equipment diagnosis. The domain expert supplies expertise; the knowledge engineer elicits and encodes it; the inference engine reasons over a knowledge base and working facts. The user interface handles interaction; an explanation facility presents why or how a conclusion was reached.

Study-note section AI30

A fuzzy controller fuzzifies measurements, applies graded IF-THEN rules, combines outputs and often defuzzifies to a numerical action. Fuzzy control suits linguistic rules about degrees; reinforcement learning suits reward-based adaptation. Merely saying an environment is complex or uncertain does not uniquely select either method.

Question sources

Artificial Intelligence practice questions · Question 6

Question 56 | Q01013

Which learning regime discovers structure in unlabeled data without action-reward interaction? Select the regime rather than a neural architecture family.

A. Supervised learning

B. Unsupervised learning

C. Reinforcement learning

D. Deep learning

Hint

Identify the training feedback, prediction target or measured error. Keep learning objectives separate from model architecture and data modality.

Answer B: Unsupervised learning

Unsupervised learning seeks clusters, associations or other structure without target labels. Reinforcement learning also need not receive correct-action labels, but it learns through actions and rewards, which this scenario excludes. Deep learning describes an architecture family that can use several learning regimes. Supervised learning requires labeled targets. Naming both the feedback and the requested category therefore isolates the intended regime.

Why each choice is right or wrong

A - Incorrect: Supervised learning requires labeled input-target examples.

B - Correct: Unsupervised learning discovers structure without target labels.

C - Incorrect: RL learns from action rewards, excluded by the stem.

D - Incorrect: Deep learning is an architecture family, not the specific unlabeled structure-discovery regime requested.

Primary note proof

Study-note section AI32

> Unsupervised learning seeks structure without target labels: clustering groups similar examples; association finds co-occurrence; dimensionality reduction compresses features. Good clusters have high within-cluster similarity and low between-cluster similarity under an appropriate distance. K-means alternates assignment to nearest centroids and centroid updates.

Study-note section AI33

> An RL agent observes state information, takes an action, receives reward and a new observation, and improves its policy to maximize expected cumulative reward. Rewards evaluate outcomes rather than supply the correct action label. Rewards may be delayed; not every correct-looking action receives immediate reward.

Study-note section AI43

> ANNs, genetic search and reinforcement learning all improve candidate behavior or performance through experience in different ways. Deep learning is an architecture family usable with supervised, unsupervised or reinforcement objectives. Decision trees and deep models may both be supervised. To distinguish learning regimes, specify labels, reward or unlabeled structure.

Question sources

Artificial Intelligence practice questions · Question 7

Question 57 | Q01014

What does the Turing test assess?

A. Machine learning capabilities

B. Expert system knowledge

C. Natural language processing proficiency

D. Artificial intelligence in simulating human conversation

Hint

Match the input, output and purpose to the appropriate language, perception or physical-action task.

Answer D: Artificial intelligence in simulating human conversation

Turing's test asks whether an interrogator can distinguish a computer from a human using textual questions (PDF p. 5). D captures the overall conversational behavioral test; NLP proficiency is a component rather than the full criterion.

Why each choice is right or wrong

A - Incorrect: Not a test specifically of learning. See PDF p. 5.

B - Incorrect: Not restricted to expert-system domain knowledge. See PDF p. 5.

C - Incorrect: A required conversational ability, not the complete assessment. See PDF p. 5.

D - Correct: Matches indistinguishability in textual human conversation. See PDF p. 5.

Primary note proof

Study-note section AI02

> The conversational Turing test asks whether a judge can reliably distinguish a machine from a human through their dialogue. It requires language use, knowledge, reasoning and often learning. It tests an operational behavior criterion, not proof of consciousness. Cognitive models can be tested against response times, errors and psychological experiments.

Study-note section AI37

> NLP interprets and generates human language: translation, dialogue, summarization, question answering and text generation. Speech recognition converts audio to text; speech synthesis generates speech. They overlap language processing but solve different input/output tasks.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Introduction to Artificial Intelligence module | PDF page 5 | lines 18-20

> interrogator could not distinguish them by questioning, then it would be unreasonable not to call the computer intelligent. Turing's 'imitation game' is now usually called 'the Turing test' for intelligence.

Question sources

Artificial Intelligence practice questions · Question 8

Question 58 | Q01015

Which AI technique aims to mimic the structure and function of the human brain?

A. Genetic algorithms

B. Neural networks

C. Expert systems

D. Reinforcement learning

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer B: Neural networks

Artificial neural networks are brain-inspired abstractions built from connected processing units with adjustable weights. This is inspiration rather than a literal recreation of the brain. Genetic algorithms use evolutionary population mechanisms, expert systems use encoded domain knowledge, and reinforcement learning defines a feedback regime that can be implemented with many model types, including neural networks.

Why each choice is right or wrong

A - Incorrect: Genetic algorithms are inspired by population selection and genetic variation, not a network of neural processing units.

B - Correct: Artificial neural networks are brain-inspired abstractions of interconnected weighted processing units.

C - Incorrect: Expert systems encode domain knowledge for inference rather than defining a brain-inspired network structure.

D - Incorrect: Reinforcement learning defines reward-based interaction and can use neural or non-neural implementations.

Primary note proof

Study-note section AI34

> A neuron computes z=Σiwixi+b and output a=φ(z). For x=(2,1), w=(0.5,−1), b=0.2, z=0.2. Linear activation returns z; sigmoid returns 1/(1+e^(−z)); tanh is bipolar; ReLU returns max(0,z). Nonlinearities let multiple layers represent nonlinear relationships.

Study-note section AI20

> A genetic algorithm maintains a population, evaluates fitness, selects parents, applies crossover and mutation, and repeats replacement. It searches without guaranteeing global optimality. Means-ends analysis selects a difference between current and goal states, chooses an operator

reducing it, and recursively solves its preconditions. Neither method is simply A* running backward.

Study-note section AI40

An expert system applies specialized knowledge to a domain such as equipment diagnosis. The domain expert supplies expertise; the knowledge engineer elicits and encodes it; the inference engine reasons over a knowledge base and working facts. The user interface handles interaction; an explanation facility presents why or how a conclusion was reached.

Study-note section AI33

An RL agent observes state information, takes an action, receives reward and a new observation, and improves its policy to maximize expected cumulative reward. Rewards evaluate outcomes rather than supply the correct action label. Rewards may be delayed; not every correct-looking action receives immediate reward.

Study-note section AI34

Feedforward networks pass signals toward outputs without recurrent state loops; recurrent networks carry state across sequence steps. Training adjusts weights, often through gradients and backpropagation. Backpropagation is not the same as a recurrent connection. Deep learning uses multiple representation layers and can learn features from images, sound and text. CNNs share filters across image locations. ANN is a brain-inspired abstraction, not a literal brain simulation; DL⊂ML⊂AI.

Introduction to Artificial Intelligence module | PDF page 71 | lines 6-8

An Artificial Neural Network (ANN) is an information processing paradigm that is inspired by the way
biological nervous systems, such as the brain, process information. The key element of this paradigm
is the novel structure of the information processing system.

Question sources

Artificial Intelligence practice questions · Question 9

Question 59 | Q01016

Which AI application is used to make predictions based on historical data?

A. Data mining

B. Pattern recognition

C. Predictive analytics

D. Genetic algorithms

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer C: Predictive analytics.

AI31 directly defines predictive analytics as using historical patterns to forecast outcomes. This names the application requested by the question. Data mining and pattern recognition are broader related activities that can contribute, while genetic algorithms perform evolutionary optimization. Their possible supporting roles do not make them the precise application term defined in the note.

Why each choice is right or wrong

A - Incorrect: Data mining is a broader discovery activity; the note names historical-outcome forecasting specifically as predictive analytics.

B - Incorrect: Recognizing patterns can support prediction, but does not name the defined historical-forecasting application as precisely.

C - Correct: Predictive analytics is explicitly defined as forecasting outcomes using historical patterns.

D - Incorrect: Genetic algorithms evolve candidate solutions through fitness and variation, rather than naming historical forecasting itself.

Primary note proof

Study-note section AI31

> Supervised learning fits a mapping from labeled input-target examples. Classification predicts discrete labels, such as institution generations or spam/nonspam; regression predicts numeric quantities, such as prices. Predictive analytics uses historical patterns to forecast outcomes and can use either. Specify the target before choosing a method.

Study-note section AI32

> Unsupervised learning seeks structure without target labels: clustering groups similar examples; association finds co-occurrence; dimensionality reduction compresses features. Good clusters have high within-cluster similarity and low between-cluster similarity under an appropriate distance. K-means alternates assignment to nearest centroids and centroid updates.

Study-note section AI20

> A genetic algorithm maintains a population, evaluates fitness, selects parents, applies crossover and mutation, and repeats replacement. It searches without guaranteeing global optimality. Means-ends analysis selects a difference between current and goal states, chooses an operator reducing it, and recursively solves its preconditions. Neither method is simply A* running backward.

Question sources

Artificial Intelligence practice questions · Question 10

Question 60 | Q01017

Which descriptions explicitly establish a bounded task-specific AI capability, rather than only a body shape or an unspecified “general-purpose” label? Select all that apply.

A. Autonomous vehicles limited to driving tasks.

B. Virtual assistants like Siri or Alexa performing bounded assistant tasks.

C. Humanoid robots

D. Robots described only as general-purpose, with no capability details.

Hint

Match the input, output and purpose to the appropriate language, perception or physical-action task.

Answer A, B: Autonomous vehicles limited to driving tasks.; Virtual assistants like Siri or Alexa performing bounded assistant tasks.

Narrow AI addresses bounded tasks rather than broad competence transferable across domains. Driving-only automation and a bounded voice assistant therefore establish task-specific capabilities. A humanoid body reveals shape, not intellectual scope, while an unexplained general-purpose label supplies no demonstrated cross-domain competence. The question asks which descriptions establish narrowness, so the two insufficient descriptions are excluded without claiming that their particular robots could never be narrow.

Why each choice is right or wrong

A - Correct: Autonomous driving is a bounded capability and does not by itself establish broad cross-domain general intelligence.

B - Correct: Virtual voice assistants are the note’s direct examples of bounded narrow-AI capability.

C - Incorrect: Humanoid shape alone does not establish a bounded task-specific capability.

D - Incorrect: An undefined general-purpose label does not establish a specific bounded capability.

Primary note proof

Study-note section AI01

> Narrow or weak AI addresses bounded tasks, such as face recognition, spam filtering or a voice assistant. General AI denotes broad competence transferable across domains; strong AI also has a philosophical meaning involving actual understanding. Do not equate a humanoid body, autonomous vehicle, or many features with general intelligence.

Study-note section AI39

> Robotics combines mechanical, electrical, control and computing systems to sense, plan and act physically. Components include sensors, controller, power supply, actuators and an end effector. Locomotion may be legged, wheeled or tracked, with trade-offs in terrain, stability and efficiency. Software can act autonomously without being a robot. Humanoid shape is not evidence of general intelligence.

Question sources

Artificial Intelligence practice questions · Question 11

Question 61 | Q01018

Which learning regime is defined by an agent choosing actions and improving its policy from environmental rewards or penalties, rather than by a model architecture?

A. Reinforcement learning

B. Supervised learning

C. Unsupervised learning

D. Deep learning

Hint

Identify the training feedback, prediction target or measured error. Keep learning objectives separate from model architecture and data modality.

Answer A: Reinforcement learning

Reinforcement learning is defined by interaction: the agent acts, receives reward feedback and improves its policy to increase expected cumulative return. Correct-action target labels are not required. Supervised and unsupervised learning use different feedback definitions. Deep learning describes a model architecture and may support reinforcement learning, but it does not name the particular feedback regime asked for.

Why each choice is right or wrong

A - Correct: Reinforcement learning uses action-reward interaction to improve expected return.

B - Incorrect: Supervised learning uses supplied input-target pairs rather than this reward-feedback definition.

C - Incorrect: Unsupervised learning seeks unlabeled structure rather than an action-reward policy.

D - Incorrect: Deep learning specifies multilayer neural representations and can implement several feedback regimes.

Primary note proof

Study-note section AI33

> An RL agent observes state information, takes an action, receives reward and a new observation, and improves its policy to maximize expected cumulative reward. Rewards evaluate outcomes rather than supply the correct action label. Rewards may be delayed; not every correct-looking action receives immediate reward.

Study-note section AI43

> ANNs, genetic search and reinforcement learning all improve candidate behavior or performance through experience in different ways. Deep learning is an architecture family usable with supervised, unsupervised or reinforcement objectives. Decision trees and deep models may both be supervised. To distinguish learning regimes, specify labels, reward or unlabeled structure.

Study-note section AI31

> Supervised learning fits a mapping from labeled input-target examples.

Study-note section AI32

> Unsupervised learning seeks structure without target labels: clustering groups similar examples; association finds co-occurrence; dimensionality reduction compresses features.

Question 62 | Q01019

Which AI application is used to identify and classify objects in images?

A. Natural language processing

B. Speech recognition

C. Computer vision

D. Expert systems

Hint

Match the input, output and purpose to the appropriate language, perception or physical-action task.

Answer C: Computer vision

Computer vision automatically analyzes image information and includes object recognition (PDF p. 84), directly matching identifying/classifying image objects.

Why each choice is right or wrong

A - Incorrect: Processes language rather than image objects. See PDF p. 84, 84.

B - Incorrect: Transcribes speech. See PDF p. 84, 84.

C - Correct: The explicitly visual recognition application. See PDF p. 84, 84.

D - Incorrect: Domain expertise alone does not specify vision. See PDF p. 84, 84.

Primary note proof

Study-note section AI39

Computer vision interprets images or video: classification names image content, detection locates objects, segmentation labels pixels, and recognition identifies objects or people. Occlusion, lighting change, noise, unfamiliar conditions and incomplete context make open-world perception difficult even when a face detector works well.

Study-note section AI37

NLP interprets and generates human language: translation, dialogue, summarization, question answering and text generation. Speech recognition converts audio to text; speech synthesis generates speech. They overlap language processing but solve different input/output tasks.

Study-note section AI40

An expert system applies specialized knowledge to a domain such as equipment diagnosis. Question sources

Artificial Intelligence practice questions · Question 13

Question 63 | Q01020

Which approach represents imprecise linguistic categories such as warm by graded membership between zero and one, rather than treating membership as strictly true or false?

A. Genetic algorithms

B. Fuzzy logic

C. Neural networks

D. Reinforcement learning

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer B: Fuzzy logic

Fuzzy logic represents imprecise categories through graded membership, so an input can belong to a category to a degree rather than only completely or not at all. This differs from uncertainty about whether an event occurs. Genetic search, neural networks and reinforcement learning can be combined with fuzzy methods, but their defining mechanisms do not supply this membership interpretation.

Why each choice is right or wrong

A - Incorrect: Genetic algorithms evolve populations; graded category membership is not their defining mechanism.

B - Correct: Fuzzy logic represents degrees of membership in vague categories.

C - Incorrect: Neural networks adjust weighted representations and do not inherently define fuzzy membership.

D - Incorrect: Reinforcement learning uses rewards and policy improvement rather than defining graded category membership.

Primary note proof

Study-note section AI30

> Fuzzy sets assign graded membership μ(x) between 0 and 1 to concepts such as warm or tall. A temperature can belong to warm with degree 0.7. This is not a 70% probability that an otherwise crisp warm proposition is true. Boolean logic uses only true and false; probability describes uncertainty about events.

Study-note section AI20

> A genetic algorithm maintains a population, evaluates fitness, selects parents, applies crossover and mutation, and repeats replacement. It searches without guaranteeing global optimality. Means-ends analysis selects a difference between current and goal states, chooses an operator reducing it, and recursively solves its preconditions. Neither method is simply A* running backward.

Study-note section AI33

> An RL agent observes state information, takes an action, receives reward and a new observation, and improves its policy to maximize expected cumulative reward. Rewards evaluate outcomes rather than supply the correct action label. Rewards may be delayed; not every correct-looking action receives immediate reward.

Question 64 | Q01021

Which AI application is used to generate human-like text or speech?

A. Natural language processing

B. Speech recognition

C. Computer vision

D. Expert systems

Hint

Match the input, output and purpose to the appropriate language, perception or physical-action task.

Answer A: Natural language processing

NLG is the NLP component for generating language from computerized representations, including text and sentence planning (PDF pp. 79-80). Thus NLP is the offered application matching generation; the source does not provide a full speech-synthesis treatment.

Why each choice is right or wrong

A - Correct: Includes the explicit language-generation component. See PDF p. 79, 80.

B - Incorrect: Recognizes spoken input rather than generating output. See PDF p. 79, 80.

C - Incorrect: Works with image understanding. See PDF p. 79, 80.

D - Incorrect: Generates domain conclusions, not necessarily natural-language output. See PDF p. 79, 80.

Primary note proof

Study-note section AI37

> NLP interprets and generates human language: translation, dialogue, summarization, question answering and text generation. Speech recognition converts audio to text; speech synthesis generates speech. They overlap language processing but solve different input/output tasks.

Study-note section AI39

> Computer vision interprets images or video: classification names image content, detection locates objects, segmentation labels pixels, and recognition identifies objects or people. Question sources

Artificial Intelligence practice questions · Question 15

Question 65 | Q01022

Which technique involves evolving solutions using principles from genetics and natural selection?

A. Genetic algorithms

B. Neural networks

C. Reinforcement learning

D. Expert systems

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer A: Genetic algorithms

AI20 describes a genetic algorithm as maintaining a population, evaluating fitness, selecting parents and applying crossover and mutation. Those operations embody the genetics and natural-selection principles in the stem. Neural networks, reward-based learning and rule-based expert systems use different organizing mechanisms, even where hybrid systems combine them with evolutionary search.

Why each choice is right or wrong

A - Correct: Genetic algorithms use fitness, parent selection, crossover and mutation to evolve candidate populations.

B - Incorrect: Neural networks learn weighted representations; evolutionary population replacement is not required.

C - Incorrect: Reinforcement learning improves policies from environmental rewards rather than requiring genetic variation.

D - Incorrect: Expert systems reason with specialized encoded knowledge rather than requiring evolutionary populations.

Primary note proof

Study-note section AI20

A genetic algorithm maintains a population, evaluates fitness, selects parents, applies crossover and mutation, and repeats replacement. It searches without guaranteeing global optimality. Means-ends analysis selects a difference between current and goal states, chooses an operator reducing it, and recursively solves its preconditions. Neither method is simply A* running backward.

Study-note section AI34

A neuron computes z=Σiwixi+b and output a=φ(z). For x=(2,1), w=(0.5,−1), b=0.2, z=0.2. Linear activation returns z; sigmoid returns 1/(1+e^(−z)); tanh is bipolar; ReLU returns max(0,z). Nonlinearities let multiple layers represent nonlinear relationships.

Study-note section AI33

An RL agent observes state information, takes an action, receives reward and a new observation, and improves its policy to maximize expected cumulative reward. Rewards evaluate outcomes rather than supply the correct action label. Rewards may be delayed; not every correct-looking action receives immediate reward.

Study-note section AI40

An expert system applies specialized knowledge to a domain such as equipment diagnosis. The domain expert supplies expertise; the knowledge engineer elicits and encodes it; the inference engine reasons over a knowledge base and working facts. 1. Which one of the following is correctly matched with the definition and approaches of AI

Question sources

Artificial Intelligence practice questions · Question 16

Question 66 | Q01023

Which technique directly represents degrees of linguistic concepts such as warm and applies graded IF-THEN rules to choose an action?

A. Fuzzy logic

B. Reinforcement learning

C. Expert systems

D. Genetic algorithms

Hint

Identify the training feedback, prediction target or measured error. Keep learning objectives separate from model architecture and data modality.

Answer A: Fuzzy logic

Fuzzy control represents degrees of membership in concepts such as warm and combines graded rules to produce an action. This handles vague category boundaries rather than requiring probabilistic uncertainty or reward-based adaptation. Reinforcement learning improves policies through rewards, expert systems apply specialized knowledge, and genetic algorithms evolve populations. The added representation and rule requirements distinguish fuzzy control from other methods that may also address complex decisions.

Why each choice is right or wrong

A - Correct: Fuzzy logic uses graded membership and fuzzy IF-THEN rules.

B - Incorrect: RL uses reward-driven adaptation rather than defining graded linguistic membership.

C - Incorrect: An ordinary expert system need not represent degrees of membership in linguistic categories.

D - Incorrect: Genetic algorithms evolve candidates through fitness and variation rather than fuzzy rule evaluation.

Primary note proof

Study-note section AI30

> Fuzzy sets assign graded membership μ(x) between 0 and 1 to concepts such as warm or tall. A temperature can belong to warm with degree 0.7. This is not a 70% probability that an otherwise crisp warm proposition is true. Boolean logic uses only true and false; probability describes uncertainty about events.

Study-note section AI30

> A fuzzy controller fuzzifies measurements, applies graded IF-THEN rules, combines outputs and often defuzzifies to a numerical action. Fuzzy control suits linguistic rules about degrees; reinforcement learning suits reward-based adaptation. Merely saying an environment is complex or uncertain does not uniquely select either method.

Study-note section AI33

> An RL agent observes state information, takes an action, receives reward and a new observation, and improves its policy to maximize expected cumulative reward. Rewards evaluate outcomes rather than supply the correct action label. Rewards may be delayed; not every correct-looking action receives immediate reward.

Question 67 | Q01024

Which AI application is used to simulate human conversation?

A. Natural language processing

B. Speech recognition

C. Computer vision

D. Expert systems

Hint

Match the input, output and purpose to the appropriate language, perception or physical-action task.

Answer A: Natural language processing

The module lists chatbots as an important NLP application used for chat services (PDF p. 82). That directly supports NLP for simulated conversation.

Why each choice is right or wrong

A - Correct: Includes the chatbot application. See PDF p. 82.

B - Incorrect: Transcription alone is not conversation. See PDF p. 82.

C - Incorrect: Image comprehension does not define conversation. See PDF p. 82.

D - Incorrect: Expert conclusions may be communicated, but chat is specifically listed under NLP. See PDF p. 82.

Primary note proof

Study-note section AI37

> NLP interprets and generates human language: translation, dialogue, summarization, question answering and text generation. Speech recognition converts audio to text; speech synthesis generates speech. They overlap language processing but solve different input/output tasks.

Study-note section AI02

> The conversational Turing test asks whether a judge can reliably distinguish a machine from a human through their dialogue. It requires language use, knowledge, reasoning and often learning. It tests an operational behavior criterion, not proof of consciousness. Cognitive models can be tested against response times, errors and psychological experiments.

Question sources

Artificial Intelligence practice questions · Question 18

Question 68 | Q01025

A collection of documents has no target labels. The task is to group similar documents, with no action-reward interaction. Which learning regime describes this objective, regardless of the architecture used?

A. Supervised learning

B. Unsupervised learning

C. Reinforcement learning

D. Deep learning

Hint

Identify the training feedback, prediction target or measured error. Keep learning objectives separate from model architecture and data modality.

Answer B: Unsupervised learning

Grouping similar documents without target labels is clustering, an unsupervised learning objective. The data modality does not determine the feedback regime, and a neural architecture could still be used for this task. Supervised learning requires targets; reinforcement learning requires an action-and-reward objective. The question asks for the learning regime rather than which architecture might process documents.

Why each choice is right or wrong

A - Incorrect: Supervised learning requires target labels, absent from the described task.

B - Correct: Unsupervised learning discovers structure, including clusters, without supplied targets.

C - Incorrect: No actions or reward feedback are present, so this is not the reinforcement objective.

D - Incorrect: Deep learning describes a multilayer architecture that might implement clustering, not the learning regime.

Primary note proof

Study-note section AI32

> Unsupervised learning seeks structure without target labels: clustering groups similar examples; association finds co-occurrence; dimensionality reduction compresses features. Good clusters have high within-cluster similarity and low between-cluster similarity under an appropriate distance. K-means alternates assignment to nearest centroids and centroid updates.

Study-note section AI43

> ANNs, genetic search and reinforcement learning all improve candidate behavior or performance through experience in different ways. Deep learning is an architecture family usable with supervised, unsupervised or reinforcement objectives. Decision trees and deep models may both be supervised. To distinguish learning regimes, specify labels, reward or unlabeled structure.

Study-note section AI31

> Supervised learning fits a mapping from labeled input-target examples.

Study-note section AI33

> An RL agent observes state information, takes an action, receives reward and a new observation, and improves its policy to maximize expected cumulative reward.

Artificial Intelligence practice questions · Question 19

Question 69 | Q01026

Which AI technique involves training a model on a large dataset and multiple layers of artificial neurons?

A. Genetic algorithms

B. Neural networks

C. Expert systems

D. Reinforcement learning

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer B: Neural networks

AI34 describes artificial neurons with learned weights and nonlinear outputs, then defines deep learning through multiple representation layers. This matches the large-data, multilayer neural architecture in the stem. Reinforcement learning defines reward-based feedback rather than a specific architecture; genetic algorithms and expert systems do not inherently consist of layered artificial neurons.

Why each choice is right or wrong

A - Incorrect: Genetic algorithms evolve populations and are not defined by layered artificial neurons.

B - Correct: A layered collection of artificial neurons is a neural-network architecture whose weights are adjusted during training.

C - Incorrect: Expert systems define knowledge-base reasoning rather than layers of trainable neurons.

D - Incorrect: Reinforcement learning specifies the reward objective, not a required layered-neuron architecture.

Primary note proof

Study-note section AI34

A neuron computes $z=\Sigma iwixi+b$ and output $a=\varphi(z)$. For $x=(2,1)$, $w=(0.5,-1)$, $b=0.2$, $z=0.2$. Linear activation returns z; sigmoid returns $1/(1+e^{(-z)})$; tanh is bipolar; ReLU returns $\max(0,z)$. Nonlinearities let multiple layers represent nonlinear relationships.

Study-note section AI20

A genetic algorithm maintains a population, evaluates fitness, selects parents, applies crossover and mutation, and repeats replacement. It searches without guaranteeing global optimality. Means-ends analysis selects a difference between current and goal states, chooses an operator reducing it, and recursively solves its preconditions. Neither method is simply A* running backward.

Study-note section AI40

An expert system applies specialized knowledge to a domain such as equipment diagnosis. The domain expert supplies expertise; the knowledge engineer elicits and encodes it; the inference engine reasons over a knowledge base and working facts. The user interface handles interaction; an explanation facility presents why or how a conclusion was reached.

Study-note section AI33

An RL agent observes state information, takes an action, receives reward and a new observation, and improves its policy to maximize expected cumulative reward. Rewards evaluate outcomes rather than supply the correct action label. Rewards may be delayed; not every correct-looking action receives immediate reward.

Study-note section AI34

Feedforward networks pass signals toward outputs without recurrent state loops; recurrent networks carry state across sequence steps. Question sources

Artificial Intelligence practice questions · Question 20

Question 70 | Q01027

What is Artificial Intelligence?

A. Artificial Intelligence is a field that aims to make humans more intelligent

B. Artificial Intelligence is a field that aims to improve the security

C. Artificial Intelligence is a field that aims to develop intelligent machines

D. Artificial Intelligence is a field that aims to mine the data

Hint

Read the definition and the classification axis requested; distinguish the defining purpose from supporting techniques or implementation resources.

Answer C: Artificial Intelligence is a field that aims to develop intelligent machines

The module defines AI as designing intelligence in an artificial device (PDF p. 4). Developing intelligent machines is the matching general description, rather than an individual application.

Why each choice is right or wrong

A - Incorrect: Making people smarter is not the stated field definition. See PDF p. 4.

B - Incorrect: Security is a possible application, not the field definition. See PDF p. 4.

C - Correct: Matches intelligence in an artificial device. See PDF p. 4.

D - Incorrect: Data mining is one learning application, not the field's definition. See PDF p. 4.

Primary note proof

Study-note section AI01

> Artificial intelligence studies systems that perform tasks requiring intelligence: reasoning, learning, planning, perception and language. Applied AI builds useful solutions; cognitive AI uses computational models to investigate biological intelligence. A model should be compared with human behavior or experimental observations before claiming it explains human thought.

Module passages - related reading

Introduction to Artificial Intelligence module | PDF page 4 | lines 26-27

> is concerned with the design of intelligence in an artificial device. The term was coined by McCarthy
> in 1956. There are two ideas in the definition. i.e Intelligence, and Artificial device.

Question sources

Artificial Intelligence practice questions · Question 21

Question 71 | Q01028

Who is credited with coining the term artificial intelligence in the proposal for the Dartmouth summer research project?

A. Geoffrey Hinton

B. Andrew Ng

C. John McCarthy

D. Jürgen Schmidhuber

Hint

Read the definition and the classification axis requested; distinguish the defining purpose from supporting techniques or implementation resources.

Answer C: John McCarthy

John McCarthy is credited with coining the term in the 1955 proposal for the Dartmouth summer research project. The workshop itself took place in 1956 and helped establish the research field. This naming attribution does not make McCarthy the sole inventor of every AI idea or method. The question now asks for the documented attribution rather than an oversimplified invention claim.

Why each choice is right or wrong

A - Incorrect: The historical naming attribution in the note is to McCarthy, not Hinton.

B - Incorrect: The historical naming attribution in the note is to McCarthy, not Ng.

C - Correct: McCarthy is credited with introducing the term in the 1955 Dartmouth proposal.

D - Incorrect: The historical naming attribution in the note is to McCarthy, not Schmidhuber.

Primary note proof

Study-note section AI-S04

> John McCarthy is credited with coining the term artificial intelligence in the 1955 proposal for the Dartmouth summer research project. The Dartmouth workshop took place in 1956 and helped establish the field. Naming the field does not mean that one person invented all its ideas or methods.

Study-note section AI43

> Face recognition is both an applied task and a narrow capability. Broad machine-intelligence goals can include emulating human intelligence and building systems that learn. Humanlike problem-solving alone does not uniquely select expert systems. Python is widely used, but C++ and Java also implement AI; “commonly used” does not isolate one language. McCarthy is associated with naming AI, not its sole invention.

Introduction to Artificial Intelligence module | PDF page 4 | lines 26-27

is concerned with the design of intelligence in an artificial device. The term was coined by McCarthy
in 1956. There are two ideas in the definition. i.e Intelligence, and Artificial device.

Question sources

Artificial Intelligence practice questions · Question 22

Question 72 | Q01029

Which activity, as stated, directly requires an intelligence-related capability, rather than merely naming a computing operation that may or may not use AI?

A. It helps to exploit vulnerabilities to secure the firm

B. Language understanding and problem-solving (Text analytics and NLP)

C. Easy to create a website

D. It helps to deploy applications on the cloud

Hint

Match the input, output and purpose to the appropriate language, perception or physical-action task.

Answer B: Language understanding and problem-solving (Text analytics and NLP)

AI concerns capabilities such as reasoning, learning and language understanding. The language-understanding and problem-solving option explicitly names such capabilities. Website creation, cloud deployment and security operations can incorporate AI, but the activity names alone do not establish its use. The distinction is between an explicit intelligence-related task and a computing context that could host many kinds of software.

Why each choice is right or wrong

A - Incorrect: Security testing or exploitation can use ordinary programmed tools; the activity alone does not require intelligent learning or reasoning.

B - Correct: Understanding human language and solving problems directly name intelligence-related capabilities.

C - Incorrect: Creating a website can use conventional software tools without intelligent behavior.

D - Incorrect: Deploying an application to a cloud platform does not itself require an intelligent application.

Primary note proof

Study-note section AI01

Artificial intelligence studies systems that perform tasks requiring intelligence: reasoning, learning, planning, perception and language. Applied AI builds useful solutions; cognitive AI uses computational models to investigate biological intelligence. A model should be compared with human behavior or experimental observations before claiming it explains human thought.

Study-note section AI37

NLP interprets and generates human language: translation, dialogue, summarization, question answering and text generation. Speech recognition converts audio to text; speech synthesis generates speech. They overlap language processing but solve different input/output tasks.

Question sources

Artificial Intelligence practice questions · Question 23

Question 73 | Q01030

Which of the following is a component of Artificial Intelligence?

A. Learning

B. Training

C. Designing

D. Puzzling

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer A: Learning

Learning appears explicitly among intelligent behaviors (PDF p. 6), and is defined as improving performance from experience on p. 67. The other words are not offered as parallel components in the module.

Why each choice is right or wrong

A - Correct: Explicitly named intelligent capability. See PDF p. 6.

B - Incorrect: Training is a model-building activity, not the named component here. See PDF p. 6.

C - Incorrect: Designing is not presented as the matching intelligent capability. See PDF p. 6.

D - Incorrect: Puzzling is not a defined component. See PDF p. 6.

Primary note proof

Study-note section AI08

> The performance element selects actions. The learning element changes the agent to improve future performance. The critic evaluates behavior against a performance standard and supplies feedback. The problem generator suggests exploratory actions likely to yield useful experience.

Study-note section AI08

> Learning is improvement on task T, measured by P, through experience E. For spam filtering, T is classifying email, E is past labeled messages, and P might be recall at a required precision. Exploration trades immediate reward for information; exploitation uses the best action currently known. Learning can improve reflex, goal-based or utility-based agents.

Question sources

Artificial Intelligence practice questions · Question 24

Question 74 | Q01032

Which of the following is not a type of Artificial Intelligence agent?

A. Learning AI agent

B. Goal-based AI agent

C. Simple reflex AI agent

D. Unity-based AI agent

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer D: Unity-based AI agent

The module lists simple reflex, model-based reflex, goal-based, utility-based and learning agents (PDF pp. 14-15). “Unity-based” is not “utility-based” and is not one of those classes.

Why each choice is right or wrong

A - Incorrect: Learning is a listed class. See PDF p. 14, 15.

B - Incorrect: Goal-based is listed. See PDF p. 14, 15.

C - Incorrect: Simple reflex is listed. See PDF p. 14, 15.

D - Correct: Unity-based is not a listed class. See PDF p. 14, 15.

Primary note proof

Study-note section AI42

> The common teaching list contains five agent classes when learning agents are included, or four decision architectures before learning is added. State the convention when counting agent types. “Target-based” can mean goal-based; “unity-based” is not utility-based.

Study-note section AI06

> A simple reflex agent matches condition-action rules against the current percept only: if dirty, clean. It has no persistent world-state memory. This is adequate when the current observation contains everything needed for its rule, but partial observability can make the same percept require different actions.

Study-note section AI08

> The performance element selects actions. The learning element changes the agent to improve future performance. The critic evaluates behavior against a performance standard and supplies feedback. The problem generator suggests exploratory actions likely to yield useful experience.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Introduction to Artificial Intelligence module | PDF page 14 | lines 10-11

> Agents can be grouped into five classes based on their degree of perceived intelligence and capability.
> All these agents can improve their performance and generate better action over the time.

Introduction to Artificial Intelligence module | PDF page 15 | lines 20-21

> 2.9.5 Learning agent
> • Learning allows an agent to operate in initially unknown environments.

Question sources

Artificial Intelligence practice questions · Question 26

Question 75 | Q01033

Which agent architecture applies fixed condition-action rules directly to the current percept, without retaining an internal world-state model?

A. Simple reflex agent

B. Model-based agent

C. Goal-based agent

D. Utility-based agent

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer A: Simple reflex agent

The absence of persistent internal state is the key distinction. A simple reflex agent maps the current percept to an action using condition-action rules. Model-based reflex agents may also use rules, but they maintain a world-state representation. Goal-based and utility-based agents use goals or outcome preferences to guide selection, rather than being defined by current-percept-only rule matching.

Why each choice is right or wrong

A - Correct: A simple reflex agent chooses from the current percept without persistent world-state memory.

B - Incorrect: A model-based reflex agent adds internal state and applies rules to that modeled state.

C - Incorrect: Goal-based selection evaluates actions or future sequences against a desired state.

D - Incorrect: Utility-based selection ranks outcomes by desirability or expected utility.

Primary note proof

Study-note section AI06

> A simple reflex agent matches condition-action rules against the current percept only: if dirty, clean. It has no persistent world-state memory. This is adequate when the current observation contains everything needed for its rule, but partial observability can make the same percept require different actions.

Study-note section AI06

> A model-based reflex agent maintains internal state using the previous state, previous action, current percept, and models of world change and action effects. It then applies rules to that state. Both kinds can use condition-action rules; memory and a world model distinguish them.

Study-note section AI07

> A goal-based agent considers future action sequences that reach a desired state. A utility-based agent compares degrees of desirability and trade-offs, choosing maximum expected utility: $EU(a)=\Sigma s\ P(s|a,evidence)U(s)$. Reaching the destination is a goal; balancing arrival time, safety and cost requires preferences among outcomes.

Question sources

Artificial Intelligence practice questions · Question 27

Question 76 | Q01034

Which type of agent maintains an internal model of the world to make decisions?

A. Simple reflex agent

B. Model-based agent

C. Goal-based agent

D. Utility-based agent

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer B: Model-based agent

An internal state based on percept history and a model of how the world changes define the model-based category. Goal and utility agents can extend that architecture, so the requested defining type is B. Evidence: PDF 14.

Why each choice is right or wrong

A - Incorrect: Current-percept rules omit history. See PDF p. 14.

B - Correct: Matches the internal model definition. See PDF p. 14.

C - Incorrect: Adds explicit goal information to a model. See PDF p. 14.

D - Incorrect: Adds a numerical utility criterion. See PDF p. 14.

Primary note proof

Study-note section AI06

A model-based reflex agent maintains internal state using the previous state, previous action, current percept, and models of world change and action effects. It then applies rules to that state. Both kinds can use condition-action rules; memory and a world model distinguish them.

Study-note section AI07

A goal-based agent considers future action sequences that reach a desired state. A utility-based agent compares degrees of desirability and trade-offs, choosing maximum expected utility: $EU(a)=\Sigma s\ P(s|a,evidence)U(s)$. Reaching the destination is a goal; balancing arrival time, safety and cost requires preferences among outcomes.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Introduction to Artificial Intelligence module | PDF page 14 | lines 29-31

- Internal State: It is a representation of the current state based on percept history.
• These agents have the model, "which is knowledge of the world" and based on the model they perform actions.

Question sources

Artificial Intelligence practice questions · Question 28

Question 77 | Q01035

Which type of agent selects actions based on their expected utility or desirability?

A. Simple reflex agent

B. Model-based agent

C. Goal-based agent

D. Utility-based agent

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer D: Utility-based agent

A utility function assigns real numbers to states to compare how efficiently actions achieve goals; this is precisely desirability-based selection. Evidence: PDF 15.

Why each choice is right or wrong

A - Incorrect: Uses condition-action rules. See PDF p. 15.

B - Incorrect: A world model alone supplies no preference scale. See PDF p. 15.

C - Incorrect: Goal achievement alone does not rank desirable outcomes. See PDF p. 15.

D - Correct: Numerical utility ranks alternatives. See PDF p. 15.

Primary note proof

Study-note section AI07

> A goal-based agent considers future action sequences that reach a desired state. A utility-based agent compares degrees of desirability and trade-offs, choosing maximum expected utility: EU(a)=Σs P(s|a,evidence)U(s). Reaching the destination is a goal; balancing arrival time, safety and cost requires preferences among outcomes.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Introduction to Artificial Intelligence module | PDF page 15 | lines 18-20

> • The utility function maps each state to a real number to check how efficiently each action achieves
> the goals.
> 2.9.5 Learning agent

Question sources

Artificial Intelligence practice questions · Question 29

Question 78 | Q01036

Which type of agent represents goals and selects actions that maximize the achievement of those goals?

A. Simple reflex agent

B. Model-based agent

C. Goal-based agent

D. Utility-based agent

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer C: Goal-based agent

Explicit desirable goal situations and choosing actions to reach them characterize goal-based agents. Evidence: PDF 15.

Why each choice is right or wrong

A - Incorrect: Responds to current percept. See PDF p. 15.

B - Incorrect: Tracks state without necessarily representing a goal. See PDF p. 15.

C - Correct: Explicit goal information supplies the requested criterion. See PDF p. 15.

D - Incorrect: Adds utility rankings beyond mere goal achievement. See PDF p. 15.

Primary note proof

Study-note section AI07

> A goal-based agent considers future action sequences that reach a desired state. A utility-based agent compares degrees of desirability and trade-offs, choosing maximum expected utility: EU(a)=Σs P(s|a,evidence)U(s). Reaching the destination is a goal; balancing arrival time, safety and cost requires preferences among outcomes.

Study-note section AI07

> Updating an internal state after selecting an action predicts the action’s effect; it does not itself modify the external environment. A stored variable named goal is insufficient to prove a goal-based policy if BEST_ACTION never uses it. Model-based, goal-based, utility-based and learning capabilities can coexist.

Question 79 | Q01037

Which type of agent improves its performance over time through learning from experience?

A. Simple reflex agent

B. Model-based agent

C. Goal-based agent

D. Learning agent

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer D: Learning agent

Learning agents adapt using past experience and a learning element that changes performance. Evidence: PDF 15.

Why each choice is right or wrong

A - Incorrect: Current rules do not themselves explain improvement. See PDF p. 15.

B - Incorrect: Tracking state is not itself learning. See PDF p. 15.

C - Incorrect: Goal pursuit need not change performance over time. See PDF p. 15.

D - Correct: Explicitly learns from experience. See PDF p. 15.

Primary note proof

Study-note section AI08

> The performance element selects actions. The learning element changes the agent to improve future performance. The critic evaluates behavior against a performance standard and supplies feedback. The problem generator suggests exploratory actions likely to yield useful experience.

Study-note section AI08

> Learning is improvement on task T, measured by P, through experience E. For spam filtering, T is classifying email, E is past labeled messages, and P might be recall at a required precision. Exploration trades immediate reward for information; exploitation uses the best action currently known. Learning can improve reflex, goal-based or utility-based agents.

• A learning agent in AI is the type of agent which can learn from its past experiences, or it has learning
capabilities.
• It starts to act with basic knowledge and then able to act and adapt automatically through learning.

Question sources

Artificial Intelligence practice questions · Question 31

Question 80 | Q01038

A face-recognition system is built to control entry to a building, without trying to explain biological recognition processes. Which approach classifies this practical engineering purpose, rather than its breadth of capability?

A. Weak AI approach

B. Applied AI approach

C. Cognitive AI approach

D. Strong AI approach

Hint

Read the definition and the classification axis requested; distinguish the defining purpose from supporting techniques or implementation resources.

Answer B: Applied AI approach

Applied AI builds useful solutions to practical tasks, so building-access recognition fits that purpose. The same system is also narrow or weak AI in capability scope. These labels answer different classification questions and are compatible. Cognitive AI would investigate biological intelligence, while strong-AI claims concern broader competence or actual understanding. The explicit purpose axis isolates the intended selection.

Why each choice is right or wrong

A - Incorrect: Weak AI describes bounded capability, which also fits face recognition, but does not classify the purpose requested.

B - Correct: Applied AI builds a useful practical solution, matching the entry-control purpose.

C - Incorrect: Cognitive AI investigates biological intelligence; that is not the stated purpose.

D - Incorrect: Strong AI concerns actual understanding or broad intelligence claims, not the application purpose described.

Primary note proof

Study-note section AI01

Artificial intelligence studies systems that perform tasks requiring intelligence: reasoning, learning, planning, perception and language. Applied AI builds useful solutions; cognitive AI uses

computational models to investigate biological intelligence. A model should be compared with human behavior or experimental observations before claiming it explains human thought.

Study-note section AI01

Narrow or weak AI addresses bounded tasks, such as face recognition, spam filtering or a voice assistant. General AI denotes broad competence transferable across domains; strong AI also has a philosophical meaning involving actual understanding. Do not equate a humanoid body, autonomous vehicle, or many features with general intelligence.

Study-note section AI43

Face recognition is both an applied task and a narrow capability. Broad machine-intelligence goals can include emulating human intelligence and building systems that learn. Humanlike problem-solving alone does not uniquely select expert systems. Python is widely used, but C++ and Java also implement AI; “commonly used” does not isolate one language. McCarthy is associated with naming AI, not its sole invention.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Introduction to Artificial Intelligence module | PDF page 7 | lines 6-8

Applied AI: aims to produce commercially viable smart system. For example, a security system that
is able to recognize the faces of people who are permitted to enter a particular building. Applied AI
has already enjoyed considerable success.

Question sources

Artificial Intelligence practice questions · Question 32

Question 81 | Q01039

Which single option gives the complete set of possible AI benefits in suitable, evaluated applications? Interpret the choices operationally, without assuming consciousness or guaranteed improvement.

A. Can reduce search work and time with an effective heuristic.

B. Can support protective filtering by detecting unwanted spam messages.

C. Can automate reasoning and learning to help solve tasks.

D. All of the above

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer D: All of the above

Useful AI methods can reduce search work when a heuristic guides exploration effectively. Learned detection of unwanted spam can support protective filtering, and computational reasoning or learning can automate parts of a task. These are possible operational benefits rather than guarantees for every deployment or claims of consciousness. Each individual choice gives only one benefit, so the inclusive response supplies the complete set.

Why each choice is right or wrong

A - Incorrect: Effective heuristics can reduce explored work, but this is only one of the listed possible benefits.

B - Incorrect: Spam classification can support protective filtering, but this alone is incomplete.

C - Incorrect: Automating computational reasoning and learning can help tasks, but this alone is incomplete.

D - Correct: All three are possible operational benefits under the stated suitable-application scope.

Primary note proof

Study-note section AI17

> A heuristic h(n) estimates remaining cost or evaluates promise using problem-specific knowledge. It can reduce explored work, but computing it also costs time. Uninformed algorithms use only the problem definition and known costs; UCS remains uninformed despite using g.

Study-note section AI08

> Learning is improvement on task T, measured by P, through experience E. For spam filtering, T is classifying email, E is past labeled messages, and P might be recall at a required precision. Exploration trades immediate reward for information; exploitation uses the best action currently known. Learning can improve reflex, goal-based or utility-based agents.

Study-note section AI01

> Artificial intelligence studies systems that perform tasks requiring intelligence: reasoning, learning, planning, perception and language. Applied AI builds useful solutions; cognitive AI uses computational models to investigate biological intelligence. A model should be compared with human behavior or experimental observations before claiming it explains human thought.

Introduction to Artificial Intelligence module | PDF page 79 | lines 11-12

- It is very time efficient.
- Most of the companies use NLP to improve the efficiency of documentation processes,

Introduction to Artificial Intelligence module | PDF page 7 | lines 3-5

Weak AI: deals with the creation of some form of computer-based artificial intelligence that cannot
truly reason and solve problems, but can act as if it were intelligent. Weak AI holds that suitably programmed machines can simulate human cognition.

Question sources

Artificial Intelligence practice questions · Question 33

Question 82 | Q01040

Which of the following is/are the composition for AI agents?

A. Program only

B. Architecture only

C. Both Program and Architecture

D. None of the mentioned

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer C: Both Program and Architecture

The structural equation adds architecture and agent program; neither component alone is the complete agent. Evidence: PDF 12.

Why each choice is right or wrong

A - Incorrect: Omits executing machinery. See PDF p. 12.

B - Incorrect: Omits implementing program. See PDF p. 12.

C - Correct: Contains both terms in the equation. See PDF p. 12.

D - Incorrect: Contradicts the explicit equation. See PDF p. 12.

Primary note proof

Study-note section AI03

A percept is one observation; a percept sequence is the entire observation history. An agent function maps percept sequences to actions: f:P*→A. An agent program implements that mapping on an architecture; agent = architecture + program. Environment means the setting in which it senses and acts, not merely the search space. Autonomy means relying substantially on experience rather than only a designer’s prior instructions.

Study-note section AI-S03

> An AI task is modeled as an agent interacting with its environment: observations enter through sensors and selected actions affect the environment through actuators. This task-level description differs from an agent implementation, which combines a program with a computing architecture.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Introduction to Artificial Intelligence module | PDF page 12 | lines 25-27

> • Agent = Architecture + Agent Program
> • Architecture = the machinery that an agent executes on.
> • Agent Program = an implementation of an agent function.

Question sources

Artificial Intelligence practice questions · Question 34

Question 83 | Q01041

Which are examples of artificial agents, assuming the spacecraft and robot use constructed controllers that sense and select actions autonomously? Select all that apply.

A. Autonomous Spacecraft

B. Human

C. Robot

D. All of the mentioned

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer A, C: Autonomous Spacecraft; Robot

An artificial agent uses a constructed sensing and action-selection system to interact with its environment. Under the explicit control assumption, both the autonomous spacecraft and robot qualify. Humans also perceive and act, so they are agents, but they are not artificial agents. The inclusive choice fails because it includes humans. This classification concerns artificial agency and does not assert that a robot has general intelligence.

Why each choice is right or wrong

A - Correct: An autonomous spacecraft uses constructed sensing and action-selection mechanisms to interact with its environment.

B - Incorrect: A human is an agent but is not an artificial agent.

C - Correct: An AI-controlled robot senses and acts physically and is an artificial-agent example.

D - Incorrect: Including humans makes this aggregate false under the question's artificial-agent wording.

Primary note proof

Study-note section AI03

> An agent perceives an environment through sensors and acts through actuators or effectors. Cameras sense; motors move. Software sensors may be incoming messages and software actions may be API requests. Humans are agents but are not artificial agents.

Study-note section AI39

> Robotics combines mechanical, electrical, control and computing systems to sense, plan and act physically. Components include sensors, controller, power supply, actuators and an end effector. Locomotion may be legged, wheeled or tracked, with trade-offs in terrain, stability and efficiency. Software can act autonomously without being a robot. Humanoid shape is not evidence of general intelligence.

Question sources

Artificial Intelligence practice questions · Question 35

Question 84 | Q01042

Which of the following is an expansion of Artificial Intelligence application?

A. Game Playing

B. Planning and Scheduling

C. Diagnosis

D. All of the mentioned

Hint

Read the definition and the classification axis requested; distinguish the defining purpose from supporting techniques or implementation resources.

Answer D: All of the mentioned

The application list includes medical diagnosis, telescope planning/scheduling, and grand-master game play. All three categories are present. Evidence: PDF 7, 7.

Why each choice is right or wrong

A - Incorrect: Games are explicitly listed. See PDF p. 7, 7.

B - Incorrect: Planning and scheduling are explicitly listed. See PDF p. 7, 7.

C - Incorrect: Medical diagnosis is explicitly listed. See PDF p. 7, 7.

D - Correct: Combines all three documented applications. See PDF p. 7, 7.

Primary note proof

Study-note section AI-S03

> Planning constructs actions to reach a goal. Scheduling additionally assigns activities to times and resources while respecting constraints such as resource conflicts and precedence. It is an AI application when search or constraint reasoning chooses feasible or useful assignments; automated telescope experiment scheduling is an example.

Study-note section AI22

> Adversarial search models agents with competing objectives. A game specifies states, player to move, legal actions, successor function, terminal test and utility. Perfect information means previous moves and current state are visible; it does not reveal future choices or imply absence of chance. Zero-sum utility makes one player’s gain the other’s loss.

Study-note section AI40

> An expert system applies specialized knowledge to a domain such as equipment diagnosis. The domain expert supplies expertise; the knowledge engineer elicits and encodes it; the inference engine reasons over a knowledge base and working facts. The user interface handles interaction; an explanation facility presents why or how a conclusion was reached.

Question sources

Artificial Intelligence practice questions · Question 36

Question 85 | Q01043

Which option gives the complete set of valid general descriptions or examples of artificial agents?

A. Receives input from its surroundings and selects operations that act on those surroundings.

B. A line-following robot controller that reads sensors and commands the robot's motors.

C. Perceives its environment through sensors and acting upon that environment through actuators

D. All of the mentioned

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer D: All of the mentioned

An agent perceives its environment and acts on it. The input-and-operation paraphrase describes that interaction, the sensor-driven line-following controller is an implementation example, and the sensor/actuator statement supplies the general definition. All are valid under the stated descriptions. Since the question requests the complete set in one selection, the aggregate is selected; each individual statement is true but incomplete.

Why each choice is right or wrong

A - Incorrect: This is a valid input-and-action paraphrase, but it alone omits the other valid descriptions.

B - Incorrect: The controller senses and acts through the robot, so it is a valid example, but alone is not the complete set.

C - Incorrect: This gives the general sensing-and-acting definition, but alone omits the valid paraphrase and example.

D - Correct: The paraphrase, robot-controller example and sensor/actuator definition all fit artificial agency.

Primary note proof

Study-note section AI03

An agent perceives an environment through sensors and acts through actuators or effectors. Cameras sense; motors move. Software sensors may be incoming messages and software actions may be API requests. Humans are agents but are not artificial agents.

Study-note section AI03

A percept is one observation; a percept sequence is the entire observation history. An agent function maps percept sequences to actions: f:P*→A. An agent program implements that mapping on an architecture; agent = architecture + program. Environment means the setting in which it senses and acts, not merely the search space. Autonomy means relying substantially on experience rather than only a designer's prior instructions.

Module passages - related reading

Introduction to Artificial Intelligence module | PDF page 10 | lines 21-23

• An agent is anything that can perceive its environment through sensors and acts upon that environment through effectors. An agent perceives its environment through sensors.
• The complete set of inputs at a given time is called a percept.

Question sources

Artificial Intelligence practice questions · Question 37

Question 86 | Q01044

What is the name of Artificial Intelligence which allows machines to handle vague information with a deftness that mimics human intuition?

A. Human intelligence

B. Boolean logic

C. Functional logic

D. Fuzzy logic

Hint

Translate the statement carefully, then check the scope of its quantifiers, connectives or inference rule. Distinguish guaranteed consequences from plausible generalizations or explanations.

Answer D: Fuzzy logic.

AI30 represents vague categories with degrees between zero and one and explains fuzzy control using graded rules. This supplies the concrete mechanism behind the stem's loose phrase about human intuition. Boolean logic uses only true or false. Human intelligence is not the named machine-reasoning formalism here, and functional logic is not the provided graded-membership method.

Why each choice is right or wrong

A - Incorrect: Human intelligence names biological capability, not the specified artificial graded-membership technique.

B - Incorrect: Boolean logic uses crisp true/false values rather than degrees of membership in vague categories.

C - Incorrect: Functional logic is not the graded-membership and fuzzy-rule formalism described in AI30.

D - Correct: Fuzzy logic handles vague linguistic categories through graded membership and graded rules.

Primary note proof

Study-note section AI30

> Fuzzy sets assign graded membership μ(x) between 0 and 1 to concepts such as warm or tall. A temperature can belong to warm with degree 0.7. This is not a 70% probability that an otherwise crisp warm proposition is true. Boolean logic uses only true and false; probability describes uncertainty about events.

Study-note section AI25

> Propositional atoms represent whole true-or-false claims. ¬P negates; P∧Q requires both; P∨Q requires at least one; P→Q is false only when P is true and Q false; P↔Q requires matching truth values. Thus P→Q ≡ ¬P∨Q. De Morgan gives ¬(P∧Q) ≡ ¬P∨¬Q.

Question sources

Artificial Intelligence practice questions · Question 38

Question 87 | Q01045

An AI system is composed of?

A. agent

B. environment

C. Both A and B

D. None of the Above

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer C: Both A and B

The explicit system composition is agent plus environment. Evidence: PDF 11.

Why each choice is right or wrong

A - Incorrect: Only one component. See PDF p. 11.

B - Incorrect: Only the other component. See PDF p. 11.

C - Correct: Exactly both documented components. See PDF p. 11.

D - Incorrect: Conflicts with the explicit composition. See PDF p. 11.

Primary note proof

Study-note section AI-S03

> An AI task is modeled as an agent interacting with its environment: observations enter through sensors and selected actions affect the environment through actuators. This task-level description differs from an agent implementation, which combines a program with a computing architecture.

Study-note section AI03

> A percept is one observation; a percept sequence is the entire observation history. An agent function maps percept sequences to actions: f:P*→A. An agent program implements that mapping on an architecture; agent = architecture + program. Environment means the setting in which it senses and acts, not merely the search space. Autonomy means relying substantially on experience rather than only a designer's prior instructions.

> • An AI system is composed of an agent and its environment.
> • The agents act in their environment. The environment may contain other agents.
> • An agent is anything that can perceive its environment through sensors and acts upon that

Question sources

Artificial Intelligence practice questions · Question 39

Question 88 | Q01046

What are Agent?

A. An agent perceives its environment through sensors and acts on it through actuators.

B. An agent is anything that can change its environment through sensors

C. An agent is anything that can control its environment through sensors

D. None of the Above

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer A: An agent perceives its environment through sensors and acts on it through actuators.

An agent is an entity that perceives an environment through sensors and acts on it through actuators or effectors. Sensing alone is only part of this definition, so the first option now includes acting. The other descriptions incorrectly give sensors the action or control role. An agent need not control everything in its environment or guarantee a desired outcome.

Why each choice is right or wrong

A - Correct: This states both parts of the agent interaction: sensing and acting.

B - Incorrect: Sensors supply observations; they are not the general components that execute environmental changes.

C - Incorrect: Sensors do not generally control the environment; action uses actuators or effectors.

D - Incorrect: A complete agent definition is supplied by the sensing-and-acting statement.

Primary note proof

Study-note section AI03

> An agent perceives an environment through sensors and acts through actuators or effectors. Cameras sense; motors move. Software sensors may be incoming messages and software actions may be API requests. Humans are agents but are not artificial agents.

Question 89 | Q01047

Which instruments are used for perceiving and acting upon the environment?

A. Sensors and Actuators

B. Sensors

C. Perceiver

D. Perceiver and Sensor

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer A: Sensors and Actuators

Sensors receive environmental input and actuators deliver output, so both are needed. Evidence: PDF 13.

Why each choice is right or wrong

A - Correct: Includes perception and action interfaces. See PDF p. 13.

B - Incorrect: Omits action interface. See PDF p. 13.

C - Incorrect: Does not identify the two instruments. See PDF p. 13.

D - Incorrect: Two perception terms omit actuators. See PDF p. 13.

Primary note proof

Question sources

Artificial Intelligence practice questions · Question 41

Question 90 | Q01048

In the teaching taxonomy of decision architectures before learning agents are added as a separate class, how many agent types are counted?

A. 1

B. 2

C. 3

D. 4

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer D: 4

The note distinguishes a four-architecture convention from a five-class list that also includes learning agents. The specified convention counts simple reflex, model-based reflex, goal-based and utility-based architectures. Learning can improve several of those architectures, but it is excluded as a separate class for this count. The explicit taxonomy therefore determines the number without claiming a universal count for every possible classification.

Why each choice is right or wrong

A - Incorrect: One does not match either teaching convention described in AI42.

B - Incorrect: Two does not match the stated architecture or learning-inclusive list.

C - Incorrect: Three is not either count given here.

D - Correct: The stated pre-learning architecture taxonomy contains four types.

Primary note proof

Study-note section AI42

> The common teaching list contains five agent classes when learning agents are included, or four decision architectures before learning is added. State the convention when counting agent types. “Target-based” can mean goal-based; “unity-based” is not utility-based.

Study-note section AI06

> A simple reflex agent matches condition-action rules against the current percept only: if dirty, clean. It has no persistent world-state memory. This is adequate when the current observation contains everything needed for its rule, but partial observability can make the same percept require different actions.

Study-note section AI07

A goal-based agent considers future action sequences that reach a desired state. A utility-based agent compares degrees of desirability and trade-offs, choosing maximum expected utility: EU(a)=Σs P(s | a,evidence)U(s). Reaching the destination is a goal; balancing arrival time, safety and cost requires preferences among outcomes.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Introduction to Artificial Intelligence module | PDF page 14 | lines 10-12

Agents can be grouped into five classes based on their degree of perceived intelligence and capability.
All these agents can improve their performance and generate better action over the time.
2.9.1 Simple reflex agent

Question sources

Artificial Intelligence practice questions · Question 42

Question 91 | Q01049

Which of the following is not an agent decision architecture?

A. Model based

B. Utility based

C. Simple reflex

D. Search frontier

Hint

Read the definition and the classification axis requested; distinguish the defining purpose from supporting techniques or implementation resources.

Answer D: Search frontier

Model-based, utility-based and simple reflex describe ways to organize agent decision making. A search frontier instead stores generated nodes awaiting selection or expansion during a search. It is an algorithm component rather than a decision architecture. The overlapping target-based distractor has been replaced because target-based can reasonably mean goal-based, which is a valid agent category.

Why each choice is right or wrong

A - Incorrect: A model-based architecture maintains an internal representation used in action selection.

B - Incorrect: A utility-based architecture selects using outcome desirability.

C - Incorrect: Simple reflex is a current-percept condition-action architecture.

D - Correct: A search frontier is the collection of generated candidates awaiting selection, not an agent decision architecture.

Primary note proof

Study-note section AI42

The common teaching list contains five agent classes when learning agents are included, or four decision architectures before learning is added. State the convention when counting agent types. “Target-based” can mean goal-based; “unity-based” is not utility-based.

Study-note section AI12

A search node records a state plus parent, action, depth and path cost. Expanding a node generates its successors. OPEN or frontier stores discovered candidates awaiting expansion; CLOSED records expanded states. Reaching the same state through different paths does not imply the same node or cost.

Study-note section AI06

A simple reflex agent matches condition-action rules against the current percept only: if dirty, clean.

Study-note section AI06

A model-based reflex agent maintains internal state using the previous state, previous action, current percept, and models of world change and action effects.

Study-note section AI07

A goal-based agent considers future action sequences that reach a desired state. A utility-based agent compares degrees of desirability and trade-offs, choosing maximum expected utility: $EU(a)=\Sigma s\ P(s|a,evidence)U(s)$. Reaching the destination is a goal; balancing arrival time, safety and cost requires preferences among outcomes.

Question sources

Artificial Intelligence practice questions · Question 43

Question 92 | Q01050

Which is used to improve the agents performance?

A. Perceiving

B. Observing

C. Learning

D. Sequence

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer C: Learning

The learning element makes improvements from the environment; perception and observation supply data but are not the improvement mechanism. Evidence: PDF 15.

Why each choice is right or wrong

A - Incorrect: Supplies input without necessarily changing policy. See PDF p. 15.

B - Incorrect: Observation alone need not improve performance. See PDF p. 15.

C - Correct: Named improvement mechanism. See PDF p. 15.

D - Incorrect: A history is data, not the learning operation. See PDF p. 15.

Primary note proof

Study-note section AI08

> The performance element selects actions. The learning element changes the agent to improve future performance. The critic evaluates behavior against a performance standard and supplies feedback. The problem generator suggests exploratory actions likely to yield useful experience.

Study-note section AI08

> Learning is improvement on task T, measured by P, through experience E. For spam filtering, T is classifying email, E is past labeled messages, and P might be recall at a required precision. Exploration trades immediate reward for information; exploitation uses the best action currently known. Learning can improve reflex, goal-based or utility-based agents.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Introduction to Artificial Intelligence module | PDF page 15 | lines 28-30

> - Learning element is for making improvements by learning from environment
> - Critic Learning element takes feedback from critic which describes that how well the agent is doing with respect to a fixed performance standard.

Question sources

Artificial Intelligence practice questions · Question 44

Question 93 | Q01051

Rationality is?

A. being reasonable

B. being sensible

C. having good sense of judgment.

D. All of the above

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer D: All of the above

The module defines rationality with all three phrases: reasonable, sensible, and good judgment. Evidence: PDF 11.

Why each choice is right or wrong

A - Incorrect: Part of the definition. See PDF p. 11.

B - Incorrect: Part of the definition. See PDF p. 11.

C - Incorrect: Part of the definition. See PDF p. 11.

D - Correct: Includes every listed phrase. See PDF p. 11.

Primary note proof

Study-note section AI-S03

> In ordinary usage, rationality means reasonable, sensible judgment. For an AI agent, the operational criterion is the action with the best expected performance given its percept history and available knowledge, rather than guaranteed success or knowledge of the actual future.

Study-note section AI04

> A performance measure defines success externally: safety, useful deliveries, elapsed time, or cost. Rationality depends on that measure, prior knowledge, percept history, and available actions. A rational agent selects the action with the best expected performance given its information.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Introduction to Artificial Intelligence module | PDF page 11 | lines 27-29

• Rationalityis nothing but status of being reasonable, sensible, and having good sense of judgment.
• Rationality is concerned with expected actions and results depending upon what the agent has perceived.

Question sources

Artificial Intelligence practice questions · Question 45

Question 94 | Q01052

Rationality of an agent does not depends on?

A. performance measures

B. Percept Sequence

C. reaction

D. actions

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer C: reaction

The explicit determinants are performance measures, percept history, environmental knowledge, and available actions. Reaction is not a separate determinant in that list. Evidence: PDF 12, 12.

Why each choice is right or wrong

A - Incorrect: Explicit determinant. See PDF p. 12, 12.

B - Incorrect: Explicit determinant. See PDF p. 12, 12.

C - Correct: Not a separate listed factor; may colloquially refer to action. See PDF p. 12, 12.

D - Incorrect: Available actions explicitly matter. See PDF p. 12, 12.

Primary note proof

Study-note section AI04

A performance measure defines success externally: safety, useful deliveries, elapsed time, or cost. Rationality depends on that measure, prior knowledge, percept history, and available actions. A rational agent selects the action with the best expected performance given its information.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Question 95 | Q01053

What is the full form of PEAS?

A. Perceptual Measure, Environment, Actuators, and Sensors

B. Performance Measure, Environment, Actuators, and Sensors

C. Performance Measure, Entity, Actuators, and Sensors

D. Performance Measure, Environment, Agent Function, and Sensors

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer B: Performance Measure, Environment, Actuators, and Sensors

PEAS comprises Performance measure, Environment, Actuators, Sensors, spanning the page boundary. Evidence: PDF 13, 14.

Why each choice is right or wrong

A - Incorrect: Perceptual replaces Performance incorrectly. See PDF p. 13, 14.

B - Correct: All four components match. See PDF p. 13, 14.

C - Incorrect: Entity replaces Environment. See PDF p. 13, 14.

D - Incorrect: Agent Function replaces Actuators. See PDF p. 13, 14.

Primary note proof

Study-note section AI05

PEAS means Performance measure, Environment, Actuators, Sensors. Specify all four before designing an agent. For a taxi: performance includes safety and travel time; environment includes roads, traffic and passengers; actuators include steering, brakes and displays; sensors include cameras, positioning and speed readings.

Question sources

Artificial Intelligence practice questions · Question 47

Question 96 | Q01054

Chess is example of which properties?

A. Discrete

B. Continuous

C. Episodic

D. Non-deterministic

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer A: Discrete

Chess is the explicit discrete-environment example: finitely many distinct states/actions. Evidence: PDF 13, 13.

Why each choice is right or wrong

A - Correct: Explicit chess classification. See PDF p. 13, 13.

B - Incorrect: Driving, not chess, is the continuous example. See PDF p. 13, 13.

C - Incorrect: Moves affect future positions rather than independent episodes. See PDF p. 13, 13.

D - Incorrect: Board transitions are determined by state and selected move. See PDF p. 13, 13.

Primary note proof

Study-note section AI09

> Episodic decisions are independent; sequential decisions affect later situations. Static worlds do not change while deliberating; dynamic ones do. A clock affecting score makes an otherwise static game semidynamic. Discrete quantities have distinct alternatives; continuous quantities

vary along real-valued ranges. Known versus unknown concerns knowledge of the transition model, not observability.

Module passages - related reading

Introduction to Artificial Intelligence module | PDF page 13 | lines 11-13

✓ Discrete / Continuous − If there are a limited number of distinct, clearly defined, states of the environment, the environment is discrete (For example, chess); otherwise it is continuous (For example, driving).

Introduction to Artificial Intelligence module | PDF page 13 | lines 23-28

✓ Deterministic / Non-deterministic − If the next state of the environment is completely determined
by the current state and the actions of the agent, then the environment is deterministic; otherwise it
is non-deterministic.
✓ Episodic / Non-episodic − In an episodic environment, each episode consists of the agent perceiving
and then acting. The quality of its action depends just on the episode itself. Subsequent episodes do
not depend on the actions in the previous episodes. Episodic environments are much simpler because

Question sources

Artificial Intelligence practice questions · Question 48

Question 97 | Q01055

For an untimed crossword puzzle whose clues and grid do not change while the solver deliberates, which environment property follows from that lack of change?

A. Dynamic

B. Static

C. Semi Dynamic

D. Continuous

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer B: Static

A static environment remains unchanged while the agent deliberates. The untimed, fixed-grid puzzle meets that condition. A running clock that affects performance could make an otherwise fixed task semidynamic, but the stem excludes it. Dynamic change and continuous-valued state or action descriptions are separate properties and do not follow from the stated puzzle setting.

Why each choice is right or wrong

A - Incorrect: Dynamic means the environment can change during deliberation, excluded by the premise.

B - Correct: Static means the relevant environment does not change while the agent deliberates.

C - Incorrect: Semidynamic describes changing performance, such as a running clock, despite an otherwise fixed environment; none is present.

D - Incorrect: Continuity concerns real-valued states or actions, not whether the puzzle changes during deliberation.

Primary note proof

Study-note section AI09

> Episodic decisions are independent; sequential decisions affect later situations. Static worlds do not change while deliberating; dynamic ones do. A clock affecting score makes an otherwise static game semidynamic. Discrete quantities have distinct alternatives; continuous quantities vary along real-valued ranges. Question sources

Artificial Intelligence practice questions · Question 49

Question 98 | Q01056

Which learning regime improves an agent’s action choices through interaction with an environment that supplies rewards or penalties?

A. Supervised learning

B. Reinforcement learning

C. Semi-supervised learning

D. Unsupervised learning

Hint

Identify the training feedback, prediction target or measured error. Keep learning objectives separate from model architecture and data modality.

Answer B: Reinforcement learning

Interaction alone is too broad to identify a learning regime. Here the environment supplies rewards or penalties for the agent's actions, and the agent improves its choices from that feedback. This defines reinforcement learning. Supervised and semi-supervised methods depend on target labels; unsupervised methods discover unlabeled structure. None of those label-based descriptions specifies this action-and-reward loop.

Why each choice is right or wrong

A - Incorrect: Supervised learning supplies correct target outputs rather than defining action-reward interaction.

B - Correct: Reinforcement learning improves decisions through environmental reward feedback.

C - Incorrect: Semi-supervised learning mixes labeled and unlabeled examples, not a defining action-reward objective.

D - Incorrect: Unsupervised learning seeks unlabeled structure without the stated reward-feedback objective.

Primary note proof

Study-note section AI33

> An RL agent observes state information, takes an action, receives reward and a new observation, and improves its policy to maximize expected cumulative reward. Rewards evaluate outcomes rather than supply the correct action label. Rewards may be delayed; not every correct-looking action receives immediate reward.

Study-note section AI32

> Semi-supervised learning combines some labels with additional unlabeled data. Active learning chooses informative cases for an oracle to label; it still uses labels. "Exploratory learning" is not an exclusive standard synonym: it can mean unsupervised exploration or active data acquisition, so define the feedback. A task named summarization or time-series analysis is not automatically supervised; its training targets determine that.

Study-note section AI31

> Supervised learning fits a mapping from labeled input-target examples.

Study-note section AI32

> Unsupervised learning seeks structure without target labels: clustering groups similar examples; association finds co-occurrence; dimensionality reduction compresses features.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Introduction to Artificial Intelligence module | PDF page 69 | lines 15-17

> ⇒ Reinforcement learning is a feedback-based learning method, in which a learning agent gets a reward for each right action and gets a penalty for each wrong action.
> The agent learns automatically with these feedbacks and improves its performance. In reinforcement

Question sources

Artificial Intelligence practice questions · Question 50

Question 99 | Q01057

Which is reinforcement learning's immediate parent field in the AI → machine learning → reinforcement learning hierarchy?

A. Artifical Intelligence

B. Data Analytics

C. Machine Learning

D. None of the above

Hint

Identify the training feedback, prediction target or measured error. Keep learning objectives separate from model architecture and data modality.

Answer C: Machine Learning

Reinforcement learning is a branch of machine learning, and machine learning is within artificial intelligence. Artificial intelligence therefore also contains reinforcement learning, but it is the broader ancestor rather than the immediate parent requested. Data analytics is an application context rather than the stated parent field. The explicit hierarchy makes the nearer containing field the unique taxonomic selection.

Why each choice is right or wrong

A - Incorrect: AI contains RL indirectly through machine learning, but is not the immediate parent requested.

B - Incorrect: Data analytics is not the stated parent-field classification of RL in the note.

C - Correct: Machine learning is the immediate parent of reinforcement learning in the stated hierarchy.

D - Incorrect: The immediate parent is present among the choices.

Primary note proof

Study-note section AI33

An RL agent observes state information, takes an action, receives reward and a new observation, and improves its policy to maximize expected cumulative reward. Rewards evaluate outcomes rather than supply the correct action label. Rewards may be delayed; not every correct-looking action receives immediate reward.

Study-note section AI43

ANNs, genetic search and reinforcement learning all improve candidate behavior or performance through experience in different ways. Deep learning is an architecture family usable with supervised, unsupervised or reinforcement objectives. Decision trees and deep models may both be supervised. To distinguish learning regimes, specify labels, reward or unlabeled structure.

Question sources

Artificial Intelligence practice questions · Question 51

Question 100 | Q01058

Which type of feedback does an agent in reinforcement learning receive?

A. Predictions

B. Labels

C. Clusters

D. Rewards or penalties

Hint

Identify the training feedback, prediction target or measured error. Keep learning objectives separate from model architecture and data modality.

Answer D: Rewards or penalties

Rewards and penalties are the stated reinforcement feedback; supervised targets and unsupervised grouping differ. Evidence: PDF 69.

Why each choice is right or wrong

A - Incorrect: A prediction is output, not the reward signal. See PDF p. 69.

B - Incorrect: Labels belong to supervised examples. See PDF p. 69.

C - Incorrect: Clusters are an unsupervised result. See PDF p. 69.

D - Correct: Matches the explicit feedback description. See PDF p. 69.

Primary note proof

Study-note section AI33

> An RL agent observes state information, takes an action, receives reward and a new observation, and improves its policy to maximize expected cumulative reward. Rewards evaluate outcomes rather than supply the correct action label. Rewards may be delayed; not every correct-looking action receives immediate reward.

Study-note section AI31

> Supervised learning fits a mapping from labeled input-target examples. Classification predicts discrete labels, such as institution generations or spam/nonspam; regression predicts numeric quantities, such as prices. Predictive analytics uses historical patterns to forecast outcomes and can use either. Specify the target before choosing a method.

Study-note section AI32

> Unsupervised learning seeks structure without target labels: clustering groups similar examples; association finds co-occurrence; dimensionality reduction compresses features. Good clusters have high within-cluster similarity and low between-cluster similarity under an appropriate distance. K-means alternates assignment to nearest centroids and centroid updates.

For DFS on an implicit tree with branching factor b and maximum depth m, storing pending siblings, which expression gives the standard worst-case space bound?

A. b

B. b^2

C. b^b

D. O(bm)

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer D: O(bm)

Depth-first search retains the active branch and pending alternatives rather than an entire breadth frontier. With up to b pending entries per level over depth m, the standard stored-frontier space bound is O(bm). Path-only on-demand generation can use O(m), but that is a different implementation convention. The expression gives the depth-dependent storage bound rather than an exponential time bound.

Why each choice is right or wrong

A - Incorrect: b omits growth with search depth m in the general DFS storage bound.

B - Incorrect: b^2 is not the stated depth-dependent worst-case DFS storage expression.

C - Incorrect: b^b is neither of the note's DFS space bounds.

D - Correct: With pending siblings, at most a branching-factor-sized set per depth gives the standard O(bm) space bound.

Primary note proof

Study-note section AI14

> DFS follows the deepest pending branch using a LIFO stack or recursion. FILO means the same order as LIFO. With the same children as BFS, a left-first DFS visits S,A,C before B; push rightmost children first to pop the leftmost first.

Study-note section AI14

> Implicit-tree worst-case time is O(b^m), and space is O(bm) when pending siblings are stored, or O(m) for path-only recursive generation. DFS is not generally optimal and can fail on infinite paths or cycles. On a finite graph, visited-state tracking makes traversal complete but needs O(V) storage. Do not confuse the O(b^m) worst-case time bound with the DFS space bounds above.

Introduction to Artificial Intelligence module | PDF page 19 | lines 20-22

• Space Complexity: DFS algorithm needs to store only single path from the root node, hence space
complexity of DFS is equivalent to the size of the fringe set, which is O(bm).
• Optimal: DFS search algorithm is non-optimal, as it may generate a large number of steps or high

Question sources

Artificial Intelligence practice questions · Question 54

Question 103 | Q01061

For BFS on an implicit tree with branching factor b>1 and shallowest goal depth d, using generation-time goal testing, which expression gives the standard worst-case generated-node order?

A. b

B. b^d

C. b^2

D. b^b

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer B: b^d

BFS generates levels in order. Under generation-time goal testing, the generated nodes through the shallowest goal depth d are bounded by the geometric sum 1+b+...+b^d, whose dominant term is b^d when b>1. Testing only after expanding deeper nodes can change the conventional bound by another factor of b, so the question states the goal-test convention.

Why each choice is right or wrong

A - Incorrect: b counts one level and does not account for arbitrary goal depth.

B - Correct: The sum 1+b+...+b^d has order b^d for b>1.

C - Incorrect: b^2 only describes a fixed depth-two case rather than general depth d.

D - Incorrect: b^b wrongly replaces solution depth d with the branching factor.

Primary note proof

Study-note section AI13

The tree contains 1+b+...+b^d nodes through depth d, giving O(b^d) under generation-time goal testing. Expanding depth-d nodes before testing can generate depth d+1 and yields O(b^(d+1)); specify the convention. Explicit finite graph traversal with visited-state tracking takes O(V+E) time and O(V) space.

Question sources

Artificial Intelligence practice questions · Question 55

Question 104 | Q01062

Which labels describe the recursive DFS stack’s removal order? Select all that apply.

A. LIFO

B. LILO

C. FIFO

D. FILO

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer A, D: LIFO; FILO

Recursive depth-first search returns first from the most recently entered unfinished call. That is last-in-first-out stack order, also called first-in-last-out. The two labels are synonyms rather than distinct data structures. FIFO or LILO describes the opposite end-to-end order and does not characterize the DFS call stack. The multiple-selection instruction therefore retains both correct names for the same discipline.

Why each choice is right or wrong

A - Correct: LIFO is the stack order used by recursion and depth-first exploration.

B - Incorrect: LILO does not express the required last-in-first-out removal order.

C - Incorrect: FIFO is queue order, associated with breadth-first rather than depth-first selection.

D - Correct: FILO is another name for LIFO and therefore also describes the DFS stack.

Primary note proof

Study-note section AI14

> DFS follows the deepest pending branch using a LIFO stack or recursion. FILO means the same order as LIFO. With the same children as BFS, a left-first DFS visits S,A,C before B; push rightmost children first to pop the leftmost first.

Study-note section AI13

BFS removes the oldest frontier entry using a FIFO queue. Start with the root, remove the head, test it, append unseen successors at the tail, and repeat. It explores depths 0,1,2,... and is complete for finite b and a finite-depth goal. It minimizes number of edges, so minimum cost requires equal positive step costs.

Question sources

Artificial Intelligence practice questions · Question 56

Question 105 | Q01063

Which of the following search algorithm searches forward from initial state and backward from goal state till both meet to identify a common state?

A. Uniform Cost Search

B. Iterative Deepening Depth-First Search

C. Bidirectional Search

D. None of the Above

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer C: Bidirectional Search

The algorithm starts one search at the initial state and another at the goal and stops at their intersection. Evidence: PDF 23.

Why each choice is right or wrong

A - Incorrect: Orders by path cost rather than two directions. See PDF p. 23.

B - Incorrect: Repeats depth-limited search from the start. See PDF p. 23.

C - Correct: Exactly the two-front definition. See PDF p. 23.

D - Incorrect: C explicitly fits. See PDF p. 23.

Primary note proof

Study-note section AI16

Bidirectional search grows from start and goal until frontiers connect. With suitable reverse actions, meeting tests and equal-cost BFS, time and space may fall to O(b^(d/2)). Weighted variants require a sound stopping bound; the first intersection need not be cheapest. IDA* deepens an f=g+h threshold rather than only a depth limit.

Study-note section AI15

UCS uses a priority queue ordered by actual accumulated path cost g(n). Remove a minimum-g node; accept a goal when removed, not when first generated. Relax each edge: if a cheaper path is found, update its frontier cost and parent.

Study-note section AI16

DLS runs DFS to depth l and reports cutoff separately from failure. It misses goals deeper than l. Iterative deepening runs DLS with limits 0,1,2,...; for finite b it finds the shallowest solution with O(b^d) time and O(bd) frontier space, optimal for equal step costs. Repeated shallow work is small compared with the deepest level.

• Bidirectional search algorithm runs two simultaneous searches, one form initial state called as forward-search and other from goal node called as backward-search, to find the goal node.
• Bidirectional search replaces one single search graph with two small sub-graphs in which one starts

Question sources

Artificial Intelligence practice questions · Question 57

Question 106 | Q01064

When is breadth-first search is optimal?

A. When there is less number of nodes

B. When all step costs are equal

C. When all step costs are unequal

D. All of the above

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer B: When all step costs are equal

Equal positive step costs make total path cost proportional to depth; BFS first reaches a shallowest solution and hence a cheapest one. Evidence: PDF 20.

Why each choice is right or wrong

A - Incorrect: Node count alone says nothing about cost. See PDF p. 20.

B - Correct: Equal step costs ensure depth order is cost order. See PDF p. 20.

C - Incorrect: Unequal costs can make a deeper path cheaper. See PDF p. 20.

D - Incorrect: A and C are not sufficient conditions. See PDF p. 20.

Primary note proof

Study-note section AI13

> BFS removes the oldest frontier entry using a FIFO queue. Start with the root, remove the head, test it, append unseen successors at the tail, and repeat. Question sources

Artificial Intelligence practice questions · Question 58

Question 107 | Q01065

What is the heuristic function of greedy best-first search?

A. f(n) != h(n)

B. f(n) < h(n)

C. f(n) = h(n)

D. f(n) > h(n)

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer C: f(n) = h(n)

The operational rule removes the node with lowest h(n), so the greedy evaluation is f(n)=h(n). The printed f(n)=g(n) on this same page conflicts with its own algorithm and nearby h definition; the operational evidence supports C. Evidence: PDF 25.

Why each choice is right or wrong

A - Incorrect: Inequality would not express that rule. See PDF p. 25.

B - Incorrect: Strictly smaller is not the definition. See PDF p. 25.

C - Correct: Matches ranking exclusively by h. See PDF p. 25.

D - Incorrect: Strictly greater is not the definition. See PDF p. 25.

Primary note proof

Study-note section AI17

> Best-first is a family that orders OPEN by an evaluation function. Greedy best-first uses f=h and removes the smallest estimate, ignoring the cost already paid. It can choose an expensive route, loop without duplicate checks, or follow an infinite misleading branch. On a finite graph with full duplicate handling it is complete, but not generally optimal. Its implicit finite-tree worst case can be O(b^m).

Question sources

Artificial Intelligence practice questions · Question 59

Question 108 | Q01066

Greedy best-first search selects which descriptions of the next node? Interpret “closest” as estimated remaining cost h, not actual distance. Select all that apply.

A. Shallowest

B. Deepest

C. The one closest to the goal node

D. Minimum heuristic cost

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer C, D: The one closest to the goal node; Minimum heuristic cost

Greedy best-first search orders the frontier by h alone, choosing the smallest estimated remaining cost and ignoring cost already paid. Under the explicit interpretation, estimated closest to the goal and minimum heuristic cost express that same rule. Shallowest-first uses depth as in breadth-first search, while deepest-first follows depth-first ordering. Both heuristic descriptions are therefore valid and neither depth description is selected.

Why each choice is right or wrong

A - Incorrect: Shallowest-first is BFS-style depth ordering rather than greedy heuristic selection.

B - Incorrect: Deepest-first is DFS-style selection rather than minimum estimated remaining cost.

C - Correct: Read closest as estimated by h; it is the same greedy criterion as minimum heuristic cost.

D - Correct: Greedy best-first selects a node with minimum h, ignoring already-paid path cost.

Primary note proof

Study-note section AI17

> Best-first is a family that orders OPEN by an evaluation function. Greedy best-first uses f=h and removes the smallest estimate, ignoring the cost already paid. It can choose an expensive route, loop without duplicate checks, or follow an infinite misleading branch. On a finite graph with full duplicate handling it is complete, but not generally optimal. Question sources

Artificial Intelligence practice questions · Question 60

Question 109 | Q01067

Which general search family contains A* because it selects frontier nodes by a minimum evaluation value?

A. Breadth-First-Search

B. Depth-First-Search

C. Uniform Cost Search

D. Best-First-Search

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer D: Best-First-Search

Best-first search is the general family that selects a frontier node according to an evaluation value. A* is one member, using f=g+h. Uniform-cost search is another member, using g alone. Breadth-first and depth-first names describe depth-oriented selection disciplines. The question asks for the containing family rather than claiming A* is identical to one simpler algorithm.

Why each choice is right or wrong

A - Incorrect: BFS selects by depth/FIFO order rather than the general evaluation-priority family.

B - Incorrect: DFS follows stack/deepest-branch order rather than minimum evaluation priority.

C - Incorrect: UCS is another best-first method using g alone; it is not the general family containing A*.

D - Correct: Best-first search is the family that selects by an evaluation, with A* using g+h.

Primary note proof

Study-note section AI18

A* orders by f(n)=g(n)+h(n). Admissibility means 0≤h(n)≤h*(n), the true cheapest remaining cost. Consistency means h(n)≤c(n,n′)+h(n′) on every edge, with h(goal)=0; it implies admissibility on states with goal paths. Consistency makes f nondecreasing along a path.

Study-note section AI15

UCS uses a priority queue ordered by actual accumulated path cost g(n). Remove a minimum-g node; accept a goal when removed, not when first generated. Relax each edge: if a cheaper path is found, update its frontier cost and parent.

Study-note section AI17

• A* search is the most commonly known form of best-first search.
• It uses heuristic function h(n), and cost to reach the node n from the start state g(n). It has combined
features of UCS and greedy best-first search, by which it solves the problem efficiently.

Question sources

Artificial Intelligence practice questions · Question 61

Question 110 | Q01188

Function MY_AGENT (PERCEPT) return action
static state, a description of the current world state
goal, a description of the goal to achieve may be in terms of state
state ← UPDATE_STATE(state, percept)
actionSet ← POSSIBLE_ACTIONS(state)
action ← BEST_ACTION(actionSet)
state ← UPDATE_STATE(state, action)
return action
What is the purpose of the final instruction state ← UPDATE_STATE(state, action), after BEST_ACTION has selected an action?

A. Modify the state of the environment if necessary

B. Update the state information to be like the one after executing the best action chosen

C. Update the environment so that the agent can perceive the next percept

D. Modify the state of the environment once the decision of which action to choose is made.

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer B: Update the state information to be like the one after executing the best action chosen

The final update uses the chosen action to predict what the agent's internal state representation should look like after that action. It is distinct from the earlier update using the current percept. Updating memory does not execute an actuator or directly modify the external environment. Naming the exact instruction resolves the missing referent while preserving the model-update interpretation of the original prototype.

Why each choice is right or wrong

A - Incorrect: Updating an internal state representation does not itself modify the external environment.

B - Correct: The final call predicts and records the internal state after the selected action.

C - Incorrect: Neither internal update executes an environmental action or produces the next percept.

D - Incorrect: Selecting an action and updating memory are distinct from changing the external world through execution.

Primary note proof

Study-note section AI07

Updating an internal state after selecting an action predicts the action's effect; it does not itself modify the external environment. A stored variable named goal is insufficient to prove a goal-based policy if BEST_ACTION never uses it. Model-based, goal-based, utility-based and learning capabilities can coexist.

Study-note section AI06

A model-based reflex agent maintains internal state using the previous state, previous action, current percept, and models of world change and action effects. It then applies rules to that state. Both kinds can use condition-action rules; memory and a world model distinguish them.

• Updating the agent state requires information about:
- How the world evolves
- How the agent's action affects the world.

Question sources

Computer Science model exam 2 · Question 9

Question 111 | Q01194

To implement greedy best-first search, let the evaluation be the estimated remaining cost h(n). Which OPEN-list insertion policy supplies its node-selection order?

A. Append newly generated nodes at the beginning of the open list

B. Append newly generated nodes at the end of the open list

C. Insert newly generated nodes in the open list according to their path cost (lowest values first)

D. Insert newly generated nodes in the open list according to their evaluation function (lowest values first)

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer D: Insert newly generated nodes in the open list according to their evaluation function (lowest values first)

Greedy best-first search orders its frontier by h alone, the estimate of remaining cost. A priority-ordered OPEN list with the smallest evaluation first therefore implements the rule when that evaluation is h. Ordering by g would instead implement uniform-cost search. Unconditionally prepending or appending nodes gives stack-like or FIFO behavior without the required heuristic ranking.

Why each choice is right or wrong

A - Incorrect: Prepending every new node gives a stack-like policy rather than ordering by remaining-cost estimates.

B - Incorrect: Appending every new node gives FIFO breadth order rather than heuristic priority.

C - Incorrect: Ordering by accumulated path cost g implements uniform-cost selection, not greedy h-only selection.

D - Correct: Ordering by the stated evaluation h puts the smallest estimated remaining cost first.

Primary note proof

Study-note section AI17

> Best-first is a family that orders OPEN by an evaluation function. Greedy best-first uses f=h and removes the smallest estimate, ignoring the cost already paid. It can choose an expensive route, loop without duplicate checks, or follow an infinite misleading branch. On a finite graph with full duplicate handling it is complete, but not generally optimal. Its implicit finite-tree worst case can be O(b^m).

Study-note section AI15

> UCS uses a priority queue ordered by actual accumulated path cost g(n). Remove a minimum-g node; accept a goal when removed, not when first generated. Relax each edge: if a cheaper path is found, update its frontier cost and parent.

Study-note section AI13

> BFS removes the oldest frontier entry using a FIFO queue. Start with the root, remove the head, test it, append unseen successors at the tail, and repeat. It explores depths 0,1,2,... and is complete for finite b and a finite-depth goal. It minimizes number of edges, so minimum cost requires equal positive step costs.

Study-note section AI14

> DFS follows the deepest pending branch using a LIFO stack or recursion. FILO means the same order as LIFO. With the same children as BFS, a left-first DFS visits S,A,C before B; push rightmost children first to pop the leftmost first.

Question sources

Computer Science model exam 2 · Question 15

Question 112 | Q01199

In classical propositional logic over a nonempty set of interpretations, which statements are false? In D, “models” means all interpretations. Select all that apply.

A. A sentence is said to be invalid iff it is unsatisfiable.

B. A sentence is valid if it is satisfiable.

C. A sentence which is not invalid is satisfiable.

D. A sentence is unsatisfiable if it is false in all models.

Hint

Translate the statement carefully, then check the scope of its quantifiers, connectives or inference rule. Distinguish guaranteed consequences from plausible generalizations or explanations.

Answer A, B: A sentence is said to be invalid iff it is unsatisfiable.; A sentence is valid if it is satisfiable.

Validity requires truth in every interpretation, while satisfiability requires truth in at least one. A contingent atom can therefore be satisfiable and invalid, refuting both the proposed invalid-unsatisfiable equivalence and the claim that satisfiability implies validity. Not invalid means valid and hence satisfiable in the stated nonempty setting. Unsatisfiable means false in every interpretation, so the remaining two statements are true.

Why each choice is right or wrong

A - Correct: False: a satisfiable contingent sentence can be invalid without being unsatisfiable.

B - Correct: False: truth in one interpretation does not imply truth in every interpretation.

C - Incorrect: True: not invalid means valid, which entails satisfiability in the ordinary model setting.

D - Incorrect: True: unsatisfiable means there is no interpretation making the sentence true.

Primary note proof

Study-note section AI25

> A model is an interpretation making a sentence true. Valid means true in every interpretation; satisfiable means true in at least one; unsatisfiable means true in none. Invalid means not valid, and may still be satisfiable. P∨¬P is valid; P is satisfiable but not valid; P∧¬P is unsatisfiable. Entailment KB⊨α means every model of KB also satisfies α.

Question sources

Computer Science model exam 2 · Question 20

Question 113 | Q01202

Consider this agent prototype:
Function MY_AGENT(percept) returns action
static state, goal
state ← UPDATE_STATE(state, percept)
actionSet ← POSSIBLE_ACTIONS(state)
action ← BEST_ACTION(actionSet, state, goal)
state ← UPDATE_STATE(state, action)
return action
BEST_ACTION uses lookahead over future action sequences and chooses by whether the specified desired state is reached; it does not rank successful outcomes by utility or learn from experience. Which category best describes this action-selection criterion?

A. Goal based

B. Model based reflex

C. Simple reflex

D. Utility based

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer A: Goal based

The action selector explicitly consults the desired state and looks ahead over sequences that can reach it. That is the defining goal-based decision criterion. Persistent state also gives the agent a model-based capability, but memory alone does not identify its selection policy. A reflex policy would apply condition-action rules instead of goal-directed lookahead, and utility-based choice would rank degrees of desirability among outcomes.

Why each choice is right or wrong

A - Correct: Goal-directed lookahead chooses sequences reaching a desired state, matching goal-based action selection.

B - Incorrect: The agent maintains a model, but the stated policy uses goal-directed lookahead rather than reflex rules.

C - Incorrect: Persistent state and future-sequence evaluation contradict a current-percept-only reflex policy.

D - Incorrect: No utility ranking is used; the selector evaluates attainment of the desired state.

Primary note proof

Study-note section AI07

A goal-based agent considers future action sequences that reach a desired state. A utility-based agent compares degrees of desirability and trade-offs, choosing maximum expected utility: EU(a)=Σs P(s | a,evidence)U(s). Reaching the destination is a goal; balancing arrival time, safety and cost requires preferences among outcomes.

Study-note section AI07

Updating an internal state after selecting an action predicts the action's effect; it does not itself modify the external environment. A stored variable named goal is insufficient to prove a goal-based policy if BEST_ACTION never uses it. Model-based, goal-based, utility-based and learning capabilities can coexist.

Study-note section AI06

A simple reflex agent matches condition-action rules against the current percept only: if dirty, clean. It has no persistent world-state memory. This is adequate when the current observation contains everything needed for its rule, but partial observability can make the same percept require different actions.

Question sources

Computer Science model exam 2 · Question 23

Question 114 | Q01220

Which are general terms for the components through which an arbitrary AI agent acts on its environment, rather than sensing components or one particular robot subtype? Select all that apply.

A. Sensors

B. Effectors

C. Actuators

D. Manipulators

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer B, C: Effectors; Actuators

Actuators and effectors are equivalent general names for the agent's acting interface here. Sensors instead supply observations. A manipulator can be a particular physical acting device, but it is not the general term covering every agent, including software agents. The scope allows the two synonymous general terms without incorrectly denying that robotic manipulators can carry out actions.

Why each choice is right or wrong

A - Incorrect: Sensors receive observations rather than enact the agent's selected environmental changes.

B - Correct: Effectors are an accepted name for the components through which the agent acts.

C - Correct: Actuators are the note's equivalent general term for acting components.

D - Incorrect: A manipulator is a particular physical device, not the general acting-interface term requested.

Primary note proof

Study-note section AI03

> An agent perceives an environment through sensors and acts through actuators or effectors. Cameras sense; motors move. Software sensors may be incoming messages and software actions may be API requests. Humans are agents but are not artificial agents.

Study-note section AI42

> A generic rule does not distinguish simple from model-based reflex without specifying memory. A goal declaration unused by the action policy does not establish goal-based behavior. "Sensors and effectors" describes interaction, not omniscience or intelligence by itself. Define the mechanical distinction when comparing effectors and actuators as acting components.

Study-note section AI39

> Robotics combines mechanical, electrical, control and computing systems to sense, plan and act physically. Components include sensors, controller, power supply, actuators and an end effector. Locomotion may be legged, wheeled or tracked, with trade-offs in terrain, stability and efficiency. Software can act autonomously without being a robot. Humanoid shape is not evidence of general intelligence.

- An operation involving an effector is called an action.
- Actions can be grouped into action sequences.

Question sources

Computer Science model exam 2 · Question 41

Question 115 | Q01252

A control agent has incomplete observations, uncertain transition outcomes, actions that affect later decisions, a world that changes during deliberation, and real-valued measurements and controls. Which list matches all these properties?

A. Fully observable, discrete, episodic, static.

B. Static, episodic, continuous, partially observable.

C. Partially observable, non-deterministic, non-episodic, dynamic, continuous.

D. Deterministic, sequential (non-episodic), dynamic, continuous.

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer C: Partially observable, non-deterministic, non-episodic, dynamic, continuous.

The scenario establishes each environment dimension directly. Incomplete observations give partial observability; uncertain outcomes give non-determinism; effects on later decisions give sequentiality; ongoing change gives dynamics; and real-valued quantities give continuity. Only one list matches the whole combination. This classification avoids claiming that these dimensions establish a universal numerical ranking of task difficulty.

Why each choice is right or wrong

A - Incorrect: Full observability, episodic independence and a static discrete setting contradict the scenario.

B - Incorrect: Partial observability and continuity fit, but static and episodic do not.

C - Correct: Partial observability, non-determinism, sequentiality, dynamics and continuity all match.

D - Incorrect: The other stated properties fit, but determinism contradicts uncertain transition outcomes.

Primary note proof

Study-note section AI09

Fully observable means sensors reveal relevant state; partially observable means relevant information is hidden or noisy. Deterministic means state and action determine the next state;

stochastic means outcomes involve randomness. Strategic uncertainty about an opponent is distinct from dice-like randomness.

Study-note section AI09

Episodic decisions are independent; sequential decisions affect later situations. Static worlds do not change while deliberating; dynamic ones do. A clock affecting score makes an otherwise static game semidynamic. Discrete quantities have distinct alternatives; continuous quantities vary along real-valued ranges. Known versus unknown concerns knowledge of the transition model, not observability.

✓ The most challenging environments are partially observable, stochastic, sequential, dynamic, and
continuous, and contain multiple intelligent agents.
2.11 Questions

Question sources

Computer Science model exam 2 · Question 73

Question 116 | Q01279

Which described training tasks are supervised learning? Select all that apply.

A. Summarization trained on document/reference-summary pairs.

B. Time-series forecasting trained on history/next-value target pairs.

C. Sequence discovery without target labels.

D. Clustering unlabeled examples.

Hint

Identify the training feedback, prediction target or measured error. Keep learning objectives separate from model architecture and data modality.

Answer A, B: Summarization trained on document/reference-summary pairs.; Time-series forecasting trained on history/next-value target pairs.

Supervised training uses paired inputs and target outputs. Document/reference-summary pairs therefore make the summarization task supervised, and history/next-value pairs make the forecasting task supervised. Sequence discovery and clustering without targets instead seek structure in unlabeled data. The labels in the descriptions determine the regime; task names alone would not establish whether summarization or time-series analysis is supervised.

Why each choice is right or wrong

A - Correct: The reference summary is a target output paired with each input document.

B - Correct: The next value is a numeric target paired with each input history.

C - Incorrect: Without target labels, sequence discovery seeks unlabeled structure.

D - Incorrect: Clustering unlabeled examples is unsupervised structure discovery.

Primary note proof

Study-note section AI31

> Supervised learning fits a mapping from labeled input-target examples. Classification predicts discrete labels, such as institution generations or spam/nonspam; regression predicts numeric quantities, such as prices. Predictive analytics uses historical patterns to forecast outcomes and can use either. Specify the target before choosing a method.

Study-note section AI32

> Unsupervised learning seeks structure without target labels: clustering groups similar examples; association finds co-occurrence; dimensionality reduction compresses features. Good clusters have high within-cluster similarity and low between-cluster similarity under an appropriate distance. K-means alternates assignment to nearest centroids and centroid updates.

Question sources

Computer Science model exam 2 · Question 100

Question 117 | Q01485

A common name used to describe search-based optimization technique based on the principles of Genetics and Natural Selection is ____.

A. Genetic algorithms

B. Heuristic algorithm

C. Hill climbing

D. Simulated annealing

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer A: Genetic algorithms.

AI20 names the search method with population, fitness, parent selection, crossover and mutation as a genetic algorithm. That is the specific common name requested by the genetics/natural-selection description. Heuristic algorithm is a broad umbrella rather than this name; hill climbing follows improved neighbors, and simulated annealing is not the population-selection mechanism described.

Why each choice is right or wrong

A - Correct: This is the specific name of the evolutionary search technique based on fitness, selection and genetic variation.

B - Incorrect: Heuristic algorithm is a broad category and does not specifically name the genetics-based population method.

C - Incorrect: Hill climbing improves a candidate through neighbors rather than maintaining the described genetic population.

D - Incorrect: Simulated annealing is not the named selection/crossover/mutation method defined in the note.

Primary note proof

Study-note section AI20

> A genetic algorithm maintains a population, evaluates fitness, selects parents, applies crossover and mutation, and repeats replacement. It searches without guaranteeing global optimality. Means-ends analysis selects a difference between current and goal states, chooses an operator reducing it, and recursively solves its preconditions. Neither method is simply A* running backward.

Study-note section AI20

> Local search keeps a complete candidate configuration and improves its objective; the path may be irrelevant. Hill climbing chooses better neighbors. First-improvement accepts the first improvement; steepest-ascent examines all neighbors; stochastic variants choose among improvements. Local maxima, plateaus and ridges can stop progress. Random restarts or limited sideways steps can help without guaranteeing success.

Study-note section AI-S05

> Simulated annealing follows a current candidate and randomly samples a neighboring move. It accepts improvements and sometimes accepts worse moves according to a temperature that decreases over time. Unlike genetic search, its defining mechanism is not a population undergoing parent selection, crossover and mutation.

Mock exam 1 · Question 1

Question 118 | Q01486

A complete history of everything that the agent has ever perceived is

A. Agent program

B. Agent function

C. Percept

D. Percept sequence

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer D: Percept sequence

Percept sequence is explicitly the history of all the agent has perceived, unlike a single current percept. Evidence: PDF 10.

Why each choice is right or wrong

A - Incorrect: Implementation of agent function, not history. See PDF p. 10.

B - Incorrect: Maps history to actions, not history itself. See PDF p. 10.

C - Incorrect: One perceptual instant. See PDF p. 10.

D - Correct: Exact history definition. See PDF p. 10.

Primary note proof

Study-note section AI03

> A percept is one observation; a percept sequence is the entire observation history. An agent function maps percept sequences to actions: f:P*→A. An agent program implements that mapping on an architecture; agent = architecture + program. Environment means the setting in which it senses and acts, not merely the search space. Autonomy means relying substantially on experience rather than only a designer’s prior instructions.

Mock exam 1 · Question 2

Question 119 | Q01487

A good cluster is characterized by

A. Equal number of instances

B. Equal distance among cluster members

C. High inter-class similarity

D. High intra-class similarity

Hint

Identify the training feedback, prediction target or measured error. Keep learning objectives separate from model architecture and data modality.

Answer D: High intra-class similarity

The module groups similar input vectors into clusters. Good within-cluster (intra-class) similarity follows from that grouping principle, with no requirement of equal sizes or equal pairwise distances. Evidence: PDF 75.

Why each choice is right or wrong

A - Incorrect: No equal-size condition given. See PDF p. 75.

B - Incorrect: Similarity does not require identical distances. See PDF p. 75.

C - Incorrect: Between-cluster similarity is not the grouping objective. See PDF p. 75.

D - Correct: Matches similarity inside a group. See PDF p. 75.

Primary note proof

Study-note section AI32

> Unsupervised learning seeks structure without target labels: clustering groups similar examples; association finds co-occurrence; dimensionality reduction compresses features. Good clusters have high within-cluster similarity and low between-cluster similarity under an appropriate distance. K-means alternates assignment to nearest centroids and centroid updates.

Question sources

Mock exam 1 · Question 3

Question 120 | Q01569

A problem in supervised machine learning model due to too much attention to the particular data set it is trained on, causing it to perform poorly on unseen data is ____

A. Under fitting

B. Over fitting

C. Learning curve

D. Variance

Hint

Identify the training feedback, prediction target or measured error. Keep learning objectives separate from model architecture and data modality.

Answer B: Overfitting.

AI35 directly defines overfitting as fitting training-specific details so performance drops on unseen data. This is the complete failure pattern described in the stem. Underfitting is insufficient fit even on training data; a learning curve is a plot used to inspect performance. Variance may describe sensitivity but does not name the training-versus-generalization failure asked for.

Why each choice is right or wrong

A - Incorrect: Underfitting means the model is too limited or poorly fitted even on the training data.

B - Correct: Overfitting captures training-specific details at the expense of performance on unseen examples.

C - Incorrect: A learning curve plots performance against training size or progress; it is not the failure itself.

D - Incorrect: Variance is related to sensitivity, but overfitting is the precise failure pattern defined by the stem.

Primary note proof

Study-note section AI35

> Overfitting means fitting training-specific details so performance drops on unseen data; underfitting means the model is too limited or poorly fitted even on training data. A learning curve plots performance against training size or training progress. Complexity control, regularization, pruning and more representative data can help.

Study-note section AI-S06

> Support-vector machines include supervised classification and regression methods. They use support vectors in their decision function rather than being defined by a next-state conditional-dependence assumption. In estimation, variance measures how predictions change across different training samples; overfitting instead names poor generalization caused by fitting training-specific details.

Question sources

Mock exam 3 · Question 1

Question 121 | Q01570

Which general AI search category uses the problem definition and known costs without a problem-specific estimate of remaining cost to a goal?

A. Informed search

B. Uninformed search

C. Greedy best-first search

D. Binary search

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer B: Uninformed search

Uninformed search uses the problem definition, including legal actions, goal tests and known action costs, without a domain-specific remaining-cost estimate. Informed methods add such guidance, and greedy best-first uses it directly as h. Binary search is a different ordered-lookup algorithm for sorted sequences. The formerly undefined circular-search distractor is replaced with a meaningful search method.

Why each choice is right or wrong

A - Incorrect: Informed search adds problem-specific guidance beyond the basic problem definition.

B - Correct: Uninformed search uses the problem definition without a heuristic estimate of remaining cost.

C - Incorrect: Greedy best-first explicitly uses h, an estimate of remaining cost.

D - Incorrect: Binary search narrows a sorted sequence by comparisons; it is a specific ordered-lookup algorithm, not the broad AI search category requested.

Primary note proof

Study-note section AI17

A heuristic h(n) estimates remaining cost or evaluates promise using problem-specific knowledge. It can reduce explored work, but computing it also costs time. Uninformed algorithms use only the problem definition and known costs; UCS remains uninformed despite using g.

Study-note section AI-S02

Binary search exploits the order of a sorted sequence: a comparison narrows the remaining candidate interval instead of exploring arbitrary successor states. Array bisection therefore differs from breadth-first or depth-first traversal of a general state-space graph. A storage container such as an array does not by itself specify FIFO or LIFO frontier behavior.

Study-note section AI17

Best-first is a family that orders OPEN by an evaluation function. Greedy best-first uses f=h and removes the smallest estimate, ignoring the cost already paid. It can choose an expensive route, loop without duplicate checks, or follow an infinite misleading branch. On a finite graph with full duplicate handling it is complete, but not generally optimal. Its implicit finite-tree worst case can be O(b^m).

• The uninformed search does not contain any domain knowledge such as closeness, the location of
the goal. It is also called level order traversal.
• It operates in a brute-force way as it only includes information about how to traverse the tree and

Question sources

Mock exam 3 · Question 2

Question 122 | Q01571

Which named test uses a judge’s inability to distinguish a machine from a human through conversation as its operational criterion?

A. The Chinese room

B. A psychological response-time experiment

C. Turing test

D. Black box testing

Hint

Read the definition and the classification axis requested; distinguish the defining purpose from supporting techniques or implementation resources.

Answer C: Turing test

The conversational Turing test evaluates whether a judge can reliably distinguish a machine's dialogue from a human's. It supplies an observable behavior criterion rather than proof of understanding. The Chinese-room argument addresses understanding philosophically, response-time experiments test cognitive models empirically, and black-box testing concerns externally visible software functionality. Those are different questions or procedures.

Why each choice is right or wrong

A - Incorrect: The Chinese-room argument concerns whether formal symbol manipulation suffices for understanding; it is not the judge-and-conversation test.

B - Incorrect: A response-time experiment evaluates a cognitive model against human measurements rather than applying conversational indistinguishability.

C - Correct: The conversational Turing test uses this judge-and-hidden-participant criterion.

D - Incorrect: Black-box testing checks external software functionality without inspecting internals; it does not inherently require humanlike conversation.

Primary note proof

Study-note section AI02

> The conversational Turing test asks whether a judge can reliably distinguish a machine from a human through their dialogue. It requires language use, knowledge, reasoning and often learning. It tests an operational behavior criterion, not proof of consciousness. Cognitive models can be tested against response times, errors and psychological experiments.

Study-note section AI-S07

> Searle's Chinese-room argument challenges whether executing formal symbol-manipulation rules is sufficient for understanding. It is a philosophical argument about understanding, not the conversational judge-and-hidden-participant procedure of the Turing test.

Study-note section AI-S07

> Black-box software testing examines externally visible functionality without inspecting implementation internals. A specification may concern any software behavior; this testing method does not by itself require conversational indistinguishability from a human.

Question 123 | Q01612

A learning agent has mainly four conceptual components, which component is responsible for suggesting actions that will lead to new and informative experiences.

A. Problem generator

B. Performance element

C. Learning element

D. Critic

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer A: Problem generator

Problem generator proposes actions producing new informative experience, while the performance element chooses external action, learning element improves it, and critic evaluates it. Evidence: PDF 15.

Why each choice is right or wrong

A - Correct: Matches the explicit exploration role. See PDF p. 15.

B - Incorrect: Selects external action, different component role. See PDF p. 15.

C - Incorrect: Changes performance based on feedback. See PDF p. 15.

D - Incorrect: Evaluates against a performance standard. See PDF p. 15.

Primary note proof

Study-note section AI08

> The performance element selects actions. The learning element changes the agent to improve future performance. The critic evaluates behavior against a performance standard and supplies feedback. The problem generator suggests exploratory actions likely to yield useful experience.

Question 124 | Q01613

A learning scheme in which agent learns from a series of rewards & punishments is ____

A. Opinion mining

B. Unsupervised learning

C. Supervised learning

D. Reinforcement learning

Hint

Identify the training feedback, prediction target or measured error. Keep learning objectives separate from model architecture and data modality.

Answer D: Reinforcement learning

Rewards and penalties define the module reinforcement scheme. Evidence: PDF 69.

Why each choice is right or wrong

A - Incorrect: Opinion mining is a language application. See PDF p. 69.

B - Incorrect: Input-only pattern discovery lacks reward feedback. See PDF p. 69.

C - Incorrect: Uses paired desired outputs. See PDF p. 69.

D - Correct: Exactly reward/penalty feedback. See PDF p. 69.

Primary note proof

Study-note section AI33

> An RL agent observes state information, takes an action, receives reward and a new observation, and improves its policy to maximize expected cumulative reward. Rewards evaluate outcomes rather than supply the correct action label. Rewards may be delayed; not every correct-looking action receives immediate reward.

Study-note section AI37

There is no feedback from the environment as to what should be the desired output and if it is correct or incorrect. Hence, in this type of learning, the network itself must discover the patterns and features from the input data, and the relation for the input data over the output.

Question sources

Mock exam 2 · Question 3

Question 126 | SM0010

Suppose you have developed a self-driving car equipped with relevant sensors and cameras. Its sensors are able to detect the environment but not all the aspects. Hence, in which environment is your car
acting?

A. Stochastic

B. Discrete

C. Fully observable

D. Partially observable

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer D: Partially observable

The sensors cannot determine complete state; this is precisely partial observability. It says nothing about transition randomness. Evidence: PDF 13.

Why each choice is right or wrong

A - Incorrect: Stochastic describes transitions, not hidden aspects. See PDF p. 13.

B - Incorrect: Discrete describes state structure, not visibility. See PDF p. 13.

C - Incorrect: Contradicted by incomplete detection. See PDF p. 13.

D - Correct: Matches missing state information. See PDF p. 13.

Primary note proof

Study-note section AI09

> Fully observable means sensors reveal relevant state; partially observable means relevant information is hidden or noisy. Deterministic means state and action determine the next state; stochastic means outcomes involve randomness. Strategic uncertainty about an opponent is distinct from dice-like randomness.

Study-note section AI09

> Episodic decisions are independent; sequential decisions affect later situations. Static worlds do not change while deliberating; dynamic ones do. Question 127 | SM0020

Which quantifier can be used for some portion of the universe?

A. For all (universal)

B. Implies

C. There exists (existential)

D. And

Hint

Translate the statement carefully, then check the scope of its quantifiers, connectives or inference rule. Distinguish guaranteed consequences from plausible generalizations or explanations.

Answer C: There exists (existential)

Some or at least one is existential quantification; universal applies to all. Evidence: PDF 49.

Why each choice is right or wrong

A - Incorrect: All instances rather than some. See PDF p. 49.

B - Incorrect: A connective, not a quantifier. See PDF p. 49.

C - Correct: Matches some/at least one. See PDF p. 49.

D - Incorrect: A connective, not a quantifier. See PDF p. 49.

Primary note proof

Study-note section AI26

First-order logic adds objects, predicates, functions and quantified object variables. Human(a) is a property; Likes(a,b) a relation; father(a) a function term. Propositional logic has no object quantifiers, but its truth still depends on the assigned atom values.

Study-note section AI25

Propositional atoms represent whole true-or-false claims. ¬P negates; P∧Q requires both; P∨Q requires at least one; P→Q is false only when P is true and Q false; P↔Q requires matching truth values. Thus P→Q ≡ ¬P∨Q. De Morgan gives ¬(P∧Q) ≡ ¬P∨¬Q.

Module passages - related reading

Question 128 | SM0037

Which one of the following is a step in problem solving that lists the actions and states that the agent has to consider provided a goal?

A. Problem formulation

B. Execute

C. Search

D. Goal formulation

Hint

Read the definition and the classification axis requested; distinguish the defining purpose from supporting techniques or implementation resources.

Answer A: Problem formulation.

AI11 says the goal is formulated first, then the problem specifies initial state, legal actions, transitions, goal test and action costs. Given a goal, listing the relevant actions and states belongs to that second step. Search chooses a sequence within the formulated problem, and execution applies it; neither defines the alternatives initially.

Why each choice is right or wrong

A - Correct: Problem formulation specifies the states, available actions and model the agent must consider for its goal.

B - Incorrect: Execution applies a selected action sequence after formulation and search.

C - Incorrect: Search selects a solution using the already specified states, actions, model and goal test.

D - Incorrect: Goal formulation chooses the objective; the stem already provides a goal before listing actions and states.

Primary note proof

Study-note section AI11

> First formulate the goal; then formulate the problem by specifying initial state, legal actions, transition model, goal test, and action costs. Search selects a sequence; execution applies it. A state abstracts away irrelevant world details.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Introduction to Artificial Intelligence module | PDF page 18 | lines 16-18

> Actions: It gives the description of all the available actions to the agent.
> Transition model: A description of what each action do, can be represented as a transition model.
> Path Cost: It is a function which assigns a numeric cost to each path.

Question 129 | SM0061

Which term names the entire ordered history of observations an agent has received so far?

A. Performance measure

B. Percept sequence

C. Knowledge

D. Action

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer B: Percept sequence

A percept is one observation, while a percept sequence is the entire observation history. A performance measure defines success instead of storing observations. Knowledge may include prior facts and inferences beyond the observation history, and an action is selected behavior rather than observed input. Replacing the overly broad perception option supplies the precise established term without changing the agent-history concept.

Why each choice is right or wrong

A - Incorrect: A performance measure defines success, not what the agent has observed.

B - Correct: A percept sequence is the entire observation history.

C - Incorrect: Knowledge includes prior and inferred information, not precisely the observation history.

D - Incorrect: An action is selected behavior rather than the agent's accumulated observations.

Primary note proof

Study-note section AI03

> A percept is one observation; a percept sequence is the entire observation history. An agent function maps percept sequences to actions: f:P*→A. An agent program implements that mapping on an architecture; agent = architecture + program. Environment means the setting in which it senses and acts, not merely the search space. Autonomy means relying substantially on experience rather than only a designer's prior instructions.

Study-note section AI04

> A performance measure defines success externally: safety, useful deliveries, elapsed time, or cost. Rationality depends on that measure, prior knowledge, percept history, and available actions. A rational agent selects the action with the best expected performance given its information.

Module passages - related reading

Question 130 | SM0211

Every training example has an input and its desired target output; there is no extra unlabeled training pool or interaction reward. Which learning regime fits this setup?

A. Semi-supervised learning

B. Unsupervised learning

C. Supervised learning

D. Reinforcement learning

Hint

Identify the training feedback, prediction target or measured error. Keep learning objectives separate from model architecture and data modality.

Answer C: Supervised learning

The training data consist entirely of input-target pairs, so the task is supervised learning. The desired target provides the learning signal. Semi-supervised learning would add an unlabeled pool, unsupervised learning would seek structure without targets, and reinforcement learning would use rewards from interaction. Stating the complete data setup distinguishes the regimes without implying that any use of labels excludes semi-supervised methods.

Why each choice is right or wrong

A - Incorrect: Semi-supervised learning requires additional unlabeled training data alongside labeled examples, absent here.

B - Incorrect: Unsupervised learning discovers structure without the supplied target labels.

C - Correct: Supervised learning fits the mapping from the labeled input-target pairs described.

D - Incorrect: Reinforcement learning uses evaluative interaction rewards, not the described desired-output pairs.

Primary note proof

Study-note section AI31

> Supervised learning fits a mapping from labeled input-target examples. Classification predicts discrete labels, such as institution generations or spam/nonspam; regression predicts numeric quantities, such as prices. Predictive analytics uses historical patterns to forecast outcomes and can use either. Specify the target before choosing a method.

Study-note section AI32

> Semi-supervised learning combines some labels with additional unlabeled data. Active learning chooses informative cases for an oracle to label; it still uses labels. “Exploratory learning” is not an exclusive standard synonym: it can mean unsupervised exploration or active data acquisition, so define the feedback. A task named summarization or time-series analysis is not automatically supervised; its training targets determine that.

Study-note section AI33

An RL agent observes state information, takes an action, receives reward and a new observation, and improves its policy to maximize expected cumulative reward. Rewards evaluate outcomes rather than supply the correct action label. Rewards may be delayed; not every correct-looking action receives immediate reward.

Computer Science Exit Exam practice collection · Question 207

Question 131 | SM0222

The simple strategy in which the root node is expanded first, then all successors are expanded next, layer by layer, refers to:

A. Greedy best-first search

B. Depth-first search (DFS)

C. Depth limited search (DLS)

D. Breadth-first search (BFS)

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer D: Breadth-first search (BFS)

Expanding every node at one level before the next is the stated BFS order. Evidence: PDF 19.

Why each choice is right or wrong

A - Incorrect: Ranks by estimated goal distance. See PDF p. 19.

B - Incorrect: Follows a path deeply before siblings. See PDF p. 19.

C - Incorrect: Restricts DFS to a bound. See PDF p. 19.

D - Correct: Exact layer-order expansion. See PDF p. 19.

Primary note proof

Study-note section AI13

BFS removes the oldest frontier entry using a FIFO queue. Start with the root, remove the head, test it, append unseen successors at the tail, and repeat. It explores depths 0,1,2,... and is complete for finite b and a finite-depth goal. It minimizes number of edges, so minimum cost requires equal positive step costs.

Study-note section AI14

DFS follows the deepest pending branch using a LIFO stack or recursion. FILO means the same order as LIFO. With the same children as BFS, a left-first DFS visits S,A,C before B; push rightmost children first to pop the leftmost first.

Study-note section AI16

DLS runs DFS to depth l and reports cutoff separately from failure. It misses goals deeper than l. Iterative deepening runs DLS with limits 0,1,2,...; for finite b it finds the shallowest solution with O(b^d) time and O(bd) frontier space, optimal for equal step costs. Repeated shallow work is small compared with the deepest level.

Study-note section AI17

Best-first is a family that orders OPEN by an evaluation function. Greedy best-first uses f=h and removes the smallest estimate, ignoring the cost already paid. It can choose an expensive route, loop without duplicate checks, or follow an infinite misleading branch. On a finite graph with full duplicate handling it is complete, but not generally optimal. Its implicit finite-tree worst case can be O(b^m).

These source passages provide context; the primary note proof is identified separately above.

Introduction to Artificial Intelligence module | PDF page 19 | lines 25-26

• BFS algorithm starts searching from the root node of the tree and expands all successor node at the
current level before moving to nodes of next level.

Question sources

Computer Science Exit Exam · Sene 2016 · Question 7-3

Computer Science Exit Exam practice collection · Question 206

Question 132 | SM0253

Which statement is not a correct characterization of reasoning?

A. Using knowledge to derive conclusions that can guide what a system does.

B. A process of thinking, logically arguing, and drawing inference

C. Theory of blind searching

D. The act of deriving a conclusion from certain premises using a given methodology

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer C: Theory of blind searching

Reasoning uses knowledge and a specified methodology to derive conclusions from premises. Logical argument and inference are therefore appropriate descriptions. Blind search is instead a search strategy that explores alternatives without heuristic guidance; it does not define reasoning as a whole. Clarifying the incomplete knowledge-system option into a claim about deriving conclusions leaves the intended search-versus-inference distinction as the unique exception.

Why each choice is right or wrong

A - Incorrect: Using knowledge to derive conclusions is a valid characterization, so it is not the exception.

B - Incorrect: Logical argument and drawing inferences describe reasoning, so this is not a false characterization for the negative question.

C - Correct: Blind search is one search strategy rather than a definition of reasoning.

D - Incorrect: Deriving a conclusion from premises using a methodology describes reasoning and does not satisfy the negative question.

Primary note proof

Study-note section AI24

> Knowledge representation encodes facts, objects, relations, events and rules so a machine can use them. Syntax defines legal expressions; semantics defines their meaning. A knowledge base stores assertions; an inference system derives consequences. Declarative knowledge says what is true; procedural knowledge specifies how to act.

Study-note section AI17

> A heuristic h(n) estimates remaining cost or evaluates promise using problem-specific knowledge. It can reduce explored work, but computing it also costs time. Uninformed algorithms use only the problem definition and known costs; UCS remains uninformed despite using g.

Introduction to Artificial Intelligence module | PDF page 53 | lines 18-20

> - Reasoning - is the mental process of deriving logical conclusion and making predictions from available knowledge, facts, and beliefs. "Reasoning is a way to infer facts from existing data." It is a general process of thinking rationally, to find valid conclusions. In artificial intelligence, the

Question sources

Computer Science Exit Exam · Sene 2016 · Question 17-2

Computer Science Exit Exam practice collection · Question 208

Question 133 | SM0261

Which reasoning technique applies valid inference rules so that true premises guarantee a true conclusion?

A. Abductive reasoning

B. Analogical reasoning

C. Deductive reasoning

D. Inductive reasoning

Hint

Translate the statement carefully, then check the scope of its quantifiers, connectives or inference rule. Distinguish guaranteed consequences from plausible generalizations or explanations.

Answer C: Deductive reasoning

Deductive reasoning uses truth-preserving inference: when the premises are true and the rule is valid, the conclusion must be true. Rules in a broad sense are not sufficient to identify deduction, since many reasoning methods use procedures. Induction generalizes from cases, abduction proposes explanations, and analogy transfers conclusions across similarities; these do not supply the stated logical guarantee.

Why each choice is right or wrong

A - Incorrect: Abduction proposes plausible explanatory hypotheses that can still be false.

B - Incorrect: Analogy transfers a conclusion from a similar case without a truth-preservation guarantee.

C - Correct: Valid deductive inference preserves truth from premises to conclusion.

D - Incorrect: Induction generalizes beyond the observed cases and remains revisable.

Primary note proof

Study-note section AI28

> Deduction applies truth-preserving rules: all people are mortal; Ada is a person; therefore Ada is mortal. Induction generalizes observations to a broader rule and can be overturned by new

examples. Abduction proposes a plausible explanation: wet ground suggests rain, although sprinklers could explain it. Analogy transfers a pattern between similar situations.

Study-note section AI28

Classical logical entailment is monotonic: adding premises preserves previous consequences. Default reasoning can be nonmonotonic: infer a bird usually flies, then withdraw this when told it is a penguin. Common-sense defaults are useful with incomplete knowledge, but are not guaranteed truths. Blind search is a search strategy, not a definition of reasoning.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Science Exit Exam · Sene 2016 · Question 20-1

Computer Science Exit Exam practice collection · Question 204

Question 134 | SM0269

For A* tree search with an admissible heuristic and positive step costs, what is the intended benefit of using the heuristic alongside accumulated edge costs?

A. To seek a least-cost path while potentially reducing expansions through heuristic guidance.

B. To find the path with the maximum distance from the start to the goal node

C. To find paths with non-optimal searches from node to the goal node

D. To find the path with the maximum cost from the start to the goal node

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer A: To seek a least-cost path while potentially reducing expansions through heuristic guidance.

A* adds accumulated cost g to an admissible remaining-cost estimate h. Under the stated tree-search conditions, this supports least-cost solutions, while useful heuristic guidance can reduce expansions. It does not guarantee a speed improvement for every problem or heuristic. Maximizing distance or cost is a different objective, and deliberately seeking nonoptimal paths is not the benefit described.

Why each choice is right or wrong

A - Correct: An admissible remaining-cost estimate supports optimal tree search and can guide exploration toward useful candidates.

B - Incorrect: A* minimizes total path cost; it does not seek maximum path length.

C - Incorrect: Nonoptimality is not the purpose of admissible A* tree search.

D - Incorrect: A* seeks minimum, not maximum, total cost.

Primary note proof

Study-note section AI18

A* orders by f(n)=g(n)+h(n). Admissibility means 0≤h(n)≤h*(n), the true cheapest remaining cost. Consistency means h(n)≤c(n,n′)+h(n′) on every edge, with h(goal)=0; it implies admissibility on states with goal paths. Consistency makes f nondecreasing along a path.

Study-note section AI18

Admissibility suffices for optimal A* tree search; graph search that never reopens CLOSED states normally requires consistency. With an admissible inconsistent heuristic, reopen states when g improves. Test a goal when removed at minimum f. Completeness also needs finite branching and positive lower-bounded costs in infinite spaces. Worst-case time and memory can be exponential; no heuristic universally guarantees speed.

Module passages - related reading

Question 135 | SM0299

What role does machine learning play in understanding human perception?

A. Machine learning helps simulate human perception through neural networks

B. Machine learning has no relevance to understanding human perception

C. Machine learning is not capable of analyzing perceptual data

D. Machine learning only focuses on logical reasoning and decision-making

SYSTEMS

Hint

Identify the training feedback, prediction target or measured error. Keep learning objectives separate from model architecture and data modality.

Answer A: Machine learning helps simulate human perception through neural networks

ANNs model brain-inspired processing and learn pattern recognition; combined with p67 recognition applications this supports the perception-modeling role. Evidence: PDF 71, 71, 67.

Why each choice is right or wrong

A - Correct: Matches brain-inspired models applied to recognition. See PDF p. 71, 71, 67.

B - Incorrect: Contradicts documented pattern-recognition applications. See PDF p. 71, 71, 67.

C - Incorrect: Contradicts recognition/classification capabilities. See PDF p. 71, 71, 67.

D - Incorrect: Machine learning also handles sensory patterns, not only logic. See PDF p. 71, 71, 67.

Primary note proof

Study-note section AI34

> Feedforward networks pass signals toward outputs without recurrent state loops; recurrent networks carry state across sequence steps. Training adjusts weights, often through gradients and backpropagation. Backpropagation is not the same as a recurrent connection. Deep learning uses multiple representation layers and can learn features from images, sound and text. CNNs share filters across image locations. ANN is a brain-inspired abstraction, not a literal brain simulation; DL⊂ML⊂AI.

Study-note section AI39

> Computer vision interprets images or video: classification names image content, detection locates objects, segmentation labels pixels, and recognition identifies objects or people. Occlusion, lighting change, noise, unfamiliar conditions and incomplete context make open-world perception difficult even when a face detector works well.

Computer Science Exit Exam · Sene 2016 · Question 32-2

Computer Science Exit Exam practice collection · Question 210

Question 136 | SS100

An informed search keeps one priority frontier ordered by g(n)+h(n), permanently closes states, and tests goals on removal. With a consistent heuristic, finite branching and positive lower-bounded step costs, which algorithm is this?

A. Iterative Deepening A* Search

B. Greedy Best-First Search

C. Uniform Cost Search

D. A* Search

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer D: A* Search

A* uses a best-first priority frontier ordered by g+h. Consistency provides the standard guarantee for graph search that permanently closes states, with the stated cost and goal-test conditions. IDA* also uses f values but organizes repeated depth-first threshold searches instead. Greedy search omits g, and UCS omits h. The frontier organization distinguishes the algorithms rather than a worst-case complexity shared by several methods.

Why each choice is right or wrong

A - Incorrect: IDA* repeats depth-first searches under increasing f thresholds rather than retaining this single priority frontier.

B - Incorrect: Greedy best-first uses h alone and does not have the stated cost-aware priority.

C - Incorrect: UCS uses g alone, without the heuristic term.

D - Correct: A* uses g+h; consistency supports optimality when graph states are closed without reopening.

Primary note proof

Study-note section AI18

A* orders by f(n)=g(n)+h(n). Admissibility means 0≤h(n)≤h*(n), the true cheapest remaining cost. Consistency means h(n)≤c(n,n′)+h(n′) on every edge, with h(goal)=0; it implies admissibility on states with goal paths. Consistency makes f nondecreasing along a path.

Study-note section AI18

Admissibility suffices for optimal A* tree search; graph search that never reopens CLOSED states normally requires consistency. With an admissible inconsistent heuristic, reopen states when g improves. Test a goal when removed at minimum f. Completeness also needs finite branching and positive lower-bounded costs in infinite spaces. Worst-case time and memory can be exponential; no heuristic universally guarantees speed.

Study-note section AI16

Bidirectional search grows from start and goal until frontiers connect. With suitable reverse actions, meeting tests and equal-cost BFS, time and space may fall to O(b^(d/2)). Weighted variants require a sound stopping bound; the first intersection need not be cheapest. IDA* deepens an f=g+h threshold rather than only a depth limit.

Study-note section AI17

Best-first is a family that orders OPEN by an evaluation function. Greedy best-first uses f=h and removes the smallest estimate, ignoring the cost already paid. It can choose an expensive route, loop without duplicate checks, or follow an infinite misleading branch. On a finite graph with full duplicate handling it is complete, but not generally optimal. Its implicit finite-tree worst case can be O(b^m).

Study-note section AI15

UCS uses a priority queue ordered by actual accumulated path cost g(n).

Question sources

Computer Science model exam collection · Question 7

Question 137 | SS143

Which general term denotes an entity that perceives its environment through sensors and acts on it through effectors?

A. API

B. Expert System

C. Intelligence

D. Agent

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer D: Agent

An agent is defined by perceiving an environment and acting on it through sensors and effectors. The acting mechanism may be physical or software-based. An API can expose operations used by an agent, and an expert system can contribute domain reasoning, but neither names the general entity defined here. Intelligence is a capability rather than the entity itself.

Why each choice is right or wrong

A - Incorrect: An API exposes software operations; it may support an agent's actions but is not the general perceiving-and-acting entity.

B - Incorrect: An expert system is a specialized knowledge-based application, not the general term for every sensing-and-acting entity.

C - Incorrect: Intelligence is a capability, not the name of the defined entity.

D - Correct: Agent is the general term for an entity with this perception-and-action interaction.

Primary note proof

Study-note section AI03

> An agent perceives an environment through sensors and acts through actuators or effectors. Cameras sense; motors move. Software sensors may be incoming messages and software actions may be API requests. Humans are agents but are not artificial agents.

Study-note section AI40

> An expert system applies specialized knowledge to a domain such as equipment diagnosis. The domain expert supplies expertise; the knowledge engineer elicits and encodes it; the inference engine reasons over a knowledge base and working facts. The user interface handles interaction; an explanation facility presents why or how a conclusion was reached.

Study-note section AI-S06

> An application programming interface (API) exposes defined operations through which software requests functionality. It can be an interface used by an agent, but the interface alone is not the general entity that perceives an environment and selects actions.

Module passages - related reading

Introduction to Artificial Intelligence module | PDF page 10 | lines 21-23

> • An agent is anything that can perceive its environment through sensors and acts upon that environment through effectors. An agent perceives its environment through sensors.
> • The complete set of inputs at a given time is called a percept.

Question sources

Computer Science model exam collection · Question 50

Question 138 | SS171

A new dataset has no target labels. The objective is to discover its groups or structure, with neither interaction rewards nor reuse of a pretrained model. Which learning regime applies?

A. Reinforcement learning

B. Unsupervised learning

C. Transfer learning

D. Supervised learning

Hint

Identify the training feedback, prediction target or measured error. Keep learning objectives separate from model architecture and data modality.

Answer B: Unsupervised learning

The objective is structure discovery without target labels, which defines unsupervised learning. The stem separately excludes action-reward interaction and reuse of a pretrained model. Those exclusions distinguish reinforcement feedback and transfer learning from this task. Transfer learning describes a reuse strategy rather than a label-availability regime and can be combined with different learning objectives.

Why each choice is right or wrong

A - Incorrect: Reinforcement learning requires a reward-based interaction objective, which is excluded.

B - Correct: Unsupervised learning discovers structure in data without supplied target labels.

C - Incorrect: Transfer learning concerns reuse of prior learned representations or models; no such reuse is present.

D - Incorrect: Supervised learning requires target outputs paired with the inputs.

Primary note proof

Study-note section AI32

> Unsupervised learning seeks structure without target labels: clustering groups similar examples; association finds co-occurrence; dimensionality reduction compresses features. Good clusters have high within-cluster similarity and low between-cluster similarity under an appropriate distance. K-means alternates assignment to nearest centroids and centroid updates.

Study-note section AI31

> Supervised learning fits a mapping from labeled input-target examples. Classification predicts discrete labels, such as institution generations or spam/nonspam; regression predicts numeric quantities, such as prices. Predictive analytics uses historical patterns to forecast outcomes and can use either. Specify the target before choosing a method.

Study-note section AI33

> An RL agent observes state information, takes an action, receives reward and a new observation, and improves its policy to maximize expected cumulative reward. Rewards evaluate outcomes rather than supply the correct action label. Rewards may be delayed; not every correct-looking action receives immediate reward.

Study-note section AI-S06

> Transfer learning reuses representations or a model learned on an earlier task for a new task, for example adapting pretrained image features to new image classes. This is a reuse strategy, not a specification that the new task has no labels or rewards.

Question 139 | SS175

One of the following statement is correct about Artificial Intelligence (Al)?

A. It refers to the development of machines that can perform tasks only in a controlled laboratory setting.

B. It refers to the development of machines that can only perform simple, repetitive tasks.

C. Itrefers to the development of machines that can only perform physical tasks.

D. It refers to the development of machines that can perform tasks that typically require human intelligence.

Hint

Match the input, output and purpose to the appropriate language, perception or physical-action task.

Answer D: It refers to the development of machines that can perform tasks that typically require human intelligence.

AI designs intelligence in artificial devices and includes language, learning, reasoning and real-world action, not the restrictive only-claims. Evidence: PDF 4, 6.

Why each choice is right or wrong

A - Incorrect: Real-world robots contradict laboratory-only. See PDF p. 4, 6.

B - Incorrect: Reasoning and complex problem solving exceed repetition. See PDF p. 4, 6.

C - Incorrect: Language/reasoning are not merely physical. See PDF p. 4, 6.

D - Correct: Matches design of artificial intelligence. See PDF p. 4, 6.

Primary note proof

Study-note section AI01

Artificial intelligence studies systems that perform tasks requiring intelligence: reasoning, learning, planning, perception and language. Applied AI builds useful solutions; cognitive AI uses computational models to investigate biological intelligence. A model should be compared with human behavior or experimental observations before claiming it explains human thought.

Study-note section AI39

Robotics combines mechanical, electrical, control and computing systems to sense, plan and act physically. Components include sensors, controller, power supply, actuators and an end effector.

Locomotion may be legged, wheeled or tracked, with trade-offs in terrain, stability and efficiency. Software can act autonomously without being a robot. Humanoid shape is not evidence of general intelligence.

These source passages provide context; the primary note proof is identified separately above.

Introduction to Artificial Intelligence module | PDF page 4 | lines 26-28

is concerned with the design of intelligence in an artificial device. The term was coined by McCarthy
in 1956. There are two ideas in the definition. i.e Intelligence, and Artificial device.
What is intelligence?

Introduction to Artificial Intelligence module | PDF page 6 | lines 12-21

1.3Intelligent behaviour
This discussion brings us back to the question of what constitutes intelligent behavior. Some ofthese
tasks and applications are:
• Perception involving image recognition and computer vision
• Reasoning
• Learning
• Understanding language involving natural language processing, speech processing
• Solving problems
• Robotics
• Thinking

Question sources

Computer Science model exam collection · Question 82

Question 140 | SS187

A techniques for generating plans with conditionals and loops are almost identical to those for generating programs from logical specifications is
called__

A. Automatic learning

B. Automatic goal testing

C. Automatic monitoring

D. Automatic programming

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer D: Automatic programming

Automatic programming, also called program synthesis, constructs a program that satisfies a specification. Generating conditional plans or loops is analogous because the output must implement the required behavior. Learning changes performance through experience, goal testing checks whether a candidate succeeds, and monitoring checks execution. None of those by itself names the specification-to-program construction task.

Why each choice is right or wrong

A - Incorrect: Learning improves performance through experience rather than specifically synthesizing a program from logical requirements.

B - Incorrect: A goal test checks whether a candidate meets the goal; it does not generate a program from its specification.

C - Incorrect: Monitoring checks an executing system rather than generating a program from a specification.

D - Correct: Automatic programming or program synthesis constructs a program meeting a specification, including conditional or looping behavior.

Primary note proof

Study-note section AI11

> In route finding, states are cities, actions are roads, successors are neighboring cities, and path cost is accumulated distance or time. A solution is a legal path ending at a goal; an optimal solution has minimum cost. Automatic programming or program synthesis searches for a program satisfying a specification; conditional plans and loops require richer representations than a fixed action list.

Study-note section AI08

> Learning is improvement on task T, measured by P, through experience E. For spam filtering, T is classifying email, E is past labeled messages, and P might be recall at a required precision. Exploration trades immediate reward for information; exploitation uses the best action currently known. Learning can improve reflex, goal-based or utility-based agents.

Study-note section AI11

> First formulate the goal; then formulate the problem by specifying initial state, legal actions, transition model, goal test, and action costs. Search selects a sequence; execution applies it. A state abstracts away irrelevant world details.

Question sources

Computer Science model exam collection · Question 94

Question 141 | AM0624

Which choices describe broad intelligence-related goals of AI rather than implementation means or hardware capacity? Select all that apply.

A. Emulating human intelligence

B. Creating machines that can think and learn

C. Developing advanced algorithms

D. Enhancing computer processing power

Hint

Read the definition and the classification axis requested; distinguish the defining purpose from supporting techniques or implementation resources.

Answer A, B: Emulating human intelligence; Creating machines that can think and learn

AI can aim to emulate aspects of human intelligence or to build systems that reason and learn. Those are compatible broad goals, although different AI approaches evaluate humanlike behavior and rational performance differently. Advanced algorithms are means that may serve many fields, while additional processing power is hardware capacity rather than intelligence itself. The distinction therefore permits both intelligence-related objectives.

Why each choice is right or wrong

A - Correct: Humanlike thought and behavior are established AI approaches and fit this broad goal.

B - Correct: Building systems with intelligent reasoning and learning is another supported broad AI objective.

C - Incorrect: Advanced algorithms are implementation means, not the defining intelligence goal.

D - Incorrect: More processing power alone does not establish intelligent behavior or learning.

Primary note proof

Study-note section AI01

Artificial intelligence studies systems that perform tasks requiring intelligence: reasoning, learning, planning, perception and language. Applied AI builds useful solutions; cognitive AI uses computational models to investigate biological intelligence. A model should be compared with human behavior or experimental observations before claiming it explains human thought.

Study-note section AI43

> Face recognition is both an applied task and a narrow capability. Broad machine-intelligence goals can include emulating human intelligence and building systems that learn. Humanlike problem-solving alone does not uniquely select expert systems. Python is widely used, but C++ and Java also implement AI; “commonly used” does not isolate one language. McCarthy is associated with naming AI, not its sole invention.

Question sources

Computer Science MCQ practice collection · Question 624

Question 142 | AM0625

What is knowledge representation in artificial intelligence?

A. The process of storing information in a computer

B. The ability of machines to reason and make decisions

C. The study of how humans acquire knowledge

D. The process of encoding knowledge for machine use

Hint

Read the definition and the classification axis requested; distinguish the defining purpose from supporting techniques or implementation resources.

Answer D: The process of encoding knowledge for machine use

Knowledge representation organizes and formalizes knowledge in a machine-usable knowledge base. Storage alone omits the encoding/formalization purpose. Evidence: PDF 62.

Why each choice is right or wrong

A - Incorrect: Too broad: mere storage need not represent usable knowledge. See PDF p. 62.

B - Incorrect: Reasoning uses representations but is not representation itself. See PDF p. 62.

C - Incorrect: Human acquisition is a different subject. See PDF p. 62.

D - Correct: Best match to formal machine-usable encoding. See PDF p. 62.

Primary note proof

Study-note section AI24

> Knowledge representation encodes facts, objects, relations, events and rules so a machine can use them. Syntax defines legal expressions; semantics defines their meaning. A knowledge base stores assertions; an inference system derives consequences. Declarative knowledge says what is true; procedural knowledge specifies how to act.

Study-note section AI40

> An expert system applies specialized knowledge to a domain such as equipment diagnosis. The domain expert supplies expertise; the knowledge engineer elicits and encodes it; the inference engine reasons over a knowledge base and working facts. The user interface handles interaction; an explanation facility presents why or how a conclusion was reached.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

> o It is the method used to organize and formalize the knowledge in the knowledge base.

Question sources

Computer Science MCQ practice collection · Question 625

Question 143 | AM0626

Which representation system matches IF-THEN production rules against working memory and applies a selected rule to derive a conclusion or action?

A. Semantic networks

B. Neural networks

C. Production systems

D. Bayesian networks

Hint

Identify the training feedback, prediction target or measured error. Keep learning objectives separate from model architecture and data modality.

Answer C: Production systems

A production system uses IF-THEN rules whose conditions are matched against working memory; an applicable rule is selected and applied. Semantic networks encode concept relationships, neural networks learn weighted representations, and Bayesian networks encode probabilistic dependencies. All can support reasoning in broader systems, so the distinctive feature here is the explicit production-rule cycle rather than inference in general.

Why each choice is right or wrong

A - Incorrect: Semantic networks represent concepts and labeled relationships, not this working-memory production-rule cycle.

B - Incorrect: Neural networks compute through weighted units and learned representations rather than the specified rule-matching architecture.

C - Correct: Production systems match condition-action or condition-conclusion rules against working memory.

D - Incorrect: Bayesian networks represent conditional probabilistic dependencies rather than the stated production-rule mechanism.

Primary note proof

Study-note section AI24

A semantic network connects concept nodes by labeled relations such as is-a. Frames describe stereotyped entities through slots, values and defaults. Production systems use IF conditions THEN conclusions or actions, matching rules against working memory and selecting among applicable rules. A graph suits relationships such as frequently bought together; frames suit attributes. No representation is always best for recommendation without task requirements.

Study-note section AI29

A Bayesian network is a directed acyclic graph with conditional probability tables; its joint distribution factors as the product of each node's probability given its parents. A Markov model assumes the next state depends on the current state rather than the entire past. These represent uncertainty; fuzzy membership represents a different issue.

Study-note section AI34

Feedforward networks pass signals toward outputs without recurrent state loops; recurrent networks carry state across sequence steps. Training adjusts weights, often through gradients and backpropagation. Backpropagation is not the same as a recurrent connection. Deep learning uses multiple representation layers and can learn features from images, sound and text. CNNs share filters across image locations. ANN is a brain-inspired abstraction, not a literal brain simulation; DL⊂ML⊂AI.

Question sources

Computer Science MCQ practice collection · Question 626

Question 144 | AM0627

Which reasoning technique involves drawing conclusions from specific observations or examples?

A. Deductive reasoning

B. Inductive reasoning

C. Abductive reasoning

D. Probabilistic reasoning

Hint

Translate the statement carefully, then check the scope of its quantifiers, connectives or inference rule. Distinguish guaranteed consequences from plausible generalizations or explanations.

Answer B: Inductive reasoning

Specific facts generalized into a conclusion define induction. The conclusion is supported rather than logically guaranteed by the finite examples. Evidence: PDF 53.

Why each choice is right or wrong

A - Incorrect: Typically general premises to specific conclusion. See PDF p. 53.

B - Correct: Exact specific-to-general pattern. See PDF p. 53.

C - Incorrect: Seeks most likely explanation for observations. See PDF p. 53.

D - Incorrect: Uses probability to express uncertainty, not this defining direction. See PDF p. 53.

Primary note proof

Study-note section AI28

> Deduction applies truth-preserving rules: all people are mortal; Ada is a person; therefore Ada is mortal. Induction generalizes observations to a broader rule and can be overturned by new examples. Abduction proposes a plausible explanation: wet ground suggests rain, although sprinklers could explain it. Analogy transfers a pattern between similar situations.

Study-note section AI29

> Probability describes uncertainty about events. $P(\neg A)=1-P(A)$; $P(A|B)=P(A\cap B)/P(B)$, for $P(B)>0$. Bayes gives $P(H|E)=P(E|H)P(H)/P(E)$: posterior equals likelihood times prior divided by evidence probability. For mutually exclusive exhaustive hypotheses, $P(E)=\Sigma_i P(E|Hi)P(Hi)$.

Question sources

Computer Science MCQ practice collection · Question 627

Question 145 | AM0628

A classifier is trained on labeled examples and predicts by following attribute tests from a root to a class-labeled leaf. Which learning technique matches this representation?

A. Reinforcement learning

B. Unsupervised learning

C. Deep learning

D. Decision tree learning

Hint

Identify the training feedback, prediction target or measured error. Keep learning objectives separate from model architecture and data modality.

Answer D: Decision tree learning

A decision tree predicts by testing an attribute at each internal node, following a branch and returning the leaf prediction. Labeled training makes this a supervised classification task. Deep learning can also be supervised, so supervision alone would not distinguish it. The representation in the stem provides the distinction; reinforcement and unsupervised learning describe different feedback regimes.

Why each choice is right or wrong

A - Incorrect: Reinforcement learning specifies environmental reward feedback rather than this attribute-test representation.

B - Incorrect: Unsupervised learning seeks structure without supplied target labels.

C - Incorrect: Deep learning uses multiple neural representation layers; it can be supervised but is not the attribute-test-and-leaf model described.

D - Correct: Decision tree learning produces attribute-test branches with predictions at leaves.

Primary note proof

Study-note section AI31

Supervised learning fits a mapping from labeled input-target examples. Classification predicts discrete labels, such as institution generations or spam/nonspam; regression predicts numeric quantities, such as prices. Predictive analytics uses historical patterns to forecast outcomes and can use either. Specify the target before choosing a method.

Study-note section AI31

A decision tree tests an attribute at each internal node, follows the corresponding branch and predicts at a leaf. ID3 chooses high information gain: $H(S)=-\Sigma p_i \log_2 p_i$; gain is parent entropy minus weighted child entropy. Gini impurity is $1-\Sigma p_i^2$, zero for a pure class. Pruning limits overfitting. Neural networks, support-vector machines and trees can all be supervised.

Study-note section AI43

ANNs, genetic search and reinforcement learning all improve candidate behavior or performance through experience in different ways. Deep learning is an architecture family usable with supervised, unsupervised or reinforcement objectives. Decision trees and deep models may both be supervised. To distinguish learning regimes, specify labels, reward or unlabeled structure.

Study-note section AI34

Feedforward networks pass signals toward outputs without recurrent state loops; recurrent networks carry state across sequence steps. Training adjusts weights, often through gradients and backpropagation. Backpropagation is not the same as a recurrent connection. Deep learning uses multiple representation layers and can learn features from images, sound and text. CNNs share filters across image locations. Computer Science MCQ practice collection · Question 628

Question 146 | AM0629

What is the primary objective of natural language processing (NLP) in artificial intelligence?

A. Understanding and generating human language by machines

B. Analyzing and processing large datasets

C. Enhancing computer hardware capabilities

D. Simulating human-like decision-making

Hint

Match the input, output and purpose to the appropriate language, perception or physical-action task.

Answer A: Understanding and generating human language by machines

Understanding/interpretation is defined in NLP, and NLG turns data into language, supporting both understanding and generation. Evidence: PDF 79, 79.

Why each choice is right or wrong

A - Correct: Matches understanding plus NLG. See PDF p. 79, 79.

B - Incorrect: Large-data processing is broader than language. See PDF p. 79, 79.

C - Incorrect: Not a hardware discipline. See PDF p. 79, 79.

D - Incorrect: Too broad; omits the defining language objective. See PDF p. 79, 79.

Primary note proof

Study-note section AI37

> NLP interprets and generates human language: translation, dialogue, summarization, question answering and text generation. Speech recognition converts audio to text; speech synthesis generates speech. They overlap language processing but solve different input/output tasks.

Question sources

Computer Science MCQ practice collection · Question 629

Question 147 | AM0630

Which model family assumes that the distribution of the next state depends on the current state rather than the entire earlier history?

A. Decision trees

B. Markov models

C. Support vector machines

D. Reinforcement learning

Hint

Identify the training feedback, prediction target or measured error. Keep learning objectives separate from model architecture and data modality.

Answer B: Markov models

The Markov assumption makes the current state sufficient for the next-state distribution, rather than requiring the full preceding history. That identifies the model family. Decision trees and support-vector machines are prediction methods with other defining structures. Reinforcement learning is a reward-based learning framework that can use a Markov model, but it is not itself the particular conditional-dependence assumption.

Why each choice is right or wrong

A - Incorrect: Decision trees are defined by attribute tests and leaf predictions rather than this conditional transition assumption.

B - Correct: A Markov model conditions the next state on the current state instead of the full previous history.

C - Incorrect: Support-vector machines use support vectors for prediction; a next-state conditional-dependence assumption does not define the family.

D - Incorrect: Reinforcement learning specifies improvement from rewards and may use different model families.

Primary note proof

Study-note section AI29

> A Bayesian network is a directed acyclic graph with conditional probability tables; its joint distribution factors as the product of each node's probability given its parents. A Markov model assumes the next state depends on the current state rather than the entire past. These represent uncertainty; fuzzy membership represents a different issue.

Study-note section AI31

> A decision tree tests an attribute at each internal node, follows the corresponding branch and predicts at a leaf. ID3 chooses high information gain: $H(S)=-\Sigma p_i \log_2 p_i$; gain is parent entropy minus weighted child entropy. Gini impurity is $1-\Sigma p_i^2$, zero for a pure class. Pruning limits overfitting. Neural networks, support-vector machines and trees can all be supervised.

Study-note section AI33

An RL agent observes state information, takes an action, receives reward and a new observation, and improves its policy to maximize expected cumulative reward. Rewards evaluate outcomes rather than supply the correct action label. Rewards may be delayed; not every correct-looking action receives immediate reward.

Study-note section AI-S06

Support-vector machines include supervised classification and regression methods. They use support vectors in their decision function rather than being defined by a next-state conditional-dependence assumption. In estimation, variance measures how predictions change across different training samples; overfitting instead names poor generalization caused by fitting training-specific details.

• Probabilistic reasoning is a way of knowledge representation where we apply the concept of probability to indicate the uncertainty in knowledge.
• In probabilistic reasoning, we combine probability theory with logic to handle the uncertainty.

Question sources

Computer Science MCQ practice collection · Question 630

Question 148 | AM0631

Which learning regime is defined by an agent trying actions, receiving environmental rewards and improving a policy to maximize expected cumulative return?

A. Reinforcement learning

B. Unsupervised learning

C. Deep learning

D. Genetic algorithms

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer A: Reinforcement learning

Reinforcement learning improves an action policy through rewards received during interaction, with expected cumulative return as the objective. Generic trial and error is too broad because evolutionary search also evaluates and improves candidates. Genetic algorithms are identified by population selection and variation, while deep learning identifies architecture. Unsupervised learning concerns unlabeled structure rather than this sequential reward objective.

Why each choice is right or wrong

A - Correct: Reinforcement learning is defined by this action-reward policy-improvement objective.

B - Incorrect: Unsupervised learning discovers unlabeled structure rather than defining cumulative-return optimization.

C - Incorrect: Deep learning specifies multilayer neural representations and can be used within several learning regimes.

D - Incorrect: Genetic algorithms improve candidate populations using selection and genetic variation; trial and error alone does not make them the stated action-reward learning regime.

Primary note proof

Study-note section AI33

> An RL agent observes state information, takes an action, receives reward and a new observation, and improves its policy to maximize expected cumulative reward. Rewards evaluate outcomes rather than supply the correct action label. Rewards may be delayed; not every correct-looking action receives immediate reward.

Study-note section AI43

> ANNs, genetic search and reinforcement learning all improve candidate behavior or performance through experience in different ways. Deep learning is an architecture family usable with supervised, unsupervised or reinforcement objectives. Decision trees and deep models may both be supervised. To distinguish learning regimes, specify labels, reward or unlabeled structure.

Study-note section AI20

> A genetic algorithm maintains a population, evaluates fitness, selects parents, applies crossover and mutation, and repeats replacement. It searches without guaranteeing global optimality. Means-ends analysis selects a difference between current and goal states, chooses an operator reducing it, and recursively solves its preconditions. Neither method is simply A* running backward.

Study-note section AI32

> Unsupervised learning seeks structure without target labels: clustering groups similar examples; association finds co-occurrence; dimensionality reduction compresses features.

Question sources

Computer Science MCQ practice collection · Question 631

Question 149 | AM0632

Which type of learning algorithm aims to mimic the structure and function of the human brain?

A. Supervised learning

B. Unsupervised learning

C. Deep learning

D. Reinforcement learning

Hint

Identify the training feedback, prediction target or measured error. Keep learning objectives separate from model architecture and data modality.

Answer C: Deep learning, as a multilayer brain-inspired neural architecture.

AI34 calls ANNs brain-inspired abstractions and describes deep learning as using multiple representation layers. AI43 stresses that deep models can use supervised, unsupervised or reinforcement objectives. Thus deep learning is the offered architecture-based answer, while the other choices classify feedback regimes rather than requiring brain-inspired structure. This is inspiration, not a claim of literal brain simulation.

Why each choice is right or wrong

A - Incorrect: Supervised learning specifies labeled targets and can use non-neural models such as trees or SVMs.

B - Incorrect: Unsupervised learning specifies unlabeled structure discovery and does not require a neural architecture.

C - Correct: Deep learning uses multilayer neural representations within the brain-inspired ANN family.

D - Incorrect: Reinforcement learning specifies reward-based interaction and need not use brain-inspired neural structure.

Primary note proof

Study-note section AI34

> Feedforward networks pass signals toward outputs without recurrent state loops; recurrent networks carry state across sequence steps. Training adjusts weights, often through gradients and backpropagation. Backpropagation is not the same as a recurrent connection. Deep learning uses multiple representation layers and can learn features from images, sound and text. CNNs share filters across image locations. ANN is a brain-inspired abstraction, not a literal brain simulation; DL⊂ML⊂AI.

Study-note section AI43

ANNs, genetic search and reinforcement learning all improve candidate behavior or performance through experience in different ways. Deep learning is an architecture family usable with supervised, unsupervised or reinforcement objectives. Decision trees and deep models may both be supervised. Question 150 | AM0633

What is the primary purpose of expert systems in artificial intelligence?

A. Emulate human expertise in a specific domain

B. Perform complex mathematical calculations

C. Process and analyze large datasets

D. Optimize computer hardware performance

Hint

Read the definition and the classification axis requested; distinguish the defining purpose from supporting techniques or implementation resources.

Answer A: Emulate human expertise in a specific domain

Expert systems solve complex problems in a particular domain at the level of human expertise. Evidence: PDF 60.

Why each choice is right or wrong

A - Correct: Exact domain-expertise purpose. See PDF p. 60.

B - Incorrect: May be a tool, not defining purpose. See PDF p. 60.

C - Incorrect: May be a workload, not defining purpose. See PDF p. 60.

D - Incorrect: Not the defining expert-system purpose. See PDF p. 60.

Primary note proof

Study-note section AI40

> An expert system applies specialized knowledge to a domain such as equipment diagnosis. The domain expert supplies expertise; the knowledge engineer elicits and encodes it; the inference engine reasons over a knowledge base and working facts. The user interface handles interaction; an explanation facility presents why or how a conclusion was reached.

Question sources

Computer Science MCQ practice collection · Question 633

Question 151 | AM0634

Within the cognitive approach to AI, which listed objective expresses the use of computational models to investigate human intelligence and perception?

A. Replicate human intelligence and perception

B. Enhance computer processing power

C. Analyze large datasets efficiently

D. Improve natural language processing

Hint

Read the definition and the classification axis requested; distinguish the defining purpose from supporting techniques or implementation resources.

Answer A: Replicate human intelligence and perception

Cognitive AI uses computational models to investigate biological intelligence, including human perception and thought. Replicating relevant aspects of these processes expresses that modeling objective, provided the model is compared with observations. Greater processing power and data efficiency are resources or methods. Language processing is a narrower task and need not aim to explain biological intelligence.

Why each choice is right or wrong

A - Correct: Modeling or replicating aspects of intelligence and perception is the cognitive investigation objective.

B - Incorrect: Faster hardware enables computation but does not itself supply a model of intelligence.

C - Incorrect: Efficient dataset analysis is a method or workload, not the specific cognitive-modeling objective.

D - Incorrect: NLP is one application area and does not by itself express the broader intelligence-and-perception investigation.

Primary note proof

Study-note section AI01

> Artificial intelligence studies systems that perform tasks requiring intelligence: reasoning, learning, planning, perception and language. Applied AI builds useful solutions; cognitive AI uses computational models to investigate biological intelligence. A model should be compared with human behavior or experimental observations before claiming it explains human thought.

Study-note section AI02

> Thinking humanly models human mental processes; thinking rationally derives conclusions by valid logic. Acting humanly seeks humanlike behavior; acting rationally selects actions expected to achieve objectives. Thought processes and observed behavior are different evaluation targets.

Question sources

Computer Science MCQ practice collection · Question 634

Question 152 | AM0635

Which AI approach uses computational models to investigate human thought processes and compares those models with human behavior?

A. Machine learning,

B. Natural language processing

C. Cognitive AI (cognitive modeling)

D. Robotics

Hint

Match the input, output and purpose to the appropriate language, perception or physical-action task.

Answer C: Cognitive AI (cognitive modeling)

Cognitive AI investigates biological intelligence through computational models, testing those models against human behavior or experimental observations. This is a scientific modeling purpose rather than simply useful automation. Machine learning, NLP and robotics may contribute tools to cognitive research, but none is defined by that purpose. The option now uses the explicit approach name taught in the note.

Why each choice is right or wrong

A - Incorrect: Machine learning improves performance from experience and need not model human thought processes.

B - Incorrect: NLP focuses on language interpretation and generation rather than necessarily explaining human cognition.

C - Correct: Cognitive AI uses computational models to investigate biological intelligence and human thought.

D - Incorrect: Robotics integrates physical sensing and action; it need not aim to explain human thought.

Primary note proof

Study-note section AI01

Artificial intelligence studies systems that perform tasks requiring intelligence: reasoning, learning, planning, perception and language. Applied AI builds useful solutions; cognitive AI uses computational models to investigate biological intelligence. A model should be compared with human behavior or experimental observations before claiming it explains human thought.

Study-note section AI02

Thinking humanly models human mental processes; thinking rationally derives conclusions by valid logic. Acting humanly seeks humanlike behavior; acting rationally selects actions expected to achieve objectives. Thought processes and observed behavior are different evaluation targets.

Study-note section AI37

NLP interprets and generates human language: translation, dialogue, summarization, question answering and text generation. Speech recognition converts audio to text; speech synthesis generates speech. They overlap language processing but solve different input/output tasks.

Study-note section AI39

Robotics combines mechanical, electrical, control and computing systems to sense, plan and act physically. Components include sensors, controller, power supply, actuators and an end effector. Locomotion may be legged, wheeled or tracked, with trade-offs in terrain, stability and efficiency. Software can act autonomously without being a robot. Humanoid shape is not evidence of general intelligence.

Question 153 | AM0636

Which area of AI research focuses on understanding and replicating human vision?

A. Natural language processing

B. Computer vision

C. Robotics

D. Expert systems

Hint

Match the input, output and purpose to the appropriate language, perception or physical-action task.

Answer B: Computer vision

Computer vision extracts and comprehends image information, making it the specific vision field. Evidence: PDF 84.

Why each choice is right or wrong

A - Incorrect: Language rather than image interpretation. See PDF p. 84.

B - Correct: Exact visual-comprehension field. See PDF p. 84.

C - Incorrect: Robots may use vision but robotics is broader. See PDF p. 84.

D - Incorrect: Domain expertise rather than vision specifically. See PDF p. 84.

Primary note proof

Study-note section AI39

> Computer vision interprets images or video: classification names image content, detection locates objects, segmentation labels pixels, and recognition identifies objects or people. Occlusion, lighting change, noise, unfamiliar conditions and incomplete context make open-world perception difficult even when a face detector works well.

Study-note section AI37

> NLP interprets and generates human language: translation, dialogue, summarization, question answering and text generation. Speech recognition converts audio to text; speech synthesis generates speech. They overlap language processing but solve different input/output tasks.

Study-note section AI40

Question 154 | AM0637

Which AI technique is used to extract insights and patterns from large datasets?

A. Natural language processing

B. Machine learning

C. Expert systems

D. Robotics

Hint

Identify the training feedback, prediction target or measured error. Keep learning objectives separate from model architecture and data modality.

Answer B: Machine learning

Machine learning applications include data mining/knowledge discovery and learning patterns; ANN example p71 specifically extracts complex patterns and trends. Evidence: PDF 67, 71.

Why each choice is right or wrong

A - Incorrect: Language-specific tools do not define general data learning. See PDF p. 67, 71.

B - Correct: Matches learning/discovery from data. See PDF p. 67, 71.

C - Incorrect: Knowledge-based domain expertise rather than general learned patterns. See PDF p. 67, 71.

D - Incorrect: Physical agents rather than the broad data-analysis technique. See PDF p. 67, 71.

Primary note proof

Study-note section AI08

Learning is improvement on task T, measured by P, through experience E. For spam filtering, T is classifying email, E is past labeled messages, and P might be recall at a required precision. Exploration trades immediate reward for information; exploitation uses the best action currently known. Learning can improve reflex, goal-based or utility-based agents.

Study-note section AI31

Supervised learning fits a mapping from labeled input-target examples. Classification predicts discrete labels, such as institution generations or spam/nonspam; regression predicts numeric quantities, such as prices. Predictive analytics uses historical patterns to forecast outcomes and can use either. Specify the target before choosing a method.

Study-note section AI32

Unsupervised learning seeks structure without target labels: clustering groups similar examples; association finds co-occurrence; dimensionality reduction compresses features. Good clusters have high within-cluster similarity and low between-cluster similarity under an appropriate distance. K-means alternates assignment to nearest centroids and centroid updates.

Study-note section AI40

An expert system applies specialized knowledge to a domain such as equipment diagnosis. The domain expert supplies expertise; the knowledge engineer elicits and encodes it; the inference engine reasons over a knowledge base and working facts. Which concept in AI refers to the ability of machines to understand and interpret human language?

A. Natural language processing

B. Machine learning

C. Expert systems

D. Robotics

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer A: Natural language processing

NLP is expressly machine understanding, analysis and interpretation of human languages. Evidence: PDF 79.

Why each choice is right or wrong

A - Correct: Exact language-understanding concept. See PDF p. 79.

B - Incorrect: Can support NLP but is broader learning from data. See PDF p. 79.

C - Incorrect: Domain expertise is not language understanding generally. See PDF p. 79.

D - Incorrect: Physical embodied action is a different focus. See PDF p. 79.

Primary note proof

Question sources

Computer Science MCQ practice collection · Question 639

Question 157 | AM0640

What is the specifically computational-modeling contribution of cognitive AI to studying human thought, as distinct from collecting measurements or running psychological experiments alone?

A. By analyzing human brain activity

B. By replicating human thought processes

C. By conducting psychological experiments

D. By improving computer hardware capabilities

Hint

Read the definition and the classification axis requested; distinguish the defining purpose from supporting techniques or implementation resources.

Answer B: By replicating human thought processes

Cognitive AI contributes computational models that implement proposed mechanisms of human thought. Their predictions can then be compared with behavior, response times, errors or other observations. Brain measurements and psychological experiments can provide valuable evidence, but collecting evidence alone is distinct from constructing the computational model. Faster hardware similarly enables work without supplying a cognitive explanation.

Why each choice is right or wrong

A - Incorrect: Brain measurements can provide evidence, but measurement alone does not construct the computational thought model requested.

B - Correct: Replicating aspects of thought in a computational model provides a theory whose behavior can be tested.

C - Incorrect: Psychological experiments can test a model, but experiments alone do not supply the computational representation asked for.

D - Incorrect: More capable hardware supplies resources without itself representing a theory of human thought.

Primary note proof

Study-note section AI01

> Artificial intelligence studies systems that perform tasks requiring intelligence: reasoning, learning, planning, perception and language. Applied AI builds useful solutions; cognitive AI uses computational models to investigate biological intelligence. A model should be compared with human behavior or experimental observations before claiming it explains human thought.

Study-note section AI02

> Thinking humanly models human mental processes; thinking rationally derives conclusions by valid logic. Acting humanly seeks humanlike behavior; acting rationally selects actions expected to achieve objectives. Thought processes and observed behavior are different evaluation targets.

Study-note section AI02

Computer Science MCQ practice collection · Question 640

Question 158 | AM0641

Which field builds integrated physical agents that sense their surroundings and act autonomously through motors or other actuators?

A. Machine learning

B. Robotics

C. Natural language processing

D. Expert systems

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer B: Robotics

Robotics builds physical systems that sense, plan and act, combining mechanical, electrical, control and computing components. The requirement for integrated physical sensing and actuation distinguishes it from software autonomy in general. Machine learning, NLP and expert systems can be components of a robot, but none by itself names the field responsible for the complete physical agent.

Why each choice is right or wrong

A - Incorrect: Machine learning provides experience-based improvement but does not itself define construction of physical sensing-and-acting systems.

B - Correct: Robotics integrates the mechanical, electrical, control and computing systems of physical agents.

C - Incorrect: NLP processes human language and does not require a physical body.

D - Incorrect: Expert systems supply specialized knowledge-based reasoning and need not control physical actuators.

Primary note proof

Study-note section AI39

> Robotics combines mechanical, electrical, control and computing systems to sense, plan and act physically. Components include sensors, controller, power supply, actuators and an end effector. Locomotion may be legged, wheeled or tracked, with trade-offs in terrain, stability and efficiency. Software can act autonomously without being a robot. Humanoid shape is not evidence of general intelligence.

Robotics is a domain in artificial intelligence that deals with the study of creating intelligent and efficient robots. Robots are the artificial agents acting in real world environment. Robots are aimed at
manipulating the objects by perceiving, picking, moving, modifying the physical properties of object,

Question sources

Computer Science MCQ practice collection · Question 641

Question 159 | AM0642

When studying how people recognize objects, what is the computational-modeling contribution of cognitive AI, rather than building a sensor or gathering biological and behavioral measurements alone?

A. By simulating human sensory organs

B. By analyzing human brain waves

C. By replicating human perceptual processes

D. By conducting psychological experiments

Hint

Match the input, output and purpose to the appropriate language, perception or physical-action task.

Answer C: By replicating human perceptual processes

Cognitive AI can implement proposed perceptual processes and compare the resulting recognition behavior with human observations. This is distinct from only building an input sensor or collecting brain-wave and behavioral measurements. Those activities can inform or test the model, but they do not alone provide its computational account of perception. The scope is modeling the recognition process, not claiming that other research methods lack value.

Why each choice is right or wrong

A - Incorrect: A sensory-organ simulation models an input mechanism, but does not by itself explain how observed patterns are recognized.

B - Incorrect: Brain-wave measurements provide data rather than the computational recognition model requested.

C - Correct: Replicating aspects of perceptual processing supplies a model whose recognition behavior can be tested.

D - Incorrect: Psychological experiments provide tests or observations; by themselves they do not construct the computational perception model.

Primary note proof

Study-note section AI01

> Artificial intelligence studies systems that perform tasks requiring intelligence: reasoning, learning, planning, perception and language. Applied AI builds useful solutions; cognitive AI uses computational models to investigate biological intelligence. Computer Science MCQ practice collection · Question 642

Question 160 | AM0643

Which AI technique solves specialized domain problems by applying expert knowledge encoded in a knowledge base through an inference engine?

A. Machine learning

B. Expert systems

C. Natural language processing

D. Robotics

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer B: Expert systems

An expert system applies specialized domain knowledge through an inference engine operating on a knowledge base and working facts. This is more specific than merely exhibiting intelligent problem solving. Machine learning emphasizes improvement from experience, NLP concerns language, and robotics combines sensing, planning and physical action. Those methods may be combined with expert systems, but they are not the technique defined by the stated knowledge-based architecture.

Why each choice is right or wrong

A - Incorrect: Machine learning fits behavior from experience rather than defining this expert-knowledge architecture.

B - Correct: Expert systems use a knowledge base and inference engine for specialized domain reasoning.

C - Incorrect: NLP concerns human language rather than this domain-expertise architecture.

D - Incorrect: Robotics concerns physical sensing and action rather than the stated knowledge-base technique.

Primary note proof

Study-note section AI40

> An expert system applies specialized knowledge to a domain such as equipment diagnosis. The domain expert supplies expertise; the knowledge engineer elicits and encodes it; the inference engine reasons over a knowledge base and working facts. The user interface handles interaction; an explanation facility presents why or how a conclusion was reached.

Study-note section AI08

> Learning is improvement on task T, measured by P, through experience E. For spam filtering, T is classifying email, E is past labeled messages, and P might be recall at a required precision. Question sources

Computer Science MCQ practice collection · Question 643

Question 161 | AM0644

What is a heuristic in the context of artificial intelligence (AI)?

A. A predefined set of rules for decision making

B. A mathematical model used to solve search problems

C. An intelligent agent capable of learning from experience

D. A strategy or rule of thumb used to guide problem-solving

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer D: A strategy or rule of thumb used to guide problem-solving

A heuristic guides search toward promising states using estimated closeness; it is a problem-solving guide rather than a complete learning agent or guaranteed exact solver. Evidence: PDF 24, 24.

Why each choice is right or wrong

A - Incorrect: A predefined rule could implement a heuristic, but not all decision rules are heuristics. See PDF p. 24, 24.

B - Incorrect: A heuristic need not be a complete mathematical search model. See PDF p. 24, 24.

C - Incorrect: A learning agent is an entity, not the guiding strategy. See PDF p. 24, 24.

D - Correct: Closest to the module's guiding-way definition. See PDF p. 24, 24.

Primary note proof

Study-note section AI17

> A heuristic h(n) estimates remaining cost or evaluates promise using problem-specific knowledge. It can reduce explored work, but computing it also costs time. Uninformed algorithms use only the problem definition and known costs; UCS remains uninformed despite using g.

Question sources

Computer Science MCQ practice collection · Question 644

Question 162 | AM0645

How are heuristics useful in search problems?

A. They guarantee finding the optimal solution.

B. They reduce the search space and speed up the search process.

C. They eliminate the need for search algorithms.

D. They ensure a systematic exploration of the search space.

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer B: They reduce the search space and speed up the search process.

Problem knowledge guides search toward promising states, often reducing explored nodes and time. It does not universally guarantee optimality or replace a search algorithm. Evidence: PDF 24.

Why each choice is right or wrong

A - Incorrect: Module explicitly warns heuristic may not give best solution. See PDF p. 24.

B - Correct: Matches guided efficient exploration. See PDF p. 24.

C - Incorrect: A heuristic is used within informed search. See PDF p. 24.

D - Incorrect: Systematic exploration alone does not distinguish heuristic guidance. See PDF p. 24.

Primary note proof

Study-note section AI17

> A heuristic h(n) estimates remaining cost or evaluates promise using problem-specific knowledge. It can reduce explored work, but computing it also costs time. Uninformed algorithms use only the problem definition and known costs; UCS remains uninformed despite using g.

Study-note section AI18

> Admissibility suffices for optimal A* tree search; graph search that never reopens CLOSED states normally requires consistency. With an admissible inconsistent heuristic, reopen states when g improves. Test a goal when removed at minimum f. Completeness also needs finite branching and positive lower-bounded costs in infinite spaces. Worst-case time and memory can be exponential; no heuristic universally guarantees speed.

guaranteed for best solutions but guaranteed to find a good solution in reasonable time.

Question sources

Computer Science MCQ practice collection · Question 645

Question 163 | AM0646

Which general characterization says that search uses problem-specific knowledge to estimate remaining cost, without itself requiring either non-overestimation or an edge-by-edge consistency inequality?

A. Admissible heuristic

B. Consistent heuristic

C. Informed heuristic

D. Dominance comparison between heuristics

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer C: Informed heuristic

Informed search adds problem-specific knowledge to guide exploration, often through a remaining-cost estimate. That general characterization does not guarantee admissibility or consistency, which impose additional mathematical conditions. Dominance instead compares two estimates pointwise. The question asks for the broad knowledge-use property rather than one of those stronger conditions or comparisons.

Why each choice is right or wrong

A - Incorrect: Admissibility adds a non-overestimation bound, stronger than the general knowledge-use characterization requested.

B - Incorrect: Consistency adds an edge-by-edge inequality, stronger than the general property requested.

C - Correct: Informed heuristic guidance uses problem-specific knowledge to estimate remaining cost or promise.

D - Incorrect: Dominance compares the numerical estimates of two heuristics rather than naming general use of problem knowledge.

Primary note proof

Study-note section AI17

A heuristic h(n) estimates remaining cost or evaluates promise using problem-specific knowledge. It can reduce explored work, but computing it also costs time. Uninformed algorithms use only the problem definition and known costs; UCS remains uninformed despite using g.

Study-note section AI18

A* orders by f(n)=g(n)+h(n). Admissibility means $0 \le h(n) \le h^*(n)$, the true cheapest remaining cost. Consistency means $h(n) \le c(n,n') + h(n')$ on every edge, with h(goal)=0; it implies admissibility on states with goal paths. Consistency makes f nondecreasing along a path.

Study-note section AI-S05

For two admissible heuristics, h_2 dominates h_1 when $h_2(n) \ge h_1(n)$ for every node. Dominance compares estimates; it is not itself a condition ensuring that an arbitrary heuristic never overestimates. Both estimates must separately satisfy the relevant admissibility assumptions.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Introduction to Artificial Intelligence module | PDF page 24 | lines 14-16

• It uses domain knowledge. In an informed search, problem information is available which can guide
the search.
• Informed search strategies can find a solution more efficiently than an uninformed search strategy.

Question sources

Computer Science MCQ practice collection · Question 646

Question 164 | AM0647

Which term names the heuristic property defined by $0 \le h(n) \le h^*(n)$, where $h^*(n)$ is the true cheapest remaining cost?

A. Admissible heuristic

B. Consistent heuristic

C. Informed heuristic

D. Dominance comparison between heuristics

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer A: Admissible heuristic

The displayed non-overestimation inequality defines admissibility. Consistency is a different edge condition; with the usual nonnegative heuristic estimates and a zero goal estimate, it implies admissibility for states with a goal path. Thus a consistent heuristic can also satisfy the bound, but consistency is not the name of the property being defined. Informedness and dominance do not independently establish the bound.

Why each choice is right or wrong

A - Correct: Admissibility is exactly the non-overestimation property stated by this inequality.

B - Incorrect: Consistency is an edge-by-edge inequality with goal normalization, rather than the name of the displayed non-overestimation bound.

C - Incorrect: Being informed only means using problem knowledge and does not impose this bound.

D - Incorrect: Dominance compares two heuristic estimates and does not by itself bound either one by the true remaining cost.

Primary note proof

Study-note section AI18

> A* orders by f(n)=g(n)+h(n). Admissibility means 0≤h(n)≤h*(n), the true cheapest remaining cost. Consistency means h(n)≤c(n,n′)+h(n′) on every edge, with h(goal)=0; it implies admissibility on states with goal paths. Consistency makes f nondecreasing along a path.

Study-note section AI-S05

> For two admissible heuristics, h_2 dominates h_1 when $h_2(n) \geq h_1(n)$ for every node. Dominance compares estimates; it is not itself a condition ensuring that an arbitrary heuristic never overestimates. Both estimates must separately satisfy the relevant admissibility assumptions.

Question sources

Computer Science MCQ practice collection · Question 647

Question 165 | AM0648

Which forward best-first algorithm ranks frontier nodes by accumulated path cost plus a heuristic estimate of remaining cost?

A. Depth-first search

B. Breadth-first search

C. A* search algorithm

D. Hill climbing algorithm

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer C: A* search algorithm

A* orders frontier nodes by f(n) = g(n) + h(n), combining the cost already paid with an estimate of the cost still needed. Estimating future cost is not a backward search frontier. DFS and BFS use depth-related removal orders, while hill climbing improves neighboring complete candidates. Replacing the mistaken backward-search phrase preserves the intended heuristic-and-cost algorithm identification.

Why each choice is right or wrong

A - Incorrect: DFS follows a stack order and does not inherently combine a heuristic with backward search.

B - Incorrect: BFS uses breadth order without requiring heuristics or a backward frontier.

C - Correct: A* is forward best-first search using f = g + h.

D - Incorrect: Hill climbing selects improving neighbors rather than ordering a frontier by accumulated plus remaining path cost.

Primary note proof

Study-note section AI18

> A* orders by f(n)=g(n)+h(n). Admissibility means 0≤h(n)≤h*(n), the true cheapest remaining cost. Consistency means h(n)≤c(n,n′)+h(n′) on every edge, with h(goal)=0; it implies admissibility on states with goal paths. Consistency makes f nondecreasing along a path.

Study-note section AI13

> BFS removes the oldest frontier entry using a FIFO queue. Start with the root, remove the head, test it, append unseen successors at the tail, and repeat. It explores depths 0,1,2,... and is complete for finite b and a finite-depth goal. It minimizes number of edges, so minimum cost requires equal positive step costs.

Study-note section AI14

DFS follows the deepest pending branch using a LIFO stack or recursion. FILO means the same order as LIFO. With the same children as BFS, a left-first DFS visits S,A,C before B; push rightmost children first to pop the leftmost first.

Study-note section AI20

Local search keeps a complete candidate configuration and improves its objective; the path may be irrelevant. Hill climbing chooses better neighbors. First-improvement accepts the first improvement; steepest-ascent examines all neighbors; stochastic variants choose among improvements. Local maxima, plateaus and ridges can stop progress. Random restarts or limited sideways steps can help without guaranteeing success.

Module passages - related reading

forward-search and other from goal node called as backward-search, to find the goal node.
• Bidirectional search replaces one single search graph with two small sub-graphs in which one starts
the search from an initial vertex and other starts from goal vertex.

Question sources

Computer Science MCQ practice collection · Question 648

Question 166 | AM0649

What is the main advantage of using heuristics in game playing AI systems?

A. They guarantee victory in every game.

B. They make the game unpredictable and exciting.

C. They allow the AI to learn from its opponents.

D. They improve the AI's decision-making and gameplay.

Hint

Read the definition and the classification axis requested; distinguish the defining purpose from supporting techniques or implementation resources.

Answer D: They improve the AI's decision-making and gameplay.

Game search computes candidate moves with a heuristic and chooses the best backed-up outcome, supporting improved decision quality rather than automatic victory or learning. Evidence: PDF 33, 34.

Why each choice is right or wrong

A - Incorrect: Optimal opponent may prevent a win. See PDF p. 33, 34.

B - Incorrect: Unpredictability is not the stated purpose. See PDF p. 33, 34.

C - Incorrect: Heuristic evaluation is not necessarily learning. See PDF p. 33, 34.

D - Correct: Matches heuristic move evaluation and selection. See PDF p. 33, 34.

Primary note proof

Study-note section AI23

> At a depth cutoff use an evaluation function estimating position desirability. Positive favors the designated MAX player, negative MIN; the scale is a convention, with +1/0/−1 often win/draw/loss. Material counts weighted pieces; mobility counts legal options; territory scores controlled regions. These are different features, often combined. Heuristics improve limited computation, not guarantee victory.

Study-note section AI22

> Adversarial search models agents with competing objectives. A game specifies states, player to move, legal actions, successor function, terminal test and utility. Perfect information means previous moves and current state are visible; it does not reveal future choices or imply absence of chance. Zero-sum utility makes one player’s gain the other’s loss.

Question sources

Computer Science MCQ practice collection · Question 649

Question 167 | AM0650

Which component is the scoring mapping that assigns a heuristic desirability value to a game state, rather than a search, pruning or sampling procedure?

A. Minimax algorithm

B. Alpha-beta pruning

C. Monte Carlo simulation

D. Evaluation function

Hint

Read the definition and the classification axis requested; distinguish the defining purpose from supporting techniques or implementation resources.

Answer D: Evaluation function

An evaluation function assigns a desirability score to a game state, especially when search stops at a depth cutoff. Minimax uses scores to choose moves, and alpha-beta avoids branches that cannot alter the backed-up result. Monte Carlo sampling can estimate values from possible continuations, but the sampling procedure is distinct from the mapping whose output is a state score.

Why each choice is right or wrong

A - Incorrect: Minimax backs values up through competing choices; it uses state scores rather than being the score mapping itself.

B - Incorrect: Alpha-beta pruning skips branches that cannot affect a minimax decision; it is not the scoring mapping.

C - Incorrect: Monte Carlo simulation samples continuations whose outcomes may estimate value; sampling is a procedure, not the score mapping itself.

D - Correct: An evaluation function maps a state to its estimated desirability score.

Primary note proof

Study-note section AI23

> At a depth cutoff use an evaluation function estimating position desirability. Positive favors the designated MAX player, negative MIN; the scale is a convention, with +1/0/−1 often win/draw/loss. Material counts weighted pieces; mobility counts legal options; territory scores controlled regions. These are different features, often combined. Heuristics improve limited computation, not guarantee victory.

Study-note section AI23

> Alpha is MAX’s best lower bound; beta is MIN’s best upper bound. Pass bounds down, update alpha at MAX and beta at MIN, and prune when alpha≥beta. Pruning preserves the minimax value for the same searched tree. Good move ordering increases pruning: worst-case O(b^m), ideal ordering about O(b^(m/2)).

Study-note section AI22

Adversarial search models agents with competing objectives. A game specifies states, player to move, legal actions, successor function, terminal test and utility. Perfect information means previous moves and current state are visible; it does not reveal future choices or imply absence of chance. Zero-sum utility makes one player's gain the other's loss.

Study-note section AI-S05

A Monte Carlo game simulation samples possible continuations and uses their outcomes to estimate position value. An evaluation function is the scoring mapping itself; sampling is one way of obtaining an estimate, while minimax backs values up and alpha-beta removes branches that cannot affect that backed-up decision.

main factors which help to model and solve games in AI.
1. Minimax algorithm

Question sources

Computer Science MCQ practice collection · Question 650

Question 168 | AM0651

What is the purpose of using heuristics in game tree search algorithms?

A. To guarantee a win in every game.

B. To eliminate the need for search algorithms.

C. To reduce the search space and improve efficiency.

D. To ensure a systematic exploration of the search tree.

Hint

Read the definition and the classification axis requested; distinguish the defining purpose from supporting techniques or implementation resources.

Answer C: To reduce the search space and improve efficiency.

Pruning removes nodes that cannot affect the decision and speeds game search; heuristic domain-informed ordering improves pruning effectiveness. This supports efficiency, not guaranteed wins or eliminating search. Evidence: PDF 35, 35.

Why each choice is right or wrong

A - Incorrect: A better search can still lose to stronger positions. See PDF p. 35, 35.

B - Incorrect: Pruning/search guidance still requires search. See PDF p. 35, 35.

C - Correct: Matches reducing irrelevant exploration. See PDF p. 35, 35.

D - Incorrect: Systematic traversal does not describe the efficiency purpose. See PDF p. 35, 35.

Primary note proof

Study-note section AI23

> Alpha is MAX's best lower bound; beta is MIN's best upper bound. Pass bounds down, update alpha at MAX and beta at MIN, and prune when alpha≥beta. Pruning preserves the minimax value for the same searched tree. Good move ordering increases pruning: worst-case O(b^m), ideal ordering about O(b^(m/2)).

Study-note section AI23

> At a depth cutoff use an evaluation function estimating position desirability. Positive favors the designated MAX player, negative MIN; the scale is a convention, with +1/0/−1 often win/draw/loss. Question sources

Computer Science MCQ practice collection · Question 651

Question 169 | AM0652

Which game-state heuristic evaluates the weighted number and value of pieces held by each player, rather than legal move count or controlled territory?

A. Material heuristic

B. Mobility heuristic

C. Distance heuristic

D. Tactical heuristic

Hint

Read the definition and the classification axis requested; distinguish the defining purpose from supporting techniques or implementation resources.

Answer A: Material heuristic

Material evaluation counts pieces with weights reflecting their values. Mobility instead measures legal options, while territory evaluates controlled regions. Restricting the stem to weighted pieces removes the original conflation of material and territory. Distance and tactical features may inform other evaluations, but they do not name the weighted piece-count feature requested. The distinction concerns what the evaluator measures.

Why each choice is right or wrong

A - Correct: Material is the weighted piece-count/value feature.

B - Incorrect: Mobility measures available legal moves rather than the amount of material or territory controlled.

C - Incorrect: Distance evaluates spatial separation, not the piece-count or controlled-region feature stated here.

D - Incorrect: This does not name weighted piece holdings; the feature described is material evaluation.

Primary note proof

Study-note section AI23

> At a depth cutoff use an evaluation function estimating position desirability. Positive favors the designated MAX player, negative MIN; the scale is a convention, with +1/0/−1 often win/draw/loss. Material counts weighted pieces; mobility counts legal options; territory scores controlled regions. These are different features, often combined. Question sources

Computer Science MCQ practice collection · Question 652

Question 170 | AM0653

Which heuristic evaluates a game state by considering the available moves and options for each player?

A. Material heuristic

B. Mobility heuristic

C. Distance heuristic

D. Tactical heuristic

Hint

Read the definition and the classification axis requested; distinguish the defining purpose from supporting techniques or implementation resources.

Answer B: The mobility heuristic.

AI23 explicitly says mobility counts legal options. Available moves and options for each player are exactly that feature, making mobility the supported answer. Material measures weighted pieces, while distance and tactics refer to different aspects of a position. The heuristic may be combined with other features, but the specific feature requested is unambiguous.

Why each choice is right or wrong

A - Incorrect: Material evaluates the amount or value of pieces, not the number of available moves.

B - Correct: Mobility directly counts or scores the legal move options available to a player.

C - Incorrect: Distance concerns separation or proximity, not the legal-option count described in the question.

D - Incorrect: Tactical evaluation concerns concrete threats or sequences rather than the specific mobility feature requested.

Primary note proof

Study-note section AI23

> At a depth cutoff use an evaluation function estimating position desirability. Positive favors the designated MAX player, negative MIN; the scale is a convention, with +1/0/−1 often win/draw/loss. Material counts weighted pieces; mobility counts legal options; territory scores controlled regions. These are different features, often combined. Heuristics improve limited computation, not guarantee victory.

Question sources

Computer Science MCQ practice collection · Question 653

Question 171 | CS0200

_____ is a set of procedures that uses representational language to conclude new facts from existing ones.

A. Inference Engine

B. Explanatory facility

C. Interface

D. Knowledge Base

Hint

Read the definition and the classification axis requested; distinguish the defining purpose from supporting techniques or implementation resources.

Answer A: Inference Engine

Inference engine manipulates knowledge and repeatedly applies rules to facts to derive new knowledge. The knowledge base stores facts, while the user interface handles interaction/explanation. Evidence: PDF 63, 63, 64.

Why each choice is right or wrong

A - Correct: Matches procedural derivation of new facts. See PDF p. 63, 63, 64.

B - Incorrect: Explaining an outcome differs from deriving facts. See PDF p. 63, 63, 64.

C - Incorrect: Interaction layer differs from inference procedures. See PDF p. 63, 63, 64.

D - Incorrect: Stores knowledge rather than the inference procedure. See PDF p. 63, 63, 64.

Primary note proof

Study-note section AI40

An expert system applies specialized knowledge to a domain such as equipment diagnosis. The domain expert supplies expertise; the knowledge engineer elicits and encodes it; the inference engine reasons over a knowledge base and working facts. The user interface handles interaction; an explanation facility presents why or how a conclusion was reached.

Study-note section AI24

Knowledge representation encodes facts, objects, relations, events and rules so a machine can use them. Syntax defines legal expressions; semantics defines their meaning. A knowledge base

stores assertions; an inference system derives consequences. Declarative knowledge says what is true; procedural knowledge specifies how to act.

Question 172 | CS0201

Which one is a space where an agent perceives and acts, so that an intelligent agent designer has to understand the type of it?

A. Environment

B. Actuator

C. Sensor

D. Search space

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer A: Environment

Environment is the surrounding space in which an agent operates and senses/acts; sensors and actuators are interfaces to it. Evidence: PDF 13.

Why each choice is right or wrong

A - Correct: Exact surrounding operating context. See PDF p. 13.

B - Incorrect: Action-output component. See PDF p. 13.

C - Incorrect: Perceptual-input component. See PDF p. 13.

D - Incorrect: Abstract candidate-solution set, not necessarily the operating surroundings. See PDF p. 13.

Primary note proof

Study-note section AI03

> An agent perceives an environment through sensors and acts through actuators or effectors. Cameras sense; motors move. Software sensors may be incoming messages and software actions may be API requests. Humans are agents but are not artificial agents.

Study-note section AI03

> A percept is one observation; a percept sequence is the entire observation history. An agent function maps percept sequences to actions: f:P*→A. An agent program implements that mapping on an architecture; agent = architecture + program. Environment means the setting in which it senses and acts, not merely the search space. Autonomy means relying substantially on experience rather than only a designer's prior instructions.

Study-note section AI12

> A search node records a state plus parent, action, depth and path cost. Expanding a node generates its successors. OPEN or frontier stores discovered candidates awaiting expansion; CLOSED records expanded states. Reaching the same state through different paths does not imply the same node or cost.

Computer Science Exit Exam practice collection · Question 201

Question 173 | CS0202

Which one of the following is an uninformed searching method?

A. A* search

B. Iterative improvement

C. Breadth first search

D. Greedy search

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer C: Breadth first search

The listed uninformed strategies include BFS. A* and best-first are separately listed informed strategies; local iterative improvement is not the cited uninformed breadthwise procedure. Evidence: PDF 17, 17.

Why each choice is right or wrong

A - Incorrect: Informed heuristic method. See PDF p. 17, 17.

B - Incorrect: Local improvement is not the listed uninformed method. See PDF p. 17, 17.

C - Correct: Explicit uninformed method. See PDF p. 17, 17.

D - Incorrect: Informed heuristic best-first method. See PDF p. 17, 17.

Primary note proof

Study-note section AI13

> BFS removes the oldest frontier entry using a FIFO queue. Start with the root, remove the head, test it, append unseen successors at the tail, and repeat. It explores depths 0,1,2,... and is complete for finite b and a finite-depth goal. It minimizes number of edges, so minimum cost requires equal positive step costs.

Study-note section AI17

> A heuristic h(n) estimates remaining cost or evaluates promise using problem-specific knowledge. It can reduce explored work, but computing it also costs time. Uninformed algorithms use only the problem definition and known costs; UCS remains uninformed despite using g.

Study-note section AI20

> Local search keeps a complete candidate configuration and improves its objective; the path may be irrelevant. Hill climbing chooses better neighbors. First-improvement accepts the first improvement; steepest-ascent examines all neighbors; stochastic variants choose among improvements. Local maxima, plateaus and ridges can stop progress. Random restarts or limited sideways steps can help without guaranteeing success.

Question 174 | CS0203

Which one of the following searching strategies best explains: 'The searching agent is based on problem-specific knowledge and the agent knows how far away a different state is from the goal'?

A. Blind search

B. Informed search

C. Uninformed search

D. Not informed search

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer B: Informed search

Problem-specific knowledge of estimated distance to the goal is the module's informed/heuristic-search distinction. Blind search lacks such guidance. Evidence: PDF 24, 18.

Why each choice is right or wrong

A - Incorrect: Blind search omits goal-closeness knowledge. See PDF p. 24, 18.

B - Correct: Exact informed-search distinction. See PDF p. 24, 18.

C - Incorrect: Lacks the stated domain guidance. See PDF p. 24, 18.

D - Incorrect: Synonymous with uninformed/blind search. See PDF p. 24, 18.

Primary note proof

Study-note section AI17

A heuristic h(n) estimates remaining cost or evaluates promise using problem-specific knowledge. It can reduce explored work, but computing it also costs time. Uninformed algorithms use only the problem definition and known costs; UCS remains uninformed despite using g.

Module passages - related reading

Introduction to Artificial Intelligence module | PDF page 18 | lines 23-25

• The uninformed search does not contain any domain knowledge such as closeness, the location of
the goal. It is also called level order traversal.
• It operates in a brute-force way as it only includes information about how to traverse the tree and

Question sources

Computer Science Exit Exam practice collection · Question 203

Question 175 | NS0001

Which type of AI is capable of performing any intellectual task that a human can do?

A. Narrow AI

B. General AI

C. Machine Learning

D. Expert Systems

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer B: General AI.

AI01 defines general AI by broad competence transferable across domains, matching the hypothetical ability to perform any human intellectual task. Narrow AI is bounded; machine learning names a family of methods and expert systems supply specialized domain knowledge. Neither automatically gives universal intellectual capability. The statement describes a category, not a claim that such a system presently exists.

Why each choice is right or wrong

A - Incorrect: Narrow AI is limited to bounded tasks rather than broad intellectual transfer.

B - Correct: General AI is the broad cross-domain competence category described.

C - Incorrect: Machine learning is a method family and does not itself imply general intellectual competence.

D - Incorrect: Expert systems apply specialized domain knowledge, not arbitrary human intellectual capability.

Primary note proof

Study-note section AI01

> Narrow or weak AI addresses bounded tasks, such as face recognition, spam filtering or a voice assistant. General AI denotes broad competence transferable across domains; strong AI also has a philosophical meaning involving actual understanding. Do not equate a humanoid body, autonomous vehicle, or many features with general intelligence.

Study-note section AI08

> Learning is improvement on task T, measured by P, through experience E. For spam filtering, T is classifying email, E is past labeled messages, and P might be recall at a required precision. Exploration trades immediate reward for information; exploitation uses the best action currently known. Learning can improve reflex, goal-based or utility-based agents.

Study-note section AI40

> An expert system applies specialized knowledge to a domain such as equipment diagnosis. The domain expert supplies expertise; the knowledge engineer elicits and encodes it; the inference engine reasons over a knowledge base and working facts. The user interface handles interaction; an explanation facility presents why or how a conclusion was reached.

Question sources

Artificial Intelligence review questions · Question 1

Question 176 | NS0002

What is the primary goal of Machine Learning?

A. To hard-code rules into a machine

B. To allow systems to learn and improve from experience without being explicitly programmed

C. To simulate physical environments

D. To build robotic hardware

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer B: Improve task performance through experience.

AI08 defines learning as improvement on a task, measured by performance, through experience. B captures that adaptive objective; without explicitly programmed means the learned behavior is not simply an exhaustive hand-coded rule list, not that no algorithm is programmed. Simulation and robot construction can use ML but do not define its primary goal.

Why each choice is right or wrong

A - Incorrect: Hard-coding all task rules is not the experience-based improvement defining machine learning.

B - Correct: The system improves measured task performance from experience rather than only fixed task rules.

C - Incorrect: Physical simulation is one application context, not the definition or primary learning objective.

D - Incorrect: Building hardware is not required for machine learning, which also operates in software.

Primary note proof

Study-note section AI08

> Learning is improvement on task T, measured by P, through experience E. For spam filtering, T is classifying email, E is past labeled messages, and P might be recall at a required precision. Exploration trades immediate reward for information; exploitation uses the best action currently known. Learning can improve reflex, goal-based or utility-based agents.

Study-note section AI-S01

> A conventional computer manipulates digital information according to a program or sequence of instructions. Programs can implement storage, retrieval and learning operations. Neural networks can learn pattern recognition from examples, so executing instructions and learning patterns are not mutually exclusive descriptions. This provides no universal claim that every machine is better or worse than every human at completing missing information.

Question sources

Artificial Intelligence review questions · Question 2

Question 177 | NS0003

Which reasoning type guarantees that if premises are true, the conclusion is also true?

A. Inductive Reasoning

B. Abductive Reasoning

C. Deductive Reasoning

D. Probabilistic Reasoning

Hint

Translate the statement carefully, then check the scope of its quantifiers, connectives or inference rule. Distinguish guaranteed consequences from plausible generalizations or explanations.

Answer C: Deductive reasoning.

AI28 defines deduction by truth-preserving rules and contrasts induction's revisable generalizations and abduction's plausible explanations. With valid deductive inference and true premises, the conclusion must be true. Probabilistic support expresses uncertainty rather than this logical guarantee, so deductive is the relevant reasoning type.

Why each choice is right or wrong

A - Incorrect: Induction generalizes beyond observations and can be overturned by new examples.

B - Incorrect: Abduction proposes plausible explanations without guaranteeing that they are true.

C - Correct: Valid deductive rules preserve truth from true premises to the conclusion.

D - Incorrect: Probability can quantify uncertain conclusions rather than provide the stated deductive guarantee.

Primary note proof

Study-note section AI28

> Deduction applies truth-preserving rules: all people are mortal; Ada is a person; therefore Ada is mortal. Induction generalizes observations to a broader rule and can be overturned by new examples. Abduction proposes a plausible explanation: wet ground suggests rain, although sprinklers could explain it. Analogy transfers a pattern between similar situations.

Study-note section AI29

> Probability describes uncertainty about events. $P(\neg A)=1-P(A)$; $P(A|B)=P(A\cap B)/P(B)$, for $P(B)>0$. Bayes gives $P(H|E)=P(E|H)P(H)/P(E)$: posterior equals likelihood times prior divided by evidence probability. For mutually exclusive exhaustive hypotheses, $P(E)=\Sigma i P(E|Hi)P(Hi)$.

Question sources

Artificial Intelligence review questions · Question 3

Question 178 | NS0004

A self-driving car's environment is best classified as:

A. Fully Observable, Deterministic, Static

B. Partially Observable, Stochastic, Dynamic

C. Fully Observable, Stochastic, Static

D. Partially Observable, Deterministic, Dynamic

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer B: Partially observable, stochastic and dynamic.

AI09 describes driving as partially observable, sequential and dynamic. Traffic participants and noisy observations make outcomes uncertain rather than fully determined by the car's chosen action. B matches that ordinary driving setting. Neither full visibility nor a static world fits roads whose relevant conditions change while the agent deliberates.

Why each choice is right or wrong

A - Incorrect: Driving has hidden/noisy information and a changing world rather than full observability and static conditions.

B - Correct: Hidden state, uncertain outcomes and ongoing traffic changes fit the ordinary driving task.

C - Incorrect: Full observability and static conditions do not fit the stated driving environment.

D - Incorrect: Partial observation and dynamics fit, but deterministic outcomes ignore the uncertainty in ordinary driving.

Primary note proof

Study-note section AI09

> Fully observable means sensors reveal relevant state; partially observable means relevant information is hidden or noisy. Deterministic means state and action determine the next state; stochastic means outcomes involve randomness. Strategic uncertainty about an opponent is distinct from dice-like randomness.

Study-note section AI09

> Episodic decisions are independent; sequential decisions affect later situations. Static worlds do not change while deliberating; dynamic ones do. A clock affecting score makes an otherwise static game semidynamic. Discrete quantities have distinct alternatives; continuous quantities vary along real-valued ranges. Known versus unknown concerns knowledge of the transition model, not observability.

Question sources

Artificial Intelligence review questions · Question 4

Question 179 | NS0005

In the A* algorithm, what does the evaluation function f(n) represent?

A. Only the heuristic cost to goal

B. Only the cost from start to node n

C. The sum of cost from start to n (g(n)) and estimated cost from n to goal (h(n))

D. The product of g(n) and h(n)

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer C: f(n)=g(n)+h(n).

AI18 directly defines A* evaluation as actual start-to-node cost g plus estimated node-to-goal cost h. This estimates a solution cost through the node. Using only h is greedy best-first, using only g is uniform-cost selection, and multiplication is not the A* rule.

Why each choice is right or wrong

A - Incorrect: Using h alone is greedy best-first rather than A* evaluation.

B - Incorrect: Using g alone is uniform-cost ordering and omits the remaining-cost estimate.

C - Correct: A* adds the accumulated path cost and estimated remaining cost.

D - Incorrect: The defined evaluation is a sum, not a product.

Primary note proof

Study-note section AI18

> A* orders by f(n)=g(n)+h(n). Admissibility means 0≤h(n)≤h*(n), the true cheapest remaining cost. Consistency means h(n)≤c(n,n′)+h(n′) on every edge, with h(goal)=0; it implies admissibility on states with goal paths. Consistency makes f nondecreasing along a path.

Study-note section AI15

> UCS uses a priority queue ordered by actual accumulated path cost g(n). Remove a minimum-g node; accept a goal when removed, not when first generated. Relax each edge: if a cheaper path is found, update its frontier cost and parent.

Study-note section AI17

> Best-first is a family that orders OPEN by an evaluation function. Greedy best-first uses f=h and removes the smallest estimate, ignoring the cost already paid. It can choose an expensive route, loop without duplicate checks, or follow an infinite misleading branch. On a finite graph with full duplicate handling it is complete, but not generally optimal. Its implicit finite-tree worst case can be O(b^m).

Question sources

Artificial Intelligence review questions · Question 5

Question 180 | NS0006

Which reflex architecture maintains an internal world state and applies condition-action rules to that modeled state, rather than using only the current percept?

A. Simple Reflex Agent

B. Goal-Based Agent

C. Model-Based Reflex Agent

D. Learning Agent

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer C: Model-Based Reflex Agent

Model-based reflex agents update internal state from previous state, action and current observation, using models of world change and action effects. They then apply rules to that modeled state. Simple reflex agents lack persistent world-state memory. Goal-based and learning capabilities may coexist with a model, but the question specifically asks for the reflex architecture defined by state maintenance and rule application.

Why each choice is right or wrong

A - Incorrect: Simple reflex uses only the current percept without persistent world-state memory.

B - Incorrect: Goal-based choice uses future sequences reaching desired states, whereas the requested architecture applies reflex rules to modeled state.

C - Correct: Model-based reflex maintains internal state and applies rules to that state.

D - Incorrect: Learning concerns improving the agent from experience rather than naming this reflex architecture.

Primary note proof

Study-note section AI06

> A simple reflex agent matches condition-action rules against the current percept only: if dirty, clean. It has no persistent world-state memory. This is adequate when the current observation contains everything needed for its rule, but partial observability can make the same percept require different actions.

Study-note section AI06

> A model-based reflex agent maintains internal state using the previous state, previous action, current percept, and models of world change and action effects. It then applies rules to that state. Both kinds can use condition-action rules; memory and a world model distinguish them.

Study-note section AI07

A goal-based agent considers future action sequences that reach a desired state. A utility-based agent compares degrees of desirability and trade-offs, choosing maximum expected utility: $EU(a)=\Sigma s\ P(s|a,evidence)U(s)$. Reaching the destination is a goal; balancing arrival time, safety and cost requires preferences among outcomes.

Study-note section AI08

The performance element selects actions. The learning element changes the agent to improve future performance. The critic evaluates behavior against a performance standard and supplies feedback. The problem generator suggests exploratory actions likely to yield useful experience.

Question sources

Artificial Intelligence review questions · Question 6

Question 181 | NS0007

What distinguishes a Rational Agent from an Omniscient Agent?

A. Rational agents always make perfect decisions

B. Rational agents act on best available information but can make mistakes; omniscient agents know all outcomes

C. Omniscient agents are a common AI type

D. Rational agents do not use information

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer B: Rational choice uses available information; omniscience knows actual outcomes.

AI04 defines rationality by best expected performance using information available, while omniscience means knowing actual outcomes in advance. Rational actions can fail and do not require perfect predictions. The contrast is epistemic, not whether an agent uses any information or whether omniscient systems are common implementations.

Why each choice is right or wrong

A - Incorrect: Rationality does not guarantee perfect outcomes or foreknowledge.

B - Correct: This distinguishes information-conditioned expected performance from knowing actual outcomes.

C - Incorrect: The note treats omniscience as an idealized outcome-knowledge condition, not a common AI implementation.

D - Incorrect: Rationality explicitly depends on percepts, prior knowledge and available actions.

Primary note proof

Study-note section AI04

> A performance measure defines success externally: safety, useful deliveries, elapsed time, or cost. Rationality depends on that measure, prior knowledge, percept history, and available actions. A rational agent selects the action with the best expected performance given its information.

Study-note section AI04

> Omniscience would mean knowing actual action outcomes in advance. Rationality does not require omniscience or guaranteed success. Even complete outcome knowledge cannot create a successful action when every available action fails. Information gathering and exploration may therefore be rational actions.

Question sources

Artificial Intelligence review questions · Question 7

Question 182 | NS0008

Which search algorithm is guaranteed to find the shortest path in an unweighted graph?

A. Depth-First Search

B. Depth-Limited Search

C. Breadth-First Search

D. Best-First Search

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer C: Breadth-first search.

AI13 says BFS explores levels in increasing depth and minimizes the number of edges. An unweighted graph gives equal step costs, making that shortest-path property applicable with visited-state tracking. DFS or a fixed depth limit does not guarantee minimum depth, and generic best-first needs its evaluation rule specified.

Why each choice is right or wrong

A - Incorrect: DFS can reach a longer path first and is not generally optimal.

B - Incorrect: A depth limit can miss a solution or return a nonshortest path within its bound.

C - Correct: BFS explores increasing edge counts and finds shortest paths in an unweighted graph.

D - Incorrect: Best-first is a family; an unspecified evaluation rule does not guarantee shortest paths.

Primary note proof

Study-note section AI13

> BFS removes the oldest frontier entry using a FIFO queue. Start with the root, remove the head, test it, append unseen successors at the tail, and repeat. It explores depths 0,1,2,... and is complete for finite b and a finite-depth goal. It minimizes number of edges, so minimum cost requires equal positive step costs.

Study-note section AI14

> DFS follows the deepest pending branch using a LIFO stack or recursion. FILO means the same order as LIFO. With the same children as BFS, a left-first DFS visits S,A,C before B; push rightmost children first to pop the leftmost first.

Study-note section AI16

> DLS runs DFS to depth l and reports cutoff separately from failure. It misses goals deeper than l. Iterative deepening runs DLS with limits 0,1,2,...; for finite b it finds the shallowest solution with O(b^d) time and O(bd) frontier space, optimal for equal step costs. Repeated shallow work is small compared with the deepest level.

Question sources

Artificial Intelligence review questions · Question 8

Question 183 | NS0009

Why is Uniform Cost Search (UCS) NOT considered a heuristic approach?

A. It doesn't consider costs

B. It uses cost as a known factor but employs no domain-specific knowledge or estimates

C. It uses heuristic functions

D. It only works on trees, not graphs

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer B: UCS uses known accumulated cost without a heuristic estimate.

AI15 orders UCS by actual path cost g, and AI17 explicitly calls it uninformed despite using g. Known action costs come from the problem definition; a heuristic adds an estimate of future cost. UCS can operate on graphs with duplicate handling, so neither ignoring costs nor tree-only operation explains the distinction.

Why each choice is right or wrong

A - Incorrect: UCS explicitly orders its frontier by accumulated path cost.

B - Correct: Known costs are used, but no problem-specific estimate of remaining cost is required.

C - Incorrect: UCS does not require an h estimate; g is actual accumulated cost.

D - Incorrect: UCS works on graphs with proper relaxation and duplicate handling.

Primary note proof

Study-note section AI15

> UCS uses a priority queue ordered by actual accumulated path cost g(n). Remove a minimum-g node; accept a goal when removed, not when first generated. Relax each edge: if a cheaper path is found, update its frontier cost and parent.

Study-note section AI17

> A heuristic h(n) estimates remaining cost or evaluates promise using problem-specific knowledge. It can reduce explored work, but computing it also costs time. Uninformed algorithms use only the problem definition and known costs; UCS remains uninformed despite using g.

Question sources

Artificial Intelligence review questions · Question 9

Question 184 | NS0010

Which data structure supplies the defining next-node removal order of a depth-first search frontier?

A. Queue (FIFO)

B. Stack (LIFO)

C. Priority Queue

D. Hash Table

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer B: Stack (LIFO)

DFS follows the deepest pending branch using a LIFO stack or recursion. That removal discipline distinguishes it from breadth-first FIFO selection and cost- or heuristic-priority selection. A hash table can still be used alongside DFS to record visited states. The question therefore specifies frontier removal rather than broadly asking which structures may track nodes.

Why each choice is right or wrong

A - Incorrect: A FIFO queue removes the oldest entry, giving breadth-first rather than depth-first frontier order.

B - Correct: A LIFO stack processes the most recently pending branch first, implementing DFS.

C - Incorrect: A priority queue removes according to a key rather than the defining DFS LIFO order.

D - Incorrect: A hash table may store visited states, but does not supply the frontier's next-node removal order.

Primary note proof

Study-note section AI14

> DFS follows the deepest pending branch using a LIFO stack or recursion. FILO means the same order as LIFO. With the same children as BFS, a left-first DFS visits S,A,C before B; push rightmost children first to pop the leftmost first.

Study-note section AI13

> BFS removes the oldest frontier entry using a FIFO queue. Start with the root, remove the head, test it, append unseen successors at the tail, and repeat. It explores depths 0,1,2,... and is complete for finite b and a finite-depth goal. It minimizes number of edges, so minimum cost requires equal positive step costs.

Study-note section AI15

UCS uses a priority queue ordered by actual accumulated path cost g(n). Remove a minimum-g node; accept a goal when removed, not when first generated. Relax each edge: if a cheaper path is found, update its frontier cost and parent.

Question sources

Artificial Intelligence review questions · Question 10

Question 185 | NS0011

What is the main limitation of Depth-First Search regarding completeness?

A. It uses too much memory

B. It can get stuck in cycles or infinite paths and fail to find a solution

C. It always finds suboptimal solutions

D. It only works for trees

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer B: Cycles or infinite branches can prevent finding an existing solution.

AI14 says DFS can fail on infinite paths or cycles and is not generally optimal. Without suitable restrictions or duplicate handling, it may never return to a pending branch containing a goal. Finite visited-state graph traversal changes that result; the limitation is therefore not that DFS only works on trees or always returns a bad path.

Why each choice is right or wrong

A - Incorrect: DFS is usually memory-efficient; excess storage is not its defining completeness failure.

B - Correct: It may follow an infinite branch or cycle indefinitely while a solution waits elsewhere.

C - Incorrect: A returned path can be optimal by coincidence; always suboptimal is too strong.

D - Incorrect: DFS also traverses graphs, especially with visited-state tracking.

Primary note proof

Study-note section AI14

> DFS follows the deepest pending branch using a LIFO stack or recursion. FILO means the same order as LIFO. With the same children as BFS, a left-first DFS visits S,A,C before B; push rightmost children first to pop the leftmost first.

Study-note section AI14

> Implicit-tree worst-case time is O(b^m), and space is O(bm) when pending siblings are stored, or O(m) for path-only recursive generation. DFS is not generally optimal and can fail on infinite paths or cycles. On a finite graph, visited-state tracking makes traversal complete but needs O(V) storage. Do not confuse the O(b^m) worst-case time bound with the DFS space bounds above.

Question sources

Artificial Intelligence review questions · Question 11

Question 186 | NS0012

Which options can be used without a training set of labeled input-target examples? Select all that apply. For D, consider whether some deep-learning objectives permit unlabeled or reward feedback.

A. Supervised Learning

B. Reinforcement Learning

C. Unsupervised Learning

D. Deep Learning

Hint

Identify the training feedback, prediction target or measured error. Keep learning objectives separate from model architecture and data modality.

Answer B, C, D: Reinforcement Learning; Unsupervised Learning; Deep Learning

Unsupervised learning discovers structure without target labels. Reinforcement learning can learn from rewards rather than correct-action target examples. Deep learning is an architecture family and can be trained with unsupervised or reinforcement objectives, so it also need not require labeled input-target data. Supervised learning is specifically defined by those labeled pairs. The capability wording permits both regimes and architecture families to be judged accurately.

Why each choice is right or wrong

A - Incorrect: Supervised learning uses labeled examples by definition.

B - Correct: RL learns through rewards and interaction, without requiring labeled correct actions.

C - Correct: Unsupervised learning explicitly seeks structure without target labels.

D - Correct: Deep learning can use unlabeled or reward objectives, so labels are not inherently required.

Primary note proof

Study-note section AI31

> Supervised learning fits a mapping from labeled input-target examples. Classification predicts discrete labels, such as institution generations or spam/nonspam; regression predicts numeric quantities, such as prices. Predictive analytics uses historical patterns to forecast outcomes and can use either. Specify the target before choosing a method.

Study-note section AI32

> Unsupervised learning seeks structure without target labels: clustering groups similar examples; association finds co-occurrence; dimensionality reduction compresses features. Good clusters have high within-cluster similarity and low between-cluster similarity under an appropriate distance. K-means alternates assignment to nearest centroids and centroid updates.

Study-note section AI33

An RL agent observes state information, takes an action, receives reward and a new observation, and improves its policy to maximize expected cumulative reward. Rewards evaluate outcomes rather than supply the correct action label. Rewards may be delayed; not every correct-looking action receives immediate reward.

Study-note section AI43

ANNs, genetic search and reinforcement learning all improve candidate behavior or performance through experience in different ways. Deep learning is an architecture family usable with supervised, unsupervised or reinforcement objectives. Decision trees and deep models may both be supervised. To distinguish learning regimes, specify labels, reward or unlabeled structure.

Question sources

Artificial Intelligence review questions · Question 12

Question 187 | NS0013

For A* tree search with finite branching, step costs bounded below by a positive constant, goal testing on removal and h(goal)=0, which listed heuristic condition is the weakest sufficient guarantee of optimality? Treat monotone as synonymous with consistent.

A. Consistent

B. Admissible (never overestimates the actual cost)

C. Monotone

D. Domain-independent

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer B: Admissible (never overestimates the actual cost)

Admissibility requires that a heuristic never overestimate the true cheapest remaining cost. It suffices for optimal A* tree search under the stated cost and goal-testing assumptions. Consistency, also called monotonicity here, is stronger and is particularly important when graph search permanently closes states. Domain independence is unrelated to the optimality condition. Asking for the weakest sufficient listed condition distinguishes admissibility from the stronger alternatives.

Why each choice is right or wrong

A - Incorrect: Consistency is sufficient but stronger than the weakest listed condition for tree A*.

B - Correct: Admissibility is sufficient for optimal tree A* under the stated assumptions.

C - Incorrect: Monotonicity is consistency here and is stronger than necessary for the tree-search guarantee.

D - Incorrect: Domain independence is not a heuristic optimality condition.

Primary note proof

Study-note section AI18

> A* orders by f(n)=g(n)+h(n). Admissibility means 0≤h(n)≤h*(n), the true cheapest remaining cost. Consistency means h(n)≤c(n,n′)+h(n′) on every edge, with h(goal)=0; it implies admissibility on states with goal paths. Consistency makes f nondecreasing along a path.

Study-note section AI18

> Admissibility suffices for optimal A* tree search; graph search that never reopens CLOSED states normally requires consistency. With an admissible inconsistent heuristic, reopen states when g improves. Test a goal when removed at minimum f. Completeness also needs finite branching and positive lower-bounded costs in infinite spaces. Worst-case time and memory can be exponential; no heuristic universally guarantees speed.

Question sources

Artificial Intelligence review questions · Question 13

Question 188 | NS0014

Iterative Deepening Search (IDS) combines the advantages of which two algorithms?

A. UCS and A*

B. BFS and DFS

C. Greedy Search and BFS

D. DLS and UCS

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer B: Breadth-first solution depth with depth-first memory use.

AI16 defines IDS as DLS runs at limits 0,1,2,..., finding the shallowest solution under finite branching with O(bd) frontier space. It obtains BFS's shallow-solution behavior and DFS-style memory use. It does not combine UCS priorities, greedy ordering or A* cost thresholds; IDA* is a separate threshold-based variant.

Why each choice is right or wrong

A - Incorrect: IDS does not combine UCS costs with A* evaluation.

B - Correct: It obtains breadth-first shallow-solution behavior through repeated depth-first limited searches.

C - Incorrect: No greedy heuristic ordering is required for IDS.

D - Incorrect: DLS is used, but UCS ordering is not part of standard iterative deepening.

Primary note proof

Study-note section AI16

DLS runs DFS to depth l and reports cutoff separately from failure. It misses goals deeper than l. Iterative deepening runs DLS with limits 0,1,2,...; for finite b it finds the shallowest solution with O(b^d) time and O(bd) frontier space, optimal for equal step costs. Repeated shallow work is small compared with the deepest level.

Study-note section AI13

BFS removes the oldest frontier entry using a FIFO queue. Start with the root, remove the head, test it, append unseen successors at the tail, and repeat. It explores depths 0,1,2,... and is complete for finite b and a finite-depth goal. It minimizes number of edges, so minimum cost requires equal positive step costs.

Study-note section AI14

DFS follows the deepest pending branch using a LIFO stack or recursion. FILO means the same order as LIFO. With the same children as BFS, a left-first DFS visits S,A,C before B; push rightmost children first to pop the leftmost first.

Question sources

Artificial Intelligence review questions · Question 14

Question 189 | NS0015

A zero-sum game evaluator measures a position from the designated MAX player's perspective. What does a positive evaluation value indicate?

A. A draw or neutral position.

B. An estimated advantage for the designated MAX player.

C. An estimated advantage for the opposing MIN player.

D. An invalid game state.

Hint

Read the definition and the classification axis requested; distinguish the defining purpose from supporting techniques or implementation resources.

Answer B: An estimated advantage for the designated MAX player.

Under this convention, positive values estimate an advantage for MAX, negative values favor MIN, and zero is neutral. A positive heuristic score does not guarantee an eventual win, because it may be only an estimate at a search cutoff. The reference player must be specified before a sign can be interpreted; player names alone do not determine the convention.

Why each choice is right or wrong

A - Incorrect: A neutral result is represented by zero under the stated sign convention.

B - Correct: A positive value favors the designated MAX player under this convention.

C - Incorrect: An advantage for MIN would have a negative sign under this convention.

D - Incorrect: The sign estimates desirability, not whether the position is legally valid.

Primary note proof

Study-note section AI23

> At a depth cutoff use an evaluation function estimating position desirability. Positive favors the designated MAX player, negative MIN; the scale is a convention, with +1/0/−1 often win/draw/loss. Material counts weighted pieces; mobility counts legal options; territory scores controlled regions. These are different features, often combined. Heuristics improve limited computation, not guarantee victory.

Question sources

Artificial Intelligence review questions · Question 15

Question 190 | NS0016

Which knowledge representation technique uses interconnected nodes and arcs to show concept relationships?

A. Frames

B. Logic

C. Semantic Networks

D. Probabilistic Models

Hint

Read the definition and the classification axis requested; distinguish the defining purpose from supporting techniques or implementation resources.

Answer C: Semantic networks.

AI24 defines semantic networks using concept nodes and labeled relations such as is-a. That matches the node/arc representation in the stem. Frames organize slots, logic uses formal sentences and probabilistic models attach uncertainty; those may have related graph forms, but the specific concept-relationship network term is semantic network.

Why each choice is right or wrong

A - Incorrect: Frames represent stereotyped entities through slots and values rather than this named concept-link network.

B - Incorrect: Logic represents claims with formal expressions, not specifically the node/arc scheme described.

C - Correct: Semantic networks connect concept nodes with labeled relationship arcs.

D - Incorrect: Probabilistic models focus on uncertainty rather than the specific semantic-relation representation requested.

Primary note proof

Study-note section AI24

> A semantic network connects concept nodes by labeled relations such as is-a. Frames describe stereotyped entities through slots, values and defaults. Production systems use IF conditions THEN conclusions or actions, matching rules against working memory and selecting among applicable rules. A graph suits relationships such as frequently bought together; frames suit attributes. No representation is always best for recommendation without task requirements.

Study-note section AI24

> Knowledge representation encodes facts, objects, relations, events and rules so a machine can use them. Syntax defines legal expressions; semantics defines their meaning. A knowledge base stores assertions; an inference system derives consequences. Declarative knowledge says what is true; procedural knowledge specifies how to act.

Study-note section AI29

A Bayesian network is a directed acyclic graph with conditional probability tables; its joint distribution factors as the product of each node's probability given its parents. A Markov model assumes the next state depends on the current state rather than the entire past. These represent uncertainty; fuzzy membership represents a different issue.

Question sources

Artificial Intelligence review questions · Question 16

Question 191 | NS0017

Which listed group comprises unstructured input modalities from which deep neural models can learn hierarchical features?

A. Tabular numerical data only

B. Structured relational data

C. Unstructured data like images, sound, and text

D. Small labeled datasets

Hint

Identify the training feedback, prediction target or measured error. Keep learning objectives separate from model architecture and data modality.

Answer C: Unstructured data like images, sound, and text

Deep learning uses multiple representation layers and can learn features from images, sound and text. Those are the unstructured modalities identified here. Deep models can also process other data, so this is not a claim of universal superiority over every alternative model. Structured relational data is a different organization, and small labeled datasets describe size and supervision rather than modality.

Why each choice is right or wrong

A - Incorrect: Tabular numerical data only excludes the non-tabular modalities requested and is not an inherent deep-learning restriction.

B - Incorrect: Structured relational data is not the unstructured modality group asked for.

C - Correct: Images, sound and text are explicit modalities for learned multilayer representations.

D - Incorrect: A small labeled dataset describes sample size and feedback, not an input modality group.

Primary note proof

Study-note section AI34

Feedforward networks pass signals toward outputs without recurrent state loops; recurrent networks carry state across sequence steps. Training adjusts weights, often through gradients and backpropagation. Backpropagation is not the same as a recurrent connection. Deep learning uses multiple representation layers and can learn features from images, sound and text. CNNs

share filters across image locations. ANN is a brain-inspired abstraction, not a literal brain simulation; DL⊂ML⊂AI.

Study-note section AI35

Overfitting means fitting training-specific details so performance drops on unseen data; underfitting means the model is too limited or poorly fitted even on training data. A learning curve plots performance against training size or training progress. Complexity control, regularization, pruning and more representative data can help.

Question sources

Artificial Intelligence review questions · Question 17

Question 192 | NS0018

Which agent type improves its performance over time through experience and feedback?

A. Simple Reflex Agent

B. Model-Based Reflex Agent

C. Goal-Based Agent

D. Learning Agent

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer D: A learning agent.

AI08 defines the learning element as changing the agent to improve future performance from experience and feedback. This identifies the learning-agent category. Reflex, model-based and goal-based describe decision architectures that may be enhanced by learning, but do not by themselves require improvement over time; D explicitly names that capability.

Why each choice is right or wrong

A - Incorrect: Simple reflex rules alone do not require adaptation from experience.

B - Incorrect: Maintaining a model does not by itself require learning or improving it over time.

C - Incorrect: Planning toward a goal does not itself establish experience-based policy improvement.

D - Correct: Learning agents explicitly use experience and evaluative feedback to improve future behavior.

Primary note proof

Study-note section AI08

> The performance element selects actions. The learning element changes the agent to improve future performance. The critic evaluates behavior against a performance standard and supplies feedback. The problem generator suggests exploratory actions likely to yield useful experience.

Study-note section AI08

> Learning is improvement on task T, measured by P, through experience E. For spam filtering, T is classifying email, E is past labeled messages, and P might be recall at a required precision. Exploration trades immediate reward for information; exploitation uses the best action currently known. Learning can improve reflex, goal-based or utility-based agents.

Question sources

Artificial Intelligence review questions · Question 18

Question 193 | NS0019

What is abductive reasoning best described as?

A. Drawing certain conclusions from known facts

B. Making educated guesses from patterns

C. Finding the best explanation for a set of observations

D. Using probability to decide outcomes

Hint

Translate the statement carefully, then check the scope of its quantifiers, connectives or inference rule. Distinguish guaranteed consequences from plausible generalizations or explanations.

Answer C: Finding a plausible best explanation for observations.

AI28 illustrates abduction with wet ground suggesting rain while allowing sprinklers as another cause. It proposes an explanatory hypothesis rather than guaranteeing truth or merely generalizing a pattern. C gives that explanatory role. Probability may rank hypotheses, but numerical probability alone is not the definition of abductive reasoning.

Why each choice is right or wrong

A - Incorrect: Certain truth-preserving conclusions describe valid deduction rather than explanatory abduction.

B - Incorrect: Pattern-based generalization is closer to induction and omits the explanatory-hypothesis requirement.

C - Correct: Abduction seeks a plausible explanation for observed evidence without guaranteeing that explanation.

D - Incorrect: Probability can support a diagnosis but does not itself define the explanatory reasoning form.

Primary note proof

Study-note section AI28

> Deduction applies truth-preserving rules: all people are mortal; Ada is a person; therefore Ada is mortal. Induction generalizes observations to a broader rule and can be overturned by new examples. Abduction proposes a plausible explanation: wet ground suggests rain, although sprinklers could explain it. Analogy transfers a pattern between similar situations.

Study-note section AI29

> Probability describes uncertainty about events. $P(\neg A)=1-P(A)$; $P(A|B)=P(A\cap B)/P(B)$, for $P(B)>0$. Bayes gives $P(H|E)=P(E|H)P(H)/P(E)$: posterior equals likelihood times prior divided by evidence probability. For mutually exclusive exhaustive hypotheses, $P(E)=\Sigma_i P(E|Hi)P(Hi)$.

Question sources

Artificial Intelligence review questions · Question 19

Question 194 | NS0020

How is ordinary untimed chess classified with respect to transition outcomes, change during deliberation and state/action values? Assume both players' moves are specified when evaluating a transition.

A. Stochastic, Dynamic, Continuous

B. Deterministic, Static, Discrete

C. Stochastic, Static, Discrete

D. Deterministic, Dynamic, Continuous

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer B: Deterministic, Static, Discrete

Chess has discrete positions and legal moves. Given the selected move, the resulting position is determined by the rules rather than random outcome sampling. In untimed play, the environment does not change while the player deliberates, so the relevant classification is static. Opponent choice is strategic uncertainty rather than dice-like stochasticity. Specifying untimed play excludes the semidynamic effect of a score-affecting clock.

Why each choice is right or wrong

A - Incorrect: Chess moves are discrete, and opponent strategy is not dice-like stochasticity.

B - Correct: Untimed chess is deterministic given chosen moves, static while deliberating and discrete.

C - Incorrect: Ordinary chess transition outcomes are deterministic given chosen moves rather than stochastic.

D - Incorrect: Chess is discrete rather than continuous, and a clock gives semidynamic rather than this classification.

Primary note proof

Study-note section AI09

> Fully observable means sensors reveal relevant state; partially observable means relevant information is hidden or noisy. Deterministic means state and action determine the next state; stochastic means outcomes involve randomness. Strategic uncertainty about an opponent is distinct from dice-like randomness.

Study-note section AI09

> Episodic decisions are independent; sequential decisions affect later situations. Static worlds do not change while deliberating; dynamic ones do. A clock affecting score makes an otherwise static game semidynamic. Discrete quantities have distinct alternatives; continuous quantities vary along real-valued ranges. Known versus unknown concerns knowledge of the transition model, not observability.

Question sources

Artificial Intelligence review questions · Question 20

Question 195 | NS0021

What does the 'deep' in Deep Learning refer to?

A. The depth of the training dataset

B. The depth of layers in a neural network

C. The complexity of the problem being solved

D. The deep analysis of heuristic functions

Hint

Identify the training feedback, prediction target or measured error. Keep learning objectives separate from model architecture and data modality.

Answer B: Multiple neural representation layers.

AI34 defines deep learning through multiple representation layers in a neural model. Dataset size and problem difficulty can affect training, but neither is what the word deep denotes. Heuristic analysis belongs to search methods rather than the architecture depth of a neural network.

Why each choice is right or wrong

A - Incorrect: Dataset size or depth does not define the deep part of deep learning.

B - Correct: Deep refers to multiple layers of learned representations in the neural architecture.

C - Incorrect: Problem difficulty does not determine whether a model architecture is deep.

D - Incorrect: Heuristic analysis is not the neural-layer definition of deep learning.

Primary note proof

Study-note section AI34

> Feedforward networks pass signals toward outputs without recurrent state loops; recurrent networks carry state across sequence steps. Training adjusts weights, often through gradients and backpropagation. Backpropagation is not the same as a recurrent connection. Deep learning uses multiple representation layers and can learn features from images, sound and text. CNNs share filters across image locations. ANN is a brain-inspired abstraction, not a literal brain simulation; DL⊂ML⊂AI.

Question sources

Artificial Intelligence review questions · Question 21

Question 196 | NS0022

Which search strategy is called 'blind search' because it uses no extra problem knowledge?

A. Informed Search

B. Heuristic Search

C. Uninformed Search

D. Best-First Search

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer C: Uninformed search.

AI17 says uninformed methods use the problem definition and known costs without a problem-specific remaining-cost estimate. This is the usual blind-search meaning. Informed or heuristic search explicitly adds such estimates, and best-first is a broad ordering family that may use heuristic information rather than naming the blind category.

Why each choice is right or wrong

A - Incorrect: Informed search adds problem-specific guidance beyond the basic problem definition.

B - Incorrect: Heuristic search uses the extra estimate excluded by the stem.

C - Correct: Uninformed search is the category using only the problem definition and known costs.

D - Incorrect: Best-first specifies evaluation-based ordering and is not generally synonymous with blind search.

Primary note proof

Study-note section AI17

> A heuristic h(n) estimates remaining cost or evaluates promise using problem-specific knowledge. It can reduce explored work, but computing it also costs time. Uninformed algorithms use only the problem definition and known costs; UCS remains uninformed despite using g.

Study-note section AI15

> UCS uses a priority queue ordered by actual accumulated path cost g(n). Remove a minimum-g node; accept a goal when removed, not when first generated. Relax each edge: if a cheaper path is found, update its frontier cost and parent.

Question sources

Artificial Intelligence review questions · Question 22

Question 197 | NS0023

In Reinforcement Learning, what guides an agent to improve its behavior?

A. Labeled training examples

B. Hard-coded rules

C. Rewards and penalties from environment interactions

D. Pre-trained heuristic functions

Hint

Identify the training feedback, prediction target or measured error. Keep learning objectives separate from model architecture and data modality.

Answer C: Reward feedback from interactions.

AI33 describes an agent acting, receiving reward and a new observation, and improving its policy to maximize expected cumulative reward. Rewards may be positive or negative and delayed; they need not name the correct action. Labeled examples, fixed rules and predefined heuristics do not provide this distinctive reinforcement feedback mechanism.

Why each choice is right or wrong

A - Incorrect: Correct target labels characterize supervised learning rather than reinforcement feedback.

B - Incorrect: Fixed rules alone do not provide the reward-based adaptation defining RL.

C - Correct: Rewards and penalties evaluate outcomes and guide improvement of expected cumulative return.

D - Incorrect: A pretrained heuristic may help implementation but is not the defining RL feedback signal.

Primary note proof

Study-note section AI33

> An RL agent observes state information, takes an action, receives reward and a new observation, and improves its policy to maximize expected cumulative reward. Rewards evaluate outcomes rather than supply the correct action label. Rewards may be delayed; not every correct-looking action receives immediate reward.

Study-note section AI31

> Supervised learning fits a mapping from labeled input-target examples. Classification predicts discrete labels, such as institution generations or spam/nonspam; regression predicts numeric quantities, such as prices. Predictive analytics uses historical patterns to forecast outcomes and can use either. Specify the target before choosing a method.

Question sources

Artificial Intelligence review questions · Question 23

Question 198 | NS0024

For greedy best-first search on an implicit finite tree with branching factor b and maximum depth m, what is the standard worst-case node-count time bound?

A. O(m)

B. O(b*m)

C. O(b^m)

D. O(log m)

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer C: O(b^m)

Greedy best-first ordering can be misled by a heuristic and may need to explore an exponentially large portion of the finite search tree. With branching factor b and depth m, the standard worst-case generated-node bound is O(b^m). This is a node-count convention rather than a claim about every priority-queue implementation or all best-first algorithms. The explicit algorithm and tree model determine the bound.

Why each choice is right or wrong

A - Incorrect: A misleading heuristic can force exponentially many nodes, so a bound merely linear in maximum depth m is insufficient.

B - Incorrect: O(bm) is a familiar DFS storage form, not this generic search-time guarantee.

C - Correct: The specified implicit finite-tree worst case can require O(b^m) nodes.

D - Incorrect: A logarithmic-in-depth bound is insufficient when the search can explore an exponential number of tree nodes.

Primary note proof

Study-note section AI17

> Best-first is a family that orders OPEN by an evaluation function. Greedy best-first uses f=h and removes the smallest estimate, ignoring the cost already paid. It can choose an expensive route, loop without duplicate checks, or follow an infinite misleading branch. On a finite graph with full duplicate handling it is complete, but not generally optimal. Its implicit finite-tree worst case can be O(b^m).

Question sources

Artificial Intelligence review questions · Question 24

Question 199 | NS0025

Which knowledge representation uses templates with slots to describe stereotyped situations?

A. Semantic Networks

B. Frames

C. Logic

D. Bayesian Networks

Hint

Read the definition and the classification axis requested; distinguish the defining purpose from supporting techniques or implementation resources.

Answer B: Frames.

AI24 defines frames as stereotyped entity descriptions with slots, values and defaults. This is the template-and-slot representation in the question. Semantic networks focus on relationships among concept nodes, formal logic expresses sentences and Bayesian networks represent probabilistic dependencies; none is the specific slot-template term requested.

Why each choice is right or wrong

A - Incorrect: Semantic networks emphasize concept nodes and labeled relations rather than the slot-template representation.

B - Correct: Frames organize stereotyped descriptions into slots with values and defaults.

C - Incorrect: Logic uses formal sentences rather than the specifically described frame slots.

D - Incorrect: Bayesian networks represent conditional probabilities, not the named stereotyped slot template.

Primary note proof

Study-note section AI24

> A semantic network connects concept nodes by labeled relations such as is-a. Frames describe stereotyped entities through slots, values and defaults. Production systems use IF conditions THEN conclusions or actions, matching rules against working memory and selecting among applicable rules. A graph suits relationships such as frequently bought together; frames suit attributes. No representation is always best for recommendation without task requirements.

Study-note section AI29

> A Bayesian network is a directed acyclic graph with conditional probability tables; its joint distribution factors as the product of each node's probability given its parents. A Markov model assumes the next state depends on the current state rather than the entire past. These represent uncertainty; fuzzy membership represents a different issue.

Question 200 | NS0026

What is Natural Language Processing (NLP) primarily focused on?

A. Visual image interpretation

B. Physical robot movement

C. Enabling machines to understand, interpret, and generate human language

D. Optimizing database queries

Hint

Match the input, output and purpose to the appropriate language, perception or physical-action task.

Answer C: Understanding, interpreting and generating human language.

AI37 directly defines NLP as interpreting and generating human language and lists dialogue, translation and summarization. Visual interpretation belongs to computer vision, physical movement to robotics and query optimization to database processing. NLP can interact with those systems, but its primary language-processing domain remains distinct.

Why each choice is right or wrong

A - Incorrect: Interpreting visual images is primarily computer vision rather than language processing.

B - Incorrect: Physical robot movement concerns control and robotics, not the definition of NLP.

C - Correct: Human-language interpretation and generation are the primary NLP tasks named in AI37.

D - Incorrect: Database-query optimization is not the human-language-processing focus described.

Primary note proof

Study-note section AI37

> NLP interprets and generates human language: translation, dialogue, summarization, question answering and text generation. Speech recognition converts audio to text; speech synthesis generates speech. They overlap language processing but solve different input/output tasks.

Study-note section AI39

> Computer vision interprets images or video: classification names image content, detection locates objects, segmentation labels pixels, and recognition identifies objects or people. Occlusion, lighting change, noise, unfamiliar conditions and incomplete context make open-world perception difficult even when a face detector works well.

Study-note section AI39

> Robotics combines mechanical, electrical, control and computing systems to sense, plan and act physically. Components include sensors, controller, power supply, actuators and an end effector. Locomotion may be legged, wheeled or tracked, with trade-offs in terrain, stability and

efficiency. Software can act autonomously without being a robot. Humanoid shape is not evidence of general intelligence.

Question sources

Artificial Intelligence review questions · Question 26

Question 201 | NS0027

Which listed term is a reasoning method rather than one of the common learning regimes classified by availability of target labels?

A. Supervised Learning

B. Unsupervised Learning

C. Deductive reasoning

D. Semi-supervised Learning

Hint

Translate the statement carefully, then check the scope of its quantifiers, connectives or inference rule. Distinguish guaranteed consequences from plausible generalizations or explanations.

Answer C: Deductive reasoning

Supervised, unsupervised and semi-supervised learning differ in the target labels available during training. Deductive reasoning instead derives consequences from premises using truth-preserving rules. Deduction can be used inside a learning system, so the distinction is not that the two can never coexist. The question separates a reasoning method from the conventional label-availability taxonomy.

Why each choice is right or wrong

A - Incorrect: Supervised learning uses labeled input-target pairs, so it is a label-availability learning regime.

B - Incorrect: Unsupervised learning has no supplied targets and discovers structure, so it is a label-availability regime.

C - Correct: Deduction derives truth-preserving consequences from premises rather than naming a label-availability regime.

D - Incorrect: Semi-supervised learning combines labeled and unlabeled data, so it is a label-availability regime.

Primary note proof

Study-note section AI31

Supervised learning fits a mapping from labeled input-target examples. Classification predicts discrete labels, such as institution generations or spam/nonspam; regression predicts numeric quantities, such as prices. Predictive analytics uses historical patterns to forecast outcomes and can use either. Specify the target before choosing a method.

Study-note section AI32

Unsupervised learning seeks structure without target labels: clustering groups similar examples; association finds co-occurrence; dimensionality reduction compresses features. Good clusters have high within-cluster similarity and low between-cluster similarity under an appropriate distance. K-means alternates assignment to nearest centroids and centroid updates.

Study-note section AI32

Semi-supervised learning combines some labels with additional unlabeled data. Active learning chooses informative cases for an oracle to label; it still uses labels. “Exploratory learning” is not an exclusive standard synonym: it can mean unsupervised exploration or active data acquisition, so define the feedback. A task named summarization or time-series analysis is not automatically supervised; its training targets determine that.

Study-note section AI28

Deduction applies truth-preserving rules: all people are mortal; Ada is a person; therefore Ada is mortal. Induction generalizes observations to a broader rule and can be overturned by new examples. Abduction proposes a plausible explanation: wet ground suggests rain, although sprinklers could explain it. Analogy transfers a pattern between similar situations.

Question sources

Artificial Intelligence review questions · Question 27

Question 202 | NS0028

In adversarial search, what makes it different from traditional search?

A. It only uses one agent

B. Multiple agents with conflicting goals compete in the same search space

C. It guarantees the optimal solution always

D. It does not use evaluation functions

Hint

Read the definition and the classification axis requested; distinguish the defining purpose from supporting techniques or implementation resources.

Answer B: Competing agents with conflicting objectives.

AI22 defines adversarial search by agents with competing objectives and gives minimax for opposition. That distinguishes it from a single-agent path search. It can use evaluation functions at cutoffs, and its best-outcome guarantee is conditional on the modeled game and opponent, not an unconditional guarantee that every implementation finds a globally optimal solution.

Why each choice is right or wrong

A - Incorrect: A single decision-making agent does not capture the competing-objective feature of adversarial search.

B - Correct: Competing agents and conflicting objectives are its defining distinction.

C - Incorrect: Guarantees depend on the algorithm, model and search depth, not merely the adversarial label.

D - Incorrect: Depth-limited adversarial search commonly uses heuristic evaluation functions.

Primary note proof

Study-note section AI22

> Adversarial search models agents with competing objectives. A game specifies states, player to move, legal actions, successor function, terminal test and utility. Perfect information means previous moves and current state are visible; it does not reveal future choices or imply absence of chance. Zero-sum utility makes one player's gain the other's loss.

Study-note section AI23

> At a depth cutoff use an evaluation function estimating position desirability. Positive favors the designated MAX player, negative MIN; the scale is a convention, with +1/0/−1 often win/draw/loss. Material counts weighted pieces; mobility counts legal options; territory scores controlled regions. These are different features, often combined. Heuristics improve limited computation, not guarantee victory.

Question sources

Artificial Intelligence review questions · Question 28

Question 203 | NS0029

A Depth-Limited Search (DLS) is NOT complete in itself because:

A. It uses too much memory

B. Solutions beyond the preset depth limit will be missed

C. It explores nodes in random order

D. It requires a heuristic function

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer B: A solution beyond the fixed depth limit is missed.

AI16 defines DLS as DFS stopped at depth l and explicitly says it misses goals deeper than that. A fixed limit therefore does not establish completeness for arbitrary problem depths. This is independent of randomized ordering, heuristics or memory use; increasing limits through iterative deepening addresses the depth restriction under its stated assumptions.

Why each choice is right or wrong

A - Incorrect: Depth-limited DFS is memory-efficient; excessive memory is not the reason goals are missed.

B - Correct: A preset cutoff prevents exploring a solution whose depth exceeds that limit.

C - Incorrect: DLS need not use random order; the depth cutoff alone causes the limitation.

D - Incorrect: No heuristic is required for depth-limited DFS.

Primary note proof

Study-note section AI16

> DLS runs DFS to depth l and reports cutoff separately from failure. It misses goals deeper than l. Iterative deepening runs DLS with limits 0,1,2,...; for finite b it finds the shallowest solution with O(b^d) time and O(bd) frontier space, optimal for equal step costs. Repeated shallow work is small compared with the deepest level.

Study-note section AI14

> DFS follows the deepest pending branch using a LIFO stack or recursion. FILO means the same order as LIFO. With the same children as BFS, a left-first DFS visits S,A,C before B; push rightmost children first to pop the leftmost first.

Question sources

Artificial Intelligence review questions · Question 29

Question 204 | NS0030

Which probabilistic model represents knowledge in terms of conditional probabilities among variables?

A. Semantic Networks

B. Frames

C. Bayesian Networks

D. Ontologies

Hint

Read the definition and the classification axis requested; distinguish the defining purpose from supporting techniques or implementation resources.

Answer C: Bayesian networks.

AI29 defines a Bayesian network as a DAG with conditional probability tables and joint factorization by parents. That is the probabilistic knowledge representation in the stem. Semantic networks and frames encode relations or slots without inherently supplying conditional distributions, and ontologies specify conceptual structure rather than this particular probabilistic factorization.

Why each choice is right or wrong

A - Incorrect: Semantic networks encode labeled concept relations rather than inherently conditional probability distributions.

B - Incorrect: Frames encode slots, values and defaults rather than the named probabilistic dependency structure.

C - Correct: Bayesian networks explicitly store conditional probability relationships among variables.

D - Incorrect: An ontology's conceptual organization is not itself the conditional-probability model specified.

Primary note proof

Study-note section AI29

> A Bayesian network is a directed acyclic graph with conditional probability tables; its joint distribution factors as the product of each node's probability given its parents. A Markov model assumes the next state depends on the current state rather than the entire past. These represent uncertainty; fuzzy membership represents a different issue.

Study-note section AI24

> A semantic network connects concept nodes by labeled relations such as is-a. Frames describe stereotyped entities through slots, values and defaults. Production systems use IF conditions THEN conclusions or actions, matching rules against working memory and selecting among applicable rules. A graph suits relationships such as frequently bought together; frames suit attributes. No representation is always best for recommendation without task requirements.

Study-note section AI-S06

An ontology describes entities or individuals, classes and properties and may state logical relationships and restrictions. It organizes explicit conceptual knowledge. Conditional probability tables and a probabilistic factorization are additional modeling commitments, not inherent in the word ontology.

Question sources

Artificial Intelligence review questions · Question 30

Question 205 | NS0031

What is an 'expanded node' in a search algorithm?

A. A node that has been visited but not explored further

B. A node selected for further exploration whose neighboring nodes have been generated

C. A node removed from the open list

D. A node that has reached the goal state

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer B: A node whose successors have been generated.

AI12 defines expansion as generating successors. B states that action, unlike mere visitation, removal from OPEN or reaching a goal. A node can be removed and goal-tested without expanding it, and discovered frontier nodes await expansion. The criterion is what was generated, not whether the node was seen or selected.

Why each choice is right or wrong

A - Incorrect: Visiting without generating successors does not meet the definition of expansion.

B - Correct: Generating the selected node’s neighboring successor nodes is expansion.

C - Incorrect: Removal alone may precede a goal test without generating any successors.

D - Incorrect: Goal status is not the definition of expansion; a goal may be accepted without expanding it.

Primary note proof

Study-note section AI12

> A search node records a state plus parent, action, depth and path cost. Expanding a node generates its successors. OPEN or frontier stores discovered candidates awaiting expansion; CLOSED records expanded states. Reaching the same state through different paths does not imply the same node or cost.

Study-note section AI13

> BFS removes the oldest frontier entry using a FIFO queue. Start with the root, remove the head, test it, append unseen successors at the tail, and repeat. It explores depths 0,1,2,... and is complete for finite b and a finite-depth goal. It minimizes number of edges, so minimum cost requires equal positive step costs.

Question sources

Artificial Intelligence review questions · Question 31

Question 206 | NS0032

For which type of problem would Supervised Learning with CNNs be most appropriate?

A. Customer segmentation from unlabeled data

B. Classifying a large labeled image dataset

C. Learning chess actions from rewards obtained through trial-and-error play.

D. Finding hidden patterns in transaction data

Hint

Identify the training feedback, prediction target or measured error. Keep learning objectives separate from model architecture and data modality.

Answer B: Classifying a large labeled image dataset

The labeled images provide input-target pairs for supervised classification, and CNN filters exploit spatial image structure. Unlabeled customer segmentation and transaction-pattern discovery seek structure without class targets. Learning chess actions from rewards is a reinforcement objective.

Why each choice is right or wrong

A - Incorrect: Unlabeled segmentation seeks groups rather than supervised image classes.

B - Correct: Labeled images supply class targets, and CNN filters learn spatial image features.

C - Incorrect: Trial-and-error chess with rewards defines a reinforcement objective rather than supplied image-class targets.

D - Incorrect: Hidden transaction-pattern discovery seeks unlabeled structure rather than labeled image classification.

Primary note proof

Study-note section AI31

> Supervised learning fits a mapping from labeled input-target examples. Classification predicts discrete labels, such as institution generations or spam/nonspam; regression predicts numeric quantities, such as prices. Predictive analytics uses historical patterns to forecast outcomes and can use either. Specify the target before choosing a method.

Study-note section AI34

> Feedforward networks pass signals toward outputs without recurrent state loops; recurrent networks carry state across sequence steps. Training adjusts weights, often through gradients and backpropagation. Backpropagation is not the same as a recurrent connection. Deep learning uses multiple representation layers and can learn features from images, sound and text. CNNs share filters across image locations. ANN is a brain-inspired abstraction, not a literal brain simulation; DL⊂ML⊂AI.

Study-note section AI32

Unsupervised learning seeks structure without target labels: clustering groups similar examples; association finds co-occurrence; dimensionality reduction compresses features. Good clusters have high within-cluster similarity and low between-cluster similarity under an appropriate distance. K-means alternates assignment to nearest centroids and centroid updates.

Study-note section AI33

An RL agent observes state information, takes an action, receives reward and a new observation, and improves its policy to maximize expected cumulative reward. Rewards evaluate outcomes rather than supply the correct action label. Rewards may be delayed; not every correct-looking action receives immediate reward.

Question sources

Artificial Intelligence review questions · Question 32

Question 207 | NS0033

What does 'perfect information' mean in the context of game theory?

A. The agent knows the future

B. Both players have complete and accurate knowledge of the entire game state

C. The game has no randomness

D. Each player can see only their own pieces

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer B: The current game state and previous moves are visible to the players.

AI22 defines perfect information as visibility of previous moves and the current state. This makes B the correct state-knowledge description. It does not reveal future choices and does not by itself remove chance from a game. Seeing only one's own pieces instead describes hidden relevant state, inconsistent with perfect information.

Why each choice is right or wrong

A - Incorrect: Future choices are not known merely because the present game state is visible.

B - Correct: Complete visibility of current state and relevant move history is the intended information condition.

C - Incorrect: A game can include chance while still revealing the state and prior moves.

D - Incorrect: Seeing only one's own pieces leaves relevant state hidden and is not perfect information.

Primary note proof

Study-note section AI22

> Adversarial search models agents with competing objectives. A game specifies states, player to move, legal actions, successor function, terminal test and utility. Perfect information means previous moves and current state are visible; it does not reveal future choices or imply absence of chance. Zero-sum utility makes one player's gain the other's loss.

Study-note section AI04

> Omniscience would mean knowing actual action outcomes in advance. Rationality does not require omniscience or guaranteed success. Even complete outcome knowledge cannot create a successful action when every available action fails. Information gathering and exploration may therefore be rational actions.

Question sources

Artificial Intelligence review questions · Question 33

Question 208 | NS0034

Semi-supervised Learning is typically used when:

A. All data is labeled

B. No data is labeled

C. Obtaining a fully labeled dataset is time-consuming or costly

D. The problem requires reinforcement feedback

Hint

Identify the training feedback, prediction target or measured error. Keep learning objectives separate from model architecture and data modality.

Answer C: When labels are costly and some labeled data can be supplemented by unlabeled data.

AI32 defines semi-supervised learning as combining some labels with additional unlabeled data. Costly full labeling provides the motivation described in C, provided at least some labeled targets exist. Fully labeled data is ordinary supervised learning; wholly unlabeled structure fits unsupervised learning, and environmental rewards specify reinforcement feedback rather than this mixed dataset regime.

Why each choice is right or wrong

A - Incorrect: A fully labeled dataset does not give the defining labeled-plus-unlabeled mixture.

B - Incorrect: With no labels at all, the described regime is unsupervised rather than semi-supervised.

C - Correct: Expensive labeling motivates using a limited labeled subset together with plentiful unlabeled examples.

D - Incorrect: Reward feedback defines reinforcement learning rather than a mixture of labeled and unlabeled examples.

Primary note proof

Study-note section AI32

> Semi-supervised learning combines some labels with additional unlabeled data. Active learning chooses informative cases for an oracle to label; it still uses labels. “Exploratory learning” is not an exclusive standard synonym: it can mean unsupervised exploration or active data acquisition, so define the feedback. A task named summarization or time-series analysis is not automatically supervised; its training targets determine that.

Study-note section AI31

> Supervised learning fits a mapping from labeled input-target examples. Classification predicts discrete labels, such as institution generations or spam/nonspam; regression predicts numeric quantities, such as prices. Predictive analytics uses historical patterns to forecast outcomes and can use either. Specify the target before choosing a method.

Study-note section AI33

> An RL agent observes state information, takes an action, receives reward and a new observation, and improves its policy to maximize expected cumulative reward. Rewards evaluate outcomes rather than supply the correct action label. Rewards may be delayed; not every correct-looking action receives immediate reward.

Question sources

Artificial Intelligence review questions · Question 34

Question 209 | NS0035

In the context of AI agents, what are 'effectors'?

A. Sensors that gather environmental data

B. Components that allow an agent to take actions in its environment

C. Internal memory modules

D. Heuristic evaluation functions

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer B: Components through which an agent acts on its environment.

AI03 uses actuators or effectors for acting components and sensors for perception. Therefore B gives the correct role. Memory stores internal information and heuristic functions estimate promise; neither is the acting interface. An effector may be physical hardware or a software action mechanism depending on the agent’s architecture.

Why each choice is right or wrong

A - Incorrect: Sensors gather percepts; effectors implement actions rather than observations.

B - Correct: Effectors are the components through which selected actions affect the environment.

C - Incorrect: Internal memory maintains information but is not the general acting interface.

D - Incorrect: Heuristic functions evaluate promise and do not themselves execute environmental actions.

Primary note proof

Study-note section AI03

> An agent perceives an environment through sensors and acts through actuators or effectors. Cameras sense; motors move. Software sensors may be incoming messages and software actions may be API requests. Humans are agents but are not artificial agents.

Study-note section AI06

A model-based reflex agent maintains internal state using the previous state, previous action, current percept, and models of world change and action effects. It then applies rules to that state. Both kinds can use condition-action rules; memory and a world model distinguish them.

Study-note section AI17

A heuristic h(n) estimates remaining cost or evaluates promise using problem-specific knowledge. It can reduce explored work, but computing it also costs time. Uninformed algorithms use only the problem definition and known costs; UCS remains uninformed despite using g.

Question sources

Artificial Intelligence review questions · Question 35

Question 210 | NS0036

Which of the following best describes a Utility-Based Agent?

A. It only reacts to current perceptions using condition-action rules

B. It selects actions that maximize expected utility, handling conflicting goals through trade-offs

C. It plans sequences of actions toward a single fixed goal

D. It learns entirely from environmental feedback

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer B: Choose actions with maximum expected utility, balancing outcome trade-offs.

AI07 defines utility-based agents by comparing desirability and trade-offs and maximizing expected utility over uncertain outcomes. This is broader than merely satisfying a fixed goal. Current-percept rule matching describes simple reflex behavior, and experience-based improvement describes learning, which may coexist with utility choice but does not define it.

Why each choice is right or wrong

A - Incorrect: Current-percept condition-action matching describes a simple reflex architecture.

B - Correct: Expected-utility maximization explicitly compares trade-offs among uncertain outcomes.

C - Incorrect: Goal-reaching planning alone does not rank degrees of desirability among outcomes.

D - Incorrect: Learning describes adaptation from feedback, not the utility-based decision criterion itself.

Primary note proof

Study-note section AI07

A goal-based agent considers future action sequences that reach a desired state. A utility-based agent compares degrees of desirability and trade-offs, choosing maximum expected utility: $EU(a)=\Sigma s\ P(s|a,evidence)U(s)$. Reaching the destination is a goal; balancing arrival time, safety and cost requires preferences among outcomes.

Study-note section AI06

A simple reflex agent matches condition-action rules against the current percept only: if dirty, clean. It has no persistent world-state memory. This is adequate when the current observation contains everything needed for its rule, but partial observability can make the same percept require different actions.

Study-note section AI08

The performance element selects actions. The learning element changes the agent to improve future performance. The critic evaluates behavior against a performance standard and supplies feedback. The problem generator suggests exploratory actions likely to yield useful experience.

Question sources

Artificial Intelligence review questions · Question 36

Question 211 | NS0037

What is Computer Vision in AI primarily concerned with?

A. Processing and generating spoken language

B. Enabling machines to understand and interpret visual information

C. Designing physical robotic systems

D. Managing database indexing

Hint

Match the input, output and purpose to the appropriate language, perception or physical-action task.

Answer B: Interpreting visual information from images or video.

AI39 defines computer vision as interpreting images or video and includes classification, detection, segmentation and recognition. Language generation, robot mechanics and database indexing are separate task areas, although vision may be one component of a robot. B states the visual information-processing purpose directly.

Why each choice is right or wrong

A - Incorrect: Speech and language generation belong to language/speech processing rather than visual interpretation.

B - Correct: Computer vision extracts and interprets information from visual inputs such as images and video.

C - Incorrect: Robotic system design may use vision but is broader than the visual-processing field.

D - Incorrect: Database indexing is not the interpretation of visual scenes or objects.

Primary note proof

Study-note section AI39

> Computer vision interprets images or video: classification names image content, detection locates objects, segmentation labels pixels, and recognition identifies objects or people. Occlusion, lighting change, noise, unfamiliar conditions and incomplete context make open-world perception difficult even when a face detector works well.

Study-note section AI37

> NLP interprets and generates human language: translation, dialogue, summarization, question answering and text generation. Speech recognition converts audio to text; speech synthesis generates speech. They overlap language processing but solve different input/output tasks.

Study-note section AI39

> Robotics combines mechanical, electrical, control and computing systems to sense, plan and act physically. Components include sensors, controller, power supply, actuators and an end effector. Locomotion may be legged, wheeled or tracked, with trade-offs in terrain, stability and efficiency. Software can act autonomously without being a robot. Humanoid shape is not evidence of general intelligence.

Question sources

Artificial Intelligence review questions · Question 37

Question 212 | NS0038

In a zero-sum Tic-Tac-Toe terminal utility convention, MAX wins score +1 and MIN wins score −1. Which listed value represents a draw giving neither player an advantage?

A. +1

B. -1

C. +Infinity

D. 0

Hint

Read the definition and the classification axis requested; distinguish the defining purpose from supporting techniques or implementation resources.

Answer D: 0

The convention assigns equal and opposite utilities to the two decisive outcomes. A draw gives neither side an advantage, so its neutral utility is zero under that symmetric scale. Positive one favors MAX and negative one favors MIN; positive infinity would strongly favor MAX rather than indicate neutrality. This is an explicit utility convention, not an intrinsic numerical property of the game outcome.

Why each choice is right or wrong

A - Incorrect: Under the common stated scale, +1 is a win rather than a draw.

B - Incorrect: Under the common stated scale, −1 is a loss rather than a draw.

C - Incorrect: Positive infinity is not the draw value in the note's common scale.

D - Correct: Zero is the neutral utility between +1 and −1 under this convention.

Primary note proof

Study-note section AI23

> At a depth cutoff use an evaluation function estimating position desirability. Positive favors the designated MAX player, negative MIN; the scale is a convention, with +1/0/−1 often win/draw/loss. Material counts weighted pieces; mobility counts legal options; territory scores controlled regions. These are different features, often combined. Heuristics improve limited computation, not guarantee victory.

Question sources

Artificial Intelligence review questions · Question 38

Question 213 | NS0039

Treat a whole independently reset chess match as one episode with no effects on later matches; treat the other options as ongoing tasks at the action level described. Which task is episodic under those units?

A. A self-driving car navigating city traffic

B. A chess game (each individual match)

C. A robot cleaning a multi-room house continuously

D. A stock trading algorithm operating over months

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer B: A chess game (each individual match)

An episodic task has independent decision units. Under the stated convention, each whole chess match is reset and cannot affect later matches, so matches can be treated as episodes. Individual moves within a match remain sequential. Driving, continuous cleaning and continuing stock trading all have actions that affect later situations within the ongoing task. The classification therefore follows the explicit unit and independence assumptions.

Why each choice is right or wrong

A - Incorrect: Driving decisions affect later positions and traffic interactions, making the task sequential.

B - Correct: Whole independently reset matches are independent episodes under the stated convention.

C - Incorrect: Cleaning actions change later room states and decisions in the continuing task.

D - Incorrect: Trading decisions affect later holdings and opportunities, so the continuing task is sequential.

Primary note proof

Study-note section AI09

> Episodic decisions are independent; sequential decisions affect later situations. Static worlds do not change while deliberating; dynamic ones do. A clock affecting score makes an otherwise static game semidynamic. Discrete quantities have distinct alternatives; continuous quantities vary along real-valued ranges. Known versus unknown concerns knowledge of the transition model, not observability.

Question sources

Artificial Intelligence review questions · Question 39

Question 214 | NS0040

The heuristic function h(n) in A* represents:

A. The exact cost from start to node n

B. The total path cost already traveled

C. The estimated cost from node n to the goal state

D. The branching factor at node n

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer C: Estimated remaining cost from n to a goal.

AI17 defines h as an estimate of remaining cost or promise, and AI18 adds it to accumulated g in A*. Thus C is the heuristic component. Exact start-to-node cost belongs to g, and branching factor b is a search-size parameter rather than a cost-to-go estimate.

Why each choice is right or wrong

A - Incorrect: Exact cost from the start belongs to g(n), not the heuristic h(n).

B - Incorrect: Already-traveled path cost is g(n), not estimated future cost.

C - Correct: h estimates the remaining cost from the current node to a goal.

D - Incorrect: Branching factor counts successor alternatives and is not the heuristic cost estimate.

Primary note proof

Study-note section AI17

> A heuristic h(n) estimates remaining cost or evaluates promise using problem-specific knowledge. It can reduce explored work, but computing it also costs time. Uninformed algorithms use only the problem definition and known costs; UCS remains uninformed despite using g.

Study-note section AI18

> A* orders by f(n)=g(n)+h(n). Admissibility means $0 \le h(n) \le h^*(n)$, the true cheapest remaining cost. Consistency means $h(n) \le c(n,n') + h(n')$ on every edge, with h(goal)=0; it implies admissibility on states with goal paths. Consistency makes f nondecreasing along a path.

Study-note section AI12

> Completeness means finding a solution if one exists under stated assumptions; optimality means returning the best solution. Time counts work, often generated nodes; space counts simultaneous storage. Let b be branching factor, d shallowest goal depth, m maximum search depth, and l a depth limit. Graph-search bounds in vertices V and edges E differ from implicit-tree bounds.

Question sources

Artificial Intelligence review questions · Question 40

Question 215 | NS0041

When a doctor proposes a disease as a plausible cause explaining observed symptoms, which term names this explanatory direction of reasoning, rather than a method for numerically ranking hypotheses?

A. Deductive Reasoning

B. Inductive Reasoning

C. Abductive Reasoning

D. Probabilistic Reasoning

Hint

Translate the statement carefully, then check the scope of its quantifiers, connectives or inference rule. Distinguish guaranteed consequences from plausible generalizations or explanations.

Answer C: Abductive Reasoning

Abduction proposes an explanation for observed evidence, such as a disease that could account for symptoms. Other causes may also fit, so the conclusion is not logically guaranteed. Probability can help rank the possible explanations, but that numerical method is distinct from the explanatory direction. Deduction preserves truth from premises, and induction generalizes patterns across cases.

Why each choice is right or wrong

A - Incorrect: Deduction follows truth-preserving implications from premises, not a merely plausible cause inferred from its effects.

B - Incorrect: Induction generalizes across observations rather than specifically proposing a cause that explains an observation.

C - Correct: Abduction proposes a plausible explanation for observed evidence.

D - Incorrect: Probability can rank disease hypotheses, but does not itself name the observation-to-explanation direction.

Primary note proof

Study-note section AI28

> Deduction applies truth-preserving rules: all people are mortal; Ada is a person; therefore Ada is mortal. Induction generalizes observations to a broader rule and can be overturned by new examples. Abduction proposes a plausible explanation: wet ground suggests rain, although sprinklers could explain it. Analogy transfers a pattern between similar situations.

Study-note section AI29

> Probability describes uncertainty about events. $P(\neg A)=1-P(A)$; $P(A|B)=P(A\cap B)/P(B)$, for $P(B)>0$. Bayes gives $P(H|E)=P(E|H)P(H)/P(E)$: posterior equals likelihood times prior divided by evidence probability. For mutually exclusive exhaustive hypotheses, $P(E)=\Sigma_i P(E|Hi)P(Hi)$.

Question sources

Artificial Intelligence review questions · Question 41

Question 216 | NS0042

What major ethical concern does AI raise related to decision-making systems?

A. AI systems use too little data

B. Bias in algorithms leading to unfair or discriminatory outcomes

C. AI always makes perfectly rational decisions

D. AI cannot process unstructured data

Hint

Identify the training feedback, prediction target or measured error. Keep learning objectives separate from model architecture and data modality.

Answer B: Biased decisions causing unfair outcomes.

AI40 says bias in data or evaluation can create unfair outcomes and calls for checking errors across groups, robustness and oversight. B states the ethical concern directly. Data scarcity may be a technical issue, but little data is not the stated general ethical principle; perfect rationality and inability to process unstructured inputs are false generalizations.

Why each choice is right or wrong

A - Incorrect: Using too little data is not the specific fairness concern described here.

B - Correct: Biased data or evaluation can produce unfair or discriminatory decisions.

C - Incorrect: AI is not guaranteed perfect rational decisions or error-free outcomes.

D - Incorrect: The note explicitly includes models that process images, sound and text.

Primary note proof

Study-note section AI40

> Rules offer inspectable domain reasoning but can be brittle and costly to maintain. Learned models handle data-rich patterns but depend on representative data and validation. Search suits explicit action alternatives; probabilistic models suit uncertain evidence. Bias in data or evaluation can create unfair outcomes. Evaluate errors across relevant groups, robustness, privacy and human oversight rather than assuming automation is always beneficial.

Study-note section AI34

> Feedforward networks pass signals toward outputs without recurrent state loops; recurrent networks carry state across sequence steps. Training adjusts weights, often through gradients and backpropagation. Backpropagation is not the same as a recurrent connection. Deep learning uses multiple representation layers and can learn features from images, sound and text. CNNs share filters across image locations. ANN is a brain-inspired abstraction, not a literal brain simulation; DL⊂ML⊂AI.

Study-note section AI04

A performance measure defines success externally: safety, useful deliveries, elapsed time, or cost. Rationality depends on that measure, prior knowledge, percept history, and available actions. A rational agent selects the action with the best expected performance given its information.

Question sources

Artificial Intelligence review questions · Question 42

Question 217 | NS0043

In a continuous environment like self-driving cars, what challenge does 'continuous' specifically pose?

A. A finite set of states makes decisions trivial

B. Infinite or large state/action spaces require more complex computations

C. The environment never changes

D. All outcomes are deterministic

Hint

Read the relevant agent component, action-selection criterion or environment dimension. Use only properties established by the description.

Answer B: Real-valued state/action variables create large or infinite spaces to represent and search.

AI09 defines continuous quantities as varying along real-valued ranges, unlike distinct discrete alternatives. Such ranges can create unboundedly many state/action possibilities, motivating approximation or richer computation rather than exhaustive finite enumeration. Continuity is separate from whether a world changes over time or whether outcomes are stochastic.

Why each choice is right or wrong

A - Incorrect: Continuous ranges do not reduce the task to a trivial finite set of alternatives.

B - Correct: Real-valued ranges can produce very large or infinite possibilities needing suitable representation and computation.

C - Incorrect: No world change defines static rather than continuous.

D - Incorrect: Determinism is a separate transition-property dimension and does not follow from continuity.

Primary note proof

Study-note section AI09

> Episodic decisions are independent; sequential decisions affect later situations. Static worlds do not change while deliberating; dynamic ones do. A clock affecting score makes an otherwise static game semidynamic. Discrete quantities have distinct alternatives; continuous quantities vary along real-valued ranges. Known versus unknown concerns knowledge of the transition model, not observability.

Question sources

Artificial Intelligence review questions · Question 43

Question 218 | NS0044

The successor function in game search is responsible for:

A. Evaluating terminal game states

B. Generating new states by applying legal moves to the current game state

C. Pruning unpromising branches

D. Calculating the heuristic value of each state

Hint

Read the definition and the classification axis requested; distinguish the defining purpose from supporting techniques or implementation resources.

Answer B: Generate successor states by applying legal moves.

AI22 lists legal actions and a successor function as game components; AI11 identifies successors as states reached by actions. In game search, applying each legal move yields its successor position. Terminal utilities and heuristic scores evaluate positions, while alpha-beta pruning avoids exploring branches; neither is the transition-generation function.

Why each choice is right or wrong

A - Incorrect: Terminal utility evaluation scores a completed outcome rather than generating the next position.

B - Correct: The successor function maps legal moves at the current position to resulting game states.

C - Incorrect: Pruning skips exploration under a bound; it is not state-transition generation.

D - Incorrect: A heuristic evaluation scores a state's promise rather than producing legal successor states.

Primary note proof

Study-note section AI22

> Adversarial search models agents with competing objectives. A game specifies states, player to move, legal actions, successor function, terminal test and utility. Perfect information means previous moves and current state are visible; it does not reveal future choices or imply absence of chance. Zero-sum utility makes one player's gain the other's loss.

Study-note section AI11

> First formulate the goal; then formulate the problem by specifying initial state, legal actions, transition model, goal test, and action costs. Search selects a sequence; execution applies it. A state abstracts away irrelevant world details.

Study-note section AI23

> At a depth cutoff use an evaluation function estimating position desirability. Positive favors the designated MAX player, negative MIN; the scale is a convention, with +1/0/−1 often win/draw/loss. Material counts weighted pieces; mobility counts legal options; territory scores

controlled regions. These are different features, often combined. Heuristics improve limited computation, not guarantee victory.

Question sources

Artificial Intelligence review questions · Question 44

Question 219 | NS0045

For implicit-tree search with branching factor b and shallowest goal depth d, which is a key memory advantage of iterative deepening over BFS when each depth-limited pass stores pending siblings?

A. It finds deeper solutions faster

B. It requires storing all nodes at each level in memory

C. It uses O(bd) frontier space rather than storing an entire BFS level.

D. It does not guarantee completeness

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer C: It uses O(bd) frontier space rather than storing an entire BFS level.

Iterative deepening repeats depth-limited DFS while increasing the limit. A pass retains a depth-first path and pending siblings, giving O(bd) frontier space rather than BFS's potentially exponential level frontier. It remains complete for finite branching and a finite-depth solution, although it repeats some shallow work. The option states the correct memory advantage without claiming that every implementation stores only the current path.

Why each choice is right or wrong

A - Incorrect: IDS repeats shallow work and does not universally find deeper solutions faster than BFS.

B - Incorrect: Storing all nodes at a level is BFS-style memory behavior, not the IDS advantage.

C - Correct: The stated implementation keeps only a depth-first frontier, requiring O(bd) rather than the BFS level frontier.

D - Incorrect: IDS is complete under finite branching and a finite-depth solution, so loss of completeness is not its benefit.

Primary note proof

Study-note section AI16

DLS runs DFS to depth l and reports cutoff separately from failure. It misses goals deeper than l. Iterative deepening runs DLS with limits 0,1,2,...; for finite b it finds the shallowest solution with O(b^d) time and O(bd) frontier space, optimal for equal step costs. Repeated shallow work is small compared with the deepest level.

Study-note section AI13

The tree contains 1+b+...+b^d nodes through depth d, giving O(b^d) under generation-time goal testing. Expanding depth-d nodes before testing can generate depth d+1 and yields O(b^(d+1)); specify the convention. Explicit finite graph traversal with visited-state tracking takes O(V+E) time and O(V) space.

Study-note section AI14

DFS follows the deepest pending branch using a LIFO stack or recursion. FILO means the same order as LIFO. With the same children as BFS, a left-first DFS visits S,A,C before B; push rightmost children first to pop the leftmost first.

Question sources

Artificial Intelligence review questions · Question 45

Question 220 | NS0046

Representation learning in Deep Learning refers to:

A. Manually engineering input features

B. The ability to automatically discover and learn relevant features from raw data

C. Storing knowledge in frames and ontologies

D. Using labeled data with a teacher signal

Hint

Identify the training feedback, prediction target or measured error. Keep learning objectives separate from model architecture and data modality.

Answer B: Automatically learning useful features from data.

AI34 says deep models learn features from images, sound and text through multiple representation layers. That is representation learning rather than manually specifying every input feature. A label signal may guide training but is not required for every deep objective, and frames/ontologies are separate explicit knowledge structures rather than the learned representations meant here.

Why each choice is right or wrong

A - Incorrect: Manual feature engineering is contrasted with learning the representations automatically.

B - Correct: The model learns task-useful features or representations from the supplied data.

C - Incorrect: Frames and ontologies are explicit knowledge representations, not the deep feature-learning mechanism described.

D - Incorrect: Teacher labels define supervision; representation learning can also use unsupervised or reinforcement objectives.

Primary note proof

Study-note section AI34

Feedforward networks pass signals toward outputs without recurrent state loops; recurrent networks carry state across sequence steps. Training adjusts weights, often through gradients and backpropagation. Backpropagation is not the same as a recurrent connection. Deep learning uses multiple representation layers and can learn features from images, sound and text. CNNs share filters across image locations. ANN is a brain-inspired abstraction, not a literal brain simulation; DL⊂ML⊂AI.

Study-note section AI43

ANNs, genetic search and reinforcement learning all improve candidate behavior or performance through experience in different ways. Deep learning is an architecture family usable with supervised, unsupervised or reinforcement objectives. Decision trees and deep models may both be supervised. To distinguish learning regimes, specify labels, reward or unlabeled structure.

Study-note section AI24

A semantic network connects concept nodes by labeled relations such as is-a. Frames describe stereotyped entities through slots, values and defaults. Production systems use IF conditions THEN conclusions or actions, matching rules against working memory and selecting among applicable rules. A graph suits relationships such as frequently bought together; frames suit attributes. No representation is always best for recommendation without task requirements.

Study-note section AI-S06

An ontology describes entities or individuals, classes and properties and may state logical relationships and restrictions. It organizes explicit conceptual knowledge. Conditional probability tables and a probabilistic factorization are additional modeling commitments, not inherent in the word ontology.

Question sources

Artificial Intelligence review questions · Question 46

Question 221 | NS0047

What makes Best-First (Greedy) Search non-optimal?

A. It always explores all possible paths

B. It relies entirely on heuristics and can overlook cheaper paths, making suboptimal choices

C. It uses actual path costs rather than estimates

D. It explores nodes in breadth-first order

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer B: It uses only h and can ignore a cheaper route with a larger estimate.

AI17 defines greedy best-first as f=h, ignoring cost already paid. AI19 demonstrates a route of cost 11 selected greedily while another route costs 4. The heuristic ranking can therefore prefer a worse total solution. Greedy is neither exhaustive nor breadth-first and does not order primarily by actual path cost.

Why each choice is right or wrong

A - Incorrect: Greedy search may stop at an early found goal rather than exploring every path.

B - Correct: Ignoring accumulated cost can favor a seemingly close but expensive route over a cheaper solution.

C - Incorrect: Using actual g alone describes UCS, whereas greedy uses h.

D - Incorrect: Breadth-first depth order is not the greedy minimum-heuristic policy.

Primary note proof

Study-note section AI17

> Best-first is a family that orders OPEN by an evaluation function. Greedy best-first uses f=h and removes the smallest estimate, ignoring the cost already paid. It can choose an expensive route, loop without duplicate checks, or follow an infinite misleading branch. On a finite graph with full duplicate handling it is complete, but not generally optimal. Its implicit finite-tree worst case can be O(b^m).

Study-note section AI19

> For S→A cost 2, S→B cost 1, A→G cost 2, B→G cost 10, set h(A)=2, h(B)=1, h(G)=0. After expanding S, greedy chooses B because 1<2 and can then choose G, returning cost 11. A* compares A:f=2+2=4 and B:f=1+1=2; after B, its G entry costs 11. It next expands A and replaces G with cost 4, which is removed and accepted.

Question sources

Artificial Intelligence review questions · Question 47

Question 222 | NS0048

In AI, what does 'Acting Humanly' (Turing Test concept) primarily evaluate?

A. Whether a machine can solve math problems

B. Whether a machine's behavior is indistinguishable from a human's in conversation

C. Whether a machine can perceive visual stimuli

D. Whether a machine follows logical rules perfectly

Hint

Read the definition and the classification axis requested; distinguish the defining purpose from supporting techniques or implementation resources.

Answer B: Humanlike conversational behavior judged by indistinguishability.

AI02 asks whether a judge can reliably distinguish a machine from a human through dialogue. This operational test concerns observed conversation, not a proof of consciousness or perfect logical reasoning. Mathematical success and perception may contribute capabilities but are not the primary distinguishing conversational criterion. B states that criterion directly.

Why each choice is right or wrong

A - Incorrect: Mathematical ability alone does not supply the test's conversational indistinguishability criterion.

B - Correct: The test evaluates whether conversational behavior can be reliably distinguished from a human's.

C - Incorrect: Visual perception alone is not the conversational test described in AI02.

D - Incorrect: Perfect logic is a rationality criterion, not the test's humanlike observed-behavior requirement.

Primary note proof

Study-note section AI02

> Thinking humanly models human mental processes; thinking rationally derives conclusions by valid logic. Acting humanly seeks humanlike behavior; acting rationally selects actions expected to achieve objectives. Thought processes and observed behavior are different evaluation targets.

Study-note section AI02

> The conversational Turing test asks whether a judge can reliably distinguish a machine from a human through their dialogue. It requires language use, knowledge, reasoning and often learning. It tests an operational behavior criterion, not proof of consciousness. Cognitive models can be tested against response times, errors and psychological experiments.

Question sources

Artificial Intelligence review questions · Question 48

Question 223 | NS0049

Which of the following is the correct relationship between AI, ML, and DL?

A. DL ⊂ AI ⊂ ML

B. AI ⊂ ML ⊂ DL

C. ML ⊂ DL ⊂ AI

D. DL ⊂ ML ⊂ AI

Hint

Identify the training feedback, prediction target or measured error. Keep learning objectives separate from model architecture and data modality.

Answer D: DL⊂ML⊂AI.

AI34 explicitly gives deep learning inside machine learning inside AI. Deep neural architectures are a subset of learning methods, and learning is one component of the broader intelligence field, which also includes planning and reasoning. Every other ordering reverses at least one of these stated inclusions.

Why each choice is right or wrong

A - Incorrect: This wrongly puts AI inside machine learning rather than the reverse.

B - Incorrect: Both inclusions are reversed relative to the note's hierarchy.

C - Incorrect: Machine learning contains deep learning, not the reverse.

D - Correct: Deep learning is contained in machine learning, which is contained in AI.

Primary note proof

Study-note section AI34

> Feedforward networks pass signals toward outputs without recurrent state loops; recurrent networks carry state across sequence steps. Training adjusts weights, often through gradients and backpropagation. Backpropagation is not the same as a recurrent connection. Deep learning uses multiple representation layers and can learn features from images, sound and text. CNNs share filters across image locations. ANN is a brain-inspired abstraction, not a literal brain simulation; DL⊂ML⊂AI.

Study-note section AI33

> An RL agent observes state information, takes an action, receives reward and a new observation, and improves its policy to maximize expected cumulative reward. Rewards evaluate outcomes rather than supply the correct action label. Rewards may be delayed; not every correct-looking action receives immediate reward.

Question sources

Artificial Intelligence review questions · Question 49

Question 224 | NS0050

A recommendation system must directly represent products and labeled “frequently bought together” relationships, then traverse those relationships to find connected products. Which listed representation most directly fits that requirement?

A. Rule-based IF-THEN logic

B. Frames describing product attributes

C. Graph-based model with products as nodes and relationships as edges

D. Probabilistic Bayesian network of user demographics

Hint

Read the definition and the classification axis requested; distinguish the defining purpose from supporting techniques or implementation resources.

Answer C: Graph-based model with products as nodes and relationships as edges

A semantic graph represents entities as nodes and their labeled relationships as edges, making connected products directly traversable. Frames primarily organize attributes, rules express conditions and conclusions, and a Bayesian demographic model represents uncertain dependencies rather than the requested product-edge structure. The answer follows the explicit relational representation requirement; it does not claim that graphs are universally best for every recommendation system.

Why each choice is right or wrong

A - Incorrect: Rules can encode recommendations, but do not directly provide the requested product-node relationship structure.

B - Incorrect: Frames describe product attributes rather than making product-to-product links the primary structure.

C - Correct: Products as nodes and labeled relationships as edges directly support the required traversal.

D - Incorrect: A demographic Bayesian network models uncertain dependencies rather than the specified product-edge structure.

Primary note proof

Study-note section AI24

> A semantic network connects concept nodes by labeled relations such as is-a. Frames describe stereotyped entities through slots, values and defaults. Production systems use IF conditions THEN conclusions or actions, matching rules against working memory and selecting among applicable rules. A graph suits relationships such as frequently bought together; frames suit attributes. No representation is always best for recommendation without task requirements.

Study-note section AI29

> A Bayesian network is a directed acyclic graph with conditional probability tables; its joint distribution factors as the product of each node’s probability given its parents. A Markov model

assumes the next state depends on the current state rather than the entire past. These represent uncertainty; fuzzy membership represents a different issue.

Question sources

Artificial Intelligence review questions · Question 50

Question 225 | NS0156

What is the difference between supervised and unsupervised learning?

Hint

Identify the training feedback, prediction target or measured error. Keep learning objectives separate from model architecture and data modality.

Answer: Supervised learning fits labeled input-target examples; unsupervised learning discovers structure without target labels.

AI31 defines supervised learning through labels, with classification for discrete targets and regression for numeric targets. AI32 defines unsupervised discovery, including clustering, association and dimensionality reduction. The distinction is the supplied training feedback, not whether the data are images, text or numbers; the same modality can support either regime.

Primary note proof

Study-note section AI31

Supervised learning fits a mapping from labeled input-target examples. Classification predicts discrete labels, such as institution generations or spam/nonspam; regression predicts numeric quantities, such as prices. Predictive analytics uses historical patterns to forecast outcomes and can use either. Specify the target before choosing a method.

Study-note section AI32

Unsupervised learning seeks structure without target labels: clustering groups similar examples; association finds co-occurrence; dimensionality reduction compresses features. Good clusters have high within-cluster similarity and low between-cluster similarity under an appropriate distance. K-means alternates assignment to nearest centroids and centroid updates.

Question sources

Artificial Intelligence review questions · Question 1

Question 226 | NS0157

Under what search and heuristic conditions does A* find a least-cost path, and why?

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer: A* is optimal under its heuristic and search assumptions: admissible tree search, or consistent graph search without reopening; otherwise reopen improved states.

With admissible h, A* tree search uses f=g+h as a lower bound on solution cost through each frontier node. Removing a minimum-f goal cannot skip a cheaper represented solution. Graph search that never reopens closed states normally requires consistency; with an admissible inconsistent heuristic, improved states must be reopened. Goal testing is on removal. Finite branching and positive lower-bounded step costs supply the usual infinite-space completeness conditions.

Primary note proof

Study-note section AI18

> A* orders by f(n)=g(n)+h(n). Admissibility means 0≤h(n)≤h*(n), the true cheapest remaining cost. Consistency means h(n)≤c(n,n′)+h(n′) on every edge, with h(goal)=0; it implies admissibility on states with goal paths. Consistency makes f nondecreasing along a path.

Study-note section AI18

> Admissibility suffices for optimal A* tree search; graph search that never reopens CLOSED states normally requires consistency. With an admissible inconsistent heuristic, reopen states when g improves. Test a goal when removed at minimum f. Completeness also needs finite branching and positive lower-bounded costs in infinite spaces. Worst-case time and memory can be exponential; no heuristic universally guarantees speed.

Question sources

Artificial Intelligence review questions · Question 2

Question 227 | NS0158

What is the Turing Test and what does it measure?

Hint

Read the definition and the classification axis requested; distinguish the defining purpose from supporting techniques or implementation resources.

Answer: The conversational Turing test asks a judge to distinguish machine from human through dialogue; it measures humanlike behavior, not consciousness.

AI02 sets the observable criterion: whether a judge can reliably tell a machine's conversation from a human's. Language use, knowledge, reasoning and often learning support the performance. Passing would meet this operational behavioral standard, but it does not prove consciousness, actual understanding or that the machine internally thinks in the same way as a human.

Primary note proof

Study-note section AI02

> The conversational Turing test asks whether a judge can reliably distinguish a machine from a human through their dialogue. It requires language use, knowledge, reasoning and often learning. It tests an operational behavior criterion, not proof of consciousness. Cognitive models can be tested against response times, errors and psychological experiments.

Question sources

Artificial Intelligence review questions · Question 3

Question 228 | NS0159

What is the difference between precision and recall?

Hint

Identify the training feedback, prediction target or measured error. Keep learning objectives separate from model architecture and data modality.

Answer: Precision=TP/(TP+FP): how many predicted positives are correct. Recall=TP/(TP+FN): how many actual positives are found.

AI36 distinguishes precision's predicted-positive denominator from recall's actual-positive denominator. False positives reduce precision; false negatives reduce recall. With TP=30, FP=10 and FN=20, precision is 30/40=75% and recall is 30/50=60%. The positive class and zero-denominator convention should be fixed before comparing scores.

Primary note proof

Study-note section AI36

> With a fixed positive class, TP means true positives, FP false positive predictions, FN missed positives, TN true negatives. Accuracy=(TP+TN)/N; precision=TP/(TP+FP); recall=TP/(TP+FN); F1=2PR/(P+R). State the averaging and zero-denominator convention when relevant.

Question sources

Artificial Intelligence review questions · Question 4

Question 229 | NS0160

Why is tokenization important in natural language processing?

Hint

Match the input, output and purpose to the appropriate language, perception or physical-action task.

Answer: Tokenization divides text into processing units such as words, punctuation or subwords so later NLP stages can operate on a consistent input sequence.

AI37 defines tokenization as dividing text into processing units and lists several permitted granularities. Establishing that sequence lets later tagging, recognition and parsing refer to units consistently. Tokens need not equal whitespace-separated words, and tokenization by itself does not determine grammatical structure or resolve word meaning; those belong to later analyses.

Primary note proof

Study-note section AI37

> NLP interprets and generates human language: translation, dialogue, summarization, question answering and text generation. Speech recognition converts audio to text; speech synthesis generates speech. They overlap language processing but solve different input/output tasks.

Study-note section AI37

> Tokenization divides text into processing units; tokens may be words, punctuation or subwords. POS tagging assigns grammatical roles; named-entity recognition identifies people, organizations and locations. Parsing identifies grammatical structure; semantics concerns meaning; discourse links sentences; pragmatics uses context and speaker intent. Sentiment analysis predicts evaluative tone. Ambiguity can occur at every level: “bank” has multiple senses, and “I saw the man with a telescope” has multiple attachments.

Question sources

Artificial Intelligence review questions · Question 5

Question 230 | NS0285

Which AI approach most directly supports understanding biological intelligence behavior as a scientific goal?

A. Weak AI

B. Applied AI

C. Cognitive AI

D. Strong AI

Hint

Read the definition and the classification axis requested; distinguish the defining purpose from supporting techniques or implementation resources.

Answer C: Cognitive AI.

AI01 explicitly describes cognitive AI as using computational models to investigate biological intelligence, making it the direct scientific-goal match. Applied AI emphasizes useful solutions. Narrow AI describes capability scope, while strong AI has a philosophical understanding sense; neither is the named research approach for testing models against biological behavior.

Why each choice is right or wrong

A - Incorrect: Weak AI denotes bounded capability rather than the specific scientific modeling goal.

B - Incorrect: Applied AI builds useful solutions rather than primarily explaining biological intelligence.

C - Correct: Cognitive AI uses computational models to investigate biological intelligence and behavior.

D - Incorrect: Strong AI concerns broad or actual-understanding claims, not this specific empirical modeling approach.

Primary note proof

Study-note section AI01

> Artificial intelligence studies systems that perform tasks requiring intelligence: reasoning, learning, planning, perception and language. Applied AI builds useful solutions; cognitive AI uses computational models to investigate biological intelligence. A model should be compared with human behavior or experimental observations before claiming it explains human thought.

Study-note section AI01

> Narrow or weak AI addresses bounded tasks, such as face recognition, spam filtering or a voice assistant. General AI denotes broad competence transferable across domains; strong AI also has a philosophical meaning involving actual understanding. Do not equate a humanoid body, autonomous vehicle, or many features with general intelligence.

Question sources

Computer Science Exit Exam · 2018 · Question 2

Question 231 | NS0291

Why is Greedy Best-First Search not guaranteed to be optimal or complete?

A. It ignores path cost g(n) and relies only on h(n)

B. It always chooses the shallowest node

C. It expands nodes in FIFO order

D. It requires full knowledge of the goal state in advance

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer A: It uses h alone, ignoring accumulated g.

AI17 says greedy best-first chooses f=h and can take an expensive route or follow an infinite misleading branch. Ignoring g explains nonoptimality, while cycles or infinite paths without appropriate handling explain failure of completeness. On a finite graph with full duplicate handling it is complete, so the lack of a general guarantee does not mean every implementation fails.

Why each choice is right or wrong

A - Correct: Using only h ignores total path cost and can follow misleading or unbounded branches.

B - Incorrect: Shallowest-first describes breadth-first order rather than greedy heuristic order.

C - Incorrect: FIFO is breadth-first queue behavior, not minimum-h priority selection.

D - Incorrect: Heuristics estimate promise; exact full goal-state knowledge is not required by the algorithm.

Primary note proof

Study-note section AI17

> Best-first is a family that orders OPEN by an evaluation function. Greedy best-first uses f=h and removes the smallest estimate, ignoring the cost already paid. It can choose an expensive route, loop without duplicate checks, or follow an infinite misleading branch. On a finite graph with full duplicate handling it is complete, but not generally optimal. Its implicit finite-tree worst case can be O(b^m).

Study-note section AI19

> For S→A cost 2, S→B cost 1, A→G cost 2, B→G cost 10, set h(A)=2, h(B)=1, h(G)=0. After expanding S, greedy chooses B because 1<2 and can then choose G, returning cost 11. A* compares A:f=2+2=4 and B:f=1+1=2; after B, its G entry costs 11. It next expands A and replaces G with cost 4, which is removed and accepted.

Question sources

Computer Science Exit Exam · 2018 · Question 8

Question 232 | NS0305

Which search strategy tries to expand the node that is closest to the goal, on the grounds that this is likely to lead to a solution quickly; Thus, it evaluates nodes by using just the heuristic function: f (n) = h (n).

A. Uniform-cost search

B. Greedy best-first search

C. Depth-first search

D. A* search

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer B: Greedy best-first search.

AI17 explicitly defines greedy best-first by removing the smallest remaining-cost estimate h while ignoring paid cost g. This is exactly the stem's equation. UCS uses g, A* combines g and h, and DFS uses depth/stack discipline rather than a minimum heuristic evaluation.

Why each choice is right or wrong

A - Incorrect: UCS orders by accumulated g rather than h alone.

B - Correct: Greedy best-first selects the node with the smallest heuristic estimate h.

C - Incorrect: DFS follows a LIFO/deepest-branch order rather than minimum h.

D - Incorrect: A* uses g+h, while the stem explicitly uses only h.

Primary note proof

Study-note section AI17

> Best-first is a family that orders OPEN by an evaluation function. Greedy best-first uses f=h and removes the smallest estimate, ignoring the cost already paid. It can choose an expensive route, loop without duplicate checks, or follow an infinite misleading branch. On a finite graph with full duplicate handling it is complete, but not generally optimal. Its implicit finite-tree worst case can be O(b^m).

Study-note section AI15

> UCS uses a priority queue ordered by actual accumulated path cost g(n). Remove a minimum-g node; accept a goal when removed, not when first generated. Relax each edge: if a cheaper path is found, update its frontier cost and parent.

Study-note section AI18

> A* orders by f(n)=g(n)+h(n). Admissibility means 0≤h(n)≤h*(n), the true cheapest remaining cost. Consistency means h(n)≤c(n,n′)+h(n′) on every edge, with h(goal)=0; it implies admissibility on states with goal paths. Consistency makes f nondecreasing along a path.

Study-note section AI14

DFS follows the deepest pending branch using a LIFO stack or recursion. FILO means the same order as LIFO. With the same children as BFS, a left-first DFS visits S,A,C before B; push rightmost children first to pop the leftmost first.

Question sources

Computer Science Exit Exam · 2018 · Question 23

Question 233 | NS0312

Which of the following best defines a heuristic in the context of AI search?

A. A function that estimates how close a state is to the goal

B. A guaranteed optimal path to the goal

C. A method that always avoids revisiting states

D. A brute-force enumeration of all possible states

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer A: A problem-specific estimate of remaining cost or promise.

AI17 defines a heuristic h(n) as estimating remaining cost or evaluating promise. A's closeness wording captures that estimate rather than an exact path guarantee. A heuristic does not inherently prevent repeated states and is not exhaustive enumeration; those are separate search-policy or bookkeeping choices. Its quality and computation cost affect practical search.

Why each choice is right or wrong

A - Correct: Estimating closeness or remaining cost is the heuristic role defined in AI17.

B - Incorrect: An estimate is not itself a guaranteed optimal path.

C - Incorrect: Repeated-state avoidance requires duplicate handling rather than following from heuristic estimation.

D - Incorrect: Exhaustive enumeration is a search method, not the definition of a heuristic estimate.

Primary note proof

Study-note section AI17

> A heuristic h(n) estimates remaining cost or evaluates promise using problem-specific knowledge. It can reduce explored work, but computing it also costs time. Uninformed algorithms use only the problem definition and known costs; UCS remains uninformed despite using g.

Study-note section AI12

> A search node records a state plus parent, action, depth and path cost. Expanding a node generates its successors. OPEN or frontier stores discovered candidates awaiting expansion; CLOSED records expanded states. Reaching the same state through different paths does not imply the same node or cost.

Question sources

Computer Science Exit Exam · 2018 · Question 35

Question 234 | NS0326

Which type of heuristic search strategy that evaluates nodes by combining g (n), the cost to reach the node, and h (n.), the cost to get from the node to the goal: f (n) = g (n) + h (n) Since g(n) gives the path cost from the start node to node n, and h(n) is the estimated cost of the cheapest path from n to the goal, we have f (n) = estimated cost of the cheapest solution through n ?

A. A* search

B. Greedy Best-First Search

C. Uniform-cost search

D. Depth-first search

Hint

Check how the method selects its next candidate, what information it uses, and which cost, depth or heuristic assumptions the question supplies.

Answer A: A* search.

AI18 defines A* by f(n)=g(n)+h(n), exactly as the long stem specifies. The sum estimates the cheapest solution through the node when h estimates remaining cost. Greedy ignores g, UCS ignores h, and DFS does not prioritize this sum, so none of those matches the stated evaluation.

Why each choice is right or wrong

A - Correct: A* adds actual cost-to-node g and estimated remaining cost h.

B - Incorrect: Greedy best-first uses only h and omits accumulated path cost.

C - Incorrect: UCS uses only g and does not add a remaining-cost heuristic.

D - Incorrect: DFS uses stack/depth ordering rather than minimum g+h.

Primary note proof

Study-note section AI18

> A* orders by f(n)=g(n)+h(n). Admissibility means 0≤h(n)≤h*(n), the true cheapest remaining cost. Consistency means h(n)≤c(n,n′)+h(n′) on every edge, with h(goal)=0; it implies admissibility on states with goal paths. Consistency makes f nondecreasing along a path.

Study-note section AI17

> Best-first is a family that orders OPEN by an evaluation function. Greedy best-first uses f=h and removes the smallest estimate, ignoring the cost already paid. It can choose an expensive route, loop without duplicate checks, or follow an infinite misleading branch. On a finite graph with full duplicate handling it is complete, but not generally optimal. Its implicit finite-tree worst case can be O(b^m).

Study-note section AI15

UCS uses a priority queue ordered by actual accumulated path cost g(n). Remove a minimum-g node; accept a goal when removed, not when first generated. Relax each edge: if a cheaper path is found, update its frontier cost and parent.

Study-note section AI14

DFS follows the deepest pending branch using a LIFO stack or recursion. FILO means the same order as LIFO. With the same children as BFS, a left-first DFS visits S,A,C before B; push rightmost children first to pop the leftmost first.

Question sources

Computer Science Exit Exam · 2018 · Question 52

Question 235 | NS0349

In which of the following Learning methods an agent receives feedback in the form of rewards or penalties to maximize cumulative reward?

A. Supervised learning

B. Reinforcement learning

C. Semi-supervised learning

D. Unsupervised learning

Hint

Identify the training feedback, prediction target or measured error. Keep learning objectives separate from model architecture and data modality.

Answer B: Reinforcement learning.

AI33 defines RL through interaction, rewards and improvement of a policy to maximize expected cumulative reward. The reward may be delayed and does not provide a correct-action label. Supervised and semi-supervised learning instead concern target labels, while unsupervised discovery lacks the defining action-reward interaction described here.

Why each choice is right or wrong

A - Incorrect: Supervised learning fits labeled targets rather than defining behavior through cumulative interaction rewards.

B - Correct: Reward or penalty feedback guiding cumulative-return improvement is the defining RL mechanism.

C - Incorrect: Semi-supervised learning mixes labeled and unlabeled examples, not necessarily action rewards.

D - Incorrect: Unsupervised learning discovers unlabeled structure rather than optimizing an interaction reward policy.

Primary note proof

Study-note section AI33

An RL agent observes state information, takes an action, receives reward and a new observation, and improves its policy to maximize expected cumulative reward. Rewards evaluate outcomes rather than supply the correct action label. Rewards may be delayed; not every correct-looking action receives immediate reward.

Study-note section AI31

Supervised learning fits a mapping from labeled input-target examples. Classification predicts discrete labels, such as institution generations or spam/nonspam; regression predicts numeric quantities, such as prices. Predictive analytics uses historical patterns to forecast outcomes and can use either. Specify the target before choosing a method.

Study-note section AI32

Semi-supervised learning combines some labels with additional unlabeled data. Active learning chooses informative cases for an oracle to label; it still uses labels. “Exploratory learning” is not an exclusive standard synonym: it can mean unsupervised exploration or active data acquisition, so define the feedback. A task named summarization or time-series analysis is not automatically supervised; its training targets determine that.

Study-note section AI32

Unsupervised learning seeks structure without target labels: clustering groups similar examples; association finds co-occurrence; dimensionality reduction compresses features. Good clusters have high within-cluster similarity and low between-cluster similarity under an appropriate distance. K-means alternates assignment to nearest centroids and centroid updates.

Computer Security

Questions & Worked Answers

171 questions

Question 1 | Q00002

Which one of the following is an attack performed by wiretapping a network and illicitly copy files and programs?

A. Interception

B. Fabrication

C. Interruption

D. Modification

Hint

Classify the action actually described and distinguish observation, alteration, disruption and identity claims.

Answer A: Interception

Wiretapping and copying give an unauthorized party access without changing or destroying the resource. This is the disclosure/interception case on PDF p.4.

Why each choice is right or wrong

A - Correct: Interception directly matches unauthorized snooping/access. See PDF p.4.

B - Incorrect: Fabrication inserts a fake resource; no insertion is described. See PDF p.4.

C - Incorrect: Interruption makes the resource unavailable; copying does not imply loss of service. See PDF p.4.

D - Incorrect: Modification changes the resource; no change is stated. See PDF p.4.

Primary note proof

Study-note section SEC03

> Interception copies or observes data, modification alters it, interruption blocks it, and fabrication inserts false material. The 4D classification uses disclosure, deception, disruption and usurpation, the last meaning unauthorized control. DoS primarily demonstrates disruption/availability loss; it need not give control of the victim.

Study-note section SEC03

> Passive attacks observe without changing the target exchange: sniffing and traffic analysis.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Security module | PDF page 4 | lines 50-61

• Types of Attacks on Data CIA (W. Stallings)
o Disclosure/Interception: unauthorized party snooping, or getting access to a resource, Attack on data confidentiality:
o Modification / Deception: unauthorized party modifying a resource, acceptance of false data, E.g., providing wrong data (attack on data integrity)
o Disruption/Interruption: destroyed/unavailable services/resources, DoS (attack on data availability)
o Fabrication: unauthorized party inserts a fake asset/resource, loss of confidentiality, authenticity and integrity of the message

Question sources

MOE Computer Science Exit Exam · 2016 · Question 2

Question 2 | Q00004

Assuming the UPS is correctly installed and operating normally, which listed item is a protective power-supply control rather than an environmental hazard?

A. Improperly placed heater

B. Humidity

C. Lightning strikes

D. UPS(uninterruptible power supply)

Hint

Start with the stated attacker path or physical hazard and the limits of each control.

Answer D: UPS(uninterruptible power supply)

A working UPS supplies temporary conditioned power and normally protects equipment against power problems. The other entries name heat-placement, humidity or electrical-surge hazards that can impair operation. The revised question assumes normal installation and operation only for the UPS, rather than claiming it can never cause harm. Battery faults and installation failures remain possible in general, but they are outside this stated comparison.

Why each choice is right or wrong

A - Incorrect: An improperly placed heater can expose equipment to damaging heat.

B - Incorrect: Humidity is an environmental condition requiring protection.

C - Incorrect: Lightning can produce damaging electrical surges.

D - Correct: A correctly installed, working UPS supplies protective conditioned power.

Primary note proof

Study-note section SEC11

Protect equipment against theft, unauthorized connections, heat, humidity, water, electrical surges and fire. A UPS supplies temporary conditioned power; it is normally protective, but faulty installation/battery failure can itself be hazardous. A disconnected machine loses many network attack paths yet remains exposed to insiders, removable media, supply-chain attacks and physical access. There is no universal “most secure computer” without a threat model.

Study-note section SEC11

Choose protection proportional to asset value and credible threats.

Study-note section SEC11

Uniform configurations simplify patching and prediction but create correlated failures; diversity may reduce common-mode compromise while raising administration cost.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Security module | PDF page 11 | lines 65-68

4. Physical security
• Without physical security to protect hardware (i.e., doors that lock) nothing else about a computer system can be called secure

Computer Security module | PDF page 4 | lines 89-99

o Encryption: primary control that protects CIA, by which Cleartext scambled into ciphertext.
o Software controls: password checker, virus scanner, IDS (intrusion detection system)
o Hardware controls: provide higher degree of security; Locks, Smart cards, dongles, hadware keys...
o Policies and procedures: Alignment with users’ legal and ethical standards; eg. password policy
o Physical controls: natural and man-made disaster protection; walls, locks, guards, security, cameras, backup copies and archives

Question sources

MOE Computer Science Exit Exam · 2016 · Question 4

Question 3 | Q00006

Awgichew wants message confidentiality for Meron using asymmetric encryption, not a signature. KPRIV-A/KPUB-A are Awgichew's keys and KPRIV-M/KPUB-M are Meron's keys. Which statements are NOT correct for that confidential exchange? Select all that apply.

A. Awgichew uses Meron's private key KPRIV-M to encrypt his plain text

B. Awgichew uses his KPUB-A to encrypt his plain text

C. Meron can decode the encrypted text using her KPRIV-M

D. Meron can decode the scrambled text using her KPUB-M

Hint

Identify the intended recipient or signer and separate confidentiality from verification.

Answer A, B, D: Awgichew uses Meron's private key KPRIV-M to encrypt his plain text; Awgichew uses his KPUB-A to encrypt his plain text; Meron can decode the scrambled text using her KPUB-M

For confidentiality to Meron, the sender encrypts with Meron's authenticated public encryption key and she decrypts with her private key. Awgichew should neither possess her private key nor encrypt to his own public key for a message only she should read. Her public key is not the secret decryption key. Thus A, B and D are incorrect directions; C describes the valid recipient decryption step and is not selected in this NOT-correct question.

Why each choice is right or wrong

A - Correct: Incorrect exchange step: the sender must not use or assume possession of Meron's private key.

B - Correct: Incorrect exchange step: encrypting to Awgichew's public key addresses the wrong recipient.

C - Incorrect: This is a valid decryption step, so it must not be selected as NOT correct.

D - Correct: Incorrect exchange step: Meron decrypts with her private key, not her public key.

Primary note proof

Study-note section SEC18

> For confidentiality to B, encrypt with B's authenticated public encryption key; B decrypts with B's private key. Do not encrypt to A's public key if only B should read it, and never assume A possesses B's private key. For a signature, A signs with A's private signing key and others verify with A's public key. These are distinct operations; not every public-key algorithm supports encryption.

Study-note section SEC18

> For one-way public-key confidentiality the sender need not own a key pair; it needs the recipient's authenticated public encryption key.

Study-note section SEC18

A sender key pair is needed when the protocol requires its signature or separate recipient role.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Security module | PDF page 8 | lines 61-76

Asymmetric key cryptography
• also known as public-key encryption.
• In public key cryptography,
o unlike symmetric-key, there are two keys: a private key and a public key.
✓ The public key is announced to the public; whereas the private key is kept by the receiver.
o anyone can send messages using the public key of the receiver for encryption, but only the receiver uses his private key for decryption
✓ Secret transmission of key for decryption is not required
✓ Every entity can generate a key pair and release its public key
✓ Encryption and decryption keys are different but form a unique pair

Computer Security module | PDF page 8 | lines 89-98

• Asymmetric-key cryptosystem Model
o Both users (Bob & Alice) generates a pair of keys
o Each user places one of 2 keys in public register.
✓ This is the public key: each user maintains a collection of public keys obtained from others.
o The companion key is kept private to each.
o If Alice wishes to send a confidential message to Bob, She encrypts the message using Bob's public key.
o When Bob receives the message, he decrypts it using his private key.

Question sources

MOE Computer Science Exit Exam · 2016 · Question 6

Question 4 | Q00009

In a two-way confidential exchange, both participants send and receive encrypted messages. Which statement correctly describes symmetric versus asymmetric encryption key arrangements?

A. Both use the same shared secret as their sole confidentiality key

B. Symmetric key requires the sender and receiver to have a public and private key

C. Asymmetric encryption requires each participant, acting as a recipient, to have its own public/private encryption key pair

D. Both are recovery methods

Hint

Identify the intended recipient or signer and separate confidentiality from verification.

Answer C: Asymmetric encryption requires each participant, acting as a recipient, to have its own public/private encryption key pair

Symmetric encryption uses a secret shared by the communicating parties. For public-key confidentiality, a sender encrypts to the recipient's authenticated public encryption key, and that recipient decrypts with its private key. Because both participants receive encrypted messages in this two-way scenario, each needs its own encryption key pair. A sender in a strictly one-way exchange would not need a pair merely to send. Neither architecture is defined as a recovery method.

Why each choice is right or wrong

A - Incorrect: False: a shared secret describes symmetric confidentiality, not the asymmetric key arrangement.

B - Incorrect: False: symmetric encryption does not require each party to have a public/private pair.

C - Correct: Correct: each participant is a recipient in one direction and needs its own public/private encryption pair.

D - Incorrect: False: encryption key arrangements protect communication; they are not recovery methods.

Primary note proof

Study-note section SEC18

> For one-way public-key confidentiality the sender need not own a key pair; it needs the recipient’s authenticated public encryption key. A sender key pair is needed when the protocol requires its signature or separate recipient role.

Study-note section SEC16

> Symmetric encryption uses a shared secret and efficiently protects bulk data.

Study-note section SEC18

For confidentiality to B, encrypt with B's authenticated public encryption key; B decrypts with B's private key.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Security module | PDF page 7 | lines 48-54

Symmetric key cryptography
• Uses conventional / secret-key / single-key.
• The secret key shared by both sender and receiver.
• All classical encryption algorithms are private-key.
o Use the same key (shared key) for encryption and decryption process.
• If this key is disclosed communications are compromised.

Computer Security module | PDF page 8 | lines 61-76

Asymmetric key cryptography
• also known as public-key encryption.
• In public key cryptography,
o unlike symmetric-key, there are two keys: a private key and a public key.
✓ The public key is announced to the public; whereas the private key is kept by the receiver.
o anyone can send messages using the public key of the receiver for encryption, but only the receiver uses his private key for decryption
✓ Secret transmission of key for decryption is not required
✓ Every entity can generate a key pair and release its public key
✓ Encryption and decryption keys are different but form a unique pair

Question sources

MOE Computer Science Exit Exam · 2016 · Question 9

Question 5 | Q00030

A cipher replaces each plaintext letter with the next letter in the alphabet, wrapping Z to A. Which is the most specific standard cipher classification of this operation?

A. Transliteration

B. Translation

C. Transformation

D. Substitution

Hint

Separate symbol replacement from position changes and apply the alphabet and modular direction.

Answer D: Substitution

The operation changes each symbol's identity while leaving its position in the message unchanged. That is substitution, and using the next alphabet letter is a fixed Caesar shift. General text-conversion descriptions do not identify this specific cipher class. Transformation is especially broad and could include many cryptographic or noncryptographic changes. D is therefore the most precise classification, rather than a claim that ordinary language can never describe encryption using broader terms.

Why each choice is right or wrong

A - Incorrect: Incorrect: transliteration does not identify the specified fixed-alphabet-shift cipher class.

B - Incorrect: Incorrect: translation does not identify the specific cipher class defined by replacing symbols while retaining positions.

C - Incorrect: Incorrect: transformation is a broader description and does not distinguish substitution from other changes.

D - Correct: Correct: replacing symbol identities while keeping their positions is substitution.

Primary note proof

Study-note section SEC13

> Substitution replaces symbols; transposition changes their positions. A monoalphabetic substitution preserves one mapping throughout the message and leaks frequency patterns despite a large nominal key space. Classical ciphers are teaching devices, not modern data protection.

Study-note section SEC13

> With A=0 through Z=25, Caesar encryption is C=(P+k) mod26 and decryption P=(C-k) mod26. A shift of 3 maps A→D and HELLO→KHOOR.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Security module | PDF page 6 | lines 19-28

> Substitution ciphers
> • Replaces one symbol with another.
> • Categories monoalphabetic or polyalphabetic ciphers.
> (1) Monoalphabetic Ciphers
> o The relationship between a symbols in the plaintext to a
> symbol in the ciphertext is always one-to-one.
> o sometimes called additive cipher or shift cipher or Caesar
> cipher (key of 3)

o When the cipher is additive, the plaintext, ciphertext, and key are integers in Z26.

Computer Security module | PDF page 6 | lines 73-78

Transposition Ciphers
• Does not substitute one symbol for another, instead it changes the location of the symbols (reorders symbols).
• A transposition cipher relies on an algorithm which rearranges the order of the letters in a plaintext message

Question sources

MOE Computer Science Exit Exam · 2016 · Question 30

Question 6 | Q00039

Which one of the following is an attack detection mechanism?

A. Physical control

B. Audit log

C. Password

D. Encryption

Hint

Distinguish weaknesses, potential harmful events, actual attempts and the effect of a control.

Answer B: Audit log

Logs preserve successful and failed authentication events (PDF p.4). Reviewing this evidence can determine that an attack occurred, matching the module's detection objective; the other listed controls primarily restrict or protect.

Why each choice is right or wrong

A - Incorrect: Physical controls protect facilities; this option does not specify monitoring evidence. See PDF p.4.

B - Correct: An audit log records relevant events for identifying attacks after or during occurrence. See PDF p.4.

C - Incorrect: A password checker controls entry rather than recording evidence of attack by itself. See PDF p.4.

D - Incorrect: Encryption scrambles cleartext; it does not by itself identify an attack. See PDF p.4.

Primary note proof

Study-note section SEC02

Preventive controls block events, detective controls reveal them, corrective/recovery controls restore safe operation, and deterrents discourage attempts. Encryption is preventive for disclosure; an audit log is principally detective/accountability evidence. Physical, technical and administrative are control categories, not competing stages. An external firewall cannot replace a written policy or a locked equipment room.

Study-note section SEC01

Authentication establishes an identity or other claim; authorization decides permitted actions.

Study-note section SEC01

Accountability links actions to responsible entities through reliable identity and protected logs.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Security module | PDF page 4 | lines 28-35

• Accountability
o Ensuring an entity's action is traceable uniquely to that entity.
o Ascertains the responsibility of an entity (like a person) for its actions and decisions.
o All relevant activities events and operations on a system, e.g., failed and successful authentication attempts, are recorded in a log.

Computer Security module | PDF page 4 | lines 82-84

o Detect attack: accept that an attack will occur; the goal is to determine that an attack is under way, or has occurred, and report it.

Computer Security module | PDF page 4 | lines 89-99

o Encryption: primary control that protects CIA, by which Cleartext scambled into ciphertext.
o Software controls: password checker, virus scanner, IDS (intrusion detection system)
o Hardware controls: provide higher degree of security; Locks, Smart cards, dongles, hadware keys...
o Policies and procedures: Alignment with users' legal and ethical standards; eg. password policy
o Physical controls: natural and man-made disaster protection; walls, locks, guards, security, cameras, backup copies and archives

Question sources

MOE Computer Science Exit Exam · 2016 · Question 39

Question 7 | Q00048

Which one of the following best describes for a program that seems friendly and legitimate but contains hidden malicious codes and harms a system?

A. Trojan

B. Malware

C. Virus

D. Worm

Hint

Separate propagation, disguise and payload when classifying malicious software.

Answer A: Trojan

The defining clue is apparent legitimacy hiding malicious behavior. SEC04 assigns that disguise property to a Trojan. Malware is the broad umbrella, while viruses and worms are distinguished by replication mechanisms. Because the stem asks what best describes the program, Trojan is more specific than the umbrella term and requires no unmentioned replication behavior.

Why each choice is right or wrong

A - Correct: A Trojan presents useful or legitimate behavior as cover for concealed malicious actions.

B - Incorrect: Malware is the broad umbrella and does not specifically capture the deceptive legitimate appearance asked for.

C - Incorrect: A virus is defined by attaching to a host and replicating, neither of which the stem specifies.

D - Incorrect: A worm independently replicates; that is different from the concealed malicious disguise described.

Primary note proof

Study-note section SEC04

> A virus replicates by attaching to a host program or document; execution of the infected host spreads it. A worm replicates independently, commonly across networks. A Trojan disguises malicious behavior as something useful and does not require self-replication. These labels describe different properties, so a malware package may contain several components.

Study-note section SEC04

> Malware is the umbrella term, not a specific replication method.

Study-note section SEC04

> Update, restrict execution, isolate compromise and maintain tested offline backups; no antivirus guarantees complete protection.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Security module | PDF page 5 | lines 21-35

• Malware Attack: A generic term for software that has
malicious purpose.
o Viruses
o Worms
o Trojan horses
o Spy-wares
o Zombie
o Botnets
o Bacterium
o Logic bomb
o Backdoor(Trapdoor)
o Adware
o Flooders (DoS client)
o Key loggers
o Rootkit

Question sources

MOE Computer Science Exit Exam · 2016 · Question 48

Question 8 | Q00055

A malicious program that once installed on your machine can collect all keystrokes including username, password, emails, credit card numbers and other sensitive information is:

A. Rootkit

B. Worms

C. Key logger

D. Trojan

Hint

Separate propagation, disguise and payload when classifying malicious software.

Answer C: Keylogger

SEC04 directly assigns keystroke recording to a keylogger. Recording every entered character can capture passwords and other secrets typed by the user. Rootkits hide malicious presence, worms replicate independently and Trojans conceal malicious behavior under useful appearances; none of those names specifically denotes keystroke collection.

Why each choice is right or wrong

A - Incorrect: A rootkit hides malicious presence or privileged activity; keystroke capture is not its defining function.

B - Incorrect: Worms are defined by independent replication, not by collecting typed information.

C - Correct: A keylogger records keystrokes and can capture the sensitive values entered through the keyboard.

D - Incorrect: A Trojan describes deceptive packaging; it does not specifically name the keystroke-recording function.

Primary note proof

Study-note section SEC04

> A virus replicates by attaching to a host program or document; execution of the infected host spreads it. A worm replicates independently, commonly across networks. A Trojan disguises malicious behavior as something useful and does not require self-replication. These labels describe different properties, so a malware package may contain several components.

Study-note section SEC04

> A backdoor bypasses ordinary access paths; a rootkit hides malicious presence or privileged activity.

Study-note section SEC04

> Spyware monitors users; a keylogger records keystrokes.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Security module | PDF page 5 | lines 21-35

> • Malware Attack: A generic term for software that has
> malicious purpose.
> o Viruses
> o Worms
> o Trojan horses
> o Spy-wares
> o Zombie
> o Botnets
> o Bacterium
> o Logic bomb
> o Backdoor(Trapdoor)

> • Reconnaissance: The hackers first identifies a target to
> launch an attack, extract maximum information regarding
> this target, understand its vulnerabilities, and then only
> explore the best ways to exploit it.

o Examples: Credential Theft using Keyloggers and Spyware; Identity Theft using spam e-mail, phishing attack and social engineering attack
• Access: Ones the attacker Reconnaissance the target, S/he starts a successful exploitation and continued access to the system. Then, the attacker is in control of the target.

Question sources

MOE Computer Science Exit Exam · 2016 · Question 55

Question 9 | Q00187

Which authentication factor class uses a characteristic of the user's body, such as a fingerprint?

A. One-factor authentication

B. Two-factor authentication

C. Inherence (biometric) factor

D. Forth-factor authentication

Hint

Separate identity claims from proof, and factor type from factor count.

Answer C: Inherence (biometric) factor

An inherence factor authenticates using a biometric characteristic such as a fingerprint. That describes a factor class, not a count of independent classes combined by a procedure. One biometric alone is one factor, and biometrics may also participate in multi-factor authentication. The option identifies the factor class, while the numerical alternatives do not identify the bodily characteristic being requested.

Why each choice is right or wrong

A - Incorrect: One factor is a count and does not specify whether the factor is biometric.

B - Incorrect: Two-factor authentication is a combination count, not the body-based factor class.

C - Correct: Inherence identifies the biometric factor class.

D - Incorrect: Four-factor authentication is a count rather than the requested factor class.

Primary note proof

Study-note section SEC07

Knowledge is a password/PIN, possession is a token/card, and inherence is a biometric such as a fingerprint. Behavioral biometrics include typing rhythm or handwriting; some textbooks call these "something one does." A body characteristic is not "three-factor authentication": one biometric is one factor. Password plus PIN remains one factor class; card plus PIN is two. An OTP's factor depends on its delivery/generation mechanism.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Security module | PDF page 11 | lines 74-79

• Most OS authentication is handled through user names and passwords. Biometric (e.g. voice, face, retina, iris, fingerprint) and physical token-based (swipe cards, pin-generating cards) authentication are sometimes used to augment simple passwords, but the costs and accuracy of the technology limit their adoption.

Computer Security module | PDF page 4 | lines 15-27

• Authentication
o is proving a claim - usually that you are who you say you are.
o for example it may be obtained by the provision of a password or by a scan of your retina.
• Access controls
o provide the limitation and control of access to authorized users through identification and authentication.
o A system needs to be able to identify and authenticate users for access to data, applications and hardware.
o In a large system there may be a complex structure determining which users and applications have access to which objects.

Question sources

Addis Ababa University mock exam · Question 89

Question 10 | Q00190

is a system that monitors traffic into and out of a network and automatically alerts personnel when
suspicious traffic patterns occur, indicating a possible unauthorized intrusion attempt.

A. Anti-Virus Software

B. IDS

C. Firewall

D. Router

SS

Hint

Separate observation from blocking and sensor placement from detection method.

Answer B: Intrusion detection system

The stem describes observing traffic and alerting on suspicious patterns rather than enforcing a block. SEC24 defines that as an IDS role. Antivirus focuses on malicious software, a firewall enforces traffic policy and a router forwards packets. A product can combine functions, but detection/alerting is the specific function requested.

Why each choice is right or wrong

A - Incorrect: Antivirus targets malicious software; it is not the generic traffic-pattern detection system defined by the stem.

B - Correct: An IDS observes activity and alerts personnel about suspected intrusion patterns.

C - Incorrect: A firewall's defining role is traffic-policy enforcement rather than the stated intrusion-alerting function.

D - Incorrect: A router forwards packets between networks and is not defined by suspicious-pattern alerting.

Primary note proof

Study-note section SEC24

> An IDS observes and alerts; an IPS can enforce blocking, usually inline. Host-based sensors examine host events, network-based sensors inspect traffic. Signature detection recognizes known patterns; anomaly detection compares with a baseline and may detect novel behavior. Neither guarantees every attack is detected; anomaly detection can raise many false positives, and signatures can sometimes match variants.

Study-note section SEC-S03

> A router forwards IP packets between networks; forwarding alone is different from detecting suspicious behavior or enforcing a firewall's security policy.

Study-note section SEC23

> A firewall enforces traffic policy.

3. Firewall
• a program or network devices (e.g. router) which filters access to a protected network from the internet connection.
• protects a local or network of systems from network-based security threats,
• monitors & controls incoming & outgoing network traffic based on predetermined security rules.
• Firewall Objectives
o Keep intruders, malicious code and unwanted traffic out
o Keep private and sensitive information in
o security wall b/n private (protected) NW & outside word.

Question sources

Addis Ababa University mock exam · Question 92

Computer Science Exit Exam · Sene 2016 · Question 21-3

Question 11 | Q00231

Which attack category is defined by exhausting or disabling operating-system services so legitimate users cannot obtain service, regardless of the mechanism used?

A. Buffer Overflow

B. Malware

C. Denial of Service

D. Network Intrusion

Hint

Match the resource bottleneck or wireless mechanism to the relevant protection layer.

Answer C: Denial of Service

Denial of service is defined by exhausting or disabling a resource so legitimate users cannot use it. A buffer overflow is a memory-bounds violation that can have several consequences, including a crash in some cases; malware names malicious software, and network intrusion concerns unauthorized entry. Any of those mechanisms could participate in a service-denial incident, but they are not the availability-outcome category requested by the stem. C supplies that category.

Why each choice is right or wrong

A - Incorrect: Incorrect: a buffer overflow writes beyond allocated bounds; it is a possible mechanism rather than the service-denial category.

B - Incorrect: Incorrect: malware is an umbrella class of malicious software, not the requested availability outcome.

C - Correct: Correct: denial of service exhausts or disables a resource and blocks legitimate service.

D - Incorrect: Incorrect: network intrusion concerns unauthorized entry; the requested category is loss of service.

Primary note proof

Study-note section SEC06

> DoS exhausts or disables a resource; distributed DoS uses multiple sources, often bots or reflected/amplified responses.

Study-note section SEC25

> A buffer overflow writes beyond allocated bounds and can corrupt data or control information; code execution is a possible consequence, not its definition or an inevitable outcome.

Study-note section SEC04

> Malware is the umbrella term, not a specific replication method.

Computer Security module | PDF page 5 | lines 42-47

> • Denial of Service (DoS) Attack: Blocking access from legitimate users
> • Distributed DoS Attack: is accomplished by tricking routers into attacking a target or using Zombie hosts to simultaneously attack a given target with large number of packets.

Question sources

Mock exam 4 · Question 33

Question 12 | Q00234

Which statement is false about network-traffic denial-of-service attacks? Treat NXDOMAIN flooding here as distributed and fragmentation as a fragment-flood attack rather than ordinary IP fragmentation.

A. Distributed NXDOMAIN flooding is a form of DDoS attack.

B. An IP fragment flood is a traffic-based attack.

C. DNS Flooding is a traffic-based attack.

D. TCP SYN Flooding is not a traffic-based attack.

Hint

Match the resource bottleneck or wireless mechanism to the relevant protection layer.

Answer D: TCP SYN Flooding is not a traffic-based attack.

The stated attacks exhaust resources through network traffic. Distributed NXDOMAIN flooding stresses resolver capacity using multiple sources; fragment floods abuse reassembly or packet-processing resources; DNS floods target query capacity. A SYN flood also uses network traffic, leaving incomplete TCP handshakes that consume connection state. Its mechanism differs from raw bandwidth exhaustion, but that does not make it non-traffic-based. D is therefore the false claim under the explicitly broad traffic-based meaning.

Why each choice is right or wrong

A - Incorrect: Multiple-source NXDOMAIN flooding qualifies as distributed denial of service.

B - Incorrect: Fragment flooding abuses processing or reassembly resources through traffic.

C - Incorrect: DNS flooding consumes query capacity through traffic.

D - Correct: SYN flooding is traffic-based, so this denial is false.

Primary note proof

Study-note section SEC06

> DoS exhausts or disables a resource; distributed DoS uses multiple sources, often bots or reflected/amplified responses. A SYN flood leaves many incomplete TCP handshakes occupying state. DNS flooding targets query capacity; NXDOMAIN attacks generate queries for nonexistent names to stress resolvers. Fragment floods abuse reassembly or packet-processing resources. Rate limits, SYN cookies, filtering and upstream capacity controls address different bottlenecks.

Question sources

Mock exam 4 · Question 36

Question 13 | Q00235

Which one of the following is true about Bell-LaPadula model security properties?

A. The * (star) Security Property states that a subject at a given security level may not read an object at a higher security level.

B. Users can create content only at or below their own security level (i.e. secret users can create secret or confidential files but may not create top secret files; no write-up).

C. The Strong Star Property states that subjects may write to objects with only a matching security level.

D. The Simple Security Property states that a subject at a given security level may not write to any object at a lower security level.

Hint

Apply the named model's read and write restrictions separately.

Answer C: Strong-star permits writes only at the matching level

SEC10 separates the properties: simple security is no read up, star is no write down and strong-star restricts writing to the same level. C correctly names the strong-star condition. A and D exchange the names of the simple and star properties, while B states no write up, contrary to Bell-LaPadula's confidentiality direction.

Why each choice is right or wrong

A - Incorrect: No read up is the simple-security rule, not the star property.

B - Incorrect: Bell-LaPadula prohibits writing down; this option instead asserts no write up and allows downward disclosure.

C - Correct: Strong-star permits writes only to objects at the subject's matching level.

D - Incorrect: No write down is the star rule, not the simple-security rule.

Primary note proof

Study-note section SEC10

Bell-LaPadula protects confidentiality. The simple-security rule prohibits reading above a subject's level; the star rule prohibits writing down. The strong-star variant permits writing only at the same level. With TS>S>C>U, an S subject can read C under the simple rule but cannot write C under star; compartments and discretionary restrictions may still deny access.

Study-note section SEC10

It is not a confidentiality model. “MAC” is an enforcement category and does not force every system to use Bell-LaPadula rather than another label policy.

Study-note section SEC10

Strict Biba protects integrity by preventing read down and write up: untrusted lower-integrity input should not contaminate higher-integrity results.

Module passages - related reading

Computer Security module | PDF page 4 | lines 15-27

• Authentication
o is proving a claim - usually that you are who you say you are.
o for example it may be obtained by the provision of a password or by a scan of your retina.
• Access controls
o provide the limitation and control of access to authorized users through identification and authentication.
o A system needs to be able to identify and authenticate users for access to data, applications and hardware.
o In a large system there may be a complex structure determining which users and applications have access to which objects.

Computer Security module | PDF page 11 | lines 80-87

6. Access control
• Since many systems (such as router access control lists) define which packets may and which packets may not pass based on the sender's IP address
• An access enforcement mechanism authorizes requests from multiple subjects (e.g. users, processes, etc.) to perform operations (e.g., read, write, etc.) on objects (e.g., files, sockets, etc.).

Question sources

Mock exam 4 · Question 37

Question 14 | Q00236

Which statement most precisely identifies the programming defect underlying a buffer overflow, rather than a possible exploit outcome or a broad claim about operating-system families?

A. An overflow may allow attacker-supplied instructions to execute

B. The age or family name of an operating system alone establishes that it contains an exploitable overflow

C. All other statements precisely define the underlying defect

D. Buffer-overflow may remain as a bug in apps if boundary checks are not done fully

Hint

Identify the unsafe operation or input boundary rather than only a possible consequence.

Answer D: Buffer-overflow may remain as a bug in apps if boundary checks are not done fully

A buffer overflow writes beyond allocated bounds. Missing or incomplete boundary checks can leave that defect in application code, which is the role described by D. Executing attacker-supplied code is a possible consequence, not the underlying definition or a necessary outcome. An operating-system family name or age alone does not establish a specific vulnerable component. The revised question distinguishes cause from consequence without endorsing unsupported historical vendor claims.

Why each choice is right or wrong

A - Incorrect: This is a possible consequence rather than the underlying bounds-checking defect requested.

B - Incorrect: A family name or age is not evidence of a specific exploitable out-of-bounds write.

C - Incorrect: The other statements are not all precise descriptions of the underlying defect.

D - Correct: Incomplete bounds checking can leave an application buffer-overflow bug.

Primary note proof

Study-note section SEC25

> A buffer overflow writes beyond allocated bounds and can corrupt data or control information; code execution is a possible consequence, not its definition or an inevitable outcome. An array of eight bytes cannot store eight text characters plus a terminating zero. Bounds-check lengths and indexes, consider integer overflow, use safe abstractions and validate library return values. Canaries, non-executable memory and address randomization reduce exploitability but do not repair the underlying write.

Study-note section SEC25

> Security patches repair known weaknesses; a zero-day may lack a vendor fix, but segmentation and other mitigations can still help.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Security module | PDF page 3 | lines 53-59

• Example: If a company has antivirus software but does not use an anti-virus and keep the virus signatures up-to-date, this is vulnerability. The company is vulnerable to virus attacks. Similarly, if you fail to routinely update your operating systems or application software, these will remain vulnerable to software problems ("bugs") that have been identified and patched

Computer Security module | PDF page 10 | lines 56-62

✓ Vulnerability Assessment: the process of scanning (locating & reporting) vulnerabilities to provide a way to detect and resolve security problems by ranking the vulnerabilities.
✓ Penetration Testing: an authorized simulated attack on a computer system, performed to evaluate the security of the system.

Question sources

Mock exam 4 · Question 38

Question 15 | Q00237

Which one of the following is true about Firewalls?

A. Prevent a TCP Session Hijacking attack

B. Prevent a virus or malicious code from entering to our network

C. Can be configured to limit access based on port number or protocol

D. Detects and prevent an attack if attacker is within our network segment

Hint

Identify which traffic is mediated and what information drives the device's decisions.

Answer C: Configure access limits by protocol and port

SEC23 explicitly gives protocol/port matching as a firewall function. It also describes bypass paths, insiders and infected removable media as limits, so firewall deployment does not guarantee all hijacking, malware or same-segment attacks are prevented. C is the configurable capability supported without those absolute guarantees.

Why each choice is right or wrong

A - Incorrect: A firewall does not universally prevent every session hijack, especially traffic outside its inspected or enforced paths.

B - Incorrect: Malware can arrive through bypass paths or permitted traffic; a firewall cannot guarantee excluding all malicious code.

C - Correct: Protocol and port fields can be matched in traffic-policy rules to restrict access.

D - Incorrect: An attacker sharing an internal segment may bypass the firewall's traffic path; detection/prevention is not guaranteed.

Primary note proof

Study-note section SEC23

A firewall enforces traffic policy. Stateless packet filtering matches headers such as source/destination, protocol and ports. Stateful inspection tracks permitted connection context; application proxies terminate and relay application exchanges and can inspect their content. A circuit gateway relays connections, commonly SOCKS, without full application-content interpretation; textbooks associate it with session/transport functions. Such a gateway need not encrypt and is not automatically a VPN.

Study-note section SEC23

Bypass paths, insiders, encrypted uninspected content and infected removable media limit firewall protection.

Study-note section SEC23

Stateful and next-generation devices can also filter ports; port filtering is not exclusive to one firewall category.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Security module | PDF page 11 | lines 22-34

3. Firewall
• a program or network devices (e.g. router) which filters access to a protected network from the internet connection.
• protects a local or network of systems from network-based security threats,
• monitors & controls incoming & outgoing network traffic based on predetermined security rules.
• Firewall Objectives
o Keep intruders, malicious code and unwanted traffic out
o Keep private and sensitive information in
o security wall b/n private (protected) NW & outside word.

Computer Security module | PDF page 11 | lines 35-56

• Categorizes of firewalls
a) Network firewalls: Filter traffic b/n two or more networks and run-on NW hardware.
✓ Implemented at a specific point in the network path and protects all computers on the internal side of the firewall from all computers on the external side of

the fire wall.
b) Host-based firewalls: Run on host computers and control network traffic in/out of those machines.
a) Packet Filtering Router: Examines TCP/IP header information of network data packets going in both directions. Applies set of rules to each incoming IP packets & then forwards or discards the packets.
b) Application-Level Gateway (application firewall / proxy server): runs special software that acts as a proxy for a service request. Proxy server receives requests for Web pages, accesses the Web server on behalf of the external client, and returns the requested pages to the users.
c)Circuit Level Gateway: Standalone Software that sets up two TCP connections (inside & outside). It determines which connections will be allowed.

Question sources

Mock exam 4 · Question 39

Question 16 | Q00238

Which one of the following is true about means of authentication?

A. Something the individual does: recognition by voice pattern, handwriting characteristics, and typing rhythm.

B. Something the individual possesses: fingerprint, retina, and face.

C. Something the individual is: electronic keycards, smart cards, and physical keys.

D. Something the individual knows: possess a token.

Hint

Separate identity claims from proof, and factor type from factor count.

Answer A: Behavioral characteristics: voice/handwriting/typing patterns

SEC07 distinguishes knowledge, possession and inherence, and recognizes behavioral biometrics under the textbook “does” category. A matches that classification, including handwriting and typing rhythm. The remaining options exchange possession and biometrics or call a possessed token knowledge. Voice-pattern recognition is biometric behavior/characteristic recognition, not possession of an external object.

Why each choice is right or wrong

A - Correct: The examples describe biometric behavior/patterns consistent with the textbook something-one-does category.

B - Incorrect: Fingerprints, retina and face are body characteristics, not possessed token/card objects.

C - Incorrect: Keycards, smart cards and physical keys are possession factors, not inherent body characteristics.

D - Incorrect: Possessing a token is a possession factor; knowledge means a secret such as a password or PIN.

Primary note proof

Study-note section SEC07

> Knowledge is a password/PIN, possession is a token/card, and inherence is a biometric such as a fingerprint. Behavioral biometrics include typing rhythm or handwriting; some textbooks call these “something one does.” A body characteristic is not “three-factor authentication”: one biometric is one factor. Password plus PIN remains one factor class; card plus PIN is two. An OTP’s factor depends on its delivery/generation mechanism.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Security module | PDF page 11 | lines 74-79

> • Most OS authentication is handled through user names and passwords. Biometric (e.g. voice, face, retina, iris, fingerprint) and physical token-based (swipe cards, pin-generating cards) authentication are sometimes used to augment simple passwords, but the costs and accuracy of the technology limit their adoption.

Question sources

Mock exam 4 · Question 40

Question 17 | Q00269

Which one of the following pairs is incorrect?

A. IP Spoofing - IPSec

B. TCP Session Hijacking - TLS

C. DNS Cache Poisoning - DNSSEC

D. Buffer overflow - HTTPS

Hint

Match the resource bottleneck or wireless mechanism to the relevant protection layer.

Answer D: HTTPS does not fix buffer overflows

SEC06 matches protections to the attacked layer: authenticated IPsec can resist IP impersonation, DNSSEC authenticates DNS data and TLS protects application transport against interception/tampering. HTTPS is HTTP over TLS; it cannot make an unsafe server memory copy bounds-safe. Thus D is the mismatched attack/defense pairing, without treating the other mechanisms as unconditional guarantees.

Why each choice is right or wrong

A - Incorrect: Authenticated IPsec can resist IP impersonation, so this is a relevant defense pairing.

B - Incorrect: TLS protects authenticated transport against interception/tampering relevant to session hijacking, under correct endpoint validation.

C - Incorrect: DNSSEC authenticates DNS data and is relevant to resisting false cached DNS answers.

D - Correct: HTTPS protects the channel but does not repair writes beyond a server buffer's allocated bounds.

Primary note proof

Study-note section SEC06

> Rogue access points imitate or bypass approved wireless service. Bluesnarfing steals Bluetooth information; bluejacking sends unsolicited Bluetooth messages. Phishing is not specific to wireless. Match a defense to its layer: authenticated IPsec can resist IP impersonation, DNSSEC authenticates DNS data, TLS authenticates/protects application transport, and bounds-safe code prevents overflows. HTTPS cannot fix an unsafe memory copy in a server.

Study-note section SEC25

> A buffer overflow writes beyond allocated bounds and can corrupt data or control information; code execution is a possible consequence, not its definition or an inevitable outcome.

Study-note section SEC21

> It protects HTTP paths, headers and content on the channel, but does not hide all metadata such as IP endpoints and traffic timing, nor protect data after a compromised endpoint decrypts it.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Security module | PDF page 8 | lines 61-76

> Asymmetric key cryptography
> • also known as public-key encryption.
> • In public key cryptography,
> o unlike symmetric-key, there are two keys: a private key and a public key.
> ✓ The public key is announced to the public; whereas the private key is kept by the receiver.

o anyone can send messages using the public key of the receiver for encryption, but only the receiver uses his private key for decryption
✓ Secret transmission of key for decryption is not required
✓ Every entity can generate a key pair and release its public key
✓ Encryption and decryption keys are different but form a unique pair

Question sources

Mock exam 4 · Question 71

Question 18 | Q00341

Which statement is NOT a property of integrity under the primary CIA-goal classification?

A. Integrity can be compromised by Deception

B. Integrity can be compromised by Disclosure

C. Requires permitted modifications to be authorized

D. Protects resources against unauthorized alteration

Hint

Identify the property harmed: disclosure, improper change, unavailable service or lack of reliable attribution.

Answer B: Integrity can be compromised by Disclosure

Integrity concerns the correctness of information and protection against unauthorized or improper changes. False data introduced through deception, unauthorized alteration and violations of modification permissions can therefore threaten integrity. Pure disclosure means an unauthorized party learns information without changing it; that directly violates confidentiality. Availability instead concerns timely, usable access. Classifying the direct effect avoids treating every active attack as an integrity attack or assuming that one incident can affect only one security goal.

Why each choice is right or wrong

A - Incorrect: An integrity concern: deception can introduce false information and corrupt correctness.

B - Correct: Correct selection: pure disclosure directly compromises confidentiality rather than integrity.

C - Incorrect: An integrity concern: modification permissions distinguish authorized changes from unauthorized ones.

D - Incorrect: An integrity concern: unauthorized alteration directly damages information correctness.

Primary note proof

Study-note section SEC01

Confidentiality restricts disclosure: copying a credit-card database violates secrecy even if the original stays intact. Integrity restricts unauthorized or improper changes: altering a balance or inserting a false message damages correctness. Availability supplies timely, usable service to authorized users: crashes, resource starvation and denied access violate it. One event can harm several goals.

Study-note section SEC03

The 4D classification uses disclosure, deception, disruption and usurpation, the last meaning unauthorized control.

Study-note section SEC03

Active attacks inject, alter, replay or disrupt.

University of Gondar model exam · Question 72

Question 19 | Q00342

Assume, you went to the Ethiopian airport to catch a flight and told the airport personnel your name. For sure, they would ask you some questions like your passport number and your reservation ticket number for some proof of your identity. Then what do we call this process?

A. Authentication

B. Authorization

C. Access control

D. All

Hint

Separate identity claims from proof, and factor type from factor count.

Answer A: Authentication

The passenger first claims a name, then is asked for evidence supporting that identity. Proving who one claims to be is authentication (PDF p.4), rather than deciding what the passenger may do.

Why each choice is right or wrong

A - Correct: Passport/ticket evidence tests the claimed identity. See PDF p.4.

B - Incorrect: Authorization would grant permissions after establishing identity. See PDF p.4.

C - Incorrect: Access control is the broader restriction mechanism, while the described step is identity proof. See PDF p.4.

D - Incorrect: All incorrectly treats permission decisions as already described. See PDF p.4.

Primary note proof

Study-note section SEC07

> A common access sequence is identify the subject, authenticate the claim, authorize the operation, then record relevant events. Identification is the username/claim, not its proof. When a sequence begins with authentication, distinguish it from the preceding identification stage. User-to-host means a user proves identity to a host; host-to-user means the host proves its identity to a user; the arrow names the prover and verifier.

Question 20 | Q00343

Assume, you went to the nearby commercial bank's automatic teller machine (ATM) to withdraw money. You inserted your ATM card into the machine, and the machine asked you to enter your personal identification number (PIN). Then, when you type your password, someone intercepts your ATM card number, and which of your security goals is compromised?

A. Integrity

B. Authorization

C. Confidentiality

D. Availability

Hint

Identify the property harmed: disclosure, improper change, unavailable service or lack of reliable attribution.

Answer C: Confidentiality

Intercepting the ATM number discloses information to an unauthorized party. The module maps interception to confidentiality (PDF pp.3-4); neither data alteration nor service denial is described.

Why each choice is right or wrong

A - Incorrect: No modification is stated. See PDF p.3, PDF p.4.

B - Incorrect: The event is disclosure rather than a permission-granting decision. See PDF p.3, PDF p.4.

C - Correct: Unauthorized learning of the card number compromises confidentiality. See PDF p.3, PDF p.4.

D - Incorrect: The user is not said to lose timely access to service. See PDF p.3, PDF p.4.

Primary note proof

Study-note section SEC01

Confidentiality restricts disclosure: copying a credit-card database violates secrecy even if the original stays intact. Integrity restricts unauthorized or improper changes: altering a balance or inserting a false message damages correctness. Availability supplies timely, usable service to authorized users: crashes, resource starvation and denied access violate it. One event can harm several goals.

Study-note section SEC07

Password plus PIN remains one factor class; card plus PIN is two.

Study-note section SEC07

Knowledge is a password/PIN, possession is a token/card, and inherence is a biometric such as a fingerprint.

Question sources

Computer Science model exam · Question 74

University of Gondar model exam · Question 74

Question 21 | Q00344

Which attack can be used for monitoring children's activity?

A. Spyware

B. Ransomwares

C. Worms

D. Adware

Hint

Separate propagation, disguise and payload when classifying malicious software.

Answer A: Spyware-like monitoring capability

The capability described is monitoring user activity, which SEC04 associates with spyware. Ransomware locks or encrypts for extortion, worms replicate and adware displays unwanted advertisements. SEC05 adds an important context limit: monitoring with authorization is not automatically an attack. A matches the functionality, but the child-monitoring use alone does not establish malicious intent.

Why each choice is right or wrong

A - Correct: Spyware’s monitoring function matches collection of user activity, subject to the authorization caveat.

B - Incorrect: Ransomware denies access and extorts payment rather than primarily monitoring user activity.

C - Incorrect: A worm independently replicates; monitoring is not the defining capability.

D - Incorrect: Adware primarily displays unwanted advertisements, although some packages may also track activity.

Primary note proof

Study-note section SEC04

A virus replicates by attaching to a host program or document; execution of the infected host spreads it. A worm replicates independently, commonly across networks. A Trojan disguises malicious behavior as something useful and does not require self-replication. These labels describe different properties, so a malware package may contain several components.

Study-note section SEC04

Adware displays unwanted advertising and may also track users.

Study-note section SEC04

Ransomware denies access through encryption/locking and extortion.

Computer Security module | PDF page 5 | lines 65-74

• Reconnaissance: The hackers first identifies a target to launch an attack, extract maximum information regarding this target, understand its vulnerabilities, and then only explore the best ways to exploit it.
o Examples: Credential Theft using Keyloggers and Spyware; Identity Theft using spam e-mail, phishing attack and social engineering attack
• Access: Ones the attacker Reconnaissance the target, S/he starts a successful exploitation and continued access to the system. Then, the attacker is in control of the target.

Question sources

Computer Science model exam · Question 75

University of Gondar model exam · Question 75

Question 22 | Q00345

_____is a type of data link layer attack in TCP/IP protocol stack

A. ARP spoofing

B. DNS spoofing

C. SYNC-FLOOD attack

D. All except c

Hint

Identify the trust claim or communication mapping being abused.

Answer A: ARP spoofing

ARP spoofing targets the local mapping between IPv4 and link-layer MAC addresses, making A the data-link-oriented attack among these choices. DNS spoofing targets name resolution rather than local link associations, and SYN flooding abuses TCP handshake state. D incorrectly includes DNS spoofing in the data-link category.

Why each choice is right or wrong

A - Correct: ARP spoofing poisons the local IPv4-to-MAC mapping at the network/link addressing boundary.

B - Incorrect: DNS spoofing falsifies name-resolution data rather than manipulating the local data-link association.

C - Incorrect: The likely SYN-flood reference concerns TCP handshake state at transport scope, not link addressing.

D - Incorrect: This includes DNS spoofing, which is not a data-link mapping attack.

Primary note proof

Study-note section SEC05

> Masquerade claims another identity. ARP spoofing poisons local IPv4-to-MAC associations; DNS spoofing/cache poisoning supplies false name resolutions; IP spoofing falsifies a source address. An intermediary attack intercepts and can alter exchanges. A replay reuses a valid old message; nonces, timestamps and sequence checks can reject it. Session hijacking steals or predicts a valid session token. Protect transport, regenerate session IDs after login, restrict cookies and check authorization server-side on every sensitive request.

Study-note section SEC06

> A SYN flood leaves many incomplete TCP handshakes occupying state.

Study-note section SEC06

DNS flooding targets query capacity; NXDOMAIN attacks generate queries for nonexistent names to stress resolvers.

Question sources

Computer Science model exam · Question 76

University of Gondar model exam · Question 76

Question 23 | Q00346

Which statement correctly distinguishes the host-program dependence of viruses and worms? Here 'host' means a carrier program or document, not a computer.

A. Worms requires a host to spread while viruses doesn't require

B. Worms requires a user action for replicate while viruses doesn't require

C. Virus requires a host to spread while Worms doesn't require

D. Worms spreading speed is slower than Virus Spreading speed

Hint

Separate propagation, disguise and payload when classifying malicious software.

Answer C: Virus requires a host to spread while Worms doesn't require

A virus replicates by attaching to a carrier program or document and spreading when that infected host executes. A worm replicates independently of such a carrier. This makes C the correct direction and makes A a reversal. B wrongly makes user action a defining requirement for worm replication while denying the virus's dependence on infected-host execution. D proposes a general speed ranking, which is not a defining consequence of either replication mechanism.

Why each choice is right or wrong

A - Incorrect: Incorrect: this reverses the definitions; viruses need carrier programs/documents and worms replicate independently.

B - Incorrect: Incorrect: independent worm replication does not require a user to launch each copy; virus propagation depends on infected-host execution.

C - Correct: Correct: viruses attach to carrier hosts, whereas worms replicate independently of such carriers.

D - Incorrect: Incorrect: propagation speed does not follow from the carrier-versus-independent distinction and cannot define the requested host dependence.

Primary note proof

Study-note section SEC04

A virus replicates by attaching to a host program or document; execution of the infected host spreads it. A worm replicates independently, commonly across networks. A Trojan disguises malicious behavior as something useful and does not require self-replication. These labels describe different properties, so a malware package may contain several components.

Question sources

Computer Science model exam · Question 77

University of Gondar model exam · Question 77

Question 24 | Q00358

Which general security-control category enforces allow/block rules for incoming and outgoing network traffic? Choose the functional security category rather than a general forwarding or relay role.

A. Proxy

B. Firewall

C. Gateway

D. Router

Hint

Identify which traffic is mediated and what information drives the device's decisions.

Answer B: Firewall

A firewall is the general control that enforces a network traffic policy, allowing or blocking traffic according to rules. A router's basic role is forwarding IP packets; a proxy relays application requests, and gateway is a broader connection or mediation term. These devices can include firewall capabilities, so their hardware or networking names alone do not make mutually exclusive implementations. The stem asks for the functional security category, which makes firewall the precise answer.

Why each choice is right or wrong

A - Incorrect: A proxy's general role is relaying application exchanges; it may also implement firewall policy but is not the general category requested.

B - Correct: Correct: firewall names the general traffic-policy enforcement control.

C - Incorrect: Gateway is a broad networking or mediation role and does not by itself specify security-rule enforcement.

D - Incorrect: A router forwards IP packets; filtering added to a router is a firewall function rather than an implication of routing alone.

Primary note proof

Study-note section SEC23

> A firewall enforces traffic policy. Stateless packet filtering matches headers such as source/destination, protocol and ports. Stateful inspection tracks permitted connection context; application proxies terminate and relay application exchanges and can inspect their content. A circuit gateway relays connections, commonly SOCKS, without full application-content interpretation; textbooks associate it with session/transport functions. Such a gateway need not encrypt and is not automatically a VPN.

Study-note section SEC-S03

> A router forwards IP packets between networks; forwarding alone is different from detecting suspicious behavior or enforcing a firewall's security policy.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Security module | PDF page 11 | lines 22-34

3. Firewall
• a program or network devices (e.g. router) which filters access to a protected network from the internet connection.
• protects a local or network of systems from network-based security threats,
• monitors & controls incoming & outgoing network traffic based on predetermined security rules.
• Firewall Objectives
o Keep intruders, malicious code and unwanted traffic out
o Keep private and sensitive information in
o security wall b/n private (protected) NW & outside word.

Computer Security module | PDF page 11 | lines 35-56

• Categorizes of firewalls
a) Network firewalls: Filter traffic b/n two or more networks and run-on NW hardware.
✓ Implemented at a specific point in the network path and protects all computers on the internal side of the firewall from all computers on the external side of the fire wall.
b) Host-based firewalls: Run on host computers and control network traffic in/out of those machines.
a) Packet Filtering Router: Examines TCP/IP header information of network data packets going in both directions. Applies set of rules to each incoming IP packets & then forwards or discards the packets.
b) Application-Level Gateway (application firewall / proxy server): runs special software that acts as a proxy for a service request. Proxy server receives requests for Web pages, accesses the Web server on behalf of the external client, and returns the requested pages to the users.
c)Circuit Level Gateway: Standalone Software that sets up two TCP connections (inside & outside). It determines which connections will be allowed.

Question sources

Computer Science model exam · Question 89

University of Gondar model exam · Question 88

Question 25 | Q00642

Firewall in computer network is

A. physical boundary of network

B. an operating system of network

C. A system designed to prevent unauthorized access

D. A web browsing software

Hint

Identify which traffic is mediated and what information drives the device's decisions.

Answer C: A system designed to prevent unauthorized access

A firewall enforces rules controlling network traffic to prevent unauthorized access. It may be software or a network device and therefore need not be a physical boundary. An operating system is not the name of this specific traffic-policy function, and a web browser requests or displays web content rather than serving as the general network-access enforcement control. C captures the firewall's security purpose, subject to the normal limits of configured rules and available inspection.

Why each choice is right or wrong

A - Incorrect: Incorrect: traffic-policy enforcement is a logical control and need not be a physical boundary.

B - Incorrect: Incorrect: firewall names the traffic-policy enforcement function, not an entire network operating system.

C - Correct: Correct: preventing unauthorized network access through traffic rules is the firewall purpose.

D - Incorrect: Incorrect: browsing web content is different from enforcing network traffic policy.

Primary note proof

Study-note section SEC23

> A firewall enforces traffic policy. Stateless packet filtering matches headers such as source/destination, protocol and ports. Stateful inspection tracks permitted connection context; application proxies terminate and relay application exchanges and can inspect their content. A circuit gateway relays connections, commonly SOCKS, without full application-content interpretation; textbooks associate it with session/transport functions. Such a gateway need not encrypt and is not automatically a VPN.

Question sources

Computer Science model exam · 2015 · Question 111

Question 26 | Q00914

Assume that we are able to specify that Mr. Getahun can view the database record, but cannot change the value of the record. Which security management technique was used in this scenario?

A. Access Control

B. Availability

C. ¢.
Non-repudiation

D. Integrity

Hint

Identify subject, object and permitted operation before comparing policy models.

Answer A: Access Control

Permitting read while denying write is a subject/object/operation permission assignment, exactly the access-enforcement model (PDF p.11). Integrity is a protected goal, not the mechanism requested.

Why each choice is right or wrong

A - Correct: Access control authorizes particular operations on an object. See PDF p.3, PDF p.11.

B - Incorrect: Availability means timely usable service and access for authorized users (PDF page3), rather than selecting the allowed operation on a particular record.

C - Incorrect: Non-repudiation concerns proving an event or action so sender or receiver cannot deny it (PDF page4), rather than assigning read/write permissions.

D - Incorrect: Integrity is the desired protection against unauthorized changes, not the permission-setting mechanism. See PDF p.3, PDF p.11.

Primary note proof

Study-note section SEC09

Subjects request operations on objects. An ACL associates an object/resource with allowed subjects or actions; a network ACL matches traffic such as address, protocol and port. Classification and filtering are direct effects; high availability or malware detection is not guaranteed by an ACL.

Study-note section SEC01

Availability supplies timely, usable service to authorized users: crashes, resource starvation and denied access violate it.

Study-note section SEC09

Allowing SELECT but denying UPDATE is an access-control decision that helps integrity; it does not by itself enforce all valid business-state transitions.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Security module | PDF page 11 | lines 80-87

6. Access control
• Since many systems (such as router access control lists) define which packets may and which packets may not pass based on the sender's IP address
• An access enforcement mechanism authorizes requests from multiple subjects (e.g. users, processes, etc.) to perform operations (e.g., read, write, etc.) on objects (e.g., files, sockets, etc.).

Computer Security module | PDF page 3 | lines 79-86

• Integrity: covers Data integrity and System integrity
o the prevention of unauthorized writing or modification of information.
o Integrity in a computer system means that there is an external consistency in the system - everything is as it is expected to be.
o Data integrity: the data stored on the computer is the same as what is intended.

Computer Security module | PDF page 4 | lines 5-13

Additional objectives:
• Non-repudiation: is the prevention of either the sender or the receiver denying a transmitted message.
o It is the ability to prove the occurrence of a claimed event or action and its originating entities
o It assures that a sender of data is provided with proof of delivery and the recipient is provided with proof of the

sender's identity, so neither can later deny having processed the data.

Computer Security module | PDF page 3 | lines 87-91

• Availability:
o Assures that systems work promptly and service is not denied to authorized users.
o Information should be accessible and usable upon appropriate demand by an authorized user.

Question sources

Computer Science Exit Exam · 2018 · Question 27

Question 27 | Q00920

Which statement is NOT true about digital signatures?

A. A digital signature is not, by itself, a confidentiality-encryption mechanism

B. The sender signs a message or its encoded digest using its private signing key

C. The sender generates a digital signature using its public verification key

D. Digital signature provides authentication services

Hint

Separate a digest, shared-secret authentication and publicly verifiable signing.

Answer C: The sender generates a digital signature using its public verification key

A digital signature is generated with the signer's private signing key and checked with the corresponding public verification key. Signing may operate on a message or an encoded digest, depending on the algorithm. It is not generically private-key encryption, and it does not by itself hide the message. Under an authentic key binding and secure private-key custody, verification supports origin authentication and integrity. The public verification key cannot generate the signer's signature, making C false.

Why each choice is right or wrong

A - Incorrect: True: a signature supports origin and integrity checks without itself concealing the content.

B - Incorrect: True: signature generation uses the private signing key on the message or its encoded digest.

C - Correct: Correct selection: the public verification key verifies signatures; it does not generate them.

D - Incorrect: True: signature verification supports origin authentication under the stated key-binding assumptions.

Primary note proof

Study-note section SEC20

A signature algorithm signs a message or its encoded digest with a private key and verifies with the public key. It is not generically “encrypting with a private key,” especially for DSA/ECDSA. Verification checks origin/integrity under key-identity and key-custody assumptions; it does not conceal content. Password verification uses a salt and deliberately expensive password hash. Historical MD5/SHA-1 examples do not justify their use for new collision-resistant signatures.

Study-note section SEC18

For a signature, A signs with A’s private signing key and others verify with A’s public key.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Security module | PDF page 10 | lines 7-20

(4) Digital Signature Algorithm (DSA):
o PKI relies on DS, which uses public key cryptography.
o The basic idea is that private key is only known by
that entity & used for signing.
✓ Public key derived from it: used for verifying
signatures but cannot be used to sign.
✓ It is available to anyone, and is typically included in
the certificate document.
o Digital Signature procedure
• Sender encrypts message with its private key
• Receiver can decrypt using sender’s public key
• This authenticates sender, who has the matching key
• Does not give privacy of data i.e. Decrypt key is
public key.

Question sources

Computer Science Exit Exam · 2018 · Question 33

Question 28 | Q00923

Which one of the following party performs the technical evaluation work, using the evidence supplied by the developers, and additional testing of the product, to confirm that it satisfies the functional and assurance requirements specified in the security target?

A. Evaluator

B. Certifier

C. Sponsor

D. Developer

Hint

Distinguish requirements, technical evaluation, evidence and certification decisions.

Answer A: Evaluator

SEC29 assigns technical examination of developer evidence, testing and vulnerability analysis against Security Target claims to evaluators. The certification body oversees/reviews evaluation and issues the certification decision; sponsors commission the work and developers supply the product/evidence. A therefore names the party performing the actual technical evaluation rather than those adjacent roles.

Why each choice is right or wrong

A - Correct: Evaluators review developer evidence and perform tests/analysis against the stated functional and assurance claims.

B - Incorrect: The certifier oversees/reviews evaluation and issues the certification decision rather than being the named technical evaluator.

C - Incorrect: The sponsor commissions the work; that role does not itself perform the technical evaluation.

D - Incorrect: The developer supplies the product and supporting evidence for independent examination.

Primary note proof

Study-note section SEC29

> Under Common Criteria, define the Target of Evaluation (TOE), its configuration and environment. A Security Target (ST) states threats, assumptions, objectives, functional requirements and assurance requirements; a Protection Profile describes reusable requirements for a product category. Evaluators examine developer evidence, test and analyze vulnerabilities against those claims. A certification body oversees/reviews the evaluation and issues the certification decision; sponsors commission work and developers supply product/evidence.

Study-note section SEC29

> A certificate applies to a specified product/configuration and claims, not immunity to all future attacks.

Study-note section SEC29

> An Evaluation Assurance Level packages assurance requirements; EAL1-7 express increasing evaluation rigor, not a universal ranking of security functions.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Security module | PDF page 10 | lines 56-62

> ✓ Vulnerability Assessment: the process of scanning
> (locating & reporting) vulnerabilities to provide a
> way to detect and resolve security problems by

ranking the vulnerabilities.
✓ Penetration Testing: an authorized simulated attack on a computer system, performed to evaluate the security of the system.

Computer Security module | PDF page 10 | lines 85-90

o Penetration Test (pen test):
✓ To identify both weaknesses (vulnerabilities) & strengths, to enable a full risk assessment.
✓ Determine whether a system is vulnerable, defenses were sufficient and which defenses (if any) the test defeated.

Question sources

Computer Science Exit Exam · 2018 · Question 36

Question 29 | Q00941

Compare two incidents at Registrar X. In incident I, Negesa composes a fresh request and presents it as coming from Dereje. In incident II, Negesa retransmits, without changing it, a valid request that Dereje genuinely sent earlier. Which statement correctly distinguishes the observed attack mechanisms?

A. I makes the registrar unavailable, whereas II leaves the service available.

B. I alters the content of Dereje's existing request, whereas II leaves that request unchanged.

C. I creates a fresh message under Dereje's identity, whereas II repeats Dereje's authentic old message.

D. I repeats an authentic old message, whereas II creates a fresh message under a false identity.

Hint

Compare the claimed origin, message freshness and whether an existing message was changed.

Answer C: I creates a fresh message under Dereje's identity, whereas II repeats Dereje's authentic old message.

Incident I introduces a newly composed message under another person's identity, which is masquerade. Incident II reuses a valid old message, which is replay. The relevant distinction is false origin for a fresh message versus reuse of an authentic earlier one. Neither incident describes service denial, and I does not modify an existing request. D reverses the two histories. Replay can also support impersonation in a larger attack, so this comparison classifies the specific observed mechanisms.

Why each choice is right or wrong

A - Incorrect: Neither history includes service exhaustion or interruption; service availability does not distinguish these incidents.

B - Incorrect: I creates a new request rather than altering an existing one; message modification is a different mechanism.

C - Correct: I's fresh false-origin request demonstrates masquerade, while II's unchanged reuse of an authentic earlier request demonstrates replay.

D - Incorrect: This reverses the observed histories: II reuses the old request, while I creates the fresh false-origin request.

Primary note proof

Study-note section SEC05

Masquerade claims another identity.

Study-note section SEC05

A replay reuses a valid old message; nonces, timestamps and sequence checks can reject it.

Study-note section SEC03

Interception copies or observes data, modification alters it, interruption blocks it, and fabrication inserts false material.

Study-note section SEC06

DoS exhausts or disables a resource; distributed DoS uses multiple sources, often bots or reflected/amplified responses.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Security module | PDF page 4 | lines 50-61

• Types of Attacks on Data CIA (W. Stallings)
o Disclosure/Interception: unauthorized party snooping, or getting access to a resource, Attack on data confidentiality:
o Modification / Deception: unauthorized party modifying a resource, acceptance of false data, E.g., providing wrong data (attack on data integrity)
o Disruption/Interruption: destroyed/unavailable services/resources, DoS (attack on data availability)
o Fabrication: unauthorized party inserts a fake asset/resource, loss of confidentiality, authenticity and integrity of the message

Computer Security module | PDF page 5 | lines 65-74

• Reconnaissance: The hackers first identifies a target to launch an attack, extract maximum information regarding this target, understand its vulnerabilities, and then only explore the best ways to exploit it.
o Examples: Credential Theft using Keyloggers and

Spyware; Identity Theft using spam e-mail, phishing attack and social engineering attack
• Access: Ones the attacker Reconnaissance the target, S/he starts a successful exploitation and continued access to the system. Then, the attacker is in control of the target.

Question sources

Computer Science Exit Exam · 2018 · Question 54

Question 30 | Q00963

Which general security-control category enforces allow/block rules on incoming and outgoing network traffic? Choose the general enforcement category rather than a relay, tunnel or observing role.

A. Intrusion detection system (IDS)

B. Proxy server

C. Virtual Private Network (VPN)

D. Firewall

Hint

Identify which traffic is mediated and what information drives the device's decisions.

Answer D: Firewall

A firewall is the general traffic-policy enforcement category that permits or blocks traffic under rules. An IDS observes and alerts, whereas a proxy relays application requests and may additionally implement policy. A VPN establishes a logical private connection whose security depends on its tunnel; that does not itself define allow/block filtering. Because implementations can combine these functions, the revised stem asks for the general enforcement category rather than treating all device types as mutually exclusive.

Why each choice is right or wrong

A - Incorrect: Incorrect: an IDS observes and alerts; the requested role enforces traffic permission decisions.

B - Incorrect: Incorrect: proxy names an application-relay role, even when a particular proxy also implements firewall policy.

C - Incorrect: Incorrect: a VPN provides a logical private connection; that role alone does not specify allow/block traffic enforcement.

D - Correct: Correct: firewall names the general traffic-policy enforcement category.

Primary note proof

Study-note section SEC23

A firewall enforces traffic policy. Stateless packet filtering matches headers such as source/destination, protocol and ports. Stateful inspection tracks permitted connection context; application proxies terminate and relay application exchanges and can inspect their content. A circuit gateway relays connections, commonly SOCKS, without full application-content interpretation; textbooks associate it with session/transport functions. Such a gateway need not encrypt and is not automatically a VPN.

Study-note section SEC24

An IDS observes and alerts; an IPS can enforce blocking, usually inline.

Study-note section SEC22

A VPN is a logical private connection; its actual security depends on the chosen authenticated tunnel.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Security module | PDF page 11 | lines 22-34

3. Firewall
• a program or network devices (e.g. router) which filters access to a protected network from the internet connection.
• protects a local or network of systems from network-based security threats,
• monitors & controls incoming & outgoing network traffic based on predetermined security rules.
• Firewall Objectives
o Keep intruders, malicious code and unwanted traffic out
o Keep private and sensitive information in
o security wall b/n private (protected) NW & outside word.

Computer Security module | PDF page 11 | lines 35-56

• Categorizes of firewalls
a) Network firewalls: Filter traffic b/n two or more networks and run-on NW hardware.
✓ Implemented at a specific point in the network path and protects all computers on the internal side of the firewall from all computers on the external side of the fire wall.
b) Host-based firewalls: Run on host computers and control network traffic in/out of those machines.
a) Packet Filtering Router: Examines TCP/IP header information of network data packets going in both directions. Applies set of rules to each incoming IP packets & then forwards or discards the packets.
b) Application-Level Gateway (application firewall /

proxy server): runs special software that acts as a proxy for a service request. Proxy server receives requests for Web pages, accesses the Web server on behalf of the external client, and returns the requested pages to the users.
c)Circuit Level Gateway: Standalone Software that sets up two TCP connections (inside & outside). It determines which connections will be allowed.

Computer Security module | PDF page 4 | lines 89-99

o Encryption: primary control that protects CIA, by which Cleartext scambled into ciphertext.
o Software controls: password checker, virus scanner, IDS (intrusion detection system)
o Hardware controls: provide higher degree of security; Locks, Smart cards, dongles, hadware keys...
o Policies and procedures: Alignment with users' legal and ethical standards; eg. password policy
o Physical controls: natural and man-made disaster protection; walls, locks, guards, security, cameras, backup copies and archives

Question sources

Computer Science Exit Exam · 2018 · Question 76

Question 31 | Q00972

Which one of the following is WRONGLY stated about an importance of security policy?

A. To help minimize risk.

B. To ensure the confidentiality, integrity and availability of data.

C. .
To coordinate and enforce a security program across an organization.

D. To use the system in a passive way

Hint

Distinguish organizational rules, operational steps and recovery goals.

Answer D: To use the system in a passive way

A security policy regulates resource protection (PDF p.3); assurance reduces risk and preserves protection goals (p.2). Merely using a system passively neither establishes protection rules nor coordinates enforcement.

Why each choice is right or wrong

A - Incorrect: Minimizing risk is consistent with regulating protection. See PDF p.2, PDF p.3.

B - Incorrect: Protecting CIA is consistent with security and assurance goals. See PDF p.2, PDF p.3.

C - Incorrect: Coordinating and enforcing organizational protection is consistent with a common rule set. See PDF p.2, PDF p.3.

D - Correct: Passive system use is not a security-policy purpose derived from the definition. See PDF p.2, PDF p.3.

Primary note proof

Study-note section SEC33

> A security policy states responsibilities and rules; a procedure supplies the steps. Policies coordinate protection, reduce risk and define acceptable use, access review, incident handling and recovery. They do not prescribe merely “passive system use.” Awareness training teaches reporting and independent verification; enforcement and usable procedures make it operational.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Security module | PDF page 3 | lines 41-43

> • Security Policy: A set of rules and practices that specify or regulate how a system or organization protects sensitive and critical system resources.

Computer Security module | PDF page 2 | lines 77-83

> • IA: measures that protect and defend information and ISs by ensuring their availability, integrity, authentication, confidentiality, and non-repudiation.
> • Information protection or InfoSec: protection of information and ISs from unauthorized access, use, disclosure, disruption, modification, perusal, inspection, recording or destruction.

Question sources

Computer Science Exit Exam · 2018 · Question 85

Question 32 | Q00975

Which one of the following computer security goal prevents the disclosure of sensitive information to unauthorized users or systems on computer networks?

A. Confidentiality

B. Integrity

C. Cyberspace

D. Availability

Hint

Identify the property harmed: disclosure, improper change, unavailable service or lack of reliable attribution.

Answer A: Confidentiality

The stem restates prevention of unauthorized disclosure, the confidentiality definition on PDF p.3. It asks about secrecy rather than correctness or access timing.

Why each choice is right or wrong

A - Correct: Confidentiality is explicitly prevention of unauthorized disclosure. See PDF p.3.

B - Incorrect: Integrity prevents unauthorized writing/modification. See PDF p.3.

C - Incorrect: Cyberspace is not one of the module's CIA goals. See PDF p.3.

D - Incorrect: Availability assures usable access for authorized users. See PDF p.3.

Primary note proof

Study-note section SEC01

> Confidentiality restricts disclosure: copying a credit-card database violates secrecy even if the original stays intact. Integrity restricts unauthorized or improper changes: altering a balance or inserting a false message damages correctness. Availability supplies timely, usable service to authorized users: crashes, resource starvation and denied access violate it. One event can harm several goals.

Study-note section SEC01

> Data security protects information at rest, in use and in transit, including accidental corruption as well as intentional attacks.

Study-note section SEC01

> Information assurance includes confidence, risk management, protection, detection, response and restoration across the information lifecycle.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Security module | PDF page 3 | lines 71-78

• Confidentiality: Data confidentiality and Privacy
o is the prevention of unauthorized disclosure of information.
o In other words, confidentiality means keeping information private or safe.
o it may be important for military, business or personal reasons.
o it may also be known as privacy or secrecy.

Computer Security module | PDF page 3 | lines 79-86

• Integrity: covers Data integrity and System integrity
o the prevention of unauthorized writing or modification of information.
o Integrity in a computer system means that there is an external consistency in the system - everything is as it is expected to be.
o Data integrity: the data stored on the computer is the same as what is intended.

Computer Security module | PDF page 3 | lines 87-91

• Availability:
o Assures that systems work promptly and service is not denied to authorized users.
o Information should be accessible and usable upon appropriate demand by an authorized user.

Question sources

Computer Science Exit Exam · 2018 · Question 88

Question 33 | Q01175

Which of the following primarily provides detective evidence that can reveal an attack, rather than preventing access or disclosure?

A. Access Control

B. Encryption

C. Audit log

D. Password authentication

Hint

Distinguish weaknesses, potential harmful events, actual attempts and the effect of a control.

Answer C: Audit log

An audit log records events that can reveal suspicious activity during review or analysis and can support accountability. Its primary role in this comparison is detective evidence. Access control restricts permitted actions, password authentication checks an identity claim, and encryption limits disclosure to unauthorized readers. These are principally preventive roles in the question's comparison. A log does not automatically block an attack, and its usefulness depends on reliable recording, protection and analysis.

Why each choice is right or wrong

A - Incorrect: Access control primarily prevents actions that exceed a subject's permissions.

B - Incorrect: Encryption primarily prevents unauthorized disclosure rather than revealing attack activity through event records.

C - Correct: Correct: an audit log provides event evidence that can reveal attacks and support accountability.

D - Incorrect: Password authentication primarily checks identity before access; it is not the offered detective event record.

Primary note proof

Study-note section SEC02

> Preventive controls block events, detective controls reveal them, corrective/recovery controls restore safe operation, and deterrents discourage attempts. Encryption is preventive for disclosure; an audit log is principally detective/accountability evidence. Physical, technical and administrative are control categories, not competing stages. An external firewall cannot replace a written policy or a locked equipment room.

Study-note section SEC07

> Knowledge is a password/PIN, possession is a token/card, and inherence is a biometric such as a fingerprint.

Study-note section SEC07

> A common access sequence is identify the subject, authenticate the claim, authorize the operation, then record relevant events.

Study-note section SEC09

> Least privilege gives only needed rights, for needed time.

Related reading (context, not primary note proof)

Study-note section SEC12

Module passages - related reading

Computer Security module | PDF page 4 | lines 28-35

• Accountability
o Ensuring an entity's action is traceable uniquely to that entity.
o Ascertains the responsibility of an entity (like a person) for its actions and decisions.
o All relevant activities events and operations on a system, e.g., failed and successful authentication attempts, are recorded in a log.

Computer Security module | PDF page 4 | lines 82-84

o Detect attack: accept that an attack will occur; the goal is to determine that an attack is under way, or has occurred, and report it.

Computer Security module | PDF page 4 | lines 89-99

o Encryption: primary control that protects CIA, by which Cleartext scambled into ciphertext.
o Software controls: password checker, virus scanner, IDS (intrusion detection system)
o Hardware controls: provide higher degree of security; Locks, Smart cards, dongles, hadware keys...
o Policies and procedures: Alignment with users' legal and ethical standards; eg. password policy
o Physical controls: natural and man-made disaster protection; walls, locks, guards, security, cameras, backup copies and archives

Question sources

Computer Science Exit Exam practice questions · Question 36

Question 34 | Q01189

The process of recovering the original message without the detailed knowledge of the secret information is called:

A. Decryption

B. Decipher

C. Cryptanalysis

D. A and B

Hint

Trace message transformations and separate data, keys, algorithms and codebreaking.

Answer C: Cryptanalysis

PDF p.6 distinguishes decryption (recovering plaintext) from cryptanalysis (breaking ciphertext without the key). The explicit absence of secret knowledge selects cryptanalysis.

Why each choice is right or wrong

A - Incorrect: Decryption is ordinary plaintext recovery and omits the without-key distinction. See PDF p.6.

B - Incorrect: Decipher is the same ordinary recovery operation. See PDF p.6.

C - Correct: Cryptanalysis explicitly concerns breaking ciphertext without knowing the key. See PDF p.6.

D - Incorrect: Combining two ordinary recovery synonyms does not supply the required without-key meaning. See PDF p.6.

Primary note proof

Study-note section SEC12

> Plaintext is the original message, ciphertext its encrypted representation, a key is input to an algorithm, encryption computes C=E_k(P), and decryption recovers P=D_k(C). The five conventional symmetric ingredients are plaintext, encryption algorithm, secret key, ciphertext and decryption algorithm. Cryptanalysis seeks recovery or other breaks without the authorized secret; cryptology includes cryptography and cryptanalysis. Steganography hides that a message exists; encryption hides its meaning.

Study-note section SEC12

> Security depends on algorithm, key size, randomness, mode and implementation.

Question sources

Computer Science model exam 2 · Question 10

Question 35 | Q01203

Which of the following statements is true about crackers?

A. They attempt to break the system without permissions

B. They are legally employed to break into the system

C. They reveal the information after breaking into the system

D. All

Hint

Classify the action actually described and distinguish observation, alteration, disruption and identity claims.

Answer A: They attempt to break the system without permissions

Cracking is malicious hacking; intrusion is unauthorized access (PDF p.5). By contrast authorized simulated attacks are penetration testing (p.10). A matches unauthorized breaking, and neither legal employment nor later disclosure defines a cracker.

Why each choice is right or wrong

A - Correct: Attempted unauthorized system breaking matches malicious intrusion. See PDF p.5, PDF p.10.

B - Incorrect: Legally authorized testing belongs to penetration testing, not the definition of cracking. See PDF p.5, PDF p.10.

C - Incorrect: Revealing information afterward is not a necessary defining property of malicious intrusion. See PDF p.5, PDF p.10.

D - Incorrect: B and C are not defining truths, so All cannot hold. See PDF p.5, PDF p.10.

Primary note proof

Study-note section SEC03

> White-hat testing requires authorization and scope; black-hat activity is malicious or unauthorized. A competitor may seek commercial secrets; hacktivists pursue a cause. “Hacker” alone does not establish legality. Insider versus outsider describes origin/trust position, not the specific mechanism.

Study-note section SEC27

> Vulnerability assessment finds and prioritizes weaknesses; authorized penetration testing attempts to demonstrate consequences.

Study-note section SEC27

> Host/network/database scanners see different exposures and have false results.

These source passages provide context; the primary note proof is identified separately above.

Computer Security module | PDF page 5 | lines 37-43

• Hacking /Intrusion/ Attack: any attempt to intrude or gain unauthorized access to your system either via some operating system flaw or other means. The purpose may or may not be for malicious purposes.
• Cracking: is hacking conducted for malicious purposes.
• Denial of Service (DoS) Attack: Blocking access from legitimate users

Computer Security module | PDF page 10 | lines 56-62

✓ Vulnerability Assessment: the process of scanning (locating & reporting) vulnerabilities to provide a way to detect and resolve security problems by ranking the vulnerabilities.
✓ Penetration Testing: an authorized simulated attack on a computer system, performed to evaluate the security of the system.

Question sources

Computer Science model exam 2 · Question 24

Question 36 | Q01207

Which basic firewall category makes stateless decisions from packet-header fields such as protocol and port numbers, without tracking connection state or terminating an application exchange?

A. Packet Filtering

B. Proxy Service

C. Stateful Inspection

D. Threat-Focused NGFW

Hint

Identify which traffic is mediated and what information drives the device's decisions.

Answer A: Packet Filtering

Stateless packet filtering matches packet headers such as addresses, protocol and ports. Stateful inspection adds connection context, while an application proxy terminates and relays application exchanges. Next-generation products can also filter ports, but that capability alone does not make them the basic stateless header-only category requested. The additional constraints distinguish the model rather than incorrectly claiming port filtering is exclusive to one product type.

Why each choice is right or wrong

A - Correct: This is the stateless header-matching category.

B - Incorrect: A proxy terminates and relays application exchanges.

C - Incorrect: Stateful inspection tracks connection context, which the stem excludes.

D - Incorrect: A next-generation firewall is not the basic header-only stateless category requested.

Primary note proof

Study-note section SEC23

A firewall enforces traffic policy. Stateless packet filtering matches headers such as source/destination, protocol and ports. Stateful inspection tracks permitted connection context; application proxies terminate and relay application exchanges and can inspect their content. A circuit gateway relays connections, commonly SOCKS, without full application-content interpretation; textbooks associate it with session/transport functions. Such a gateway need not encrypt and is not automatically a VPN.

Study-note section SEC23

Stateful and next-generation devices can also filter ports; port filtering is not exclusive to one firewall category.

Study-note section SEC23

Hardware firewall does not imply any fixed number of ports.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Security module | PDF page 11 | lines 35-56

• Categorizes of firewalls
a) Network firewalls: Filter traffic b/n two or more networks and run-on NW hardware.
✓ Implemented at a specific point in the network path and protects all computers on the internal side of the firewall from all computers on the external side of the fire wall.
b) Host-based firewalls: Run on host computers and control network traffic in/out of those machines.
a) Packet Filtering Router: Examines TCP/IP header information of network data packets going in both directions. Applies set of rules to each incoming IP packets & then forwards or discards the packets.
b) Application-Level Gateway (application firewall / proxy server): runs special software that acts as a proxy for a service request. Proxy server receives requests for Web pages, accesses the Web server on behalf of the external client, and returns the requested pages to the users.
c)Circuit Level Gateway: Standalone Software that sets up two TCP connections (inside & outside). It determines which connections will be allowed.

Question sources

Computer Science model exam 2 · Question 28

Question 37 | Q01213

What will be the encrypted message if the message "ATTACK" is encrypted by Caesar's cipher with key = 25?

A. ZSSZBJ

B. ZGGZXP

C. ZTTZAK

D. BGGBDL

Hint

Separate symbol replacement from position changes and apply the alphabet and modular direction.

Answer A: ZSSZBJ

Using the additive shift on Z26 (PDF p.6), take A=0 and encryption C=(P+25) mod 26. ATTACK gives (0,19,19,0,2,10) -> (25,18,18,25,1,9) -> ZSSZBJ. This is a one-position backward shift because 25=-1 mod 26.

Why each choice is right or wrong

A - Correct: ZSSZBJ agrees at all six positions. See PDF p.6.

B - Incorrect: ZGGZXP has correct initial A->Z but T->G instead of S. See PDF p.6.

C - Incorrect: ZTTZAK leaves T unchanged and maps C incorrectly. See PDF p.6.

D - Incorrect: BGGBDL begins A->B, a forward-one shift rather than +25. See PDF p.6.

Primary note proof

Study-note section SEC13

> Substitution replaces symbols; transposition changes their positions. A monoalphabetic substitution preserves one mapping throughout the message and leaks frequency patterns despite a large nominal key space. Classical ciphers are teaching devices, not modern data protection.

Study-note section SEC13

> With A=0 through Z=25, Caesar encryption is C=(P+k) mod26 and decryption P=(C-k) mod26.

Study-note section SEC13

> Key25 moves back one: ATTACK→ZSSZBJ.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Security module | PDF page 6 | lines 19-28

Substitution ciphers
• Replaces one symbol with another.
• Categories monoalphabetic or polyalphabetic ciphers.
(1) Monoalphabetic Ciphers
o The relationship between a symbols in the plaintext to a symbol in the ciphertext is always one-to-one.
o sometimes called additive cipher or shift cipher or Caesar cipher (key of 3)
o When the cipher is additive, the plaintext, ciphertext, and key are integers in Z26.

Question sources

Computer Science model exam 2 · Question 34

Question 38 | Q01247

All are properties of a substitution cipher except:

A. The identity of the letters is changed in the encryption process.

B. The position of the letters is changed in the encryption process.

C. Uses the same key for the encryption and decryption process.

D. It has a secure key distribution problem.

Hint

Separate symbol replacement from position changes and apply the alphabet and modular direction.

Answer B: The position of the letters is changed in the encryption process.

Substitution replaces symbol identities; transposition changes positions (PDF p.6). Classical encryption is shared-key with a key-distribution problem (p.7), so position change is the exception in the standard pure-substitution model.

Why each choice is right or wrong

A - Incorrect: Changing letter identity is the defining substitution action. See PDF p.6, PDF p.7.

B - Correct: Changing letter positions defines transposition, not pure substitution. See PDF p.6, PDF p.7.

C - Incorrect: The module classifies classical encryption as shared-key encryption/decryption. See PDF p.6, PDF p.7.

D - Incorrect: The module explains the need to distribute the shared secret securely. See PDF p.6, PDF p.7.

Primary note proof

Study-note section SEC13

Substitution replaces symbols; transposition changes their positions. A monoalphabetic substitution preserves one mapping throughout the message and leaks frequency patterns despite a large nominal key space. Classical ciphers are teaching devices, not modern data protection.

Study-note section SEC16

Symmetric encryption uses a shared secret and efficiently protects bulk data.

Study-note section SEC16

Pairwise independent keys for n users require n(n-1)/2 shared keys; a trusted key distribution center changes that architecture.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Security module | PDF page 6 | lines 19-28

Substitution ciphers
• Replaces one symbol with another.
• Categories monoalphabetic or polyalphabetic ciphers.
(1) Monoalphabetic Ciphers
o The relationship between a symbols in the plaintext to a symbol in the ciphertext is always one-to-one.
o sometimes called additive cipher or shift cipher or Caesar cipher (key of 3)
o When the cipher is additive, the plaintext, ciphertext, and key are integers in Z26.

Computer Security module | PDF page 6 | lines 73-78

Transposition Ciphers
• Does not substitute one symbol for another, instead it changes the location of the symbols (reorders symbols).
• A transposition cipher relies on an algorithm which rearranges the order of the letters in a plaintext message

Computer Security module | PDF page 7 | lines 48-54

Symmetric key cryptography
• Uses conventional / secret-key / single-key.
• The secret key shared by both sender and receiver.
• All classical encryption algorithms are private-key.
o Use the same key (shared key) for encryption and decryption process.
• If this key is disclosed communications are compromised.

Computer Security module | PDF page 7 | lines 69-79

• 2 requirements for secure use of symmetric encryption:
o Strong encryption algorithm: i.e., Y = EK(X)
o Secret key known only to sender / receiver: i.e. X = DK(Y)
• Assume encryption algorithm is known
o Implies a secure channel to distribute key:
✓ Problem: - Key distribution problem
• Key Distribution
o Symmetric schemes require both parties to share a common secret key.
o Issue is how to securely distribute this key.

Question sources

Computer Science model exam 2 · Question 68

Question 39 | Q01282

Which statement is true? Assume a correctly used one-time pad and repeated-key Vigenère; compare the general cryptographic methods rather than one specially chosen implementation.

A. A correctly used one-time pad provides perfect secrecy, unlike repeated-key Vigenère

B. Symmetric key cryptography has a slow encryption process than asymmetric key encryption technique

C. Hill cipher remains secure even with enough independent known plaintext/ciphertext blocks

D. All of the above

Hint

Check the precise ordering or key-use assumptions rather than relying on a cipher's name.

Answer A: A correctly used one-time pad provides perfect secrecy, unlike repeated-key Vigenère

A one-time pad has perfect secrecy only under its strict randomness, secrecy, length and nonreuse conditions; repeated-key Vigenère leaks periodic structure. Symmetric encryption supplies efficient bulk protection, while public-key mechanisms commonly handle keys in hybrid designs, so B reverses the general efficiency account. Hill is linear: enough independent known blocks allow recovery of its key matrix, contradicting C. Because B and C are false, the all-of-the-above selection is false and A is correct.

Why each choice is right or wrong

A - Correct: Correct: the stated pad conditions provide perfect secrecy; repeated-key Vigenère has periodic structure.

B - Incorrect: Incorrect: symmetric encryption is the efficient bulk-data component; the proposed general slowdown reverses that role in hybrid protection.

C - Incorrect: Incorrect: Hill's linear rule permits recovery of K = C P^-1 mod 26 from sufficient independent known blocks.

D - Incorrect: Incorrect: B and C are false, so not all statements hold.

Primary note proof

Study-note section SEC15

A one-time pad XORs bits with an independent uniformly random secret key at least as long as the message and never reused. Its perfect secrecy depends on every condition.

Study-note section SEC14

The same plaintext letter may encrypt differently by position; repeated short keys still leak periodic structure.

Study-note section SEC14

It is linear: enough independent known plaintext/ciphertext blocks reveal K=CP^-1 mod26.

Study-note section SEC16

Symmetric encryption uses a shared secret and efficiently protects bulk data.

Study-note section SEC18

Hybrid systems establish or encapsulate a symmetric secret with public-key mechanisms, then protect bulk data symmetrically.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Security module | PDF page 6 | lines 63-72

o Vigenere Cipher
o Exercise:
✓ Encrypt the message —She is listening‖ using the 6-character keyword —PASCAL‖.
✓ The initial key stream is (15, 0, 18, 2, 0, 11). The key stream is the repetition of this initial key stream (as many times as needed)
o Hill Cipher:
✓ Key in the Hill cipher: The key matrix in the Hill cipher needs to have a multiplicative inverse.

Computer Security module | PDF page 8 | lines 4-20

• Given parties A and B have various key distribution alternatives:
o A can select key and physically deliver to B.
o Third party can select & deliver key to A & B.
o If A & B have communicated previously can use previous key to encrypt a new key.

o If A & B have secure communications with a third-party C, C can relay key between A & B.
• Key Hierarchy
o session key
✓ temporary key
✓ used for encryption of data between users
✓ for one logical session then discarded
o master key
✓ used to encrypt session keys
✓ shared by user & key distribution center
• Advantage: Simpler and faster

Question sources

Computer Science model exam 2 · Question 103

Question 40 | Q01509

An access control mechanism which works by comparing security labels with security clearances

A. Mandatory Access Control

B. Attribute Based Access Control

C. Discretionary Access Control

D. Role Based Access Control

Hint

Identify subject, object and permitted operation before comparing policy models.

Answer A: Mandatory Access Control

Security labels and clearances identify the mandatory policy mechanism in SEC09, elaborated for multilevel databases in SEC32. Owners cannot override that centrally enforced label policy. RBAC assigns role permissions and DAC allows owner grants; generic ABAC can evaluate attributes, but the specified clearance/classification mechanism is the named mandatory control model.

Why each choice is right or wrong

A - Correct: Mandatory control compares classifications/clearances under a policy ordinary owners cannot override.

B - Incorrect: ABAC evaluates general attributes; the named security-label/clearance mechanism specifically identifies mandatory control.

C - Incorrect: DAC allows owners to grant permissions rather than enforcing nonoverridable classification labels.

D - Incorrect: RBAC bases permissions on roles and user-role assignments rather than security-label clearance comparisons.

Primary note proof

Study-note section SEC09

Subjects request operations on objects. An ACL associates an object/resource with allowed subjects or actions; a network ACL matches traffic such as address, protocol and port. Classification and filtering are direct effects; high availability or malware detection is not guaranteed by an ACL.

Study-note section SEC09

DAC lets owners grant permissions; mandatory control enforces labels and policy that ordinary owners cannot override.

Study-note section SEC32

A multilevel database stores items at different labels and enforces mandatory policy using subject clearances, classifications and compartments.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Security module | PDF page 11 | lines 80-87

6. Access control
• Since many systems (such as router access control lists) define which packets may and which packets may not pass based on the sender's IP address
• An access enforcement mechanism authorizes requests from multiple subjects (e.g. users, processes, etc.) to perform operations (e.g., read, write, etc.) on objects (e.g., files, sockets, etc.).

Computer Security module | PDF page 11 | lines 88-100

• Network access control (NAC): is an umbrella term for managing access to a net-work. NAC authenticates users logging into the network and determines what data they can access and actions they can perform. NAC also examines the health of the user’s computer or mobile device (the endpoints).
• An operating system provides an access enforcement mechanism.
• Two fundamental concepts of access control:
o a protection system that defines the access control specification and
o a reference monitor that is the system’s access enforcement mechanism that enforces this specification.

Question sources

Mock exam 1 · Question 25

Question 41 | Q01510

An attack in which the DNS queries are wrongly resolved in order to redirect the users to a malicious website.

A. DNS Flooding attack

B. NXDomain attack

C. SNMP Reflection attack

D. DNS Hijacking attack

Hint

Identify the trust claim or communication mapping being abused.

Answer D: DNS hijacking/spoofed resolution

Wrong name-to-address answers redirecting users match falsified DNS resolution, described as spoofing/cache poisoning in SEC05 and called hijacking in D. DNS and NXDOMAIN floods instead stress query capacity; they need not provide a malicious replacement destination. No SNMP reflection mechanism is described by the stem.

Why each choice is right or wrong

A - Incorrect: DNS flooding exhausts query-processing capacity rather than specifically supplying false destination records.

B - Incorrect: NXDOMAIN attacks generate nonexistent-name queries to stress resolvers, not the false successful answers described.

C - Incorrect: The stem describes DNS answer manipulation, not reflected traffic using a different management protocol.

D - Correct: Hijacking DNS resolution redirects a name to an attacker-controlled destination through false resolution data.

Primary note proof

Study-note section SEC05

> Phishing impersonates a trusted source to obtain secrets or induce an unsafe action; spear phishing targets a specific person. Verify a request through an independently known channel. Shoulder surfing observes entry; pretexting invents a reason for disclosure. Monitoring software used with authorization is not necessarily an attack merely because it records activity.

Study-note section SEC06

> DNS flooding targets query capacity; NXDOMAIN attacks generate queries for nonexistent names to stress resolvers.

Study-note section SEC05

> ARP spoofing poisons local IPv4-to-MAC associations; DNS spoofing/cache poisoning supplies false name resolutions; IP spoofing falsifies a source address.

Module passages - related reading

Computer Security module | PDF page 5 | lines 42-47

> • Denial of Service (DoS) Attack: Blocking access from legitimate users
> • Distributed DoS Attack: is accomplished by tricking routers into attacking a target or using Zombie hosts to simultaneously attack a given target with large number of packets.

Computer Security module | PDF page 5 | lines 65-74

> • Reconnaissance: The hackers first identifies a target to launch an attack, extract maximum information regarding this target, understand its vulnerabilities, and then only explore the best ways to exploit it.
> o Examples: Credential Theft using Keyloggers and Spyware; Identity Theft using spam e-mail, phishing attack and social engineering attack
> • Access: Ones the attacker Reconnaissance the target, S/he starts a successful exploitation and continued access to the system. Then, the attacker is in control of the target.

Question sources

Mock exam 1 · Question 26

Question 42 | Q01511

The term injection attack refers to a wide variety of program flaws related to invalid handling of input data. Which one of the following is not a type of injection attack?

A. Cross site scripting

B. Input fuzzing

C. SQL injection

D. Command injection

Hint

Locate where untrusted data can become instructions and where they execute.

Answer B: Input fuzzing is testing, not an injection-attack category

SEC26 directly distinguishes fuzzing from injection: fuzzing varies unexpected inputs to discover defects. SQL injection changes SQL syntax and XSS introduces attacker-controlled script into a browser context. Command injection likewise names unsafe interpretation of input as commands. Fuzzing may discover those defects but does not itself identify that attack mechanism.

Why each choice is right or wrong

A - Incorrect: XSS injects attacker-controlled script/content into a browser execution context, so it is an injection-type attack.

B - Correct: Input fuzzing is a technique for finding faults with varied unexpected inputs, not an injection category.

C - Incorrect: SQL injection explicitly alters query syntax through unsafe handling of untrusted values.

D - Incorrect: Command injection names untrusted input interpreted as executable commands rather than merely a testing technique.

Primary note proof

Study-note section SEC26

> SQL injection occurs when untrusted values alter SQL syntax through unsafe string construction. A tautology can change which rows match. Bind data values in prepared statements, allow-list identifiers that cannot be parameters, and restrict the application's database account. Stored procedures/ORMs are safe only when they avoid unsafe dynamic SQL.

Study-note section SEC26

> Fuzzing sends unexpected inputs to discover faults; it is a testing technique, not itself a category of injection.

Study-note section SEC-S01

> This is an injection flaw in command interpretation, unlike fuzzing, which supplies varied inputs to discover defects.

Question sources

Mock exam 1 · Question 27

Mock exam 2 · Question 22

Question 43 | Q01590

Using the convention prover-to-verifier, which statement correctly describes the direction of an authentication setting?

A. Host-to-host authentication allows the host to prove the identity of a user

B. User-to-user authentication allows the user to prove the identity of a machine

C. User-to-host authentication allows the user to prove the identity of a machine

D. Host-to-user authentication lets the host prove its identity to the user

Hint

Separate identity claims from proof, and factor type from factor count.

Answer D: Host-to-user authentication lets the host prove its identity to the user

The arrow convention identifies the entity supplying identity proof first and the verifier second. A user-to-host exchange therefore proves the user's identity to the host, while host-to-user proves the host's identity to the user. The corrected final option follows that rule. The other options describe proving a different entity's identity from the one indicated as prover, so they do not match their stated authentication setting.

Why each choice is right or wrong

A - Incorrect: Host-to-host concerns a host proving identity to another host, not proving a user identity.

B - Incorrect: User-to-user concerns a user proving identity to another user, not a machine.

C - Incorrect: User-to-host proves the user's identity, not the machine's.

D - Correct: The host is the prover and the user is the verifier, as the convention requires.

Primary note proof

Study-note section SEC07

> A common access sequence is identify the subject, authenticate the claim, authorize the operation, then record relevant events. Identification is the username/claim, not its proof. When a sequence begins with authentication, distinguish it from the preceding identification stage. User-to-host means a user proves identity to a host; host-to-user means the host proves its identity to a user; the arrow names the prover and verifier.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Security module | PDF page 4 | lines 15-27

> • Authentication
> o is proving a claim - usually that you are who you say you are.
> o for example it may be obtained by the provision of a

password or by a scan of your retina.
• Access controls
o provide the limitation and control of access to authorized users through identification and authentication.
o A system needs to be able to identify and authenticate users for access to data, applications and hardware.
o In a large system there may be a complex structure determining which users and applications have access to which objects.

Computer Security module | PDF page 11 | lines 74-79

• Most OS authentication is handled through user names and passwords. Biometric (e.g. voice, face, retina, iris, fingerprint) and physical token-based (swipe cards, pin-generating cards) authentication are sometimes used to augment simple passwords, but the costs and accuracy of the technology limit their adoption.

Question sources

Mock exam 3 · Question 22

Question 44 | Q01591

Which one of the following is not a correct match?

A. Biba Model - Integrity

B. Bell-LaPadula Model - Confidentiality

C. Clark-Wilson Model - Confidentiality

D. Multiple Levels of Security (MLS) Model - Confidentiality

Hint

Apply the named model's read and write restrictions separately.

Answer C: Clark-Wilson protects integrity, not confidentiality

SEC10 directly gives Biba and Clark-Wilson integrity goals, and Bell-LaPadula confidentiality. SEC32 describes multilevel label enforcement for confidentiality. C therefore mismatches the model and goal; the others are compatible with the note's defined model purposes.

Why each choice is right or wrong

A - Incorrect: Biba is an integrity model, so this pairing is correct rather than the requested mismatch.

B - Incorrect: Bell-LaPadula protects confidentiality, making this pairing correct.

C - Correct: Clark-Wilson enforces integrity through well-formed transformations and separation of duties, not confidentiality.

D - Incorrect: Multilevel label restrictions can protect confidentiality, as SEC32 explains.

Primary note proof

Study-note section SEC10

> Bell-LaPadula protects confidentiality. The simple-security rule prohibits reading above a subject's level; the star rule prohibits writing down. The strong-star variant permits writing only at the same level. With TS>S>C>U, an S subject can read C under the simple rule but cannot write C under star; compartments and discretionary restrictions may still deny access.

Study-note section SEC10

> Clark-Wilson protects integrity through certified well-formed transformations, integrity checks and separation of duties.

Study-note section SEC10

> It is not a confidentiality model. "MAC" is an enforcement category and does not force every system to use Bell-LaPadula rather than another label policy.

Related reading (context, not primary note proof)

Study-note section SEC32

6. Access control
• Since many systems (such as router access control lists) define which packets may and which packets may not pass based on the sender's IP address
• An access enforcement mechanism authorizes requests from multiple subjects (e.g. users, processes, etc.) to perform operations (e.g., read, write, etc.) on objects (e.g., files, sockets, etc.).

Question sources

Mock exam 3 · Question 23

Question 45 | Q01634

What is the first step of access control?

A. Subject identification

B. ACL verification

C. Subject authorization

D. Accountability logging

Hint

Separate identity claims from proof, and factor type from factor count.

Answer A: Subject identification

PDF p.4 says users must be identified and authenticated for access; p.11 then describes authorization of operations. Identification supplies the claimed subject before checking identity and permissions.

Why each choice is right or wrong

A - Correct: Subject identification supplies the identity on which subsequent checks operate. See PDF p.4, PDF p.11.

B - Incorrect: ACL checking requires knowing the subject and request first. See PDF p.4, PDF p.11.

C - Incorrect: Authorization decides permitted operations after the identity is established. See PDF p.4, PDF p.11.

D - Incorrect: Accountability records actions and does not establish the initial identity. See PDF p.4, PDF p.11.

Primary note proof

Study-note section SEC07

A common access sequence is identify the subject, authenticate the claim, authorize the operation, then record relevant events. Identification is the username/claim, not its proof. When a sequence begins with authentication, distinguish it from the preceding identification stage.

User-to-host means a user proves identity to a host; host-to-user means the host proves its identity to a user; the arrow names the prover and verifier.

Question sources

Mock exam 2 · Question 23

Question 46 | Q01635

Which of the following is not a reason why using passwords alone is a poor security mechanism?

A. Short passwords can be discovered quickly in brute force attacks only when used against a stolen password database file.

B. When possible, users choose easy-to-remember passwords, which are therefore easy to guess or crack.

C. Passwords can be stolen through many means, including observation, recording and playback, and security database theft.

D. Randomly generated passwords are hard to remember, thus many users write them down.

Hint

Consider what the attacker can guess or steal, or which component validates a claim.

Answer A: The “only” restriction to stolen-database brute force is false

The negative stem asks which offered reason is not valid. A incorrectly restricts brute-force exposure of short passwords to stolen database files. SEC08 explicitly permits failure in online as well as offline settings, subject to rate limits. Guessable choices, theft and insecure recording are legitimate password-only weaknesses rather than exclusive claims.

Why each choice is right or wrong

A - Correct: Short passwords can be attacked online too; only against a stolen database is an unjustified restriction.

B - Incorrect: Predictable memorable choices enable likely-word guessing, a real weakness of password-only security.

C - Incorrect: Observed entry and stolen verifiers are real exposure paths, consistent with the note’s password and monitoring threats.

D - Incorrect: Difficulty remembering random secrets can encourage unsafe recording; password managers address that operational weakness.

Primary note proof

Study-note section SEC08

> Brute force enumerates guesses; dictionary attacks prioritize likely words; credential stuffing tries previously leaked credentials on another service. Online attempts face server rate limits; offline attacks against stolen verifiers do not. Short passwords can fail in either setting. Use unique long secrets and password managers, rate limiting and suitable MFA; store salted slow password hashes, not reversible plaintext passwords. A salt prevents shared precomputed lookup, but is not secret.

Study-note section SEC05

> Shoulder surfing observes entry; pretexting invents a reason for disclosure.

Study-note section SEC05

ARP spoofing poisons local IPv4-to-MAC associations; DNS spoofing/cache poisoning supplies false name resolutions; IP spoofing falsifies a source address.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Security module | PDF page 11 | lines 74-79

• Most OS authentication is handled through user names and passwords. Biometric (e.g. voice, face, retina, iris, fingerprint) and physical token-based (swipe cards, pin-generating cards) authentication are sometimes used to augment simple passwords, but the costs and accuracy of the technology limit their adoption.

Computer Security module | PDF page 5 | lines 50-60

• Password attacks: guessing password; social engineering attack, Dictionary attack
• Cryptographic Attack:
A. Frequency Analysis attack: Guess values based on frequency of occurrence
B. Brute-force attack: The attacker tries every possible key on a piece of ciphertext until an intelligible translation into plaintext is obtained. On average, half of all possible keys must be tried to achieve success.
C. Cryptanalysis: the process of breaking an encrypted code.

Computer Security module | PDF page 5 | lines 65-74

• Reconnaissance: The hackers first identifies a target to launch an attack, extract maximum information regarding this target, understand its vulnerabilities, and then only explore the best ways to exploit it.
o Examples: Credential Theft using Keyloggers and Spyware; Identity Theft using spam e-mail, phishing attack and social engineering attack
• Access: Ones the attacker Reconnaissance the target, S/he starts a successful exploitation and continued access to the system. Then, the attacker is in control of the target.

Mock exam 2 · Question 24

Question 47 | SM0040

Which one of the following is a measure taken to ensure information and information systems' availability, integrity, authentication and confidentiality?

A. Wiretapping

B. Information security

C. Information assurance

D. Interception

Hint

Identify the property harmed: disclosure, improper change, unavailable service or lack of reliable attribution.

Answer C: Information assurance

PDF p.2 explicitly defines IA as measures protecting information and systems by ensuring availability, integrity, authentication, confidentiality and non-repudiation. This matches the stem's list most closely.

Why each choice is right or wrong

A - Incorrect: Wiretapping is an interception behavior, not an assurance measure. See PDF p.2.

B - Incorrect: InfoSec is related but the exact enumerated measures definition is assigned to IA. See PDF p.2.

C - Correct: Information assurance matches the module's definition almost verbatim. See PDF p.2.

D - Incorrect: Interception compromises confidentiality rather than ensuring these properties. See PDF p.2.

Primary note proof

Study-note section SEC01

> Confidentiality restricts disclosure: copying a credit-card database violates secrecy even if the original stays intact. Integrity restricts unauthorized or improper changes: altering a balance or inserting a false message damages correctness. Availability supplies timely, usable service to authorized users: crashes, resource starvation and denied access violate it. One event can harm several goals.

Study-note section SEC01

> Non-repudiation supplies evidence supporting origin or receipt; signatures do not make denial physically impossible.

Study-note section SEC01

> Information assurance includes confidence, risk management, protection, detection, response and restoration across the information lifecycle.

Related reading (context, not primary note proof)

Study-note section SEC03

Question 48 | SM0044

Which one of the following is a security service enforced to protect disclosure of information (stored in file or in transmission) from unauthorized entities?

A. Authentication

B. Integrity

C. Availability

D. Confidentiality

Hint

Identify the property harmed: disclosure, improper change, unavailable service or lack of reliable attribution.

Answer D: Confidentiality

Unauthorized disclosure of stored or transmitted information is precisely the confidentiality concern (PDF p.3), independent of storage location.

Why each choice is right or wrong

A - Incorrect: Authentication proves identity, not disclosure restrictions. See PDF p.3, PDF p.4.

B - Incorrect: Integrity protects against unauthorized changes. See PDF p.3, PDF p.4.

C - Incorrect: Availability protects timely access. See PDF p.3, PDF p.4.

D - Correct: Confidentiality prevents unauthorized disclosure. See PDF p.3, PDF p.4.

Primary note proof

Study-note section SEC01

> Confidentiality restricts disclosure: copying a credit-card database violates secrecy even if the original stays intact. Integrity restricts unauthorized or improper changes: altering a balance or inserting a false message damages correctness. Availability supplies timely, usable service to authorized users: crashes, resource starvation and denied access violate it. One event can harm several goals.

Study-note section SEC01

> Data security protects information at rest, in use and in transit, including accidental corruption as well as intentional attacks.

Study-note section SEC01

> Authentication establishes an identity or other claim; authorization decides permitted actions.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Security module | PDF page 3 | lines 71-78

> • Confidentiality: Data confidentiality and Privacy
> o is the prevention of unauthorized disclosure of information.
> o In other words, confidentiality means keeping information private or safe.
> o it may be important for military, business or personal reasons.
> o it may also be known as privacy or secrecy.

Computer Security module | PDF page 4 | lines 15-27

> • Authentication
> o is proving a claim - usually that you are who you say you are.
> o for example it may be obtained by the provision of a password or by a scan of your retina.
> • Access controls
> o provide the limitation and control of access to authorized users through identification and authentication.
> o A system needs to be able to identify and authenticate users for access to data, applications and hardware.
> o In a large system there may be a complex structure

determining which users and applications have access to which objects.

Computer Security module | PDF page 3 | lines 79-86

• Integrity: covers Data integrity and System integrity
o the prevention of unauthorized writing or modification of information.
o Integrity in a computer system means that there is an external consistency in the system - everything is as it is expected to be.
o Data integrity: the data stored on the computer is the same as what is intended.

Computer Security module | PDF page 3 | lines 87-91

• Availability:
o Assures that systems work promptly and service is not denied to authorized users.
o Information should be accessible and usable upon appropriate demand by an authorized user.

Question 49 | SM0054

Which general security-control category creates a protected network boundary by enforcing allow/block traffic rules for a group of machines?

A. Network operating system

B. Firewall

C. Router used only for forwarding, without security filtering

D. Switch used only for forwarding, without security filtering

Hint

Identify which traffic is mediated and what information drives the device's decisions.

Answer B: Firewall

A network firewall protects a group of machines by enforcing traffic policy at a boundary. The decisive function is allowing or blocking traffic under security rules. A network operating system is not the name of that specific policy-enforcement role. The other two alternatives are explicitly limited to forwarding without security filtering, so their connectivity functions do not meet the requirement. Actual routers, switches or proxies can include firewall capabilities; the stated scope prevents that implementation overlap from making the choices ambiguous.

Why each choice is right or wrong

A - Incorrect: Incorrect: a network operating system does not name the specific boundary traffic-policy function requested.

B - Correct: Correct: a firewall enforces the allow/block rules protecting the group.

C - Incorrect: Incorrect: the explicitly forwarding-only router does not perform the required security filtering.

D - Incorrect: Incorrect: the explicitly forwarding-only switch does not perform the required security filtering.

Primary note proof

Study-note section SEC23

> A firewall enforces traffic policy.

Study-note section SEC23

> Host firewalls protect individual machines; network firewalls segment networks and can create a DMZ for public-facing services.

Study-note section SEC-S03

> A router forwards IP packets between networks; forwarding alone is different from detecting suspicious behavior or enforcing a firewall's security policy.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Security module | PDF page 11 | lines 22-34

> 3. Firewall
> • a program or network devices (e.g. router) which filters
> access to a protected network from the internet connection.
> • protects a local or network of systems from network-based
> security threats,
> • monitors & controls incoming & outgoing network traffic
> based on predetermined security rules.
> • Firewall Objectives
> o Keep intruders, malicious code and unwanted traffic
> out
> o Keep private and sensitive information in

o security wall b/n private (protected) NW & outside word.

Computer Security module | PDF page 11 | lines 35-56

• Categorizes of firewalls
a) Network firewalls: Filter traffic b/n two or more networks and run-on NW hardware.
✓ Implemented at a specific point in the network path and protects all computers on the internal side of the firewall from all computers on the external side of the fire wall.
b) Host-based firewalls: Run on host computers and control network traffic in/out of those machines.
a) Packet Filtering Router: Examines TCP/IP header information of network data packets going in both directions. Applies set of rules to each incoming IP packets & then forwards or discards the packets.
b) Application-Level Gateway (application firewall / proxy server): runs special software that acts as a proxy for a service request. Proxy server receives requests for Web pages, accesses the Web server on behalf of the external client, and returns the requested pages to the users.
c)Circuit Level Gateway: Standalone Software that sets up two TCP connections (inside & outside). It determines which connections will be allowed.

Computer Science Exit Exam practice collection · Question 168

Question 50 | SM0058

Which one of the following best explains attackers who are motivated by financial gain and perform sabotage, IP theft and steal secrets of a rival company?

A. Stealer

B. Competitor

C. Hacktivist

D. Activist

Hint

Classify the action actually described and distinguish observation, alteration, disruption and identity claims.

Answer B: Competitor

The rival-company context and commercial-secret theft identify a competitor's motive, as SEC03 states. Financial gain alone could describe many attackers, but the specific rival-company relationship distinguishes B. Hacktivists/activists pursue a cause, while stealer is a generic activity label rather than the specified commercial relationship.

Why each choice is right or wrong

A - Incorrect: Stealer describes taking information but does not identify the rival-company commercial motive.

B - Correct: A competitor can seek commercial secrets and advantage over a rival company.

C - Incorrect: Hacktivist motivation is a cause rather than the specified commercial competition.

D - Incorrect: An activist pursues a cause; the scenario instead identifies a financially motivated rival-company interest.

Primary note proof

Study-note section SEC03

> White-hat testing requires authorization and scope; black-hat activity is malicious or unauthorized. A competitor may seek commercial secrets; hacktivists pursue a cause. "Hacker" alone does not establish legality. Insider versus outsider describes origin/trust position, not the specific mechanism.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Security module | PDF page 4 | lines 50-61

> • Types of Attacks on Data CIA (W. Stallings)
> o Disclosure/Interception: unauthorized party snooping, or getting access to a resource, Attack on data confidentiality:
> o Modification / Deception: unauthorized party modifying a resource, acceptance of false data, E.g., providing wrong data (attack on data integrity)
> o Disruption/Interruption: destroyed/unavailable services/resources, DoS (attack on data availability)
> o Fabrication: unauthorized party inserts a fake asset/resource, loss of confidentiality, authenticity and integrity of the message

MOE Computer Science Exit Exam

Computer Science Exit Exam practice collection · Question 169

Question 51 | SM0060

Against an attacker whose only access is direct communication over the public Internet, which computer removes that attack path? Assume the disconnected computer has no Internet-reachable intermediary or other network route to the attacker.

A. A computer connected to the Internet with the latest firewall system

B. A computer connected to the Internet having strong intrusion detection

C. A computer that is not connected to the Internet

D. A computer connected to the Internet and the latest anti-virus installed on it

Hint

Start with the stated attacker path or physical hazard and the limits of each control.

Answer C: A computer that is not connected to the Internet

Disconnecting removes the Internet communication path available to the specified attacker. Firewalls, intrusion detection and antivirus can reduce particular risks, but they do not remove the fact that the other choices remain connected. The conclusion is deliberately limited to that attack path: the disconnected system can still face insiders, removable media or physical threats. Those are excluded from this scenario rather than silently treated as impossible.

Why each choice is right or wrong

A - Incorrect: A firewall-equipped Internet connection still exposes an Internet communication path.

B - Incorrect: Intrusion detection observes activity but does not remove connectivity.

C - Correct: The stated disconnected system has no path available to this attacker.

D - Incorrect: Antivirus does not remove the Internet communication path.

Primary note proof

Study-note section SEC11

> Protect equipment against theft, unauthorized connections, heat, humidity, water, electrical surges and fire. A UPS supplies temporary conditioned power; it is normally protective, but faulty installation/battery failure can itself be hazardous. A disconnected machine loses many network attack paths yet remains exposed to insiders, removable media, supply-chain attacks and physical access. There is no universal “most secure computer” without a threat model.

Study-note section SEC23

> Bypass paths, insiders, encrypted uninspected content and infected removable media limit firewall protection.

Study-note section SEC23

Host firewalls protect individual machines; network firewalls segment networks and can create a DMZ for public-facing services.

Question 52 | SM0072

Suppose you have received a message from your friend but the message is scrambled for security. Your friend used a program to encode messages into scrambled text. In order to read the message,
which program would you use?

A. Encryption program

B. Ciphertext

C. Secret key

D. Decryption program

Hint

Trace message transformations and separate data, keys, algorithms and codebreaking.

Answer D: Decryption program

The received message is ciphertext; recovering its readable plaintext is deciphering/decryption on PDF p.6. The question asks for the program carrying out that inverse operation.

Why each choice is right or wrong

A - Incorrect: Encryption converts plaintext into ciphertext, the opposite direction. See PDF p.6.

B - Incorrect: Ciphertext is data, not the recovery program. See PDF p.6.

C - Incorrect: A secret key may be an input but is not a program. See PDF p.6.

D - Correct: A decryption program performs plaintext recovery. See PDF p.6.

Primary note proof

Study-note section SEC12

> Plaintext is the original message, ciphertext its encrypted representation, a key is input to an algorithm, encryption computes C=E_k(P), and decryption recovers P=D_k(C). The five conventional symmetric ingredients are plaintext, encryption algorithm, secret key, ciphertext and decryption algorithm. Cryptanalysis seeks recovery or other breaks without the authorized secret; cryptology includes cryptography and cryptanalysis. Steganography hides that a message exists; encryption hides its meaning.

Study-note section SEC12

> Security depends on algorithm, key size, randomness, mode and implementation.

Study-note section SEC12

Assume the algorithm is known and protect keys: secrecy of implementation is not the main security argument.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Question 53 | SM0081

Which network security issue shows the level of weakness in networks and devices?

A. Attack

B. Availability

C. Vulnerability

D. Treat

Hint

Distinguish weaknesses, potential harmful events, actual attempts and the effect of a control.

Answer C: Vulnerability

A vulnerability is an exploitable weakness or fault in an information system or component (PDF p.3). The question asks about weakness, not the attack event or service goal.

Why each choice is right or wrong

A - Incorrect: Attack is an actual security violation. See PDF p.3.

B - Incorrect: Availability is a goal of usable access. See PDF p.3.

C - Correct: Vulnerability is the defined weakness. See PDF p.3.

D - Incorrect: Treat appears to mean threat, a potential harmful circumstance rather than the weakness. See PDF p.3.

Primary note proof

Study-note section SEC02

An asset is something valuable: data, software, hardware, service or reputation. A threat is a potentially harmful circumstance; a vulnerability is an exploitable weakness; an attack is an actual attempt; a control reduces likelihood or impact. A software flaw is not automatically an active attack. Risk concerns likelihood and consequence, not a universally meaningful numeric product of two unmeasured labels.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Security module | PDF page 3 | lines 24-40

• Threat: any circumstances or events that can potentially harm an information system by destroying it, disclosing the information stored on the system, adversely modifying data, or making the system unavailable.
• Vulnerability: weaknesses or fault in an information system or its components that could be exploited.
• Attack: actual violation of security that derives from an intelligent threat.
• Risk: An expectation of loss expressed as the probability that a particular threat will exploit a particular vulnerability with a particular harmful result.
o Risk = Threats x Vulnerabilities
• Control, safeguard, or countermeasure: An action, device, procedure, or technique that reduces a threat, a vulnerability, or an attack by eliminating or preventing it, by minimizing the harm it can cause, or by discovering and reporting it so that corrective action can be taken.

Question 54 | SM0096

Which one is a method used to obtain the meaning of encrypted information without access to the secret key?

A. Cryptography

B. Crypto-analysis

C. Decryption

D. Encryption

Hint

Trace message transformations and separate data, keys, algorithms and codebreaking.

Answer B: Crypto-analysis

Obtaining meaning without the secret key matches cryptanalysis, which the module explicitly contrasts with ordinary decryption (PDF p.6).

Why each choice is right or wrong

A - Incorrect: Cryptography studies encryption methods rather than without-key breaking. See PDF p.6.

B - Correct: Crypto-analysis matches breaking ciphertext without knowing the key. See PDF p.6.

C - Incorrect: Decryption describes plaintext recovery but lacks the no-key distinction. See PDF p.6.

D - Incorrect: Encryption produces ciphertext rather than recovering meaning. See PDF p.6.

Primary note proof

Study-note section SEC12

> Plaintext is the original message, ciphertext its encrypted representation, a key is input to an algorithm, encryption computes C=E_k(P), and decryption recovers P=D_k(C). The five conventional symmetric ingredients are plaintext, encryption algorithm, secret key, ciphertext and decryption algorithm. Cryptanalysis seeks recovery or other breaks without the authorized secret; cryptology includes cryptography and cryptanalysis. Steganography hides that a message exists; encryption hides its meaning.

Study-note section SEC12

> Symmetric cryptography is not inherently less secure than public-key cryptography, and speed ratios are not fixed constants.

Study-note section SEC12

> Security depends on algorithm, key size, randomness, mode and implementation.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Question 55 | SM0221

Which one of the following IS NOT a concern of availability?

A. Fault Tolerance

B. Alteration of resources

C. Usefulness of resources

D. Fair allocation of resources

Hint

Identify the property harmed: disclosure, improper change, unavailable service or lack of reliable attribution.

Answer B: Alteration of resources

Availability means timely, reliable, usable access for authorized users (PDF p.3). Altering resources is instead the integrity issue; fault tolerance, usability and fair allocation can support continued access.

Why each choice is right or wrong

A - Incorrect: Fault tolerance supports reliable service, consistent with availability. See PDF p.3.

B - Correct: Unauthorized alteration belongs to integrity rather than the access/continuity goal. See PDF p.3.

C - Incorrect: Useful/usable resources are expressly part of availability. See PDF p.3.

D - Incorrect: Fair allocation supports access for authorized users rather than denying service. See PDF p.3.

Primary note proof

Study-note section SEC01

> Confidentiality restricts disclosure: copying a credit-card database violates secrecy even if the original stays intact. Integrity restricts unauthorized or improper changes: altering a balance or inserting a false message damages correctness. Availability supplies timely, usable service to authorized users: crashes, resource starvation and denied access violate it. One event can harm several goals.

Study-note section SEC01

> Accountability links actions to responsible entities through reliable identity and protected logs.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Security module | PDF page 3 | lines 87-91

> • Availability:
> o Assures that systems work promptly and service is not denied to authorized users.
> o Information should be accessible and usable upon appropriate demand by an authorized user.

Computer Security module | PDF page 3 | lines 79-86

> • Integrity: covers Data integrity and System integrity
> o the prevention of unauthorized writing or modification of information.

Computer Science Exit Exam practice collection · Question 180

Question 56 | SM0223

Person A sends a message to person B. While the message is transmitted, person C gains access to the message. Which category of attack is performed by person C?

A. Modification

B. Interception

C. Interruption

D. Fabrication

Hint

Classify the action actually described and distinguish observation, alteration, disruption and identity claims.

Answer B: Interception

C gains unauthorized access to the message in transit without any stated alteration, destruction or insertion. PDF p.4 calls this disclosure/interception.

Why each choice is right or wrong

A - Incorrect: No message change is specified. See PDF p.4.

B - Correct: Unauthorized message access matches interception. See PDF p.4.

C - Incorrect: No loss of service is specified. See PDF p.4.

D - Incorrect: No fake message is inserted. See PDF p.4.

Primary note proof

Study-note section SEC03

> Interception copies or observes data, modification alters it, interruption blocks it, and fabrication inserts false material. The 4D classification uses disclosure, deception, disruption and usurpation, the last meaning unauthorized control. DoS primarily demonstrates disruption/availability loss; it need not give control of the victim.

Study-note section SEC03

> Neither category is universally easy to prevent or detect.

Study-note section SEC03

> Passive attacks observe without changing the target exchange: sniffing and traffic analysis.

Question 57 | SM0227

Which one of the following terms refers to the techniques used for deciphering ciphertext without any knowledge of the enciphering mechanism?

A. Cryptography

B. Cryptology

C. Cryptoanalysis

D. Decryption

Hint

Trace message transformations and separate data, keys, algorithms and codebreaking.

Answer C: Cryptoanalysis

The qualifier without knowledge distinguishes cryptanalysis from ordinary deciphering in PDF p.6. Cryptology includes both protective methods and codebreaking, but is not the specific technique requested.

Why each choice is right or wrong

A - Incorrect: Cryptography studies encryption principles. See PDF p.6.

B - Incorrect: Cryptology is the umbrella field including cryptography and cryptanalysis. See PDF p.6.

C - Correct: Cryptoanalysis is the offered spelling of the without-key codebreaking concept. See PDF p.6.

D - Incorrect: Decryption is ordinary plaintext recovery, not specifically without secret knowledge. See PDF p.6.

Primary note proof

Study-note section SEC12

Plaintext is the original message, ciphertext its encrypted representation, a key is input to an algorithm, encryption computes C=E_k(P), and decryption recovers P=D_k(C). The five conventional symmetric ingredients are plaintext, encryption algorithm, secret key, ciphertext and decryption algorithm. Cryptanalysis seeks recovery or other breaks without the authorized secret; cryptology includes cryptography and cryptanalysis. Steganography hides that a message exists; encryption hides its meaning.

Study-note section SEC12

Symmetric cryptography is not inherently less secure than public-key cryptography, and speed ratios are not fixed constants.

Computer Science Exit Exam practice collection · Question 182

Question 58 | SM0258

In asymmetric cryptography, the message is decrypted using _____.

A. Receiver's public key

B. Receiver's private key

C. Sender's private key

D. Sender's public key

Hint

Identify the intended recipient or signer and separate confidentiality from verification.

Answer B: Receiver's private key

For confidential public-key transmission, encryption uses the receiver's public key and decryption the receiver's private key (PDF p.8). The answer follows that communication model.

Why each choice is right or wrong

A - Incorrect: Receiver's public key performs encryption in this model. See PDF p.8.

B - Correct: Receiver's private key performs decryption. See PDF p.8.

C - Incorrect: Sender's private key is not the recipient decryption key. See PDF p.8.

D - Incorrect: Sender's public key belongs to signature verification, not confidential recipient decryption. See PDF p.8.

Primary note proof

Study-note section SEC18

> For confidentiality to B, encrypt with B's authenticated public encryption key; B decrypts with B's private key. Do not encrypt to A's public key if only B should read it, and never assume A possesses B's private key. For a signature, A signs with A's private signing key and others verify with A's public key. These are distinct operations; not every public-key algorithm supports encryption.

Study-note section SEC18

> For one-way public-key confidentiality the sender need not own a key pair; it needs the recipient's authenticated public encryption key.

Study-note section SEC18

> A sender key pair is needed when the protocol requires its signature or separate recipient role.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Security module | PDF page 8 | lines 61-76

> Asymmetric key cryptography
> • also known as public-key encryption.
> • In public key cryptography,
> o unlike symmetric-key, there are two keys: a private key and a public key.
> ✓ The public key is announced to the public; whereas the private key is kept by the receiver.
> o anyone can send messages using the public key of the receiver for encryption, but only the receiver uses his private key for decryption
> ✓ Secret transmission of key for decryption is not

required
✓ Every entity can generate a key pair and release its public key
✓ Encryption and decryption keys are different but form a unique pair

Computer Security module | PDF page 8 | lines 89-98

• Asymmetric-key cryptosystem Model
o Both users (Bob & Alice) generates a pair of keys
o Each user places one of 2 keys in public register.
✓ This is the public key: each user maintains a collection of public keys obtained from others.
o The companion key is kept private to each.
o If Alice wishes to send a confidential message to Bob, She encrypts the message using Bob's public key.
o When Bob receives the message, he decrypts it using his private key.

Computer Science Exit Exam · Sene 2016 · Question 19-1

Computer Science Exit Exam practice collection · Question 183

Question 59 | SM0272

Which one of the following cryptography systems uses the same key for encryption and decryption?

A. Public key cryptography

B. Parallel cryptography

C. Asymmetric cryptography

D. Symmetric cryptography

Hint

Distinguish shared-key architecture, key distribution and bulk-data use.

Answer D: Symmetric cryptography

PDF p.7 defines symmetric encryption as use of the same shared key for both directions; p.8 contrasts the public/private pair.

Why each choice is right or wrong

A - Incorrect: Public-key cryptography uses a key pair. See PDF p.7, PDF p.8.

B - Incorrect: Parallel cryptography is not a same-key class in the module. See PDF p.7, PDF p.8.

C - Incorrect: Asymmetric cryptography uses different paired keys. See PDF p.7, PDF p.8.

D - Correct: Symmetric cryptography explicitly uses the same shared key. See PDF p.7, PDF p.8.

Primary note proof

Study-note section SEC16

Symmetric encryption uses a shared secret and efficiently protects bulk data. Pairwise independent keys for n users require n(n-1)/2 shared keys; a trusted key distribution center changes that architecture. A session key is temporary for a communication context; a master/key-encryption key protects subordinate keys. Distribute keys physically, via an authenticated protected channel, or through a trusted third party. An uncompromised old key can protect a new key, although this does not restore secrecy after the old key is stolen.

Study-note section SEC18

For confidentiality to B, encrypt with B's authenticated public encryption key; B decrypts with B's private key.

Study-note section SEC18

For a signature, A signs with A's private signing key and others verify with A's public key.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Security module | PDF page 7 | lines 48-54

Symmetric key cryptography
• Uses conventional / secret-key / single-key.
• The secret key shared by both sender and receiver.
• All classical encryption algorithms are private-key.
o Use the same key (shared key) for encryption and decryption process.
• If this key is disclosed communications are compromised.

Computer Security module | PDF page 8 | lines 61-76

Asymmetric key cryptography
• also known as public-key encryption.
• In public key cryptography,
o unlike symmetric-key, there are two keys: a private key and a public key.
✓ The public key is announced to the public; whereas the private key is kept by the receiver.
o anyone can send messages using the public key of the receiver for encryption, but only the receiver uses his private key for decryption
✓ Secret transmission of key for decryption is not required
✓ Every entity can generate a key pair and release its public key

✓ Encryption and decryption keys are different but form a unique pair

Question sources

Computer Science Exit Exam · Sene 2016 · Question 23-3

Computer Science Exit Exam practice collection · Question 185

Question 60 | SM0301

The first step in access control is _____.

A. Audit

B. Authorization

C. Accreditation

D. Authentication

Hint

Separate identity claims from proof, and factor type from factor count.

Answer D: Authentication

The module requires identification and authentication before access and says NAC authenticates users then determines access/actions (PDF pp.4,11). Among these options authentication is the prerequisite, though identification would precede it if offered.

Why each choice is right or wrong

A - Incorrect: Audit records events rather than first proving identity. See PDF p.4, PDF p.11.

B - Incorrect: Authorization determines allowed operations for an established identity. See PDF p.4, PDF p.11.

C - Incorrect: Accreditation is not the identity-checking step defined in the module. See PDF p.4, PDF p.11.

D - Correct: Authentication is the earliest listed access-control step. See PDF p.4, PDF p.11.

Primary note proof

Study-note section SEC07

A common access sequence is identify the subject, authenticate the claim, authorize the operation, then record relevant events. Identification is the username/claim, not its proof. When a sequence begins with authentication, distinguish it from the preceding identification stage. User-to-host means a user proves identity to a host; host-to-user means the host proves its identity to a user; the arrow names the prover and verifier.

Study-note section SEC01

Authentication establishes an identity or other claim; authorization decides permitted actions.

Study-note section SEC01

Accountability links actions to responsible entities through reliable identity and protected logs.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Security module | PDF page 4 | lines 15-27

• Authentication
o is proving a claim - usually that you are who you say you are.
o for example it may be obtained by the provision of a password or by a scan of your retina.
• Access controls
o provide the limitation and control of access to authorized users through identification and authentication.
o A system needs to be able to identify and authenticate users for access to data, applications and hardware.
o In a large system there may be a complex structure determining which users and applications have access to which objects.

Computer Security module | PDF page 11 | lines 88-100

• Network access control (NAC): is an umbrella term for managing access to a net-work. NAC authenticates users logging into the network and determines what data they can access and actions they can perform. NAC also examines the health of the user's computer or mobile device (the endpoints).
• An operating system provides an access enforcement mechanism.
• Two fundamental concepts of access control:
o a protection system that defines the access control specification and
o a reference monitor that is the system's access enforcement mechanism that enforces this specification.

Computer Security module | PDF page 4 | lines 28-35

• Accountability
o Ensuring an entity's action is traceable uniquely to that entity.
o Ascertains the responsibility of an entity (like a person) for its actions and decisions.
o All relevant activities events and operations on a system, e.g., failed and successful authentication attempts, are recorded in a log.

Question sources

Computer Science Exit Exam · Sene 2016 · Question 33-1

Computer Science Exit Exam practice collection · Question 179

Question 61 | SS110

A firewall is used in a system connected to a wide area network to

A. Stop unauthorized access by hackers

B. Scanning for viruses in various files

C. Avoid spreading of fire in the network

D. Fire spreading via network through cables

Hint

Identify which traffic is mediated and what information drives the device's decisions.

Answer A: Stop unauthorized access by hackers

A firewall filters protected-network access to keep intruders out (PDF p.11). This is a logical security boundary, not a fire-suppression device.

Why each choice is right or wrong

A - Correct: Stopping unauthorized network access is an explicit objective.

B - Incorrect: File virus scanning is not the general firewall function.

C - Incorrect: Physical fire spread is unrelated to packet filtering.

D - Incorrect: Fire through cables is unrelated to the stated network security role.

Primary note proof

Study-note section SEC23

> A firewall enforces traffic policy. Stateless packet filtering matches headers such as source/destination, protocol and ports. Stateful inspection tracks permitted connection context; application proxies terminate and relay application exchanges and can inspect their content. A circuit gateway relays connections, commonly SOCKS, without full application-content interpretation; textbooks associate it with session/transport functions. Such a gateway need not encrypt and is not automatically a VPN.

Study-note section SEC11

> A disconnected machine loses many network attack paths yet remains exposed to insiders, removable media, supply-chain attacks and physical access.

Study-note section SEC04

> Ransomware denies access through encryption/locking and extortion.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Security module | PDF page 11 | lines 22-34

3. Firewall
• a program or network devices (e.g. router) which filters access to a protected network from the internet connection.
• protects a local or network of systems from network-based security threats,
• monitors & controls incoming & outgoing network traffic based on predetermined security rules.
• Firewall Objectives
o Keep intruders, malicious code and unwanted traffic out
o Keep private and sensitive information in
o security wall b/n private (protected) NW & outside word.

Question sources

Computer Science model exam collection · Question 17

Question 62 | SS112

Within OAuth, what component validates the user's identity?

A. "Gre. Authorization Server

B. Resource Server

C. d Oc. Client

D. Browser

Hint

Consider what the attacker can guess or steal, or which component validates a claim.

Answer A: Authorization server

SEC08 assigns resource-owner authentication/approval to the authorization server, which may delegate identity checks. The resource server checks access tokens for protected resources; the client seeks limited access and the browser is a user agent. OAuth is authorization rather than a complete login identity protocol, but A is the matching component role under the described flow.

Why each choice is right or wrong

A - Correct: The authorization server authenticates the resource owner or delegates that check and obtains approval.

B - Incorrect: The resource server validates access tokens for protected data rather than being the owner-authentication component.

C - Incorrect: The client requests limited access; it is not the trusted identity-validation role defined here.

D - Incorrect: The browser carries user interaction and redirects but is not the authorization server's authentication authority.

Primary note proof

Study-note section SEC08

OAuth is an authorization framework: a client obtains limited access tokens, the authorization server authenticates/obtains approval from the resource owner, and the resource server validates tokens for protected data. The authorization server can delegate identity checks. OAuth alone does not define a complete end-user login identity protocol; OpenID Connect adds an identity layer.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Security module | PDF page 4 | lines 15-27

Computer Science model exam collection · Question 19

Question 63 | SS136

Which protocol is specifically designed for secure remote login and remote command execution between a local client and a remote computer over an untrusted network?

A. Authentication, Authorization and Accounting (AAA)

B. Simple Network Management Protocol (SNMP)

C. Secure Shell (SSH)

D. Secure socket layer (SSL)

Hint

Match the communication task to the protocol and trace key handling separately from signing.

Answer C: Secure Shell (SSH)

SSH provides secure remote login, command execution and related services over an untrusted network. SSL and its successor TLS provide protected channels but do not by themselves define the remote-login and command-execution service requested here. AAA names authentication, authorization and accounting functions rather than a remote-shell protocol. SNMP supplies network-management functions. Specifying the service, rather than merely a secure local-to-remote channel, makes SSH the unique answer among these choices.

Why each choice is right or wrong

A - Incorrect: AAA describes authentication, authorization and accounting functions, not a remote-login protocol.

B - Incorrect: SNMP provides device-management functions rather than the requested remote-login and command-execution service.

C - Correct: Correct: SSH directly provides secure remote login and remote command execution.

D - Incorrect: SSL/TLS protects communication channels but does not itself specify the requested remote-shell service.

Primary note proof

Study-note section SEC22

> SSH protects remote login, commands and file transfer such as SFTP; it supports host keys and several client-authentication methods.

Study-note section SEC-S03

> AAA names authentication, authorization and accounting functions, rather than a particular remote-shell channel. SSH expands to Secure Shell and provides secure remote login and related network services. PGP expands to Pretty Good Privacy; its message-protection design combines conventional and public-key encryption with digital signatures. Protocol purpose matters when several technologies all contribute to security.

Study-note section SEC21

> TLS succeeds obsolete SSL and supplies an authenticated protected channel.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Security module | PDF page 11 | lines 2-7

> o A cryptographic protocol for operating NW services
> securely over an unsecured NW.
> o Best-known application: for remote login to computer
> systems by users.

o Common applications: remote command-line login and execution.

Question sources

Computer Science model exam collection · Question 43

Question 64 | SS150

Which of the following refers to unauthorized disclosure of information?

A. Integrity

B. Authorization

C. Confidentiality

D. Authentication

Hint

Identify the property harmed: disclosure, improper change, unavailable service or lack of reliable attribution.

Answer C: Confidentiality is the property violated by unauthorized disclosure

SEC01 defines confidentiality as restricting disclosure, so unauthorized disclosure is a breach of that property. Integrity concerns improper changes, authorization determines permitted operations and authentication establishes claims. The answer names the affected security goal rather than calling unauthorized disclosure itself a protective mechanism.

Why each choice is right or wrong

A - Incorrect: Integrity restricts improper changes, not disclosure of unchanged information.

B - Incorrect: Authorization decides which actions are permitted rather than naming the secrecy property harmed.

C - Correct: Confidentiality restricts disclosure and is directly violated when information is revealed without authorization.

D - Incorrect: Authentication establishes identity/claims rather than defining protection against disclosure.

Primary note proof

Study-note section SEC01

Confidentiality restricts disclosure: copying a credit-card database violates secrecy even if the original stays intact. Integrity restricts unauthorized or improper changes: altering a balance or inserting a false message damages correctness. Availability supplies timely, usable service to authorized users: crashes, resource starvation and denied access violate it. One event can harm several goals.

Study-note section SEC01

Authentication establishes an identity or other claim; authorization decides permitted actions.

Study-note section SEC01

Accountability links actions to responsible entities through reliable identity and protected logs.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Security module | PDF page 3 | lines 71-78

• Confidentiality: Data confidentiality and Privacy
o is the prevention of unauthorized disclosure of information.
o In other words, confidentiality means keeping information private or safe.
o it may be important for military, business or personal reasons.
o it may also be known as privacy or secrecy.

Computer Security module | PDF page 3 | lines 79-86

• Integrity: covers Data integrity and System integrity
o the prevention of unauthorized writing or modification of information.
o Integrity in a computer system means that there is an external consistency in the system - everything is as it is expected to be.
o Data integrity: the data stored on the computer is the same as what is intended.

Computer Security module | PDF page 4 | lines 15-27

• Authentication
o is proving a claim - usually that you are who you say you are.
o for example it may be obtained by the provision of a password or by a scan of your retina.
• Access controls
o provide the limitation and control of access to authorized users through identification and authentication.
o A system needs to be able to identify and authenticate users for access to data, applications and hardware.
o In a large system there may be a complex structure determining which users and applications have access to which objects.

Question sources

Computer Science model exam collection · Question 57

Question 65 | SS152

Which benefit follows directly from network ACL match-and-permit/deny rules, independently of optional traffic counters or malware-inspection features?

A. Virus detection.

B. ACLs classify and organize network traffic.

C. ACLs provide high network availability.

D. ACLs monitor the number of bytes and packets.

Hint

Identify subject, object and permitted operation before comparing policy models.

Answer B: ACLs classify and organize network traffic.

A network ACL matches traffic attributes such as addresses, protocols and ports and applies permission rules. Distinguishing the matching packet groups directly supports the offered classification and organization benefit. Malware inspection is a separate detection function, and a permission list does not guarantee high availability. An implementation may attach counters to rules, but those optional measurement features are outside the basic ACL permission function specified here. B is the direct consequence of that function.

Why each choice is right or wrong

A - Incorrect: Incorrect: matching permission rules is not malware-content detection.

B - Correct: Correct: matching packet conditions distinguishes traffic groups for permit/deny treatment.

C - Incorrect: Incorrect: a permission list does not by itself guarantee continued service availability.

D - Incorrect: Incorrect: byte/packet counters are optional measurement features, excluded from the basic permission-rule function asked about.

Primary note proof

Study-note section SEC09

> Subjects request operations on objects. An ACL associates an object/resource with allowed subjects or actions; a network ACL matches traffic such as address, protocol and port. Classification and filtering are direct effects; high availability or malware detection is not guaranteed by an ACL.

Study-note section SEC24

> An IDS observes and alerts; an IPS can enforce blocking, usually inline.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Security module | PDF page 11 | lines 80-87

6. Access control
• Since many systems (such as router access control lists) define which packets may and which packets may not pass based on the sender's IP address
• An access enforcement mechanism authorizes requests from multiple subjects (e.g. users, processes, etc.) to perform operations (e.g., read, write, etc.) on objects (e.g., files, sockets, etc.).

Computer Security module | PDF page 11 | lines 35-56

• Categorizes of firewalls
a) Network firewalls: Filter traffic b/n two or more networks and run-on NW hardware.
✓ Implemented at a specific point in the network path and protects all computers on the internal side of the firewall from all computers on the external side of the fire wall.
b) Host-based firewalls: Run on host computers and control network traffic in/out of those machines.
a) Packet Filtering Router: Examines TCP/IP header information of network data packets going in both directions. Applies set of rules to each incoming IP packets & then forwards or discards the packets.
b) Application-Level Gateway (application firewall / proxy server): runs special software that acts as a proxy for a service request. Proxy server receives requests for Web pages, accesses the Web server on behalf of the external client, and returns the requested pages to the users.
c)Circuit Level Gateway: Standalone Software that sets up two TCP connections (inside & outside). It determines which connections will be allowed.

Question sources

Computer Science model exam collection · Question 59

Question 66 | SS185

Which of the following is not an approach used by IT security specialists to enhance the security level of the network?

A. Use of Intrusion detection system

B. Use of Intrusion prevention system

C. Use of Wana cry protocol

D. Use of physical security

Hint

Distinguish a malicious-software name from a defensive control's function.

Answer C: “Wana cry protocol” is not a defensive security approach

IDS, IPS and physical controls are legitimate security approaches in SEC24 and SEC11. The option called “Wana cry protocol” supplies no defensive mechanism; treating a ransomware-like name as a security protocol is unsupported. SEC04 defines ransomware as denial/extortion, the opposite of a protective approach. Therefore C is the exception rather than a new protocol endorsed here.

Why each choice is right or wrong

A - Incorrect: An IDS observes and alerts on suspicious activity, a legitimate detective security approach.

B - Incorrect: An IPS can enforce blocking and is a legitimate preventive security approach.

C - Correct: The offered name establishes no security protocol or protective mechanism; ransomware is harmful rather than defensive.

D - Incorrect: Physical protection against unauthorized access and environmental hazards is an explicit security-control category.

Primary note proof

Study-note section SEC-S02

> WannaCry, also known as WannaCrypt, is ransomware with worm-like propagation. It encrypts files and demands payment to restore access. Its name identifies malicious software rather than a network-security protocol. Malware names must be distinguished from defensive controls such as intrusion detection, intrusion prevention and physical protection.

Study-note section SEC24

> An IDS observes and alerts; an IPS can enforce blocking, usually inline.

Study-note section SEC11

> Protect equipment against theft, unauthorized connections, heat, humidity, water, electrical surges and fire.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Security module | PDF page 4 | lines 89-99

> o Encryption: primary control that protects CIA, by
> which Cleartext scambled into ciphertext.
> o Software controls: password checker, virus scanner,
> IDS (intrusion detection system)
> o Hardware controls: provide higher degree of security;
> Locks, Smart cards, dongles, hadware keys...

o Policies and procedures: Alignment with users' legal and ethical standards; eg. password policy
o Physical controls: natural and man-made disaster protection; walls, locks, guards, security, cameras, backup copies and archives

Computer Security module | PDF page 11 | lines 65-68

4. Physical security
• Without physical security to protect hardware (i.e., doors that lock) nothing else about a computer system can be called secure

Computer Security module | PDF page 5 | lines 21-35

o Key loggers
o Rootkit

Question sources

Computer Science model exam collection · Question 92

Question 67 | AM0524

What is the primary goal of computer security?

A. Confidentiality

B. Integrity

C. Availability

D. All of the above

Hint

Identify the property harmed: disclosure, improper change, unavailable service or lack of reliable attribution.

Answer D: All of the above

The module explicitly defines computer security around all three objectives confidentiality, integrity and availability (PDF p.2). Choosing only one omits other primary goals.

Why each choice is right or wrong

A - Incorrect: Confidentiality is included but incomplete alone. See PDF p.2.

B - Incorrect: Integrity is included but incomplete alone. See PDF p.2.

C - Incorrect: Availability is included but incomplete alone. See PDF p.2.

D - Correct: All three comprise the stated CIA objective set. See PDF p.2.

Primary note proof

Study-note section SEC01

> Confidentiality restricts disclosure: copying a credit-card database violates secrecy even if the original stays intact. Integrity restricts unauthorized or improper changes: altering a balance or inserting a false message damages correctness. Availability supplies timely, usable service to authorized users: crashes, resource starvation and denied access violate it. One event can harm several goals.

Study-note section SEC01

> Authentication establishes an identity or other claim; authorization decides permitted actions.

Study-note section SEC01

> Data security protects information at rest, in use and in transit, including accidental corruption as well as intentional attacks.

Computer Science MCQ practice collection · Question 524

Question 68 | AM0525

What is the term used for a software program that attempts to gain unauthorized access to computer systems?

A. Firewall

B. Malware

C. Encryption

D. VPN

Hint

Separate propagation, disguise and payload when classifying malicious software.

Answer B: Malware

PDF p.5 calls software with malicious purpose malware and describes intrusion as attempted unauthorized access. A malicious program seeking unauthorized access therefore fits the broad malware class.

Why each choice is right or wrong

A - Incorrect: Firewall is a protective filtering mechanism, not the malicious program. See PDF p.5.

B - Correct: Malware is the umbrella for software with malicious purpose. See PDF p.5.

C - Incorrect: Encryption is a transformation for protected communication, not a malicious program class. See PDF p.5.

D - Incorrect: VPN is named as an application, not the malicious-software category. See PDF p.5.

Primary note proof

Study-note section SEC04

> A virus replicates by attaching to a host program or document; execution of the infected host spreads it. A worm replicates independently, commonly across networks. A Trojan disguises malicious behavior as something useful and does not require self-replication. These labels describe different properties, so a malware package may contain several components.

Study-note section SEC04

> Malware is the umbrella term, not a specific replication method.

Study-note section SEC04

> Ransomware denies access through encryption/locking and extortion.

Related reading (context, not primary note proof)

Study-note section SEC23

o Bacterium
o Logic bomb
o Backdoor(Trapdoor)
o Adware
o Flooders (DoS client)
o Key loggers
o Rootkit

Computer Security module | PDF page 5 | lines 37-43

• Hacking /Intrusion/ Attack: any attempt to intrude or gain unauthorized access to your system either via some operating system flaw or other means. The purpose may or may not be for malicious purposes.
• Cracking: is hacking conducted for malicious purposes.
• Denial of Service (DoS) Attack: Blocking access from legitimate users

Question sources

Computer Science MCQ practice collection · Question 525

Question 69 | AM0526

What is the practice of hiding confidential data within other data called?

A. Encryption

B. Decryption

C. Steganography

D. Intrusion detection

Hint

Trace message transformations and separate data, keys, algorithms and codebreaking.

Answer C: Steganography

Hiding confidential data inside another data object aims to conceal the message's existence. SEC12 calls that steganography and distinguishes it from encryption, which conceals meaning while leaving ciphertext observable. Decryption reverses encryption, and intrusion detection observes suspicious activity rather than embedding a hidden message.

Why each choice is right or wrong

A - Incorrect: Encryption conceals message meaning rather than specifically hiding its existence within another carrier.

B - Incorrect: Decryption recovers plaintext from ciphertext; it does not embed a hidden message.

C - Correct: Steganography conceals a message's existence by hiding it within other data.

D - Incorrect: Intrusion detection observes and alerts about suspicious activity instead of hiding confidential content.

Primary note proof

Study-note section SEC12

> Plaintext is the original message, ciphertext its encrypted representation, a key is input to an algorithm, encryption computes C=E_k(P), and decryption recovers P=D_k(C). The five conventional symmetric ingredients are plaintext, encryption algorithm, secret key, ciphertext and decryption algorithm. Cryptanalysis seeks recovery or other breaks without the authorized secret; cryptology includes cryptography and cryptanalysis. Steganography hides that a message exists; encryption hides its meaning.

Study-note section SEC24

> An IDS observes and alerts; an IPS can enforce blocking, usually inline.

Study-note section SEC24

> Signature detection recognizes known patterns; anomaly detection compares with a baseline and may detect novel behavior.

o Cryptology - the field of study which deals with both cryptography and cryptanalysis

Question sources

Computer Science MCQ practice collection · Question 526

Question 70 | AM0527

Which of the following authentication methods verifies a user's identity based on a unique physical characteristic?

A. Password authentication

B. Biometric authentication

C. Token authentication

D. Two-factor authentication

Hint

Separate identity claims from proof, and factor type from factor count.

Answer B: Biometric authentication

The module identifies face, retina, iris and fingerprint as biometrics (PDF p.11), and gives retina scanning as identity proof (p.4). A unique physical characteristic therefore selects biometrics.

Why each choice is right or wrong

A - Incorrect: Password authentication uses supplied secret knowledge, not a physical body trait. See PDF p.4, PDF p.11.

B - Correct: Biometric authentication uses the listed bodily examples. See PDF p.4, PDF p.11.

C - Incorrect: Physical tokens are cards, distinguished from biometrics. See PDF p.4, PDF p.11.

D - Incorrect: Two-factor counts combined factors and does not name the body-trait method. See PDF p.4, PDF p.11.

Primary note proof

Study-note section SEC07

Knowledge is a password/PIN, possession is a token/card, and inherence is a biometric such as a fingerprint. Behavioral biometrics include typing rhythm or handwriting; some textbooks call these “something one does.” A body characteristic is not “three-factor authentication”: one biometric is one factor. Password plus PIN remains one factor class; card plus PIN is two. An OTP’s factor depends on its delivery/generation mechanism.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Security module | PDF page 11 | lines 74-79

• Most OS authentication is handled through user names and passwords. Biometric (e.g. voice, face, retina, iris, fingerprint) and physical token-based (swipe cards, pin-generating cards) authentication are sometimes used to augment simple passwords, but the costs and accuracy of the technology limit their adoption.

Computer Security module | PDF page 4 | lines 15-27

• Authentication
o is proving a claim - usually that you are who you say you are.
o for example it may be obtained by the provision of a password or by a scan of your retina.
• Access controls
o provide the limitation and control of access to authorized users through identification and authentication.
o A system needs to be able to identify and authenticate users for access to data, applications and hardware.
o In a large system there may be a complex structure determining which users and applications have access to which objects.

Question sources

Computer Science MCQ practice collection · Question 527

Question 71 | AM0528

What is the process of converting plaintext into ciphertext called?

A. Encryption

B. Decryption

C. Hashing

D. Key exchange

Hint

Trace message transformations and separate data, keys, algorithms and codebreaking.

Answer A: Encryption

PDF p.6 directly defines encryption/enciphering as conversion of plaintext to ciphertext. Hashing instead produces a fixed-size digest (p.10).

Why each choice is right or wrong

A - Correct: Encryption exactly names the forward conversion. See PDF p.6, PDF p.10.

B - Incorrect: Decryption is the reverse conversion. See PDF p.6, PDF p.10.

C - Incorrect: Hashing produces a digest rather than the defined ciphertext representation. See PDF p.6, PDF p.10.

D - Incorrect: Key exchange distributes/agrees keys rather than converting this message. See PDF p.6, PDF p.10.

Primary note proof

Study-note section SEC12

Plaintext is the original message, ciphertext its encrypted representation, a key is input to an algorithm, encryption computes C=E_k(P), and decryption recovers P=D_k(C). The five conventional symmetric ingredients are plaintext, encryption algorithm, secret key, ciphertext and decryption algorithm. Cryptanalysis seeks recovery or other breaks without the authorized secret; cryptology includes cryptography and cryptanalysis. Steganography hides that a message exists; encryption hides its meaning.

Study-note section SEC20

A cryptographic hash maps arbitrary-length input to a fixed-length digest.

Study-note section SEC18

Authenticate the exchange and derive separate traffic keys.

o no key is used in this algorithm.
o A fixed-length hash value is computed as per the
plain text
✓ that makes it impossible for the contents of the plain
text to be recovered.

Question sources

Computer Science MCQ practice collection · Question 528

Question 72 | AM0529

Which vulnerability writes beyond an allocated buffer and may thereby allow arbitrary code execution on the target system?

A. Phishing

B. Buffer overflow

C. SQL injection

D. Cross-site scripting

Hint

Identify the unsafe operation or input boundary rather than only a possible consequence.

Answer B: Buffer overflow

The decisive mechanism is an out-of-bounds write to a buffer. That is a buffer overflow, which can corrupt data or control information and may lead to code execution. Arbitrary code execution alone would not uniquely identify it. Phishing relies on deceptive interaction, SQL injection changes query syntax and XSS executes attacker script in a victim browser. The added memory-write condition distinguishes the mechanisms without claiming every overflow executes code.

Why each choice is right or wrong

A - Incorrect: Phishing deceives a user rather than defining an out-of-bounds memory write.

B - Correct: A buffer overflow is the specified write beyond allocated bounds.

C - Incorrect: SQL injection changes SQL syntax through unsafe input construction.

D - Incorrect: XSS concerns attacker script execution in a victim browser's site context.

Primary note proof

Study-note section SEC25

> A buffer overflow writes beyond allocated bounds and can corrupt data or control information; code execution is a possible consequence, not its definition or an inevitable outcome. An array of eight bytes cannot store eight text characters plus a terminating zero. Bounds-check lengths and indexes, consider integer overflow, use safe abstractions and validate library return values. Canaries, non-executable memory and address randomization reduce exploitability but do not repair the underlying write.

Study-note section SEC26

> XSS causes attacker-controlled script to execute in a victim's browser under the site's origin.

Study-note section SEC26

SQL injection occurs when untrusted values alter SQL syntax through unsafe string construction.

Question sources

Computer Science MCQ practice collection · Question 529

Question 73 | AM0530

Which of the following is an example of a social engineering attack?

A. Denial-of-Service (DoS) attack

B. Distributed Denial-of-Service (DDoS) attack

C. Phishing attack

D. Brute-force attack

Hint

Identify the trust claim or communication mapping being abused.

Answer C: Phishing

SEC05 defines phishing through deception: impersonating a trusted source to obtain secrets or prompt unsafe actions. That is social engineering. DoS/DDoS describe service disruption and brute force describes repeated credential guesses; neither requires the deceptive human interaction that distinguishes the requested example.

Why each choice is right or wrong

A - Incorrect: DoS exhausts or disables a service; that mechanism is not inherently social deception.

B - Incorrect: DDoS distributes service-disruption traffic and does not specifically describe manipulating a person.

C - Correct: Phishing deceives a user through trusted-source impersonation to induce disclosure or unsafe action.

D - Incorrect: Brute force enumerates credential guesses rather than persuading a person through impersonation.

Primary note proof

Study-note section SEC05

> Phishing impersonates a trusted source to obtain secrets or induce an unsafe action; spear phishing targets a specific person. Verify a request through an independently known channel. Shoulder surfing observes entry; pretexting invents a reason for disclosure. Monitoring software used with authorization is not necessarily an attack merely because it records activity.

Study-note section SEC08

> Brute force enumerates guesses; dictionary attacks prioritize likely words; credential stuffing tries previously leaked credentials on another service.

Study-note section SEC06

> DoS exhausts or disables a resource; distributed DoS uses multiple sources, often bots or reflected/amplified responses.

C. Cryptanalysis: the process of breaking an encrypted code.

Question sources

Computer Science MCQ practice collection · Question 530

Question 74 | AM0531

What is the purpose of a firewall in computer security?

A. To encrypt network traffic

B. To monitor and control network traffic

C. To detect and remove malware

D. To authenticate users

Hint

Identify which traffic is mediated and what information drives the device's decisions.

Answer B: To monitor and control network traffic

PDF p.11 explicitly assigns monitoring and controlling incoming/outgoing traffic under security rules to firewalls. Encryption and identity proof are different operations.

Why each choice is right or wrong

A - Incorrect: Traffic encryption is not the firewall definition. See PDF p.4, PDF p.11.

B - Correct: Monitoring and controlling traffic is the exact stated role. See PDF p.4, PDF p.11.

C - Incorrect: Keeping malicious code out is an objective, not a general ability to detect and remove installed malware. See PDF p.4, PDF p.11.

D - Incorrect: User authentication is a separate identity-proof operation. See PDF p.4, PDF p.11.

Primary note proof

Study-note section SEC23

A firewall enforces traffic policy. Stateless packet filtering matches headers such as source/destination, protocol and ports. Stateful inspection tracks permitted connection context; application proxies terminate and relay application exchanges and can inspect their content. A circuit gateway relays connections, commonly SOCKS, without full application-content interpretation; textbooks associate it with session/transport functions. Such a gateway need not encrypt and is not automatically a VPN.

Study-note section SEC07

User-to-host means a user proves identity to a host; host-to-user means the host proves its identity to a user; the arrow names the prover and verifier.

Study-note section SEC07

When a sequence begins with authentication, distinguish it from the preceding identification stage.

Computer Security module | PDF page 11 | lines 22-34

3. Firewall
• a program or network devices (e.g. router) which filters access to a protected network from the internet connection.
• protects a local or network of systems from network-based security threats,
• monitors & controls incoming & outgoing network traffic based on predetermined security rules.
• Firewall Objectives
o Keep intruders, malicious code and unwanted traffic out
o Keep private and sensitive information in
o security wall b/n private (protected) NW & outside word.

Computer Security module | PDF page 4 | lines 15-27

• Authentication
o is proving a claim - usually that you are who you say you are.
o for example it may be obtained by the provision of a password or by a scan of your retina.
• Access controls

o provide the limitation and control of access to authorized users through identification and authentication.
o A system needs to be able to identify and authenticate users for access to data, applications and hardware.
o In a large system there may be a complex structure determining which users and applications have access to which objects.

Question sources

Computer Science MCQ practice collection · Question 531

Question 75 | AM0532

A login already uses a password. Which listed input can add an independent possession factor when generated by a separate token controlled by the user?

A. Username

B. Password

C. Security question

D. One-time password (OTP)

Hint

Separate identity claims from proof, and factor type from factor count.

Answer D: One-time password (OTP)

A password supplies knowledge. A one-time password generated by a separate user-controlled token can supply possession, making the combination two-factor under the stated mechanism. Another password or secret security-question answer remains knowledge rather than adding an independent class. A username identifies the subject but is not proof. Specifying how the OTP is generated matters because an OTP's factor class does not follow from the word one-time alone.

Why each choice is right or wrong

A - Incorrect: A username identifies the subject and is not possession proof.

B - Incorrect: Another password remains a knowledge factor.

C - Incorrect: A secret answer is another knowledge input, not an independent possession class.

D - Correct: A separately controlled token generating the OTP supplies possession under the assumption.

Primary note proof

Study-note section SEC07

Knowledge is a password/PIN, possession is a token/card, and inherence is a biometric such as a fingerprint. Behavioral biometrics include typing rhythm or handwriting; some textbooks call

these “something one does.” A body characteristic is not “three-factor authentication”: one biometric is one factor. Password plus PIN remains one factor class; card plus PIN is two. An OTP’s factor depends on its delivery/generation mechanism.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Security module | PDF page 11 | lines 74-79

• Most OS authentication is handled through user names and passwords. Biometric (e.g. voice, face, retina, iris, fingerprint) and physical token-based (swipe cards, pin-generating cards) authentication are sometimes used to augment simple passwords, but the costs and accuracy of the technology limit their adoption.

Computer Security module | PDF page 4 | lines 15-27

• Authentication
o is proving a claim - usually that you are who you say you are.
o for example it may be obtained by the provision of a password or by a scan of your retina.
• Access controls

o In a large system there may be a complex structure determining which users and applications have access to which objects.

Question sources

Computer Science MCQ practice collection · Question 532

Question 76 | AM0533

What is the term for a malicious activity where an attacker tries all possible combinations of passwords to gain unauthorized access?

A. Brute-force attack

B. Denial-of-Service (DoS) attack

C. SQL injection

D. Man-in-the-middle (MITM) attack

Hint

Consider what the attacker can guess or steal, or which component validates a claim.

Answer A: Brute-force attack

The module defines brute force as trying every possible key and separately names password guessing (PDF p.5). Applying that exhaustive-search method to all password combinations yields a brute-force password attack.

Why each choice is right or wrong

A - Correct: Exhaustive possible-combination testing is the brute-force method. See PDF p.5.

B - Incorrect: DoS blocks access rather than exhaustively guessing a secret. See PDF p.5.

C - Incorrect: SQL injection is not an exhaustive-password-search method in the module. See PDF p.5.

D - Incorrect: A man-in-the-middle is not the stated exhaustive-search process. See PDF p.5.

Primary note proof

Study-note section SEC08

> Brute force enumerates guesses; dictionary attacks prioritize likely words; credential stuffing tries previously leaked credentials on another service. Online attempts face server rate limits; offline attacks against stolen verifiers do not. Short passwords can fail in either setting. Use unique long secrets and password managers, rate limiting and suitable MFA; store salted slow password hashes, not reversible plaintext passwords. A salt prevents shared precomputed lookup, but is not secret.

Study-note section SEC05

> Monitoring software used with authorization is not necessarily an attack merely because it records activity.

Study-note section SEC26

> SQL injection occurs when untrusted values alter SQL syntax through unsafe string construction.

Question sources

Computer Science MCQ practice collection · Question 533

Question 77 | AM0534

Which statement defines a buffer overflow by its underlying memory-write mechanism, rather than merely naming a possible consequence?

A. A vulnerability that allows unauthorized access to a system's memory

B. A vulnerability that allows attackers to intercept network traffic

C. A vulnerability in which a write exceeds an allocated buffer’s bounds

D. A vulnerability that allows unauthorized access to a system's files

Hint

Identify the unsafe operation or input boundary rather than only a possible consequence.

Answer C: A vulnerability in which a write exceeds an allocated buffer’s bounds

A buffer overflow is defined by writing beyond an allocated buffer’s bounds. That unsafe write can corrupt data or control information, and code execution is possible but not inevitable. Generic unauthorized memory or file access describes broader outcomes, while interception of network traffic describes a different kind of activity. The choice identifies the mechanism; the question asks for a definition rather than a consequence.

Why each choice is right or wrong

A - Incorrect: Generic unauthorized memory access is broader than the specific out-of-bounds write.

B - Incorrect: Network interception is not the defining write mechanism.

C - Correct: This states the defining write beyond allocated buffer bounds.

D - Incorrect: Unauthorized file access is a possible harm rather than the definition.

Primary note proof

Study-note section SEC25

A buffer overflow writes beyond allocated bounds and can corrupt data or control information; code execution is a possible consequence, not its definition or an inevitable outcome. An array of eight bytes cannot store eight text characters plus a terminating zero. Bounds-check lengths and indexes, consider integer overflow, use safe abstractions and validate library return values. Canaries, non-executable memory and address randomization reduce exploitability but do not repair the underlying write.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Security module | PDF page 3 | lines 53-59

• Example: If a company has antivirus software but does not use an anti-virus and keep the virus signatures up-to-date, this is vulnerability. The company is vulnerable to virus attacks. Similarly, if you fail to routinely update your operating systems or application software, these will remain vulnerable to software problems ("bugs") that have been identified and patched

Computer Security module | PDF page 10 | lines 56-62

✓ Vulnerability Assessment: the process of scanning (locating & reporting) vulnerabilities to provide a way to detect and resolve security problems by ranking the vulnerabilities.
✓ Penetration Testing: an authorized simulated attack on a computer system, performed to evaluate the security of the system.

Question sources

Computer Science MCQ practice collection · Question 534

Question 78 | AM0535

Which statement defines SQL injection by its mechanism rather than merely describing a possible security consequence?

A. A vulnerability that allows attackers to intercept network traffic

B. A vulnerability that allows attackers to execute arbitrary code

C. A vulnerability that allows unauthorized access to a system's memory

D. Untrusted input changes SQL syntax through unsafe query construction

Hint

Locate where untrusted data can become instructions and where they execute.

Answer D: Untrusted input changes SQL syntax through unsafe query construction

SQL injection occurs when untrusted values become part of SQL syntax through unsafe query construction. That can change query behavior or expose protected records, but unauthorized database access alone does not define the flaw. Network interception and memory access are other broad harms, and arbitrary code execution can occur through multiple mechanisms. The choice identifies the query-syntax boundary that parameter binding is intended to protect.

Why each choice is right or wrong

A - Incorrect: Network interception does not define unsafe SQL construction.

B - Incorrect: Code execution is a broad possible consequence rather than the SQL-specific mechanism.

C - Incorrect: Unauthorized memory access does not identify the query-syntax boundary.

D - Correct: This states how untrusted input changes SQL command structure.

Primary note proof

Study-note section SEC26

> SQL injection occurs when untrusted values alter SQL syntax through unsafe string construction. A tautology can change which rows match. Bind data values in prepared statements, allow-list identifiers that cannot be parameters, and restrict the application's database account. Stored procedures/ORMs are safe only when they avoid unsafe dynamic SQL.

Study-note section SEC26

> Use safe text insertion and context-specific encoding; carefully sanitize allowed HTML.

Question sources

Computer Science MCQ practice collection · Question 535

Question 79 | AM0536

Which statement defines cross-site scripting by its execution context, rather than merely naming one possible effect?

A. A vulnerability that allows unauthorized access to a system's memory

B. Attacker-controlled script executes in a victim’s browser under the vulnerable site’s origin

C. A vulnerability that allows attackers to manipulate web page content

D. A vulnerability that allows unauthorized access to a database

Hint

Locate where untrusted data can become instructions and where they execute.

Answer B: Attacker-controlled script executes in a victim’s browser under the vulnerable site’s origin

XSS causes attacker-controlled script to run in a victim’s browser under the vulnerable site’s origin. Page-content manipulation can be an effect of that execution but is not a complete definition, since other flaws can also change content. Generic memory or database access likewise does not identify the browser-origin mechanism. The answer states the relevant execution context without treating all arbitrary code execution as XSS.

Why each choice is right or wrong

A - Incorrect: Unauthorized memory access does not define the browser-origin script mechanism.

B - Correct: This states the script execution and origin context that define XSS.

C - Incorrect: Page-content manipulation is a possible effect rather than the defining execution context.

D - Incorrect: Unauthorized database access is not the definition of XSS.

Primary note proof

Study-note section SEC26

> XSS causes attacker-controlled script to execute in a victim’s browser under the site’s origin. Stored content persists; reflected content returns in a response; DOM-based XSS can arise from unsafe browser sinks. Use safe text insertion and context-specific encoding; carefully sanitize allowed HTML. CSP is added protection, not the sole fix.

Module passages - related reading

These source passages provide context; the primary note proof is identified separately above.

Computer Security module | PDF page 11 | lines 12-16

> • Secure Web servers:

Question sources

Computer Science MCQ practice collection · Question 536

Question 80 | AM0537

What is the purpose of input validation in program security?

A. To ensure the confidentiality of data

B. To prevent unauthorized access to a system

C. To detect and block malicious input

D. To encrypt sensitive data during transmission

Hint

Identify the unsafe operation or input boundary rather than only a possible consequence.

Answer C: Validate and reject unacceptable input

Input validation checks whether data meets expected type, length, range and structure, allowing invalid or malicious inputs to be rejected. SEC25 requires server-side checks because clients are controllable. This supports C without claiming validation alone stops every attack: parameterized queries and context-specific output encoding remain separate protections.

Why each choice is right or wrong

A - Incorrect: Confidentiality is not the specific purpose of checking input type, range, length and structure.

B - Incorrect: Authentication/authorization enforce access; input validation instead checks whether supplied values are acceptable.

C - Correct: Validation detects values outside expected constraints so the program can reject unsafe or invalid input.

D - Incorrect: Encrypting transmission is channel protection rather than input validation.

Primary note proof

Study-note section SEC25

> Validate expected type, length, range and structure at trust boundaries. Server validation is essential because clients are controllable. Encode output for its destination; validation is not a universal substitute for query parameterization or HTML-context encoding. Security patches repair known weaknesses; a zero-day may lack a vendor fix, but segmentation and other mitigations can still help.

Study-note section SEC09

> Allowing SELECT but denying UPDATE is an access-control decision that helps integrity; it does not by itself enforce all valid business-state transitions.

Study-note section SEC09

Deny by default, mediate every access and revoke stale permissions.

Question sources

Computer Science MCQ practice collection · Question 537

Question 81 | AM0538

What is the role of secure coding practices in program security?

A. To prevent code duplication and improve program efficiency

B. To ensure compliance with industry standards and regulations

C. To minimize the number of bugs and vulnerabilities in code

D. To facilitate code collaboration among developers

Hint

Trace timing over shared state or distinguish finding a weakness from demonstrating consequences.

Answer C: Reduce software defects and vulnerabilities

Secure development aims to reduce exploitable defects through review, safe input/memory handling, least privilege and related practices described in SEC25-27. C states that direct aim. Efficiency, compliance and collaboration may be benefits of broader engineering practices, but none substitutes for minimizing flaws that can violate the program's security requirements.

Why each choice is right or wrong

A - Incorrect: Avoiding duplication and improving efficiency are general engineering concerns rather than the specific security aim.

B - Incorrect: Compliance can be relevant but does not directly state the defect-reduction purpose of secure coding.

C - Correct: Secure coding reduces bugs and exploitable vulnerabilities through safer design and implementation.

D - Incorrect: Collaboration helps engineering but is not itself the security objective of minimizing exploitable code flaws.

Primary note proof

Study-note section SEC27

> A race occurs when correctness depends on timing/interleaving over shared state. In a check-then-open file operation, another actor may replace the file between the check and use. In a balance update, two workers can both read100 and each write90, losing one debit. Protect the whole invariant with suitable atomic operations, locks or database transactions; locking an unrelated variable does not help.

Study-note section SEC27

> Build threat modeling, review, least privilege, dependency management and safe error handling into development.

Study-note section SEC25

> Canaries, non-executable memory and address randomization reduce exploitability but do not repair the underlying write.

the security of the system.

Question sources

Computer Science MCQ practice collection · Question 538

Question 82 | AM0539

What is the purpose of access control mechanisms in program security?

A. To prevent unauthorized access to sensitive resources

B. To monitor and log system activities for auditing purposes

C. To encrypt data during storage and transmission

D. To protect against malware and viruses

Hint

Identify subject, object and permitted operation before comparing policy models.

Answer A: To prevent unauthorized access to sensitive resources

Access enforcement authorizes subjects to perform operations on objects (PDF p.11), implementing limitation to authorized users (p.4). That protects sensitive resources from unauthorized access.

Why each choice is right or wrong

A - Correct: Restricting resource operations to authorized subjects is exactly access control. See PDF p.4, PDF p.11.

B - Incorrect: Logging is the separate accountability function. See PDF p.4, PDF p.11.

C - Incorrect: Encryption transforms data rather than assigning object permissions. See PDF p.4, PDF p.11.

D - Incorrect: Malware defense is broader and does not define access control. See PDF p.4, PDF p.11.

Primary note proof

Study-note section SEC09

Subjects request operations on objects. An ACL associates an object/resource with allowed subjects or actions; a network ACL matches traffic such as address, protocol and port. Classification and filtering are direct effects; high availability or malware detection is not guaranteed by an ACL.

Study-note section SEC01

Availability supplies timely, usable service to authorized users: crashes, resource starvation and denied access violate it.

Study-note section SEC09

RBAC gives permissions to roles and assigns users to roles.

Related reading (context, not primary note proof)

Computer Security module | PDF page 4 | lines 15-27

• Authentication
o is proving a claim - usually that you are who you say you are.
o for example it may be obtained by the provision of a password or by a scan of your retina.
• Access controls
o provide the limitation and control of access to authorized users through identification and authentication.
o A system needs to be able to identify and authenticate users for access to data, applications and hardware.
o In a large system there may be a complex structure determining which users and applications have access to which objects.

Computer Security module | PDF page 11 | lines 80-87

6. Access control
• Since many systems (such as router access control lists) define which packets may and which packets may not pass based on the sender's IP address
• An access enforcement mechanism authorizes requests from multiple subjects (e.g. users, processes, etc.) to perform operations (e.g., read, write, etc.) on objects (e.g., files, sockets, etc.).

Computer Security module | PDF page 4 | lines 28-35

• Accountability
o Ensuring an entity’s action is traceable uniquely to that entity.
o Ascertains the responsibility of an entity (like a person) for its actions and decisions.
o All relevant activities events and operations on a system, e.g., failed and successful authentication attempts, are recorded in a log.

Question sources

Computer Science MCQ practice collection · Question 539

Question 83 | AM0540

What is a race condition vulnerability?

A. A vulnerability that allows unauthorized access to a system's memory

B. A vulnerability that allows attackers to intercept network traffic

C. A vulnerability that allows attackers to execute arbitrary code

D. A vulnerability that occurs when the timing of program execution leads to unexpected behavior

Hint

Trace timing over shared state or distinguish finding a weakness from demonstrating consequences.

Answer D: Timing/interleaving of shared state causes incorrect behavior

SEC27 defines a race through timing-dependent correctness over shared state, such as check-then-use or lost updates. D states that mechanism. Unauthorized memory access, interception and arbitrary code execution may be possible harms from many vulnerabilities, but they do not define the interleaving dependency of a race condition.

Why each choice is right or wrong

A - Incorrect: Memory-access harm alone does not establish a shared-state timing or interleaving dependency.

B - Incorrect: Traffic interception is a different mechanism and does not define a race.

C - Incorrect: Code execution is a possible consequence of various flaws, not the timing-based race definition.

D - Correct: Timing-dependent unexpected behavior over shared state is the defining race-condition mechanism.

Primary note proof

Study-note section SEC27

> A race occurs when correctness depends on timing/interleaving over shared state. In a check-then-open file operation, another actor may replace the file between the check and use. In a balance update, two workers can both read100 and each write90, losing one debit. Protect the whole invariant with suitable atomic operations, locks or database transactions; locking an unrelated variable does not help.

What is the principle of least privilege in program security?

A. The principle of giving users the minimum necessary permissions to perform their tasks

B. The principle of encrypting all data stored in a system

C. The principle of regularly updating software to patch vulnerabilities

D. The principle of blocking all incoming network connections by default

Hint

Identify subject, object and permitted operation before comparing policy models.

Answer A: The principle of giving users the minimum necessary permissions to perform their tasks

PDF p.5 says not to give more privileges than absolutely necessary for the required job. This directly selects the minimum-permissions option.

Why each choice is right or wrong

A - Correct: Minimum required permissions exactly matches least privilege. See PDF p.5.

B - Incorrect: Encrypting all data is a separate data-protection measure. See PDF p.5.

C - Incorrect: Patching repairs vulnerabilities rather than minimizing permissions. See PDF p.5.

D - Incorrect: Default blocking is not the definition of task-based minimum privilege. See PDF p.5.

Primary note proof

Study-note section SEC09

Least privilege gives only needed rights, for needed time. Separation of duties splits sensitive steps across parties. Deny by default, mediate every access and revoke stale permissions.

Allowing SELECT but denying UPDATE is an access-control decision that helps integrity; it does not by itself enforce all valid business-state transitions.

Study-note section SEC23

Stateless packet filtering matches headers such as source/destination, protocol and ports.

Study-note section SEC23

Rules should be explicit, ordered as implemented, least-privilege and logged appropriately.

• Principles of Least Privilege: —Do not give any more privileges than absolutely necessary to do/perform the required job‖.
• Defense in Depth: having more than one layer or type of defense
• Minimization: —do not run any software, or applications that are not strictly required to do the entrusted job.‖
• Compartmentalization: limits the damage in other compartments when one compartment is compromised.

Computer Science MCQ practice collection · Question 541

Question 85 | AM0542

What is the purpose of code obfuscation in program security?

A. To enhance program performance and execution speed

B. To make the code more difficult to understand and analyze

C. To encrypt sensitive data stored in the program

D. To detect and block malicious code during program execution

Hint

Separate observation from blocking and sensor placement from detection method.

Answer B: Make code harder to understand and analyze

SEC24 describes obfuscation as complicating understanding and analysis. It does not reliably hide embedded secrets or remove defects, so it is not equivalent to encryption or malware prevention. Nor does it imply better execution performance. B states the intended analysis-resistance purpose while preserving the note's limits.

Why each choice is right or wrong

A - Incorrect: Obfuscation is not defined as a performance optimization and need not improve speed.

B - Correct: Making code more difficult to understand/analyze is the explicit obfuscation purpose.

C - Incorrect: Obfuscation is not encryption and does not reliably protect secrets embedded in a program.

D - Incorrect: Runtime malicious-code detection/blocking is a separate defensive function rather than obfuscation.

Primary note proof

Study-note section SEC24

> A true positive is a real attack detected, false negative is a missed attack, false positive is innocent activity flagged, and true negative is innocent activity accepted. Recall=TP/(TP+FN); precision=TP/(TP+FP). Detecting 90 of 100 spam messages with five innocent messages flagged gives recall90%, precision90/95≈94.7%. Obfuscation makes code harder to understand and can hamper analysis, but does not reliably protect embedded secrets or remove vulnerabilities.

> ✓ Vulnerability Assessment: the process of scanning
> (locating & reporting) vulnerabilities to provide a
> way to detect and resolve security problems by
> ranking the vulnerabilities.

✓ Penetration Testing: an authorized simulated attack on a computer system, performed to evaluate the security of the system.

Question sources

Computer Science MCQ practice collection · Question 542

Question 86 | AM0543

What is a security patch in program security?

A. A technique used to prevent buffer overflow vulnerabilities

B. A software update released to fix known security vulnerabilities

C. A hardware device used to monitor network traffic for malicious activities

D. A set of security policies implemented by an organization

Hint

Identify the unsafe operation or input boundary rather than only a possible consequence.

Answer B: A software update released to fix known security vulnerabilities

The module warns that failing to update operating systems/applications leaves software vulnerable to bugs already identified and patched (PDF p.3). A security patch is the corrective software update described by B.

Why each choice is right or wrong

A - Incorrect: Buffer overflow is only one possible weakness; this is not the general update definition. See PDF p.3.

B - Correct: A corrective software update for known weaknesses follows the module's patch/update account. See PDF p.3.

C - Incorrect: A patch is a software correction, not network-monitoring hardware. See PDF p.3.

D - Incorrect: Organizational policy is not the software bug correction discussed. See PDF p.3.

Primary note proof

Study-note section SEC25

Validate expected type, length, range and structure at trust boundaries. Server validation is essential because clients are controllable. Encode output for its destination; validation is not a universal substitute for query parameterization or HTML-context encoding. Security patches repair known weaknesses; a zero-day may lack a vendor fix, but segmentation and other mitigations can still help.

Study-note section SEC33

A security policy states responsibilities and rules; a procedure supplies the steps.
